Glossary

Apps in DSP System Toolbox

Filter Builder

Design filters starting with frequency and magnitude specifications (`filterBuilder`)

Description

The **Filter Builder** app enables you to choose a filter response and build a filter object based on the filter design specifications. The app designs the filter and exports the filter object to the base workspace. For more information, see the `filterBuilder` documentation.

Note: This app requires a screen resolution greater than 640 × 480.

Open the Filter Builder App

- MATLAB® Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the app icon.
- MATLAB command prompt: Enter `filterBuilder`.

Examples

- "Filter Builder Design Process"
- "Lowpass FIR Filter Design"

Logic Analyzer

Visualize, measure, and analyze transitions and states over time

Description

The **Logic Analyzer** is a tool for visualizing and inspecting signals in your Simulink® model. Using the **Logic Analyzer**, you can:

- Debug and analyze models
- Trace and correlate many signals simultaneously
- Detect and analyze timing violations
- Trace system execution

The Logic Analyzer does not support frame-based processing.

If you enable the Simulink **"Log Dataset data to file" (Simulink)** configuration parameter, to stream logged data to the Logic Analyzer set the `VisualizeLoggedSignalsWhenLoggingToFile` model parameter to `'on'`.

For keyboard shortcuts, click `more`.

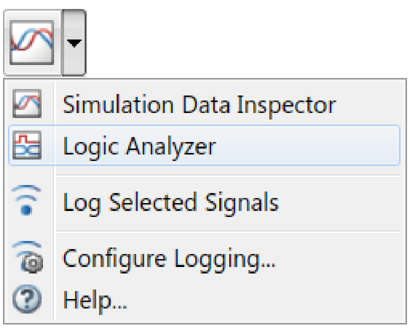
Keyboard Shortcuts

Actions	Description	Applicable When
Ctrl+X	Cut	Wave is selected
Ctrl+C	Copy	Wave is selected
Ctrl+V	Paste	Wave is selected
Delete	Delete	Wave is selected
Ctrl+-	Zoom out	Always
Shift+Ctrl+-	Zoom out around active cursor	Always
Ctrl++	Zoom in	Always
Shift+Ctrl++	Zoom out around active cursor	Always

Actions	Description	Applicable When
Shift+Ctrl+C	Move display to active cursor	When cursor is not in the display range
Space	Zoom out full	Always
Tab, **Right Arrow**	Next transition	Digital format wave is selected
Shift+Tab, **Left Arrow**	Previous transition	Digital format wave is selected
Ctrl+A	Select all waves	Always
Up Arrow	Select wave above selected	Wave is selected
Down Arrow	Select wave below selection	Wave is selected
Ctrl+Up Arrow	Move selected waves up	Wave is selected
Ctrl+Down Arrow	Move selected waves down	Wave is selected
Escape	Unselect all signals	Wave is selected
Page Up	Scroll up	Always
Page Down	Scroll down	Always

Open the Logic Analyzer App

- Simulink Toolbar: Click the Logic Analyzer button . If the button is not displayed, click the Simulation Data Inspector button arrow and select **Logic Analyzer** from the menu.



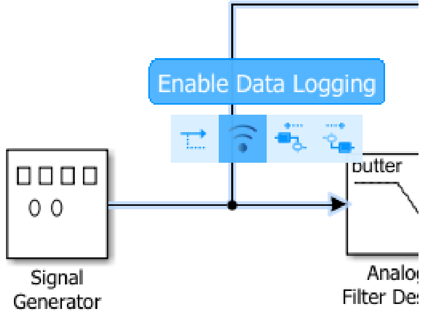
Your most recent choice for data visualization is saved across Simulink sessions.

Examples

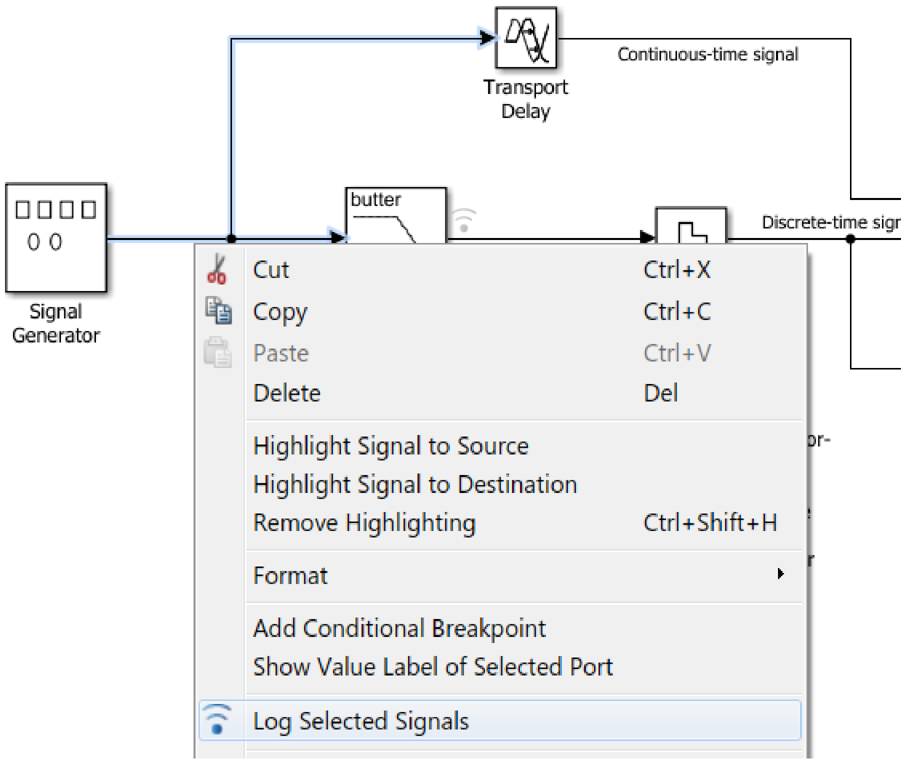
Select Signals to Analyze

The **Logic Analyzer** supports several methods for selecting data to visualize.

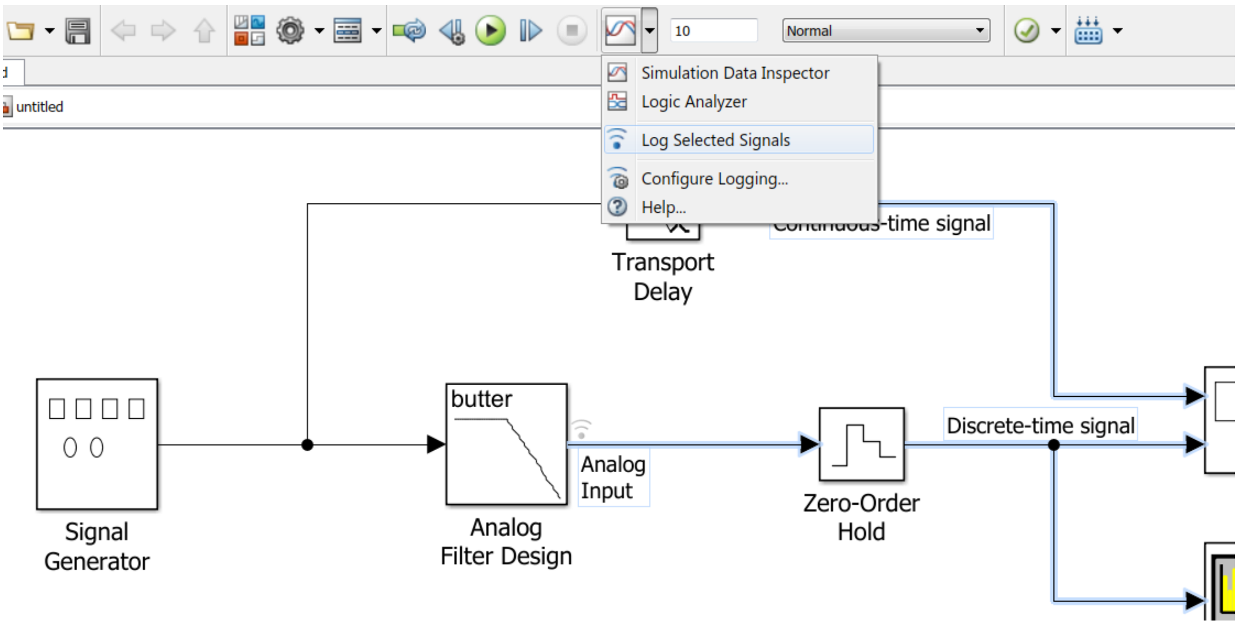
- Select a signal in your model. When you select a signal, an ellipsis appears above the signal line. Hover over the ellipsis to view options and then select the **Enable Data Logging** option.



- Right-click a signal in your model to open an options dialog box. Select the **Log Selected Signals** option.



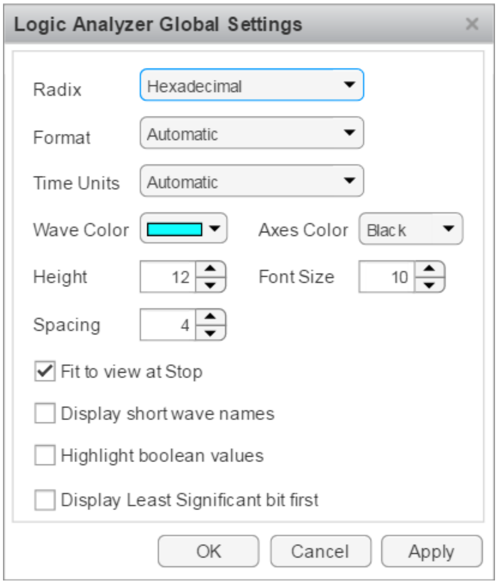
- Use any method to select multiple signal lines in your model, for example, use **Shift**+click to select multiple lines individually or **CTRL+A** to select all lines at once. Then click the Logic Analyzer button arrow and select **Log Selected Signals**.



When you open the **Logic Analyzer**, all signals marked for logging are listed. You can add and delete waves from your **Logic Analyzer** while it is open.

Modify Global Settings

Open the **Logic Analyzer** and select **Settings** from the toolstrip. A global settings dialog box opens. Any setting you change for an individual signal supersedes the global setting.



Set the display **Radix** of your signals as one of the following:

- `Hexadecimal` — Displays values as symbols from zero to nine and A to F
- `Octal` — Displays values as numbers from zero to seven
- `Binary` — Displays values as zeros and ones
- `Signed decimal` — Displays the signed, stored integer value
- `Unsigned decimal` — Displays the stored integer value

Set the display **Format** as one of the following:

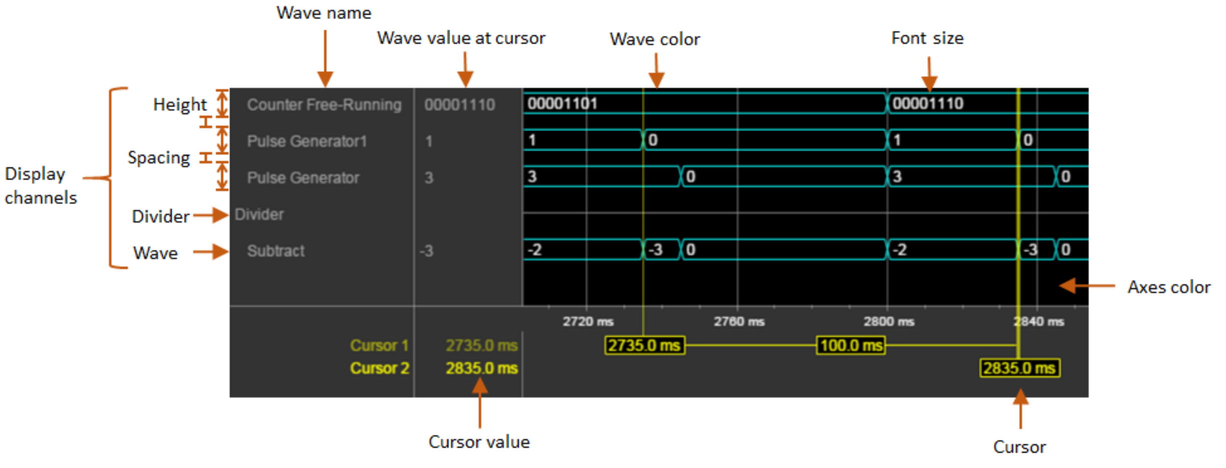
- `Automatic` — Displays floating point signals in `Analog` format and integer and fixed-point signals in `Digital` format. Boolean signals are displayed as zero or one.
- `Analog` — Displays values as an analog plot
- `Digital` — Displays values as digital transitions

Set the display **Time Units** to one of the following:

- `Automatic` — Uses a time scale appropriate to the time range shown in the current plot

- `seconds`
- `milliseconds`
- `microseconds`
- `nanoseconds`
- `picoseconds`
- `femtoseconds`

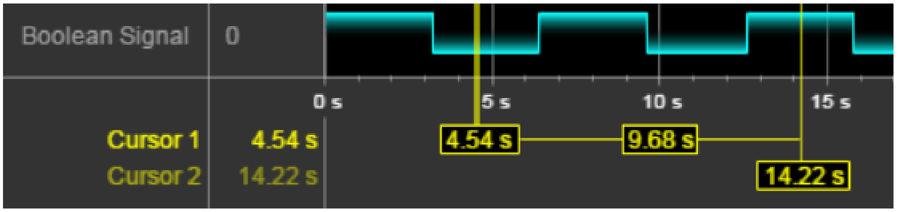
Inspect the graphic for an explanation of the global settings: `Wave Color`, `Axes Color`, `Height`, `Font Size`, and `Spacing`. `Font Size` applies only to the text within the axes.



Select **Fit to view at Stop** to plot data over the entire time range in one screen when you stop the simulation.

Select **Display short wave names** to use the short name of waves to display. Short wave names do not include path information.

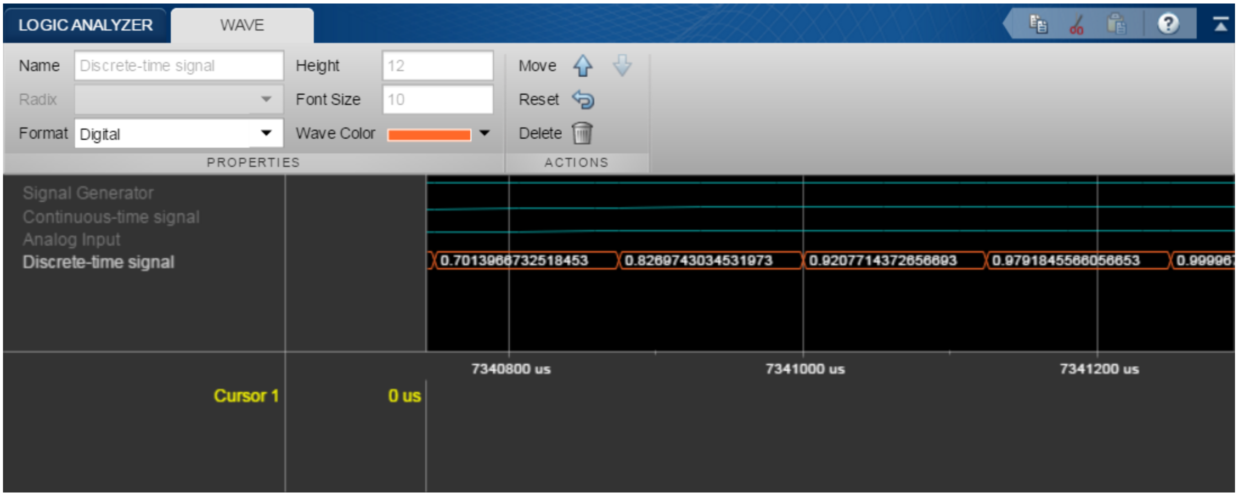
Select **Highlight boolean values** to add highlighting to Boolean signals. If the signal value is `true`, the highlight fades out below. If the signal value is `false`, the signal fades out above. This property enables you to visually deduce the value of the signal.



Select **Display Least Significant bit first** to reverse the display order of bits for bit-expanded fixed-point and integer signals.

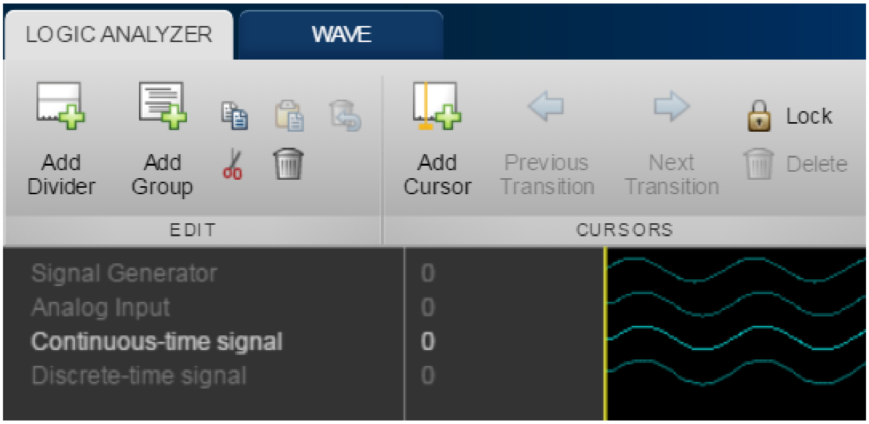
Modify Individual Wave Settings

Open the **Logic Analyzer** and select a wave by double-clicking the wave name. Then from the **Wave** tab, set parameters specific to the individual wave you selected. Any settings made on individual signals supersedes the global setting. To return individual wave parameters to the global settings, click **Reset**.



Delete and Restore Waves

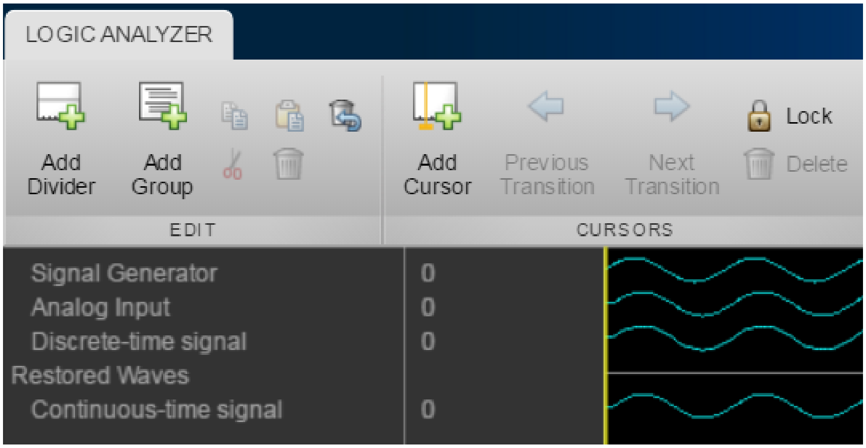
1 Open the **Logic Analyzer** and select a wave by clicking the wave name.



2 From the **Logic Analyzer** toolstrip, click . The wave is removed from the **Logic Analyzer**.

3 To restore the wave, from the **Logic Analyzer** toolstrip, click .

A divider named **Restored Waves** is added to the bottom of your channels, with all deleted waves placed below it.

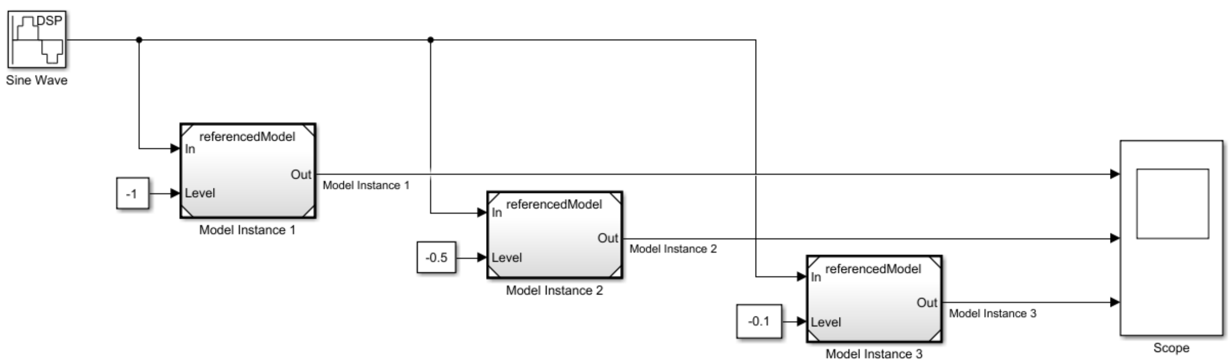


Choose Visible Instance of Multi-Instance Model Block

The **Logic Analyzer** can stream only a single instance of a multi-instance Model block. This example shows how to select an instance of a multi-instance Model block for streaming on the **Logic Analyzer**.

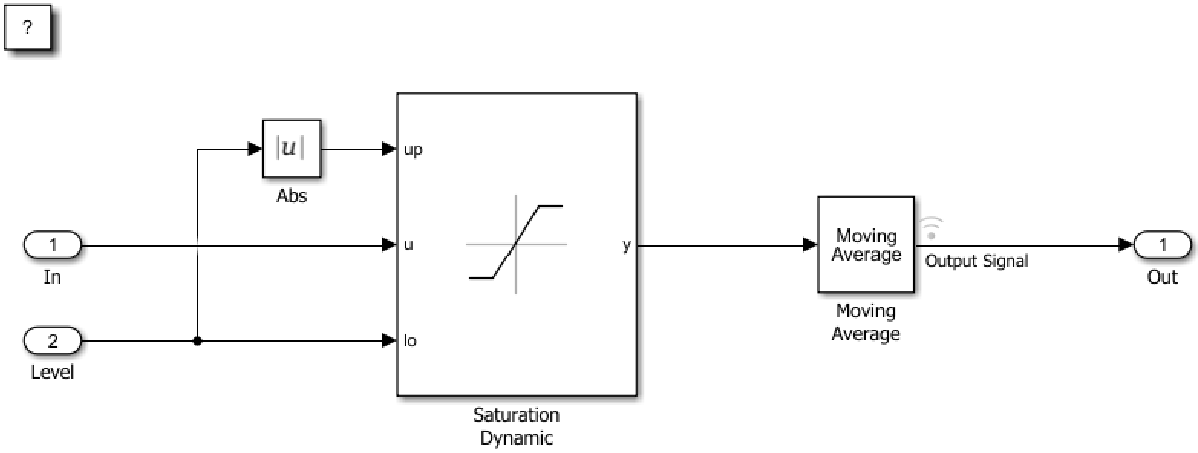
1 Open the multipleModelInstances model:

```
open_system([matlabroot,'\examples\dsp\multipleModelInstances.slx'])
```

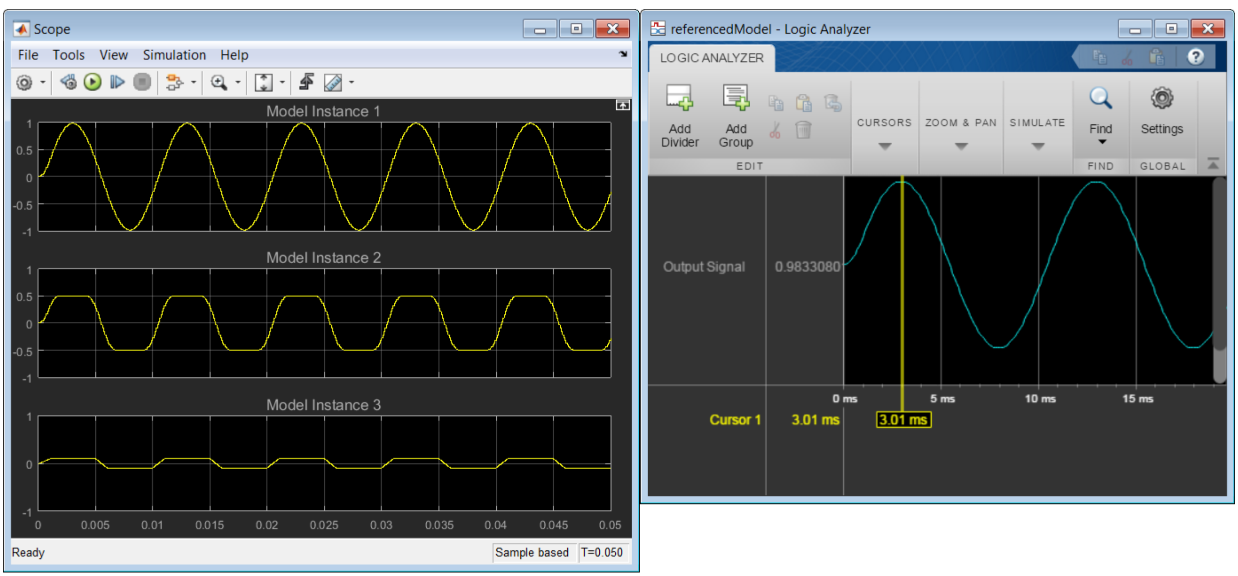


The model contains three instances of the `referencedModel` model.

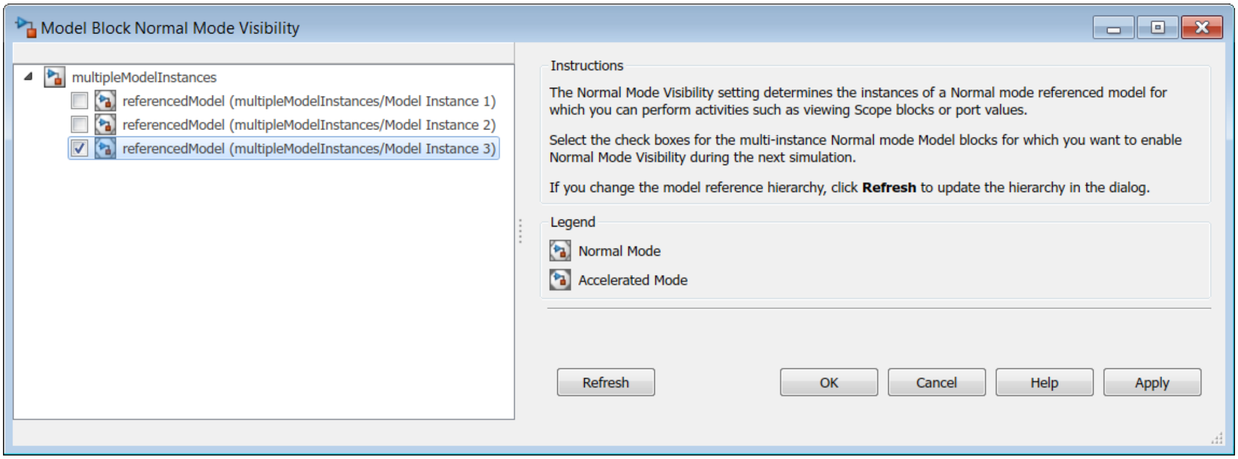
2 Double-click any of the Model blocks to open the model referenced by all three Model blocks.



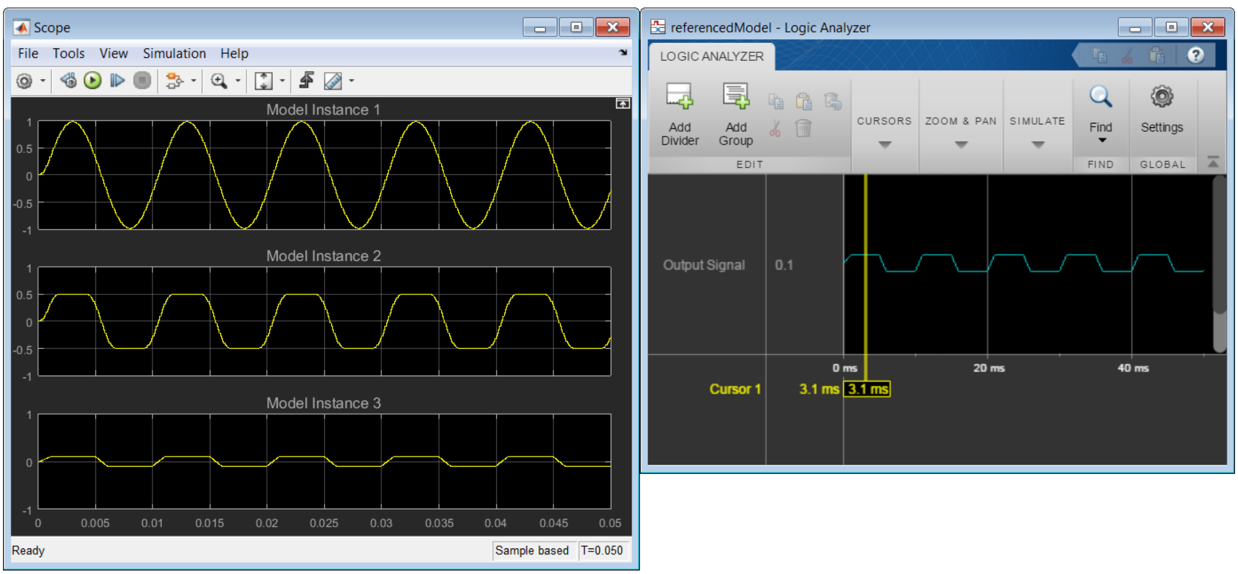
3 Open the **Logic Analyzer** in the referenced model.
4 From the `multipleModelInstances` model, run the model. The **Logic Analyzer** displays a single instance of a multi-instant Model block.



5 To switch between instances, from the Simulink Editor menu, select **Diagram** > **Subsystem & Model Reference** > **Model Block Normal Mode Visibility**. Select **Model Instance 3** and then click **OK**.

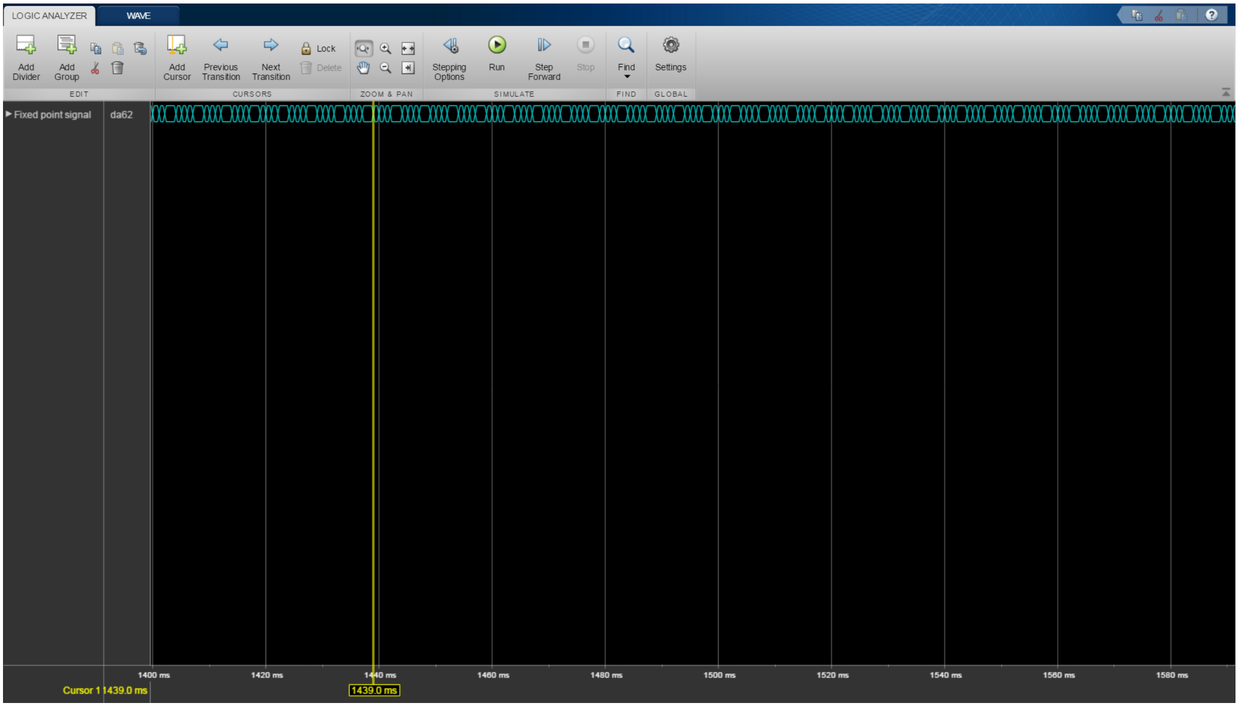


6 Run the `multipleModelInstances` model again. The **Logic Analyzer** displays `Model Instance 3` data.



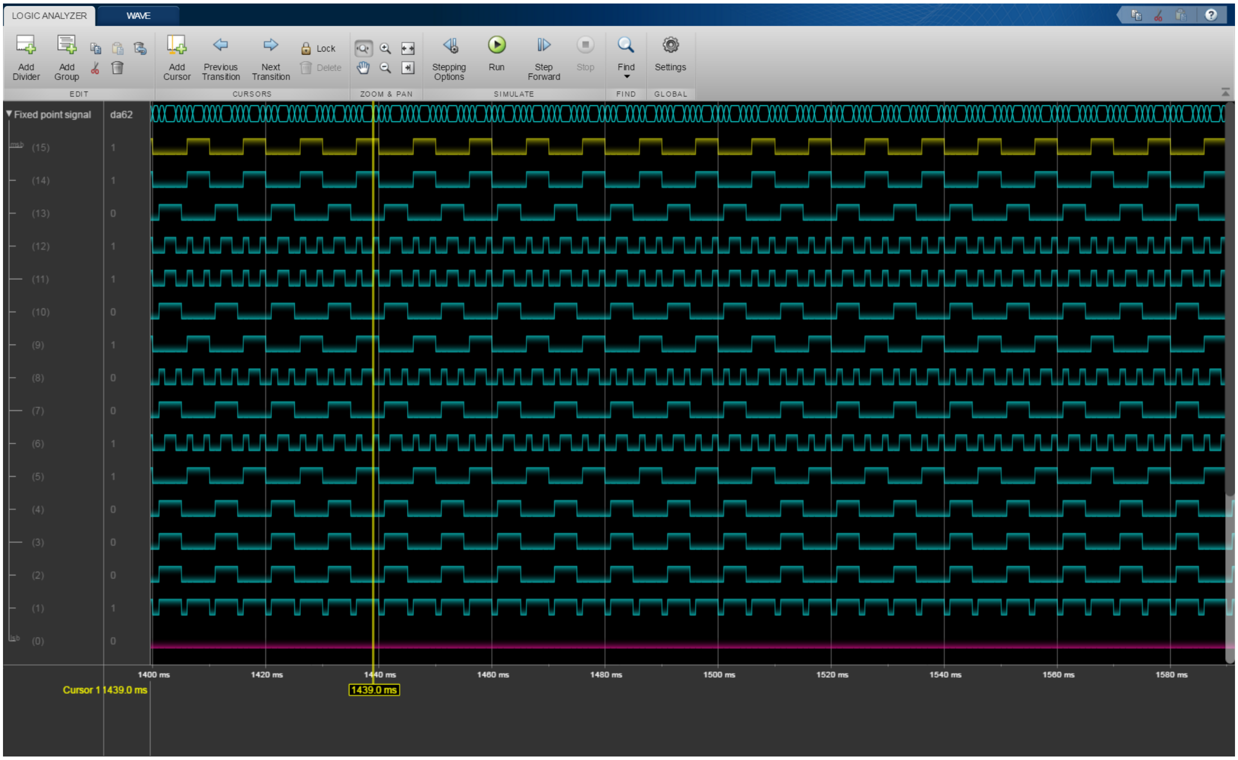
View Bit-Expanded Wave and Reverse Display Order of Bits

The **Logic Analyzer** enables you to bit-expand fixed-point and integer waves.

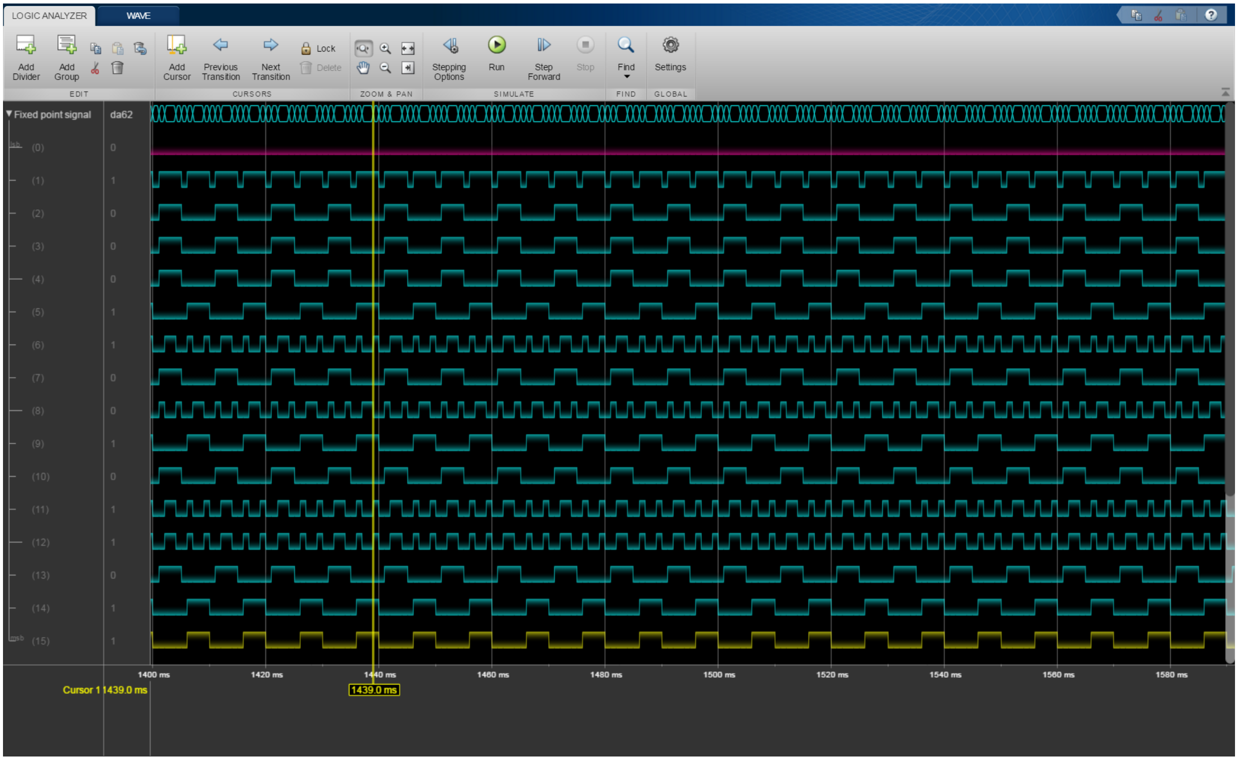


1. In the **Logic Analyzer**, click the arrow next to a fixed-point or integer wave to view the bits.

   The least significant bit and the most significant bit are marked with **lsb** and **msb** next to the wave names.



2 Click Settings, and then select **Display Least Significant bit first** to reverse the order of the displayed bits.



- “Inspect and Measure Transitions Using the Logic Analyzer”

Limitations

- You can use the **Logic Analyzer** in models running the following supported simulation modes.

Mode	Support	Notes and Limitations
Normal	Yes	
Accelerator	Yes	
Rapid Accelerator	Yes	Data is not available in the **Logic Analyzer** during simulation.

Mode	Support	Notes and Limitations
		If you simulate a model with the simulation mode set to rapid accelerator, then the following signals cannot be streamed into the **Logic Analyzer**: • Multi-instance model reference signals • Nonvirtual bus signals
Processor-in-the-loop (PIL)	No	
Software-in-the-loop (SIL)	No	
External	No	

For more information about these modes, see "How Acceleration Modes Work" (Simulink).

- The zoom and pan features of the **Logic Analyzer** are disabled while your simulation runs.
- You cannot use the **Logic Analyzer** to visualize signals in Model blocks with **Simulation mode** set to `Accelerator`.
- Signals marked for streaming for the **Logic Analyzer** must have fewer than 8000 samples per simulation step.
- Signals marked for streaming using `Simulink.sdi.markSignalForStreaming` or Dashboard Scope do not appear on the **Logic Analyzer**.

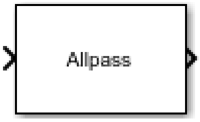
Introduced in R2016b

Blocks — Alphabetical List

Allpass Filter

Single-section or multiple-section allpass filter

Library: DSP System Toolbox / Filtering / Filter Implementations



Description

The Allpass Filter block filters each channel of the input signal independently using a single-section or multiple-section (cascaded) allpass filter. You can implement the allpass filter using a minimum multiplier, wave digital filter, or lattice structure.

In minimum multiplier form, the block uses the minimum number of required multipliers, n, with $2n$ delay units and $2n$ adders. In wave digital filter form, the block uses only n multipliers and n delay units, at the expense of $3n$ adders. The lattice structure uses 2n multipliers, n delay units, and $2n$ adders. For more details on these structures, see “Algorithms” on page 2-8.

Ports

Input

`Port_1` — Input data

column vector | row vector | matrix

Input data that is passed into the allpass filter. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. That is, you can change the size of each input channel during simulation. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Output of the allpass filter
column vector | row vector | matrix

The size of the filtered output matches the size of the input.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

`Internal allpass structure` — Filter structure
`Minimum multiplier` (default) | `Wave Digital Filter` | `Lattice`

- `Minimum multiplier` — This structure uses the minimum number of required multipliers, n, with $2n$ delay units and $2n$ adders. The coefficients to this structure are specified through the **Allpass polynomial coefficients** parameter.
- `Wave Digital Filter` — The structure uses n multipliers and n delay units, at the expense of $3n$ adders. The coefficients to this structure are specified through the **Wave Digital Filter allpass coefficients** parameter.
- `Lattice` — The structure uses $2n$ multipliers, n delay units, and $2n$ adders. The coefficients to this structure are specified through the **Lattice allpass coefficients** parameter.

For more details on these structures, see "Algorithms" on page 2-8.

`Allpass polynomial coefficients` — Coefficients in minimum multiplier form
`[-2^(-1/2), 1/2]` (default) | N-by-1 matrix | N-by-2 matrix

Specify the real allpass polynomial filter coefficients in minimum multiplier form as an N-by-1 matrix or an N-by-2 matrix.

- N-by-1 matrix — The block realizes N first-order allpass sections.
- N-by-2 matrix — The block realizes N second-order allpass sections.

The default value, `[ -2^(-1/2), 1/2 ]`, defines a stable second-order allpass filter with poles and zeros at $\pm\pi/3$ in the z-plane.

Tunable: Yes

Dependencies

To enable this parameter, set **Internal allpass structure** to `Minimum multiplier`.

`Wave Digital Filter allpass coefficients` — Coefficients in wave digital filter form

`[1/2, -2^(1/2)/3]` (default) | *N*-by-1 matrix | *N*-by-2 matrix

Specify the real allpass filter coefficients in wave digital filter form. The coefficients can be *N*-by-1 matrix for *N* first-order allpass sections and *N*-by-2 matrix for *N* second-order allpass sections. The default value, `[1/2, -2^(1/2)/3]`, is a transformed version of the default value of allpass polynomial coefficients. This value is computed using `allpass2wdf(Allpass polynomial coefficients)`. These coefficients define the same stable second-order allpass filter as when the allpass structure is set to `Minimum multiplier`.

Tunable: Yes

Dependencies

To enable this parameter, set **Internal allpass structure** to `Wave Digital Filter`.

`Indicate if last section is first order` — Is the last section first order

off (default) | on

- on — When you set select this check box, the last section is considered first order. Also, the second element of the last row of the *N*-by-2 matrix is ignored.
- off — When you do not select this check box, the last section is considered second-order.

Dependencies

To enable this parameter, set **Internal allpass structure** to `Minimum multiplier` or `Wave Digital Filter`.

`Lattice allpass coefficients` — **Coefficients in lattice form**
`[-2^(1/2)/3, 1/2]` (default) | *N*-by-1 column vector | 1-by-*N* row vector

Specify the real or complex allpass coefficients as lattice reflection coefficients. The default value, `[-2^(1/2)/3, 1/2]`, is a transformed and transposed version of the default value of the allpass polynomial coefficients. This value is computed using `transpose(tf2latc(1, [1 A]))`, where *A* is the value specified in **Allpass polynomial coefficients**.

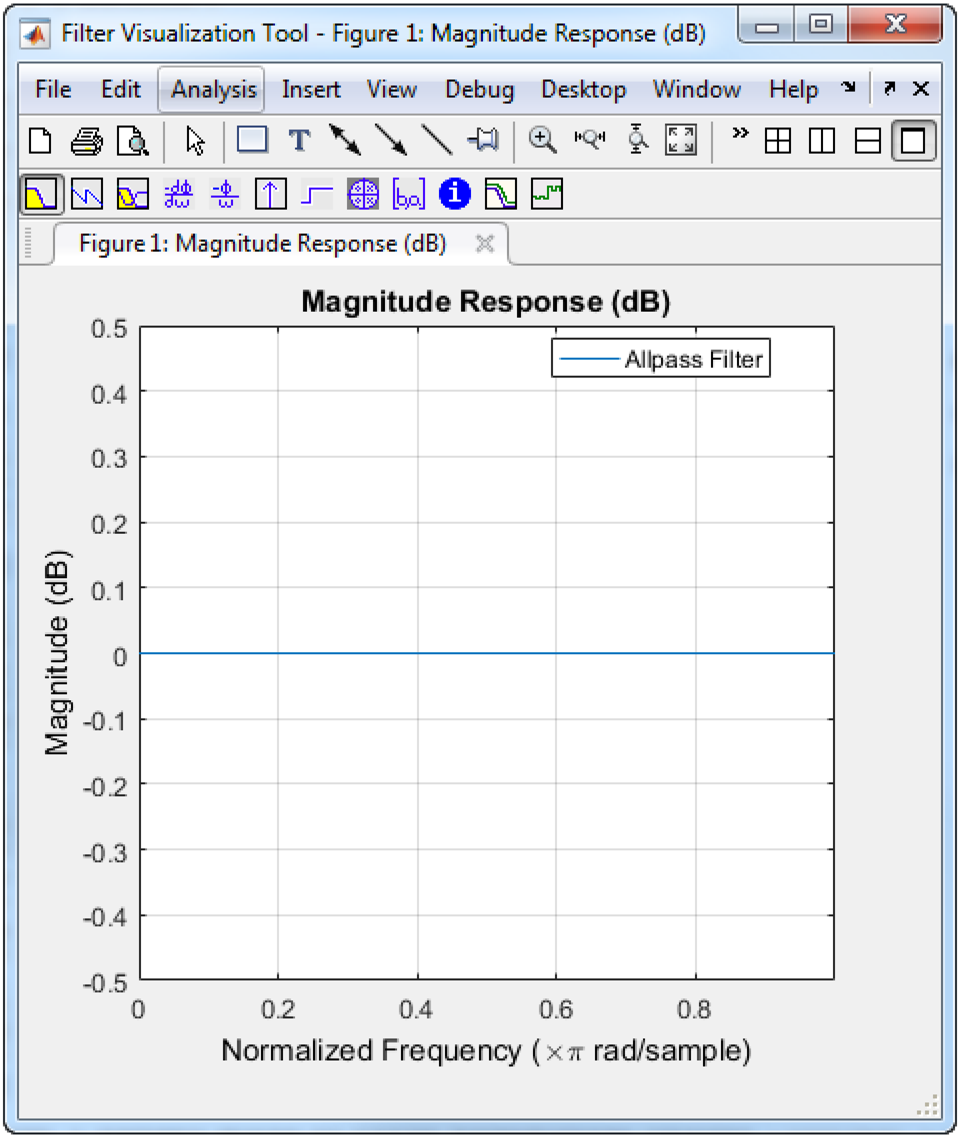
Tunable: Yes

Dependencies

To enable this parameter, set **Internal allpass structure** to `Lattice`.

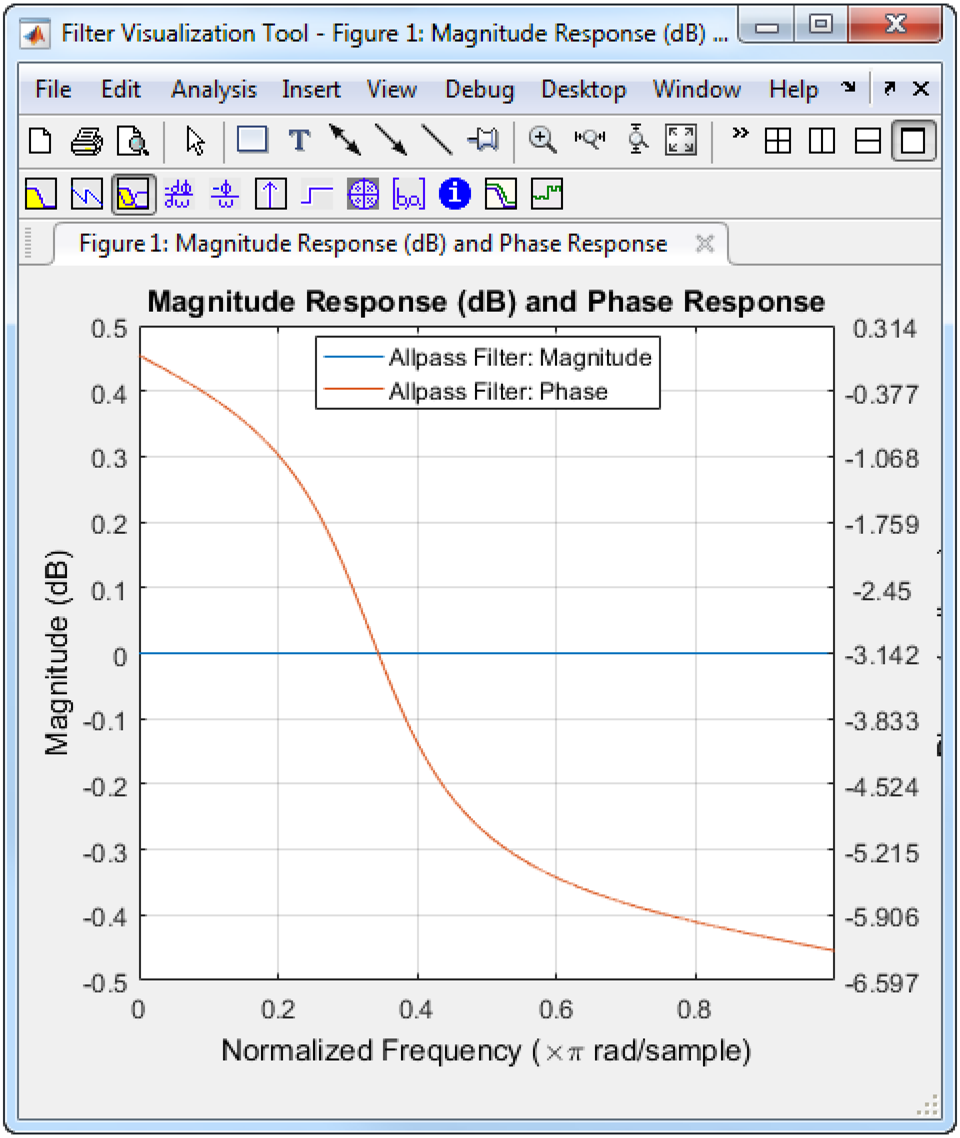
`View Filter Response` — **Visualize the filter response**
button

Opens the Filter Visualization Tool, `fvtool`, and displays the magnitude response of the allpass filter. The response is based on the parameters. Changes made to these parameters update `fvtool`.



To update the magnitude response while fvtool is running, modify the block parameters and click **Apply**.

To view the magnitude response and phase response simultaneously, click the 'Magnitude and Phase responses' button on the toolbar.



In this example, the magnitude response is flat and the phase response varies with frequencies. This varying phase response has applications in phase equalization, notch filtering, and multirate filtering. You can realize a lowpass filter using a parallel combination of two allpass filters that have 180 degrees of phase shift with respect to each other.

`Simulate using` — Type of simulation to run

`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}.$$

c is allpass polynomial coefficients vector. The order, n, of the transfer function is the length of vector c.

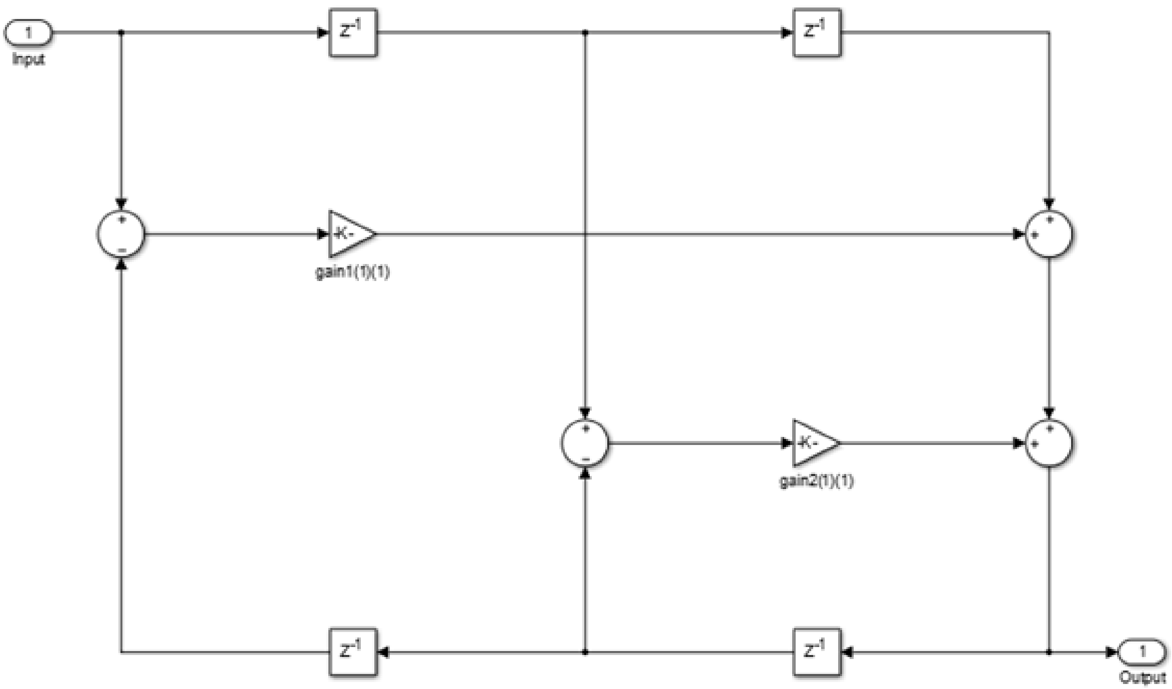
In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an N-by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an N-by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as df1, df1t, df2, df2t. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

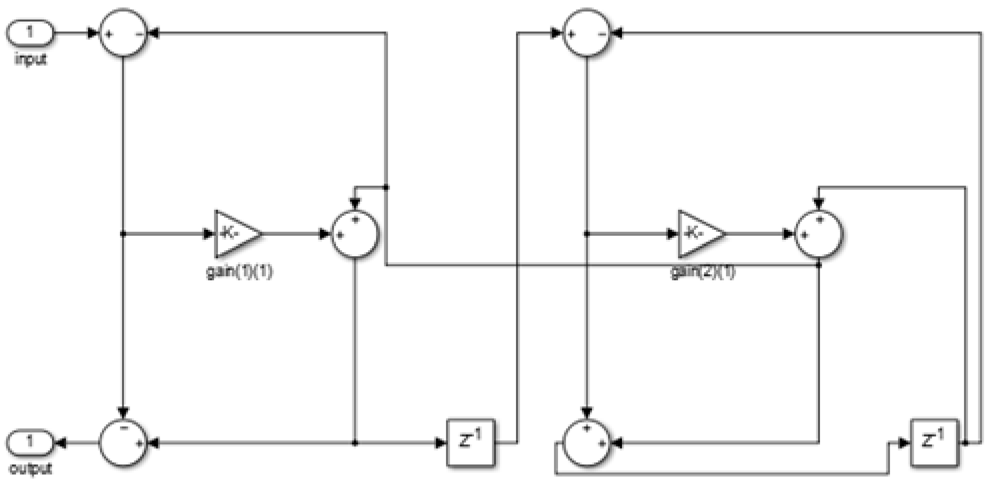
Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order `n`. It also uses `2n` delay units and `2n` adders. The multipliers uses the specified coefficients, which are equal to the polynomial vector *c* in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, *c*, is equal to [`0.1 -0.7`].



Wave Digital Filter

This structure uses n multipliers, but only n delay units, at the expense of requiring 3n adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF coefficients)`. In this second-order section of the WDF structure, the coefficients vector *w* is equal to `allpass2wdf([0.1 -0.7])`.



Lattice

This lattice structure uses 2n multipliers, n delay units, and 2n adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients [0.1 -0.7].

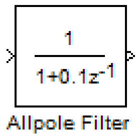
Allpole Filter

Model allpole filters



Library

Filtering / Filter Implementations

dsparch4

Description

The Allpole Filter block independently filters each channel of the input signal with the specified allpole filter. The block can implement static filters with fixed coefficients, as well as time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing).

This block supports the Simulink state logging feature. See “States” (Simulink) in the *Simulink User's Guide* for more information.

Filter Structure Support

You can change the filter structure implemented with the Allpole Filter block by selecting one of the following from the **Filter structure** parameter:

- `Direct form`
- `Direct form transposed`
- `Lattice AR`

Specifying Initial States

The Allpole Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: • The vector length equals the product of the number of input channels and the number of delay elements in the filter, `#_of_filter_coeffs-1` (or `#_of_reflection_coeffs` for `Lattice AR`). • The matrix must have the same number of rows as the number of delay elements in the filter, `#_of_filter_coeffs-1` (`#_of_reflection_coeffs` for `Lattice AR`), and must have one column for each channel of the input signal.

Data Type Support

The Allpole Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Allpole Filter block for fixed-point signals.

Direct Form

You cannot specify the state data type on the block mask for this structure because the output states have the same data types as the output.

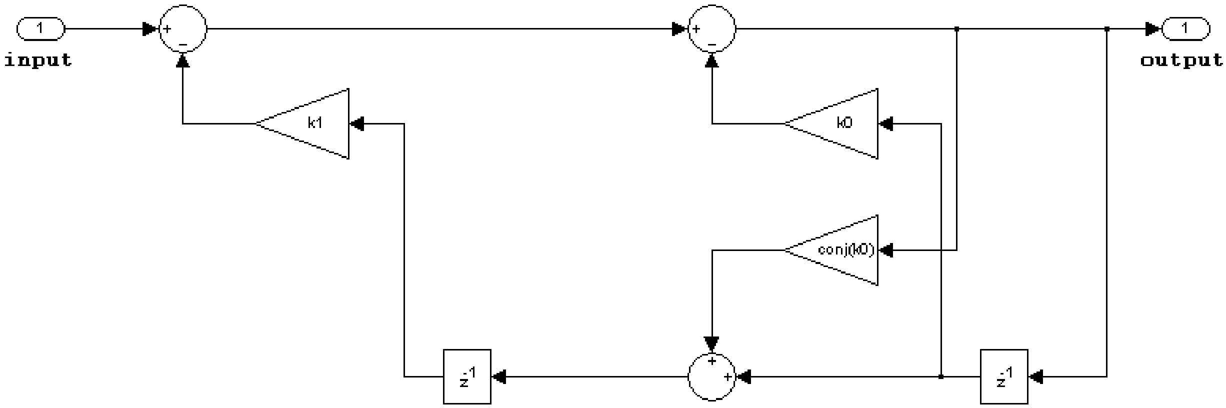
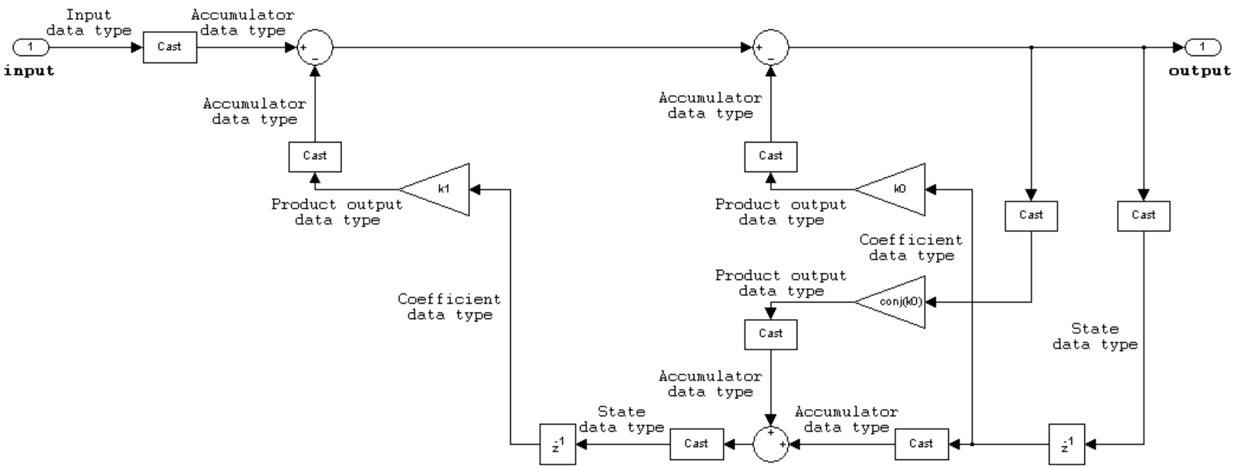
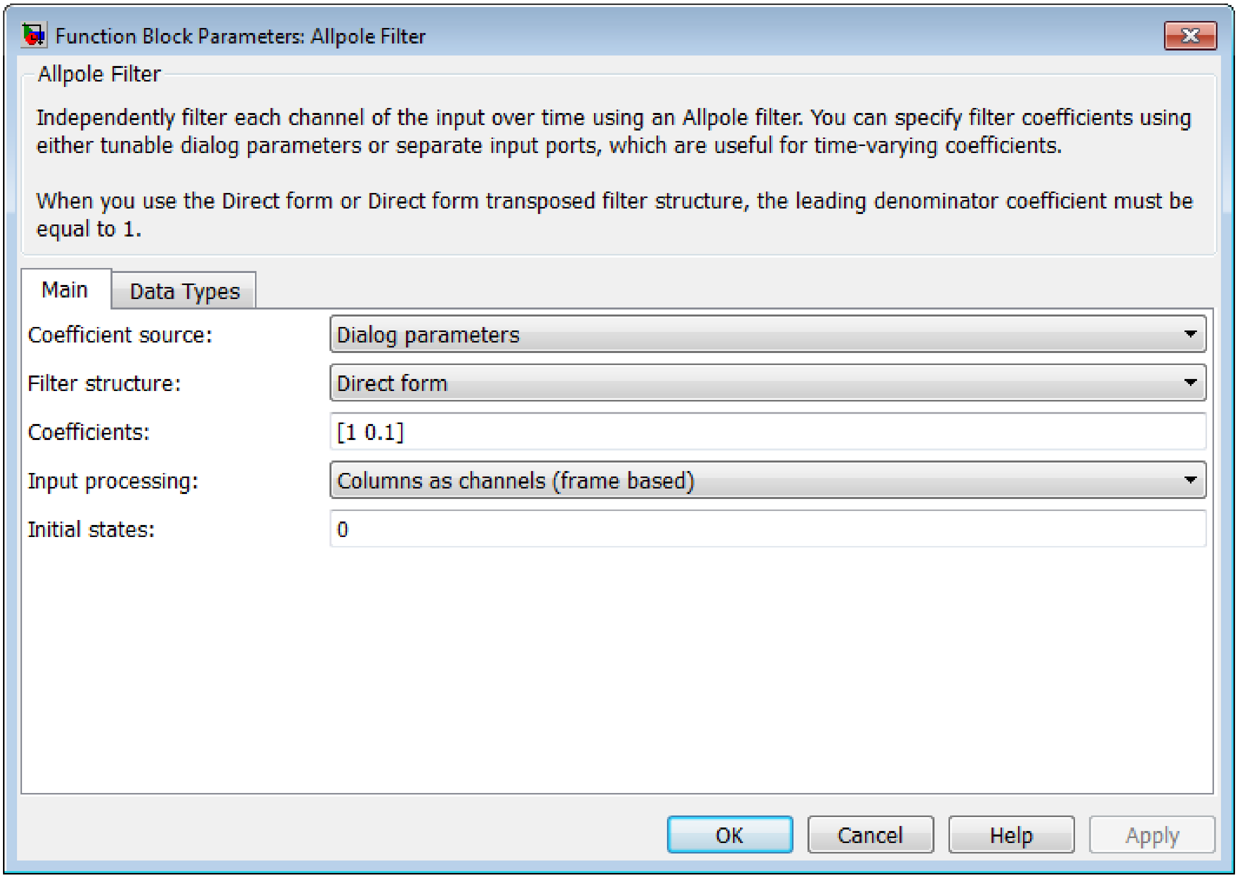
Lattice AR





Dialog Box

The **Main** pane of the Allpole Filter block dialog box appears as follows.



Coefficient source

Select whether you want to specify the filter coefficients on the block mask or through an input port.

Filter structure

Select the filter structure you want the block to implement. You can select `Direct form`, `Direct form transposed`, or `Lattice AR`.

Coefficients

Specify the row vector of coefficients of the filter's transfer function.

This parameter is visible only when you set the **Coefficient source** to `Dialog parameters`.

Input processing

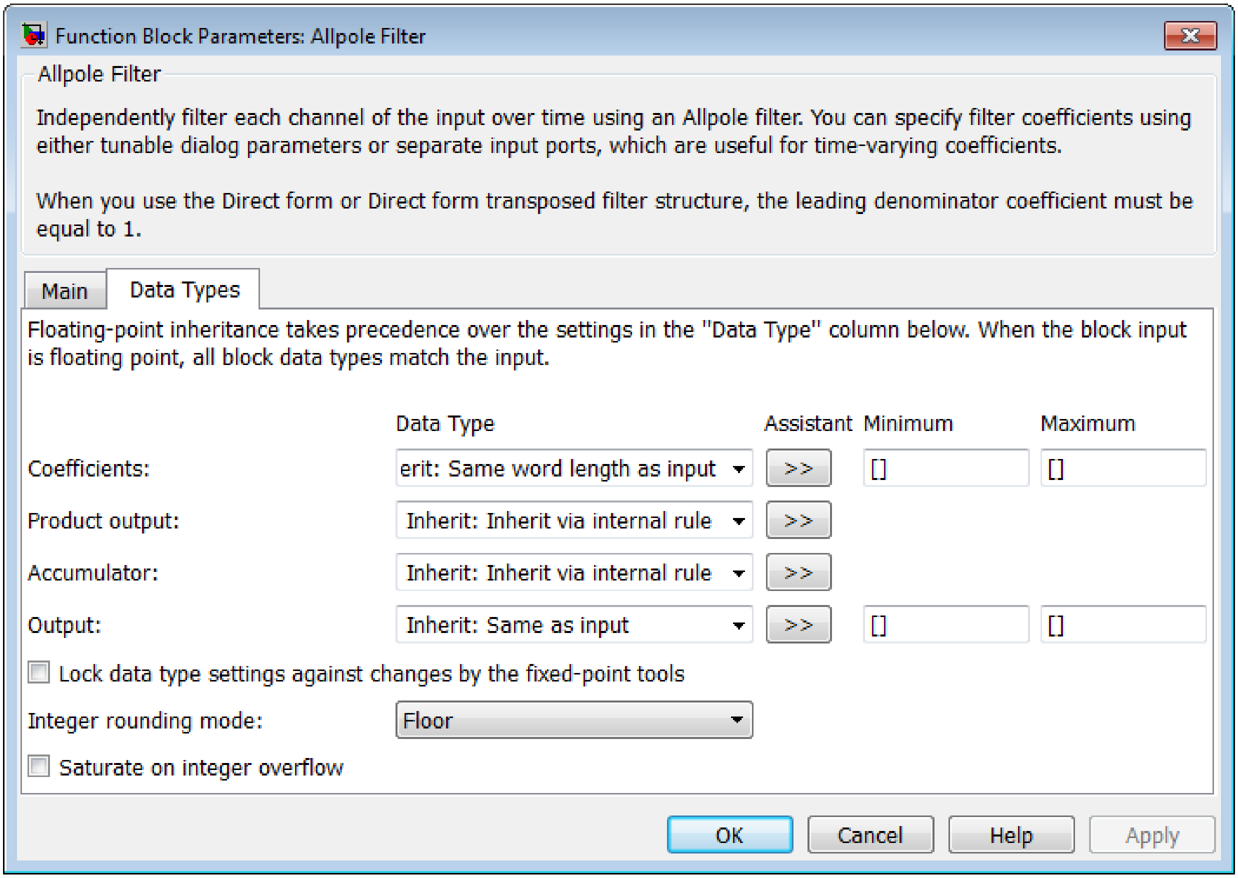
Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as an independent channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as an independent channel (frame-based processing).

Initial states

Specify the initial conditions of the filter states. To learn how to specify initial states, see "Specifying Initial States" on page 2-14.

The **Data Types** pane of the Allpole Filter block dialog box appears as follows.



Coefficients

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficient** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Coefficients minimum

Specify the minimum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Coefficients maximum

Specify the maximum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Accumulator

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

State

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is `Lattice MA`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`

- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Signal Data Types” (Simulink) in the Simulink User's Guide (Simulink) for more information.

Output minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Saturate on integer overflow

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors" (Simulink).	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Signed fixed point
- 8-, 16-, and 32-bit signed integers

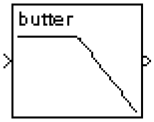
Analog Filter Design

Design and implement analog filters



Library

Filtering / Filter Implementations

`dsparch4`

Description

The Analog Filter Design block designs and implements a Butterworth, Chebyshev type I, Chebyshev type II, or elliptic filter in a highpass, lowpass, bandpass, or bandstop configuration.

The input must be a sample-based, continuous-time, real-valued, scalar signal.

The design and band configuration of the filter are selected from the **Design method** and **Filter type** pop-up menus in the dialog box. For each combination of design method and band configuration, an appropriate set of secondary parameters is displayed.

Filter Design	Description
`Butterworth`	The magnitude response of a Butterworth filter is maximally flat in the passband and monotonic overall.
`Chebyshev type I`	The magnitude response of a Chebyshev type I filter is equiripple in the passband and monotonic in the stopband.
`Chebyshev type II`	The magnitude response of a Chebyshev type II filter is monotonic in the passband and equiripple in the stopband.
`Elliptic`	The magnitude response of an elliptic filter is equiripple in both the passband and the stopband.

The following table lists the available parameters for each design/band combination. For lowpass and highpass band configurations, these parameters include the passband edge frequency Ω_p, the stopband edge frequency Ω_s, the passband ripple R_p, and the stopband attenuation R_s. For bandpass and bandstop configurations, the parameters include the lower and upper passband edge frequencies, Ω_{p1} and Ω_{p2}, the lower and upper stopband edge frequencies, Ω_{s1} and Ω_{s2}, the passband ripple R_p, and the stopband attenuation R_s. Frequency values are in rad/s, and ripple and attenuation values are in dB.

	Lowpass	Highpass	Bandpass	Bandstop
`Butterworth`	Order, Ω_p	Order, Ω_p	Order, Ω_{p1}, Ω_{p2}	Order, Ω_{p1}, Ω_{p2}
`Chebyshev Type I`	Order, Ω_p, R_p	Order, Ω_p, R_p	Order, Ω_{p1}, Ω_{p2}, $\mathrm{R_p}$	Order, Ω_{p1}, Ω_{p2}, R_p
`Chebyshev Type II`	Order, Ω_s, R_s	Order, Ω_s, R_s	Order, Ω_{s1}, Ω_{s2}, R_s	Order, Ω_{s1}, Ω_{s2}, R_s
`Elliptic`	Order, Ω_p, R_p, R_s	Order, Ω_p, R_p, R_s	Order, Ω_{p1}, Ω_{p2}, R_p, R_s	Order, Ω_{p1}, Ω_{p2}, R_p, R_s

The Analog Filter Design block uses a state-space filter representation, and applies the filter using the State-Space block in the Simulink Continuous library. All of the design methods use Signal Processing Toolbox™ functions to design the filter:

- The Butterworth design uses the toolbox function `butter`.
- The Chebyshev type I design uses the toolbox function `cheby1`.
- The Chebyshev type II design uses the toolbox function `cheby2`.
- The elliptic design uses the toolbox function `ellip`.

The Analog Filter Design block is built on the filter design capabilities of Signal Processing Toolbox software.

Note: The Analog Filter Design block does not work with the Simulink discrete solver, which is enabled when the **Solver** list is set to `Discrete (no continuous states)` in the **Solver** pane of the **Model Configuration Parameters** dialog box. Select one of the continuous solvers (such as `ode4`) instead.

Parameters

Design method

The filter design method: `Butterworth`, `Chebyshev type I`, `Chebyshev type II`, or `Elliptic`. Tunable (Simulink).

Filter type

The type of filter to design: `Lowpass`, `Highpass`, `Bandpass`, or `Bandstop`. Tunable (Simulink).

Filter order

The order of the filter, for lowpass and highpass configurations. For bandpass and bandstop configurations, the order of the final filter is *twice* this value.

Passband edge frequency

The passband edge frequency, in rad/s, for the highpass and lowpass configurations of the Butterworth, Chebyshev type I, and elliptic designs. Tunable (Simulink).

Lower passband edge frequency

The lower passband frequency, in rad/s, for the bandpass and bandstop configurations of the Butterworth, Chebyshev type I, and elliptic designs. Tunable (Simulink).

Upper passband edge frequency

The upper passband frequency, in rad/s, for the bandpass and bandstop configurations of the Butterworth, Chebyshev type I, or elliptic designs. Tunable (Simulink).

Stopband edge frequency

The stopband edge frequency, in rad/s, for the highpass and lowpass band configurations of the Chebyshev type II design. Tunable (Simulink).

Lower stopband edge frequency

The lower stopband edge frequency, in rad/s, for the bandpass and bandstop configurations of the Chebyshev type II design. Tunable (Simulink).

Upper stopband edge frequency

The upper stopband edge frequency, in rad/s, for the bandpass and bandstop filter configurations of the Chebyshev type II design. Tunable (Simulink).

Passband ripple in dB

The passband ripple, in dB, for the Chebyshev Type I and elliptic designs. Tunable (Simulink).

Stopband attenuation in dB

The stopband attenuation, in dB, for the Chebyshev Type II and elliptic designs. Tunable (Simulink).

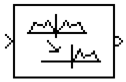
Analytic Signal

Compute analytic signals of discrete-time inputs



Library

Transforms

`dspxfrm3`

Description

The Analytic Signal block computes the complex analytic signal corresponding to each channel of the real M-by-N input, u

$$y = u + jH\{u\}$$

where $j = \sqrt{-1}$ and $H\{\}$ denotes the Hilbert transform. The real part of the output in each channel is a replica of the real input in that channel; the imaginary part is the Hilbert transform of the input. In the frequency domain, the Fourier transform of the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component.

The block computes the Hilbert transform using an equiripple FIR filter with the order specified by the **Filter order** parameter, n. The linear phase filter is designed using the Remez exchange algorithm, and imposes a delay of $n/2$ on the input samples.

The output has the same dimensions as the input.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block performs frame-based processing. In this mode, the block treats an

M-by-N matrix input as N independent channels containing M sequential time samples. The block computes the analytic signal for each channel over time.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block performs sample-based processing. In this mode, the block treats an M-by-N matrix input as $M*N$ independent channels and computes the analytic signal for each channel (matrix element) over time.

Parameters

Filter order

The length of the FIR filter used to compute the Hilbert transform.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop down list, where `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Order mode

Select `Minimum` or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the order for FIR filter, or the order of the numerator for the IIR filter.

Denominator order

Select the check box and enter the denominator order. This option is enabled only if `IIR` is selected for **Impulse response**.

Filter type

This option is available for FIR filters only. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Response Specification

Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

Specify response as

Specify the response as `Amplitudes`, `Magnitudes and phases`, `Frequency response`, or `Group delay`. `Group delay` is only available for IIR designs.

Frequency units

Specify frequency units as either `Normalized`, which means normalized by the input sampling frequency, or select from `Hz`, `kHz`, `MHz`, or `GHz`.

Input Fs

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down list. When you select the frequency units, this option is available.

Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down list. Two or three columns are presented for input. The first column is always Frequencies. The other columns are Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is `Amplitudes`.

- **Frequencies**, **Magnitudes**, and **Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is `Magnitudes and phases`.
- **Frequencies** and **Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is `Frequency response`.

Algorithm

Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

- **Window** — Replace the square brackets with the name of a `window` function or function handle. For example, `hamming` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{'kaiser',3.5}` or `{@chebwin,60}`.
- **Density factor** — Valid when the **Design method** is `Equiripple`. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

  Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade-off between the accurate approximation to the ideal filter and the time to design the filter.
- **Phase constraint** — Valid when the **Design method** is `Equiripple`, you have the DSP System Toolbox installed, and **Specify response as** is set to `Amplitudes`. Choose one of `Linear`, `Minimum`, or `Maximum`.
- **Weights** — Valid when the **Design method** is `Equiripple`. Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple

frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands.

Filter Implementation

Structure

Select the structure for the filter, available for the corresponding design method.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

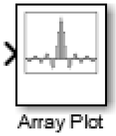
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2009b

Array Plot

Display vectors or arrays



Library

Sinks

dspsnks4

Description

The Array Plot block plots vectors or arrays of data. It is a vector plot where data is uniformly spaced along the *x*-axis. You can specify the spacing to use with the `Sample increment` property.

The Array Plot block input signals must have the following characteristics:

- Discrete sample time
- Real- or complex values
- Floating- or fixed-point data type
- Fixed dimensions
- 2-D and non-scalar

Parameters

To change the signal display settings, select **View** > **Configuration Properties** to bring up the Configuration Properties: Array Plot dialog box. Then, modify the values for the **Sample increment**, **X-offset**, **X-axis sclae** and **Maximize axes** parameters on the **Main** tab. You can modify other display parameters on the **Display** tab.

Axes Scaling Properties: Array Plot Dialog Box

The Axes Scaling Properties dialog box allows you to set the following axes properties:

Properties

Axes Scaling

Specify when the Array Plot automatically scales the axes. You can select one of the following options:

- `Manual` — When you select this option, the Array Plot does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the Array Plot figure is the active window, press **Ctrl-A**.
- `Auto` — When you select this option, the Array Plot scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the Array Plot to scale the axes after a specified number of updates. This option is useful and more efficient when your display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable (Simulink).

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable (Simulink).

Number of Updates

Specify as a positive integer the number of updates after which to scale the axes. This property appears only when you select `After N Updates` for the **Axes scaling** property. Tunable (Simulink).

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis: Data Range

Set the percentage of the *y*-axis that the Array Plot uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable (Simulink).

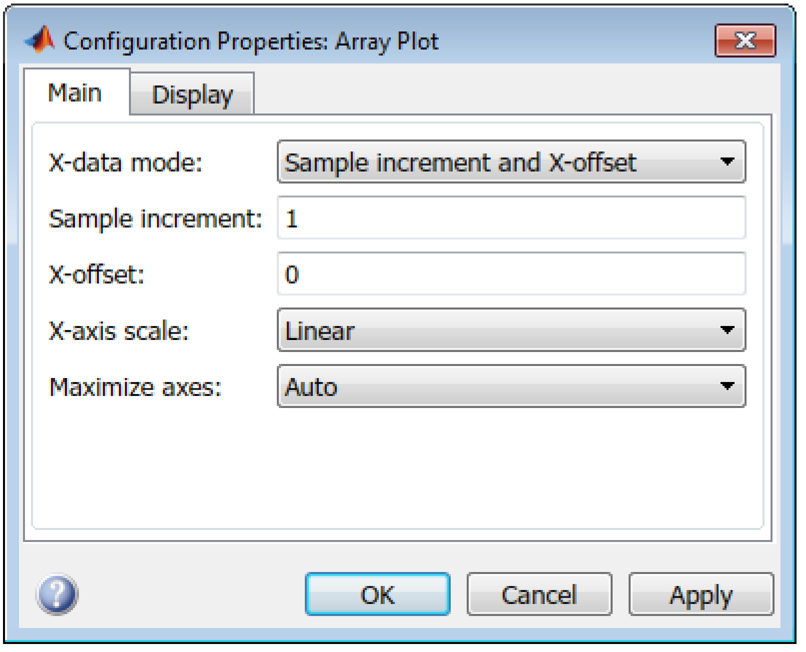
Y-axis: Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Configuration Properties: Array Plot

The Configuration Properties dialog box controls various properties about the Time Scope displays. From the Time Scope menu, select **View > Configuration Properties** to open this dialog box. Alternatively, in the Array Plot toolbar, click the Configuration Properties  button.

Main Pane



X-data mode

Select the type of spacing to use between *x*-data values. `Sample increment and X-offset` uses the **Sample increment** and **X-offset** values. To specify your own custom spacing, select `'Custom'` and specify the data values in **CustomXData**.

Sample increment

Specify the spacing between samples along the *x*-axis as a finite numeric scalar. This property is displayed only if the **XDataMode** property is `Sample increment and X-offset`. The input signal is only *y*-axis data. *x*-axis data is set automatically based on both the **Sample increment** and **X-offset** values. For example, when **X-offset** is 0 and **Sample increment** is 1, the x-data for the input signal is set to 0, 1, 2, 3, 4, etc. If you set **Sample increment** to 0.25, the x-axis data becomes 0, 0.25, 0.5, 0.75, 1, etc.

X-offset

Specify the offset to apply to the *x*-axis, as a numeric scalar. This property is displayed only if the **XDataMode** property is `Custom`, This property is Tunable (Simulink).

Specify the offset to apply to the x-axis. This property is a numeric scalar. This property is Tunable (Simulink).

Custom X-data

Specify the x-data values as a vector of length equal to the frame length of the inputs. This property is displayed only if the **XDataMode** property is `'Custom'`. If you use the default (empty vector) value, the x-data is uniformly spaced and set to (0:L-1), where L is the frame length. An example of custom logarithmic x-data scaling is `[0:log10(44100/2):1024]`.

X-axis scale

Select `Linear` or `Log` as the x-axis scale. If **X-offset** is a negative value, you cannot set **X-axis cale** to `Log`. Tunable (Simulink)

Maximize axes

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

Display Pane

Title

Specify the display title as a character vector. By default, the Array Plot has no title. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. Tunable (Simulink)

Show legend

Select this check box to show the legend in the display. The legend displays a name for each input signal. When the legend appears, you can place it anywhere inside of the scope window.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

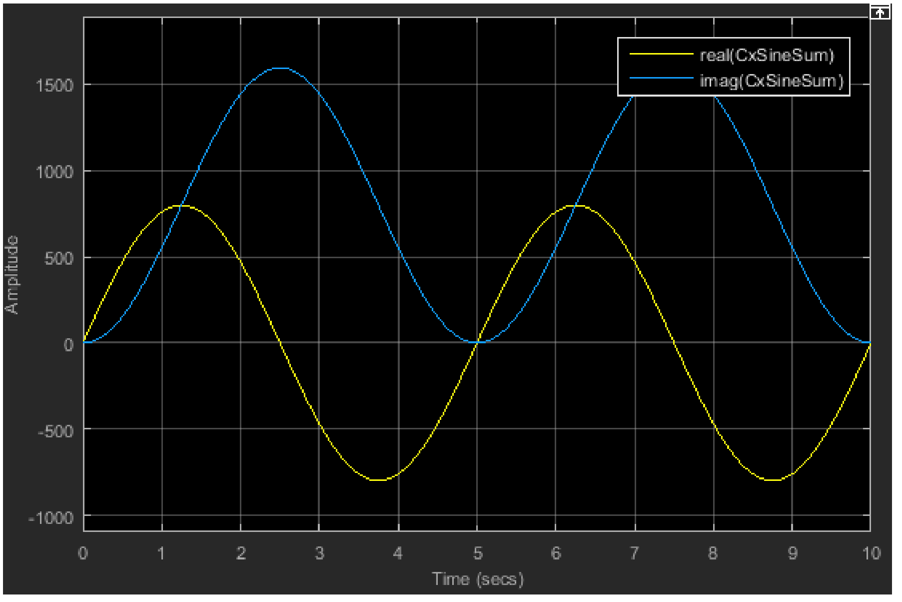
You can edit the name of any signal in the legend by double-clicking the current name, and entering a new name. By default, the scope sets each signal to its signal name or the name of the block from which it comes. Tunable (Simulink)

Show grid

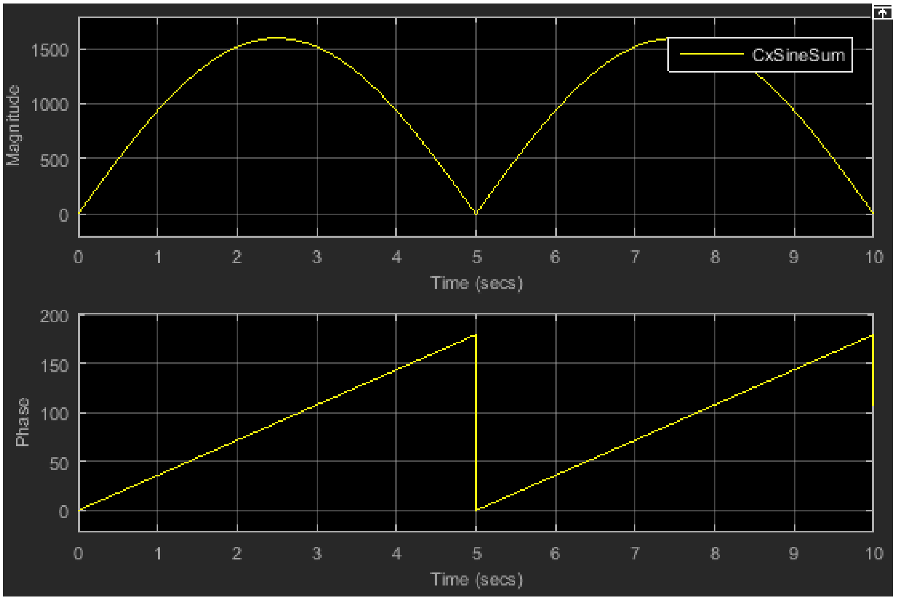
Select this check box to display a grid in the Array Plot. Tunable (Simulink)

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal has complex values, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. Tunable (Simulink)

X-label

Specify the text for the scope to display below the *x*-axis. This property is Tunable (Simulink).

Y-label

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

This property is not shown when you select the **Plot signals as magnitude and phase** check box. In that case, the *y*-axis label always appears as `Magnitude` on the top axis and `Phase` on the bottom axis.

Y-axis (Minimum)

Specify the minimum value of the *y*-axis. Tunable (Simulink)

When you select the **Plot signals as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axis. The phase plot on the bottom axis is always limited to a minimum value of -180 degrees.

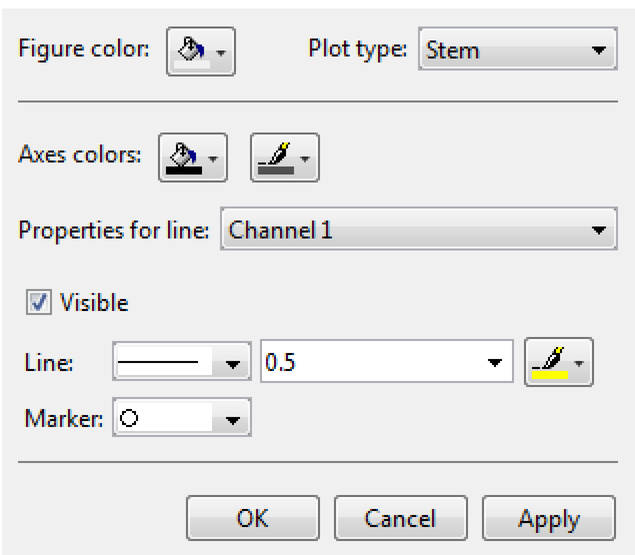
Y-axis (Maximum)

Specify the minimum value of the *y*-axis. Tunable (Simulink)

When you select the **Plot signals as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axis. The phase plot on the bottom axis is always limited to a maximum value of 180 degrees.

Style: Array Plot

Select **View** > **Style** or the Style button () in the dropdown below the Configuration Properties button to open the Style dialog box. In this dialog box, you can change the figure colors, background axes colors, foreground axes colors, and properties of lines in a display.



Properties

The **Style** dialog box allows you to modify the following properties of the array plot:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is black.

Plot type

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Stem'` , the scope displays the input signal as circles with vertical lines extending down to the *x*-axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.
- When you set this property to `'Line'` , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable (Simulink).

Axes colors

Specify the colors that you want to apply to the background and line for the array plot.

Properties for line

Select the signal for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected signal is visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected signal.

Marker

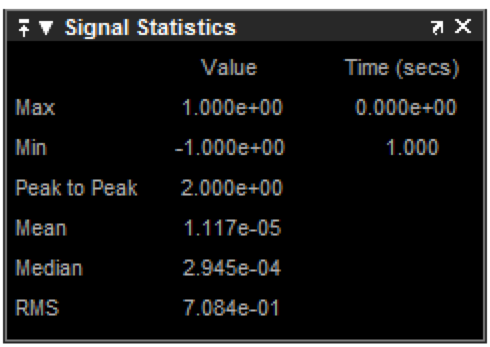
Specify marks for the selected signal to show at data points. This property is similar to the `Marker` property for plot objects. Choose any of the marker symbols from the dropdown list.

Measurements Panels

The Measurements panels are the panels that appear to the right side of the Time Scope GUI. Select the desired panels using **Tools** > **Measurements** in the scope toolbar or click the icons in the measurements dropdown.

Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. In the Array Plot menu, select **Tools** > **Measurements** > **Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.



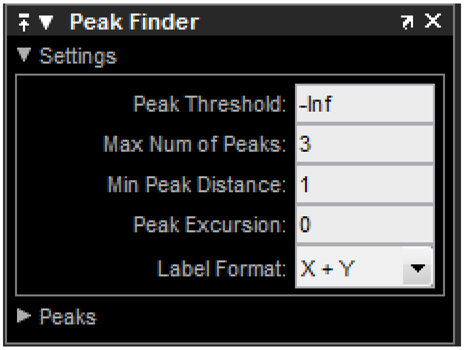
The statistics shown are:

- **Max** — The maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — The minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — The difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** —The average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — The median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Array Plot, the Signal Statistics measurements automatically adjust to the time range shown in the display. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. In the Array Plot menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the toolbar, select the Peak Finder  button.



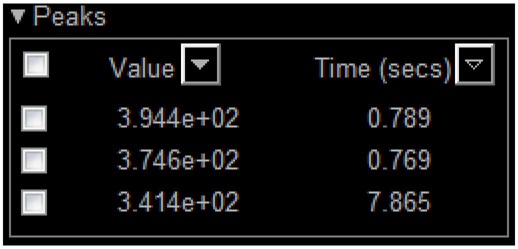
Settings

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `findpeaks` function `MINPEAKHEIGHT` parameter.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `findpeaks` function `NPEAKS` parameter.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `findpeaks` function `MINPEAKDISTANCE` parameter.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples The peak excursion setting is equivalent to the `findpeaks` function`THRESHOLD` parameter.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot.
  - `X+Y` — Display both *x*-axis and *y*-axis values
  - `X` — Display only *x*-axis values
  - `Y` — Display only *y*-axis values

Peaks

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. The value you specify in **Max Num of Peaks** determines the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `findpeaks` function `pks` output argument. The numerical values displayed in the second column are similar to the `findpeaks` function `locs` output argument.

By default, the **Peaks** pane displays the largest calculated peak values in decreasing order of peak height. Use the sort descending ( ) or ascending ( ) button to rearrange the order in which the peak values display.

Use the check boxes to control which peak values are displayed. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values.

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

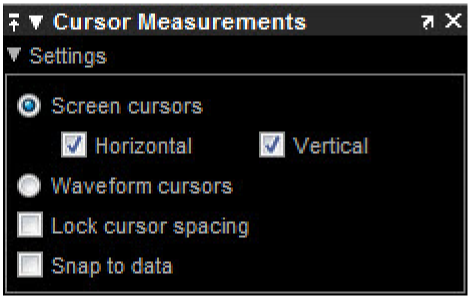
Note: If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements button.

Settings

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

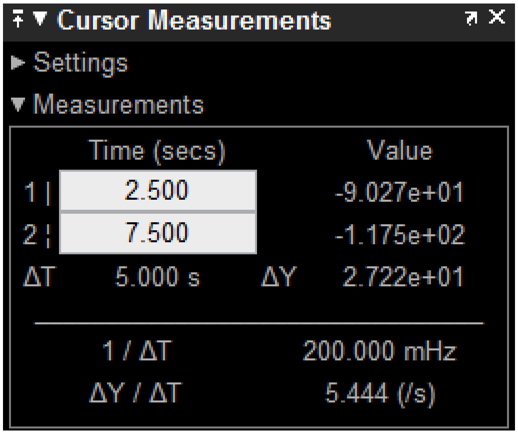


- **Screen Cursors** — Shows screen cursors
- **Horizontal** — Shows horizontal screen cursors
- **Vertical** — Shows vertical screen cursors
- **Waveform Cursors** — Shows cursors that attach to the input signals
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors
- **Snap to Data** — Positions the cursors on signal data points

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Measurements

The **Measurements** pane shows the time and value measurements.



- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the scope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

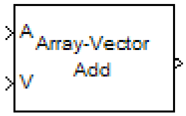
Array-Vector Add

Add vector to array along specified dimension



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Array-Vector Add block adds the values in the specified dimension of the N-dimensional input array *A* to the values in the input vector *V*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Add block adds each element of *V* to the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Add along dimension** parameter is set to 2, the output of the block *Y(i,j,k)* is

$$Y(i,j,k) = A(i,j,k) + V(j)$$

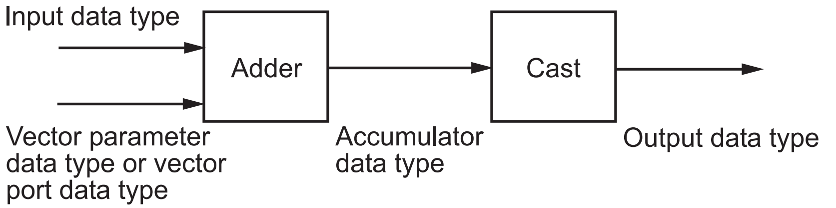
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Add block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Add block for fixed-point signals.

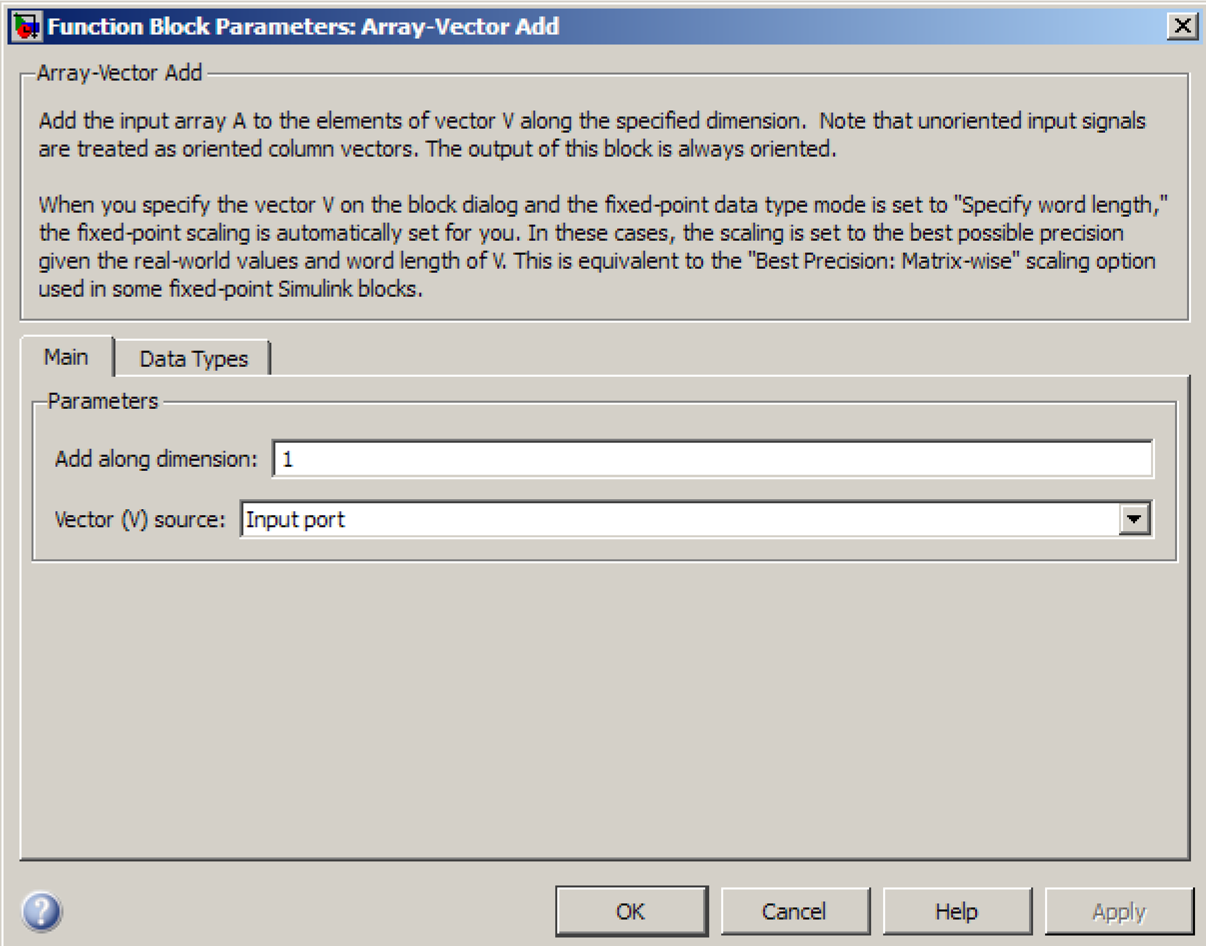


When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Add block dialog appears as follows.



Add along dimension

Specify the dimension along which to add the input array A to the elements of vector V.

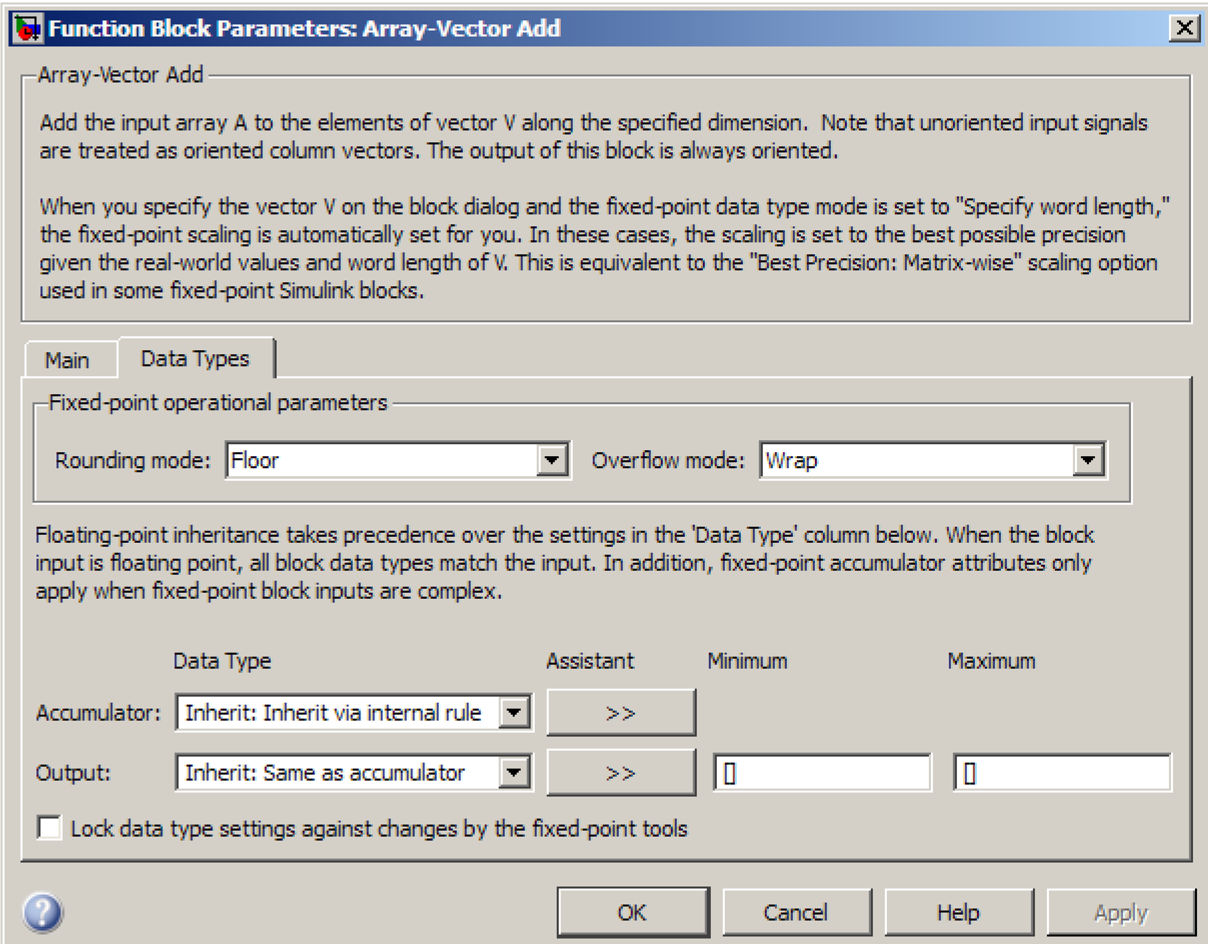
Vector (V) source

Specify the source of the vector, V. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Add block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations. If Accumulator Data Type is Inherit: Inherit via internal rule and Output Data Type is Inherit: Same as accumulator, the value of Rounding mode does not affect the numerical results.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the overflow mode for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-58 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-58 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))

- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

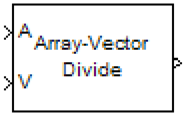
Array-Vector Divide

Divide array by vector along specified dimension



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Array-Vector Divide block divides the values in the specified dimension of the N-dimensional input array *A* by the values in the input vector *V*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Divide block divides each element of *V* by the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Divide along dimension** parameter is set to 2, the output of the block *Y(i,j,k)* is

$$Y(i,j,k) = \frac{A(i,j,k)}{V(j)}$$

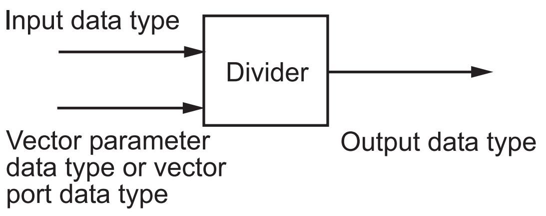
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Divide block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point input arrays, and real floating-point and fixed-point input vectors.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Divide block for fixed-point signals.

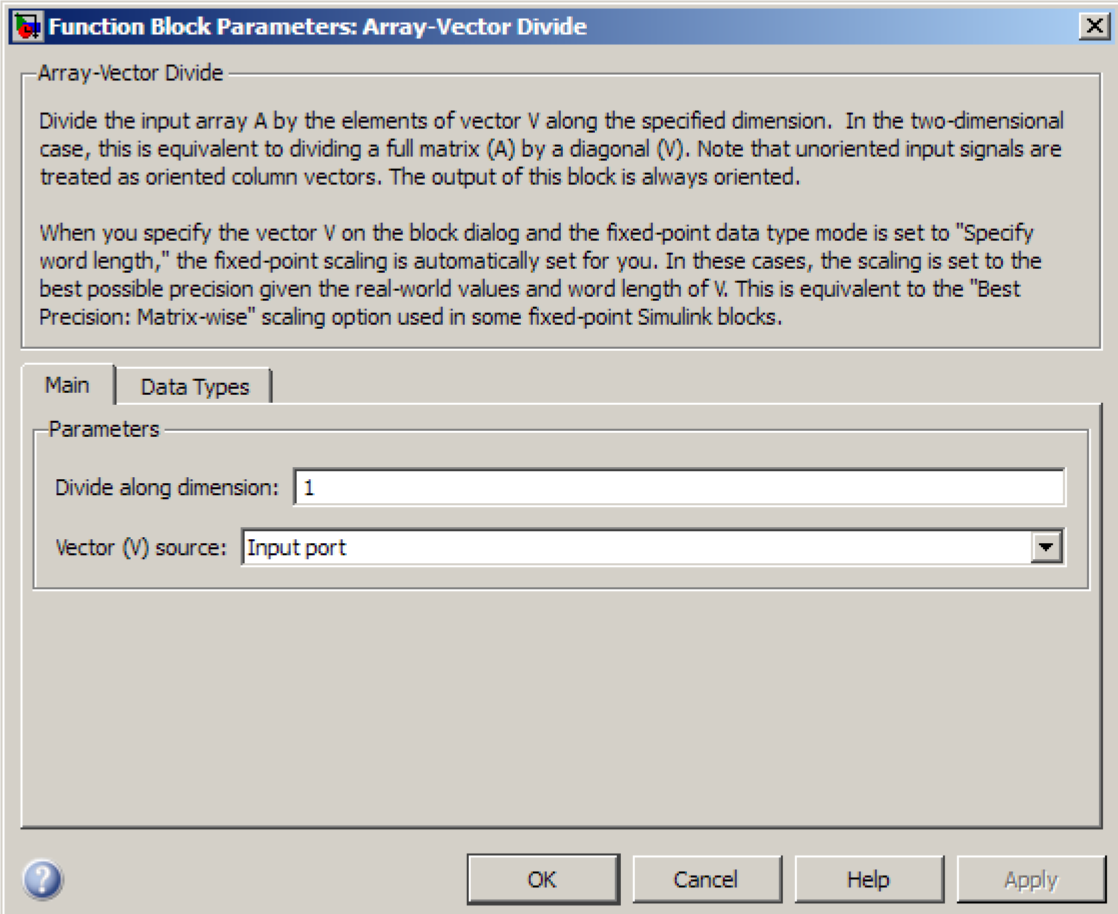


When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Divide block dialog appears as follows.



Divide along dimension

Specify the dimension along which to divide the input array *A* by the elements of vector *V*.

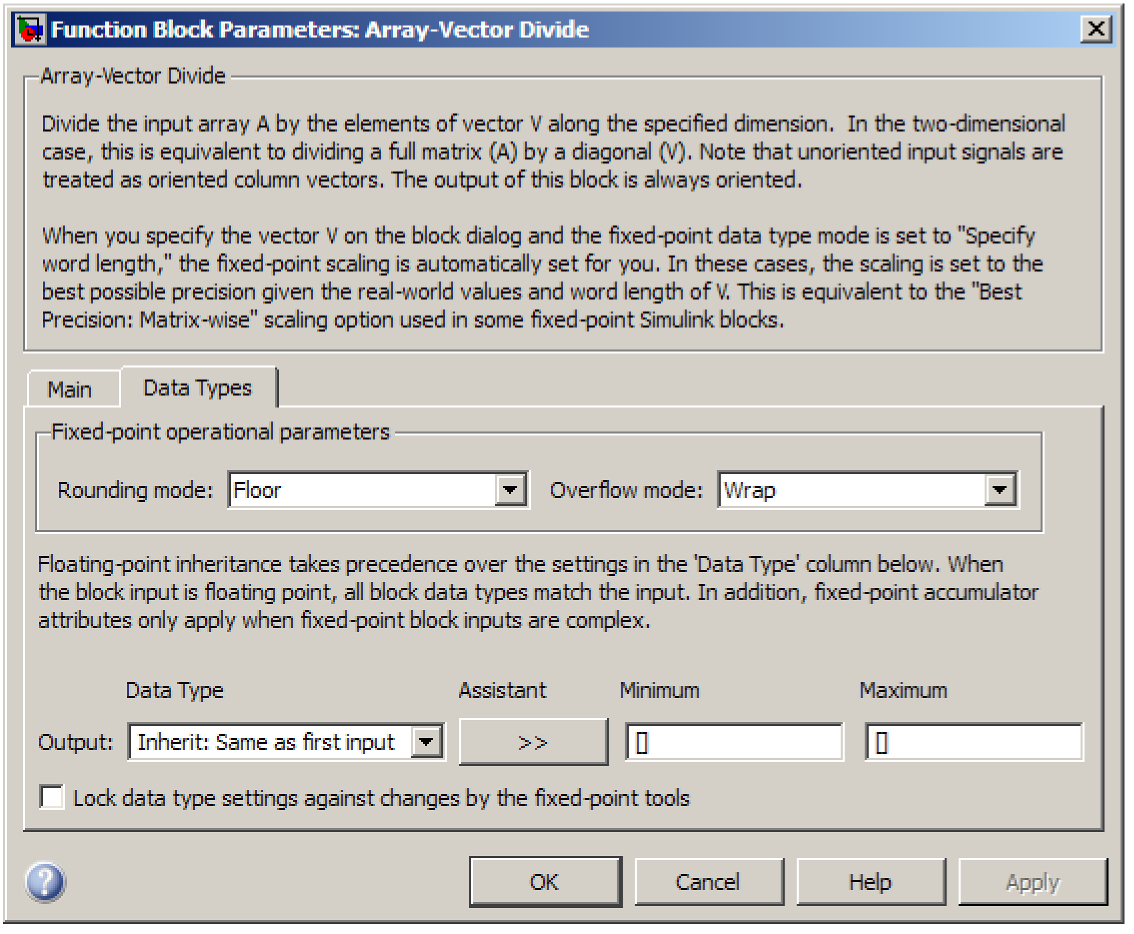
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Divide block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-65 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

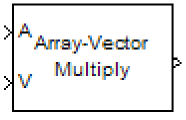
Array-Vector Multiply

Multiply array by vector along specified dimension



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Array-Vector Multiply block multiplies the values in the specified dimension of the N-dimensional input array *A* by the values in the input vector *V*.

The length of the input *V* must be the same as the length of the specified dimension of *A*. The Array-Vector Multiply block multiplies each element of *V* by the corresponding element along that dimension of *A*.

Consider a 3-dimensional *M*-by-*N*-by-*P* input array *A(i,j,k)* and a *N*-by-1 input vector *V*. When the **Multiply along dimension** parameter is set to 2, the output of the block *Y(i,j,k)* is

$$Y(i,j,k) = A(i,j,k) * V(j)$$

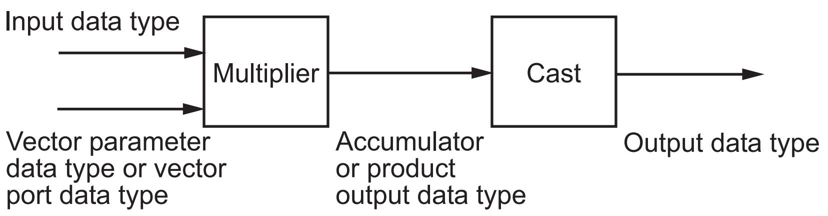
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Multiply block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Multiply block for fixed-point signals.



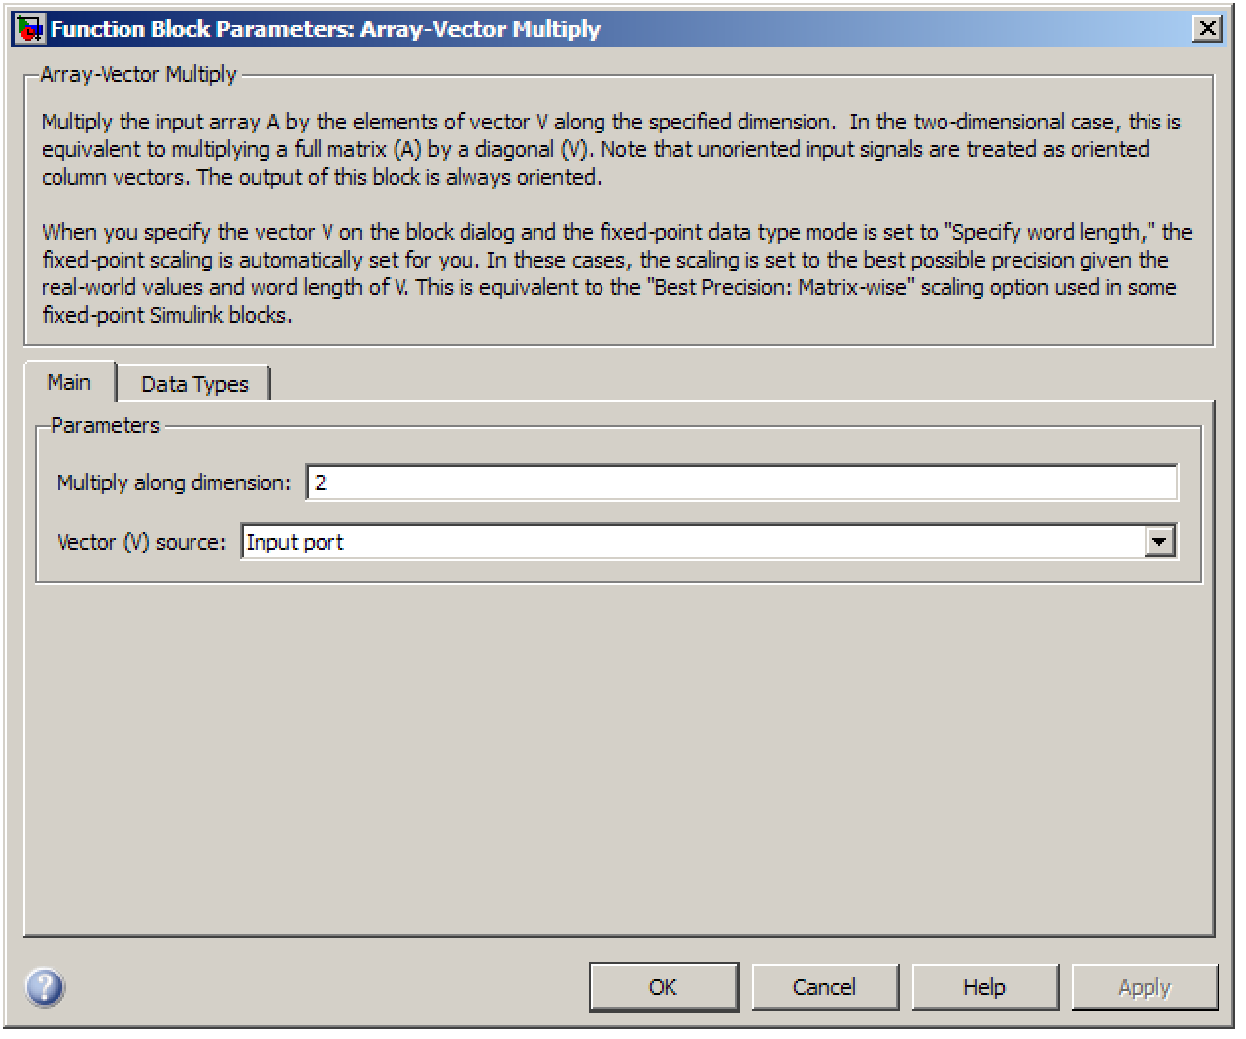
When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

You can set the vector, accumulator, product output, and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Multiply block dialog appears as follows.



Multiply along dimension

Specify the dimension along which to multiply the input array *A* by the elements of vector *V*.

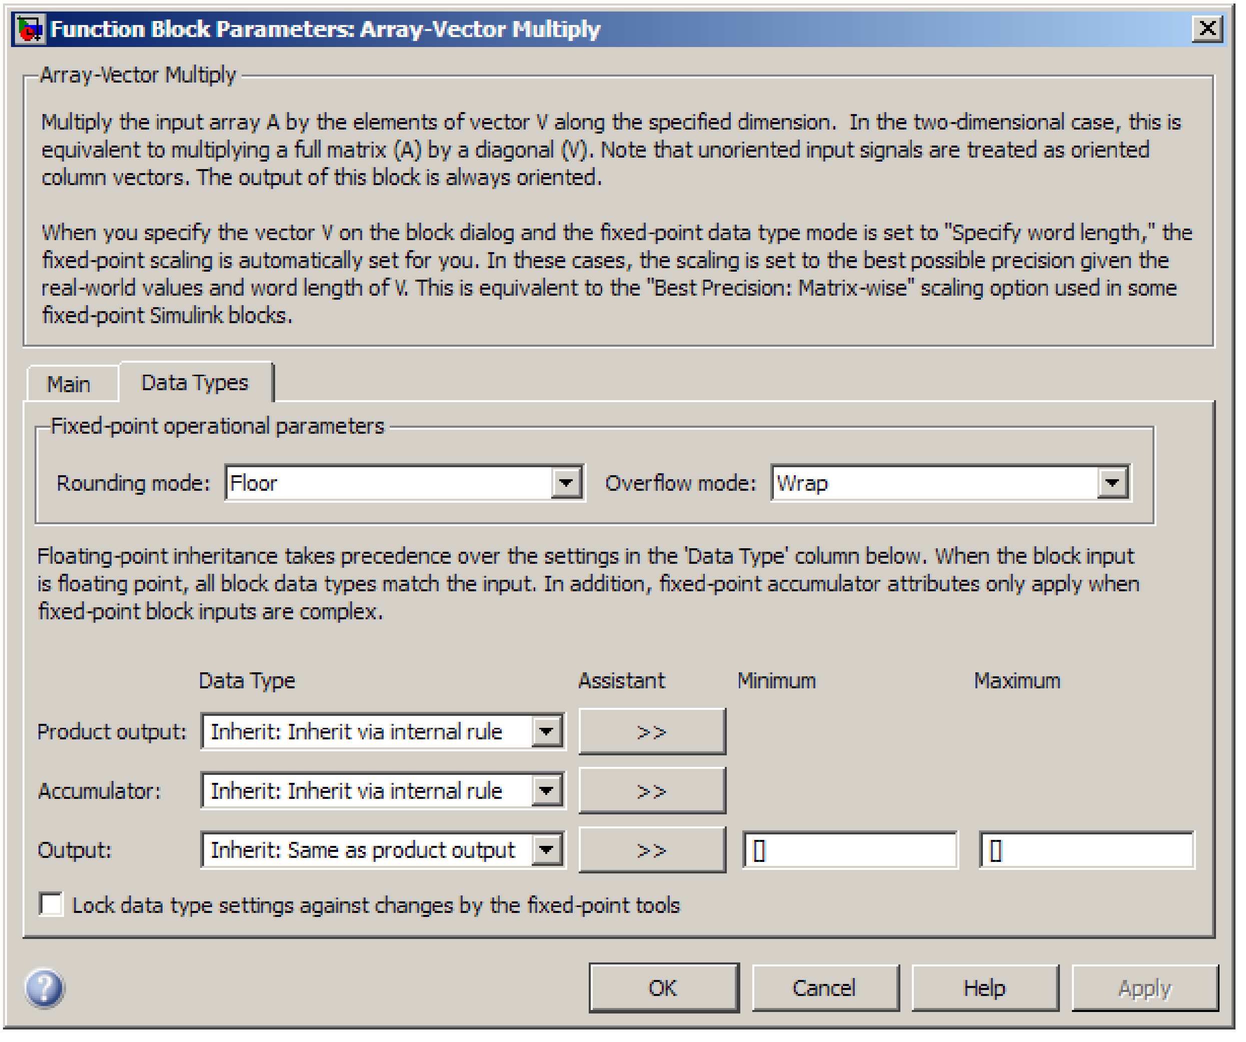
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Multiply block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-72 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-72 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-72 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

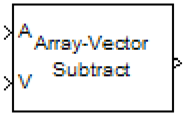
`Array-Vector Subtract`	DSP System Toolbox

Introduced in R2007b

Array-Vector Subtract

Subtract vector from array along specified dimension



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Array-Vector Subtract block subtracts the values in the input vector V from the values in the specified dimension of the N-dimensional input array A.

The length of the input V must be the same as the length of the specified dimension of A. The Array-Vector Subtract block subtracts each element of V from the corresponding element along that dimension of A.

Consider a 3-dimensional M-by-N-by-P input array $A(i,j,k)$ and a N-by-1 input vector V. When the **Subtract along dimension** parameter is set to `2`, the output of the block $Y(i,j,k)$ is

$$Y(i,j,k) = A(i,j,k) - V(j)$$

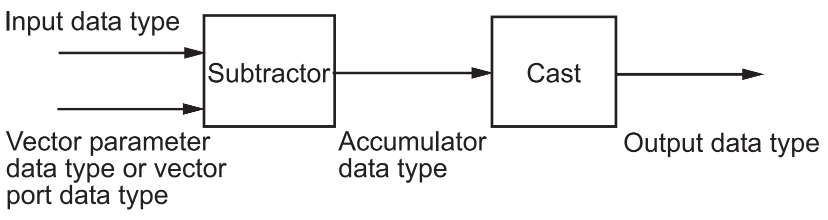
where

$$1 \le i \le M$$
$$1 \le j \le N$$
$$1 \le k \le P$$

The output of the Array-Vector Subtract block is the same size as the input array, *A*. This block accepts real and complex floating-point and fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Subtract block for fixed-point signals.



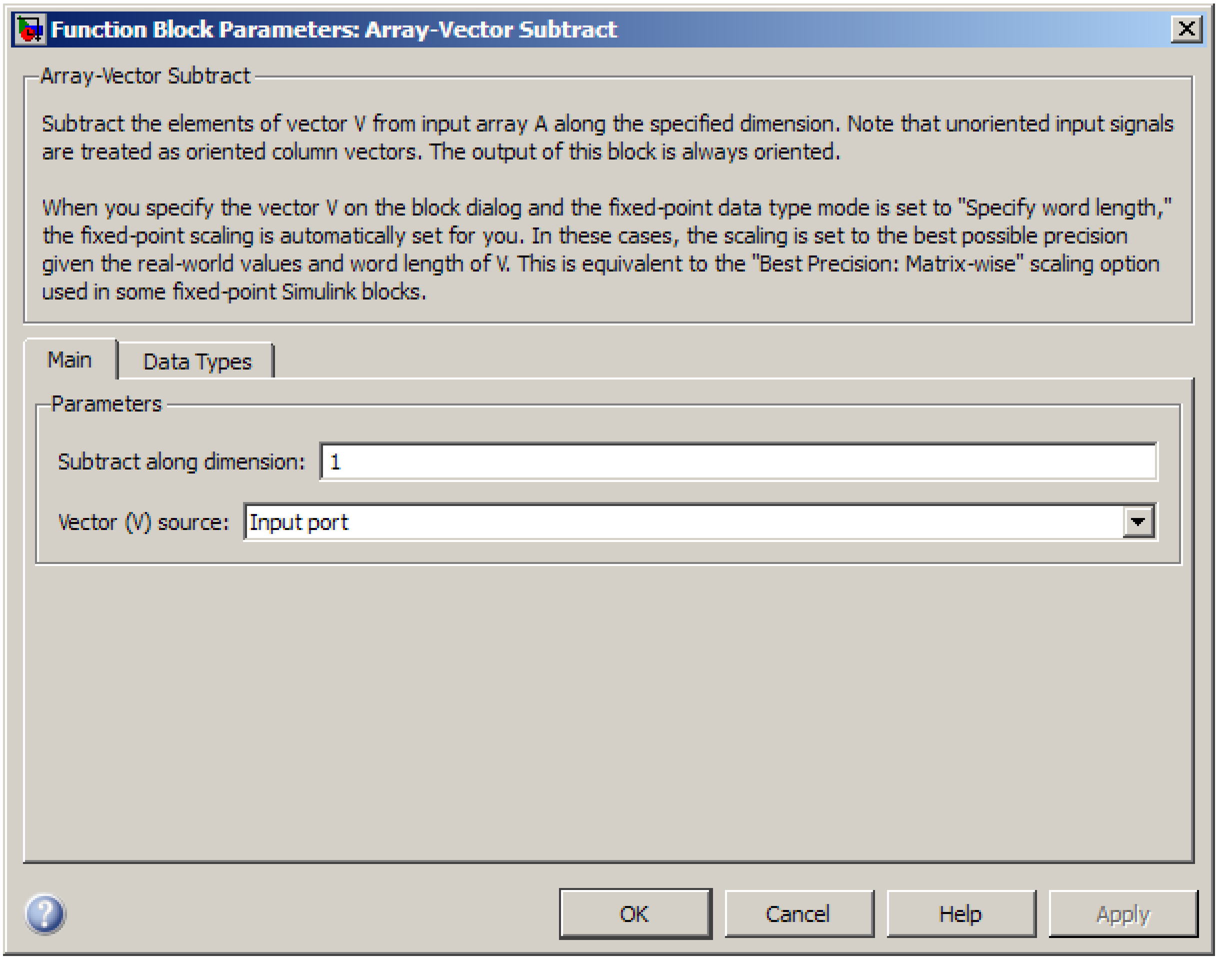
When you specify the vector *V* on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the subtractor is in the accumulator data type.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Array-Vector Subtract block dialog appears as follows.



Subtract along dimension

Specify the dimension along which to subtract the elements of vector *V* from the input array *A*.

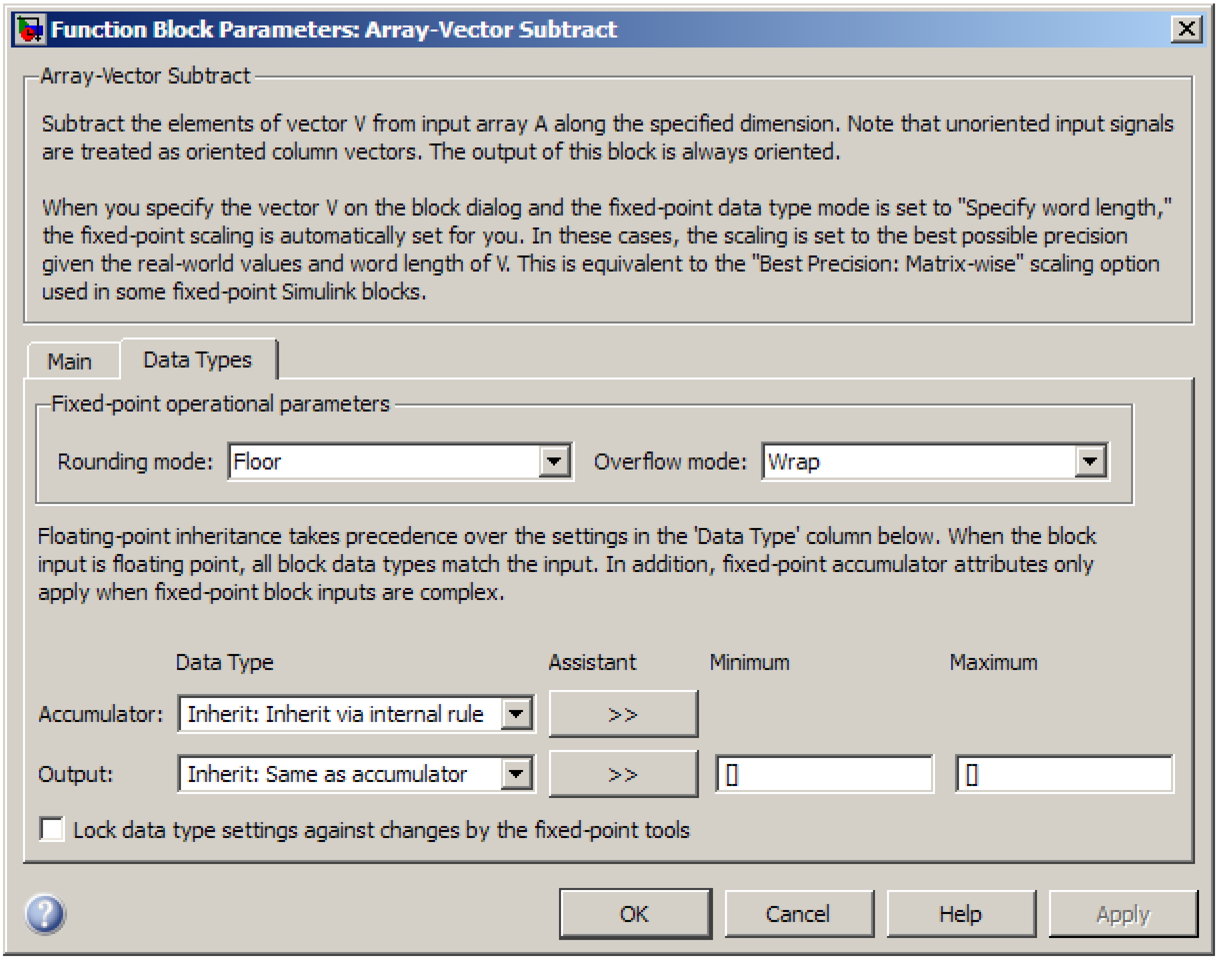
Vector (V) source

Specify the source of the vector, *V*. The vector can come from the `Input port` or from a `Dialog parameter`.

Vector (V)

Specify the vector, *V*. This parameter is visible only when you select `Dialog parameter` for the **Vector (V) source** parameter.

The **Data Types** pane of the Array-Vector Subtract block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the overflow mode for fixed-point operations.

Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Note The **Vector (V)** parameter on the **Data Types** pane is only visible when you select `Dialog parameter` for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-80 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-80 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))

- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

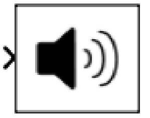
`Array-Vector Multiply`	DSP System Toolbox

Introduced in R2007b

Audio Device Writer

Play to sound card

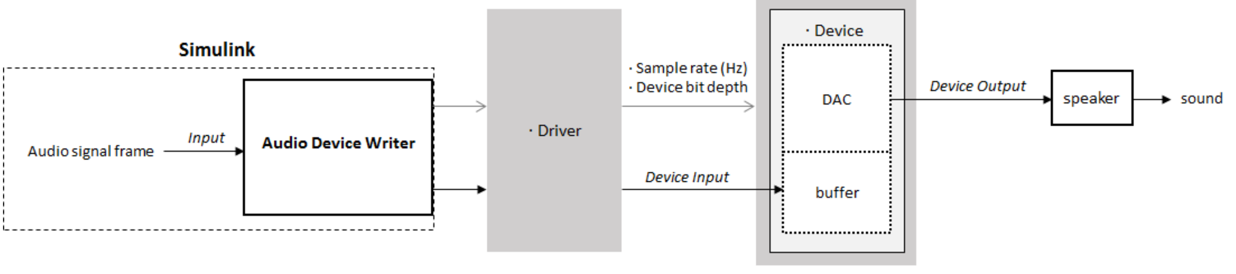
Library: DSP System Toolbox / Sinks



Description

The Audio Device Writer block writes audio samples to an audio output device.

Parameters of the Audio Device Writer block specify the driver, the device, and device attributes such as sample rate and bit depth.



Data Flow of Audio Device Writer Block

- An audio signal frame is input to the Audio Device Writer block.
- The Audio Device Writer block uses the specified driver to pass the frame (device input) to your specified audio device buffer.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

If input to the Audio Device Writer block is of data type `double` or `single`, the block clips values outside the range [–1, 1]. For other data types, the allowed input range is [min, max] of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Output

`Port_1` — Number of samples underrun

scalar

This port outputs the number of samples underrrun while writing a frame of data (one input matrix).

Dependencies

To enable this port, select the **Output number of samples underrun** parameter.

Data Types: `uint32`

Parameters

Main Tab

`Driver` — Driver used to access your audio device

`DirectSound` (default) | `ASIO` | `WASAPI`

- ASIO drivers do not come pre-installed on Windows machines. To use the `ASIO` driver option, install an ASIO driver outside of MATLAB.

Note: If **Driver** is set to `ASIO`, open the ASIO UI outside of MATLAB to set the sound card buffer size to the frame size (number of rows) input to the Audio Device Writer block. See the documentation of your ASIO driver for more information.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, supply an audio stream with a sample rate supported by your audio device.

This parameter applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault **Driver** values, you must install Audio System Toolbox™. If the toolbox is not installed, specifying nondefault **Driver** values returns an error.

`Device` — Device used to play audio samples

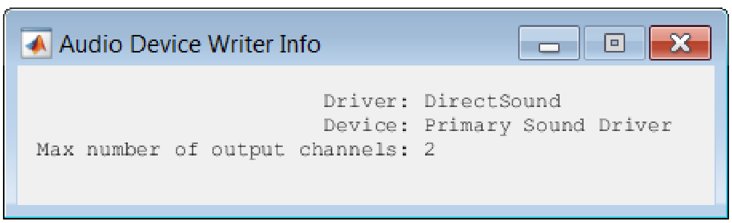
default audio device (default)

The device list is populated with devices available on your computer.

`Info` — View information about your audio output configuration

button

This button opens a dialog box that lists your selected audio driver, the full name of your audio device, and the maximum output channels for your configuration. For example:



`Inherit sample rate from input` — Specify source of input sample rate

on (default) | off

When you select this parameter, the block inherits its sample rate from the input signal. When you clear this parameter, you specify the sample rate in **Sample rate (Hz)**.

`Sample rate (Hz)` — Sample rate used by device to play audio data
`44100` (default) | positive scalar

The possible range of **Sample rate (Hz)** depends on your audio hardware.

Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

Advanced Tab

`Device bit depth` — Data type used by device to perform digital-to-analog conversion
`16-bit integer` (default) | `8-bit integer` | `24-bit integer` | `32-bit float`

Before performing digital-to-analog conversion, the input data is cast to a data type specified by this parameter.

Note: To specify a nondefault **Device bit depth**, you must install Audio System Toolbox. If the toolbox is not installed, specifying a nondefault **Device bit depth** returns an error.

`Use default mapping between columns of input of this block and sound card's output channels` — Toggle channel mapping source
on (default) | off

When you select this parameter, the block uses the default mapping between columns of the matrix input to this block and the channels of your device. When you clear this parameter, you specify the mapping in **Device output channels**.

`Device output channels` — Specify nondefault channel mapping
`[1:MaximumOutputChannels]` (default) | scalar | vector

Nondefault mapping between columns of matrix input to the Audio Device Writer block and channels of output device, specified as a scalar or vector. For example:

If **Device output channels** is specified as `1:3`, then:

- The first column of the input matrix maps to channel 1.
- The second column of the input matrix maps to channel 2.

- The third column of the input matrix maps to channel 3.

If **Device output channels** is specified as `[3,1,2]`, then:

- The first column of the input matrix maps to channel 3.
- The second column of the input matrix maps to channel 1.
- The third column of the input matrix maps to channel 2.

Note: To selectively map between columns of the input matrix and your sound card's output channels, you must install Audio System Toolbox. If the toolbox is not installed, specifying nondefault values for **Device output channels** returns an error.

Dependencies

To enable this parameter, clear the **Use default mapping between columns of input of this block and sound card's output channels** parameter.

`Output number of samples underrun` — Specify output port for number of samples underrun
off (default) | on

When you select this parameter, an output port is added to the block. The port outputs the number of samples underrrun while writing a frame of data (one input matrix).

Model Examples

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

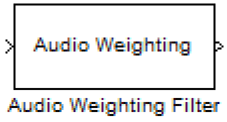
Audio Weighting Filter

Design audio weighting filter



Note: The Audio Weighting Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Audio Weighting Filter block from Audio System Toolbox instead.

Library

Filtering / Filter Designs

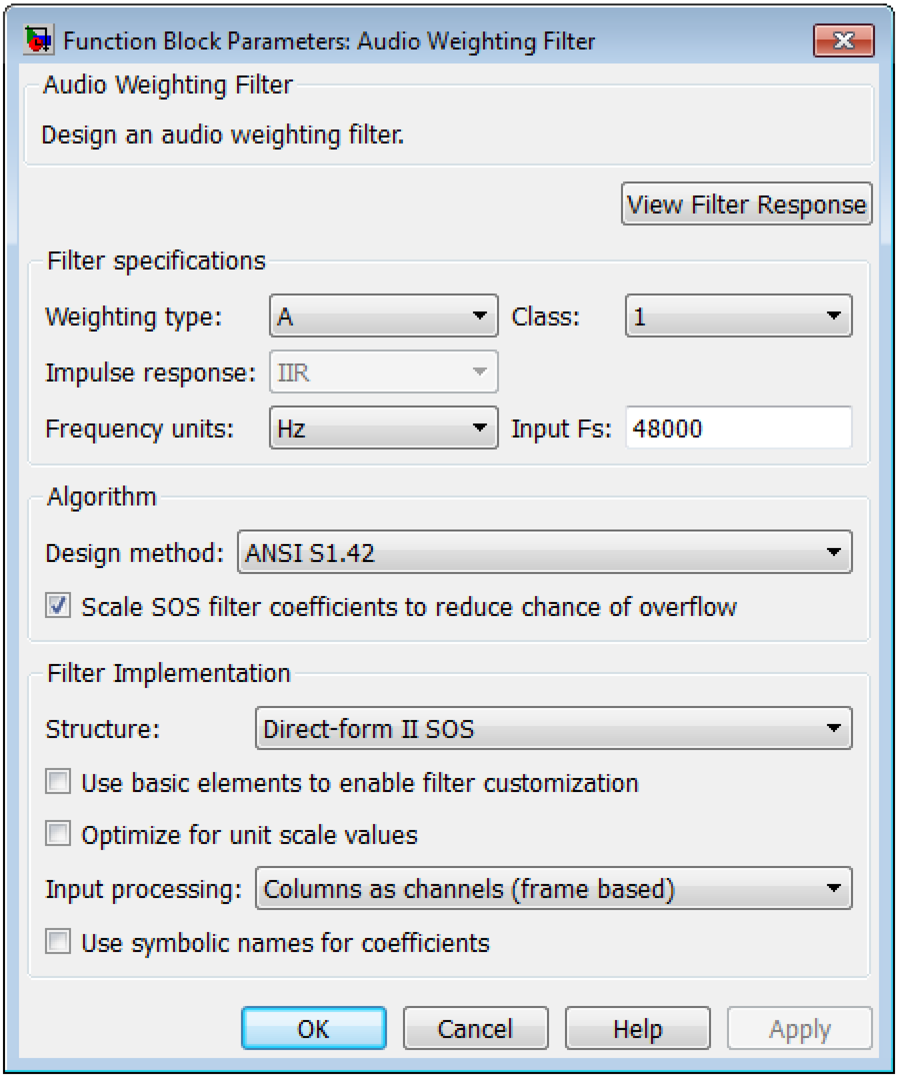
`dspfdesign`

Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

See "Audio Weighting Filter Design — Main Pane" on page 5-714 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



View Filter Response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.

- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types for this filter are `A`, `C` , `C-message`, `ITU-R 468–4`, and `ITU-T 0.41`. For definitions of the available weighting types, see the `fdesign.audioweighting` reference page.

Class

The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: `1` and `2`. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design. The default value of this parameter is `1`.

The filter class is only applicable for `A` weighting and `C` weighting filters.

Impulse response

Specify the impulse response type as one of `IIR` or `FIR`. For A, C , C-message, and ITU-R 468–4 filter, `IIR` is the only option. For a ITU-T 0.41 weighting filter, `FIR` is the only option.

Frequency units

Specify the frequency units as Hertz (Hz), kilohertz (kHz), megahertz (MHz), or gigahertz (GHz). Normalized frequency designs are not supported for audio weighting filters. The default value of this parameter is `Hz`.

Input Fs

Specify the input sampling frequency. The units correspond to the setting of the **Frequency units** parameter.

Algorithm

Design Method

Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is `ANSI S1.42`. This is an IIR design method that follows ANSI standard S1.42–2001. For a C message filter, the only valid design method is `Bell 41009`, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468–4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is `IIR least p-norm`. If you choose an FIR design, the design method choices are `Equirriple` or `Frequency Sampling`. For an ITU-T 0.41 weighting filter, the available FIR design methods are `Equirriple` or `Frequency Sampling`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose a direct form, direct-form transposed, direct-form symmetric, or direct-form asymmetric structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point

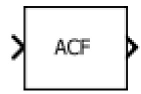
Audio Weighting Filters Example

Introduced in R2011b

Autocorrelation

Autocorrelation of *N*-D array

Library: DSP System Toolbox / Statistics



Description

The Autocorrelation block computes the autocorrelation along the first dimension of an *N*-D input array. The computation can be done in the time domain or frequency domain. You can specify the domain through the **Computation domain** parameter. In the time domain, the input signal is convolved with its time-reversed complex conjugate. In the frequency domain, the block computes the autocorrelation by taking the Fourier transform of the input signal, multiplying the Fourier transform with its conjugate, and computing the inverse Fourier transform of the product. In this domain, depending on the input length, the block can require fewer computations. For information on these two computation methods, see "Algorithms" on page 2-104.

You can specify the maximum lag for autocorrelation using the **Compute all non-negative lags** and **Maximum non-negative lag (less than input length)** parameters.

The block accepts fixed-point signals when you set the **Computation domain** to `Time`.

Ports

Input

`Port_1` — Data input

vector | matrix | *N*-D array

Data input. The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to `Time`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

Complex Number Support: Yes

Output

`Port_1` — Autocorrelated output
vector | matrix | *N*-D array

Autocorrelated output of the data input.

- When the input is an *M*-by-*N* matrix, *u*, the output, *y*, is an (*l*+1)-by-*N* matrix. *l* is the maximum positive lag for autocorrelation.
- When the input is an *N*-D array, the block outputs an *N*-D array. The size of the first dimension is *l*+1, and the sizes of all other dimensions match those of the input array. For example, when the input is an *M*-by-*N*-by-*P* array, the block outputs an (*l*+1)-by-*N*-by-*P* array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

Parameters

Main Tab

`Compute all non-negative lags` — Compute autocorrelation over all nonnegative lags
on (default) | off

When you select this parameter, the Autocorrelation block computes the autocorrelation over all nonnegative lags in the range [0, `length(input)` – 1]. When you clear this parameter, the block computes the autocorrelation using the lags in the range [0, *l*], where *l* is the value you specify in **Maximum non-negative lag (less than input length)**.

`Maximum non-negative lag (less than input length)` — Maximum positive lag
`1` (default) | integer greater than or equal to 0 and less than input length

Maximum positive lag for autocorrelation, specified as an integer that is greater than or equal to 0 and less than the input length.

Dependencies

To enable this parameter, clear the **Compute all non-negative lags** parameter.

`Scaling` — Scaling of the output

`None` (default) | `Biased` | `Unbiased` | `Unity at zero-lag`

Scaling applied to the output.

- `None` — Generates the raw autocorrelation $y_{i,j}$ without normalization.
- `Biased` — Generates the biased estimate of the autocorrelation.

  $$y_{i,j}^{biased} = \frac{y_{i,j}}{M}$$

- `Unbiased` — Generates the unbiased estimate of the autocorrelation.

  $$y_{i,j}^{unbiased} = \frac{y_{i,j}}{M-i}$$

- `Unity at zero-lag` — Normalizes the estimate of the autocorrelation for each channel so that the zero-lag sum, the first element in each column, is identically 1.

  $$y_{0,j} = 1$$

`Computation domain` — Domain in which the block computes the autocorrelation

`Time` (default) | `Frequency`

- `Time` — Computes the convolutions in the time domain, which minimizes the memory usage.
- `Frequency` — Computes the autocorrelation in frequency domain. For more information, see “Algorithms” on page 2-104.

To autocorrelate fixed-point signals, set this parameter to `Time`.

Data Types Tab

Note Fixed-point signals are supported for the time domain only. To use these parameters, on the **Main** tab, set **Computation domain** to `Time`.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.
- **Output** data type is `Inherit: Same as accumulator`.

With these data type settings, the block operates in full-precision mode.

`Saturate on integer overflow` — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

`Product output` — Product output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the Autocorrelation block. For more information on the product output data type, see “Multiplication Data Types” and the 'Fixed-Point Conversion' section in “Fixed Point” on page 2- .

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Autocorrelation block. For illustrations on how to use the accumulator data type in this block, see the 'Fixed-Point Conversion' section in "Fixed Point" on page 2- .

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see "Inherit via Internal Rule".
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Output` — Output data type

`Inherit: Same as accumulator` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt([],16,0)`

Output specifies the data type of the output of the Autocorrelation block. For more information on the output data type, see the 'Fixed-Point Conversion' section in "Fixed Point" on page 2- .

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.

- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Output Minimum` — Minimum value the block can output

[ ] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See "Signal Ranges" (Simulink).
- Automatic scaling of fixed-point data types.

`Output Maximum` — Maximum value block can output

[ ] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See "Signal Ranges" (Simulink).
- Automatic scaling of fixed-point data types.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Definitions

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, *x(n)*, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0,1,\ldots,N-1$$

where h is the lag and * denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where E{ } is the expectation operator. The `Unity at zero-lag` normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(n)x(n+h)$$

Algorithms

Time domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y, is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u^*_{k,j} u_{(k+i),j} \qquad 0 \le i \le l$$

- $y_{0,j}$ is the zero-lag element in the jth column of the input.
- i is the index of the lag.
- j is the index of the input data column.
- * denotes the complex conjugate.
- M is the number of elements in each column.
- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, $l=M–1$. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M-by-N input matrix.

Frequency Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

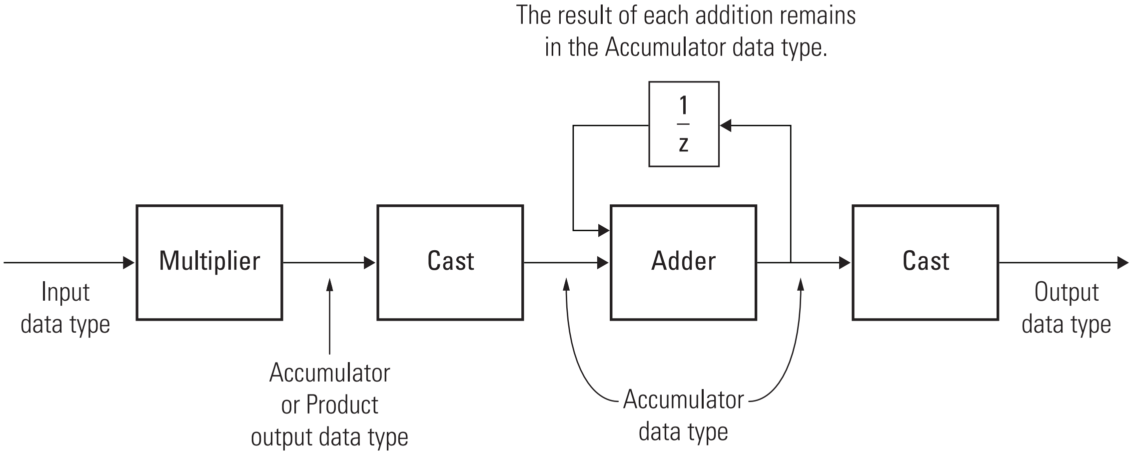
Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

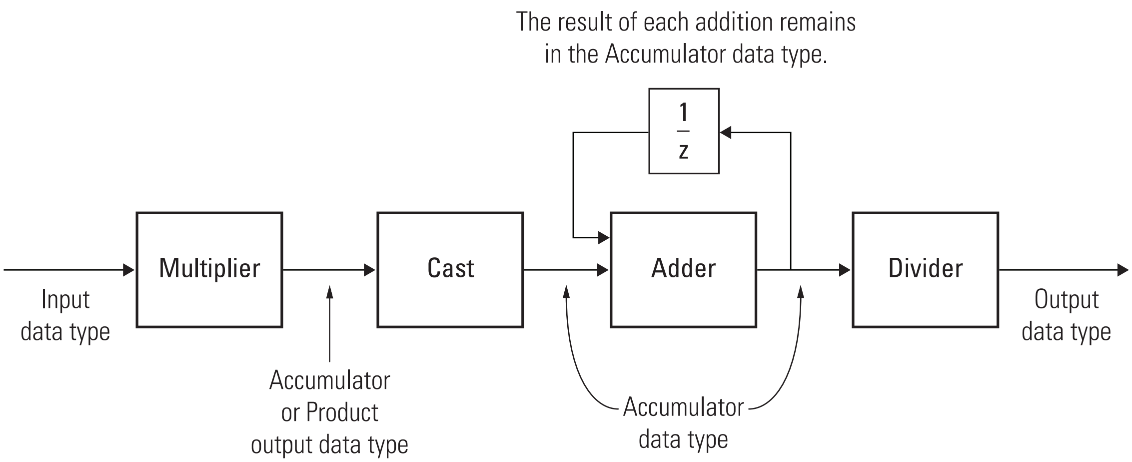
Design and simulate fixed-point algorithms using Fixed-Point Designer™.

These diagrams show the data types that the Autocorrelation block uses for fixed-point signals (time domain only).

Signal flow when Scaling is "None"



Signal flow when Scaling is other than "None"



You can set the product output, accumulator, and output data types on the **Data Types** tab of the block.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

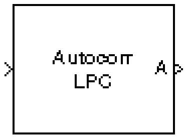
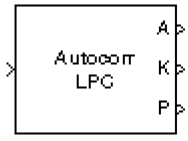
Blocks
`Correlation`

Introduced before R2006a

Autocorrelation LPC

Determine coefficients of Nth-order forward linear predictors





Library

Estimation / Linear Prediction

`dsplp`

Description

The Autocorrelation LPC block determines the coefficients of an *N-step forward linear predictor* for the time-series in each length-M input channel, u, by minimizing the prediction error in the least squares sense. A linear predictor is an FIR filter that predicts the next value in a sequence from the present and past inputs. This technique has applications in filter design, speech coding, spectral analysis, and system identification.

The Autocorrelation LPC block can output the prediction error for each channel as polynomial coefficients, reflection coefficients, or both. It can also output the prediction error power for each channel. The input u can be an unoriented vector, column vector, or a matrix. Row vectors are not valid inputs. The block treats all M-by-N matrix inputs as N channels of length M.

When you select **Inherit prediction order from input dimensions**, the prediction order, N, is inherited from the input dimensions. Otherwise, you can use the **Prediction order** parameter to specify the value of N. Note that N must be a scalar with a value less than the length of the input channels or the block produces an error.

When **Output(s)** is set to A, port A is enabled. For each channel, port A outputs an (N+1)-by-1 column vector, $a = [1\ a_2\ a_3\ \ldots\ a_{N+1}]^T$, containing the coefficients of an Nth-order moving average (MA) linear process that predicts the next value, $\hat{u}_{M+1}$, in the input time-series.

$$\hat{u}_{M+1} = -(a_2 u_M) - (a_3 u_{M-1}) - \ldots - (a_{N+1} u_{M-N+1})$$

When **Output(s)** is set to K, port K is enabled. For each channel, port K outputs a length-N column vector whose elements are the prediction error reflection coefficients. When **Output(s)** is set to `A and K`, both port A and K are enabled, and each port outputs its respective set of prediction coefficients for each channel.

When you select **Output prediction error power (P)**, port P is enabled. The prediction error power is output at port P as a vector whose length is the number of input channels.

Algorithm

The Autocorrelation LPC block computes the least squares solution to

$$\min_{\tilde{a} \in \Re^n} \| U\tilde{a} - b \|$$

where $\|\cdot\|$ indicates the 2-norm and

$$U = \begin{bmatrix} u_1 & 0 & \cdots & 0 \\ u_2 & u_1 & \ddots & \vdots \\ \vdots & u_2 & \ddots & 0 \\ \vdots & \vdots & \ddots & u_1 \\ \vdots & \vdots & \vdots & u_2 \\ \vdots & \vdots & \vdots & \vdots \\ u_M & \vdots & \vdots & \vdots \\ 0 & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & u_M \end{bmatrix}, \tilde{a} = \begin{bmatrix} a_2 \\ \vdots \\ a_n + 1 \end{bmatrix}, b = \begin{bmatrix} u_2 \\ u_3 \\ \vdots \\ u_M \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

Solving the least squares problem via the normal equations

$$U^* U \tilde{a} = U^* b$$

leads to the system of equations

$$\begin{bmatrix} r_1 & r_2^* & \cdots & r_n^* \\ r_2 & r_1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & r_2^* \\ r_n & \cdots & r_2 & r_1 \end{bmatrix} \begin{bmatrix} a_2 \\ a_3 \\ \vdots \\ a_{n+1} \end{bmatrix} = \begin{bmatrix} -r_2 \\ -r_3 \\ \vdots \\ -r_{n+1} \end{bmatrix}$$

where $r = [r_1\ r_2\ r_3\ \ldots\ r_{n+1}]^T$ is an autocorrelation estimate for u computed using the Autocorrelation block, and * indicates the complex conjugate transpose. The normal equations are solved in $O(n^2)$ operations by the Levinson-Durbin block.

Note that the solution to the LPC problem is very closely related to the Yule-Walker AR method of spectral estimation. In that context, the normal equations above are referred to as the Yule-Walker AR equations.

Parameters

Output(s)

The type of prediction coefficients output by the block. The block can output polynomial coefficients (`A`), reflection coefficients (`K`), or both (`A and K`).

Output prediction error power (P)

When selected, enables port `P`, which outputs the output prediction error power.

Inherit prediction order from input dimensions

When selected, the block inherits the prediction order from the input dimensions.

Prediction order (N)

Specify the prediction order, N, which must be a scalar. This parameter is disabled when you select the **Inherit prediction order from input dimensions** parameter.

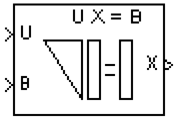
Backward Substitution

Solve $UX=B$ for X when U is upper triangular matrix



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The Backward Substitution block solves the linear system $UX=B$ by simple backward substitution of variables, where:

- U is the upper triangular M-by-M matrix input to the U port.
- B is the M-by-N matrix input to the B port.

The M-by-N output matrix X is the solution of the equations. The block does not check the rank of the inputs.

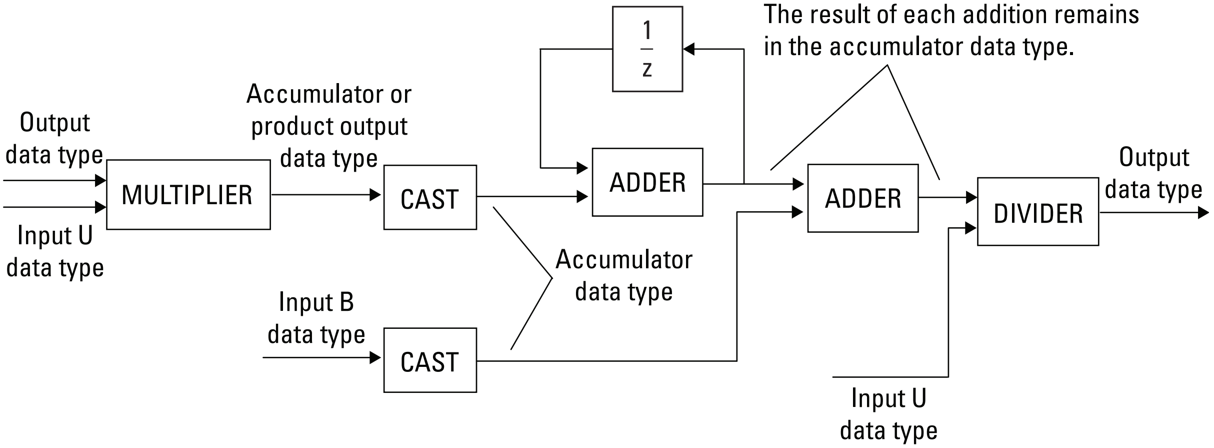
The block uses only the elements in the *upper triangle* of input U and ignores the lower elements. When you select the **Input U is unit-upper triangular** check box, the block assumes the elements on the diagonal of U are 1s. This is useful when matrix U is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the D matrix.

The block treats a length-M vector input at port B as an M-by-1 matrix.

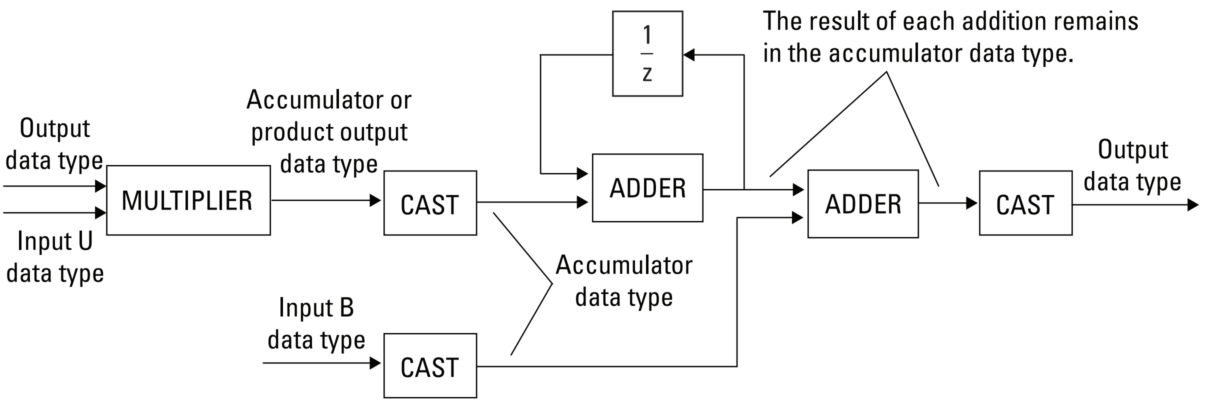
Fixed-Point Data Types

The following diagram shows the data types used within the Backward Substitution block for fixed-point signals.

When input U is not unit-upper triangular:



When input U is unit-upper triangular:

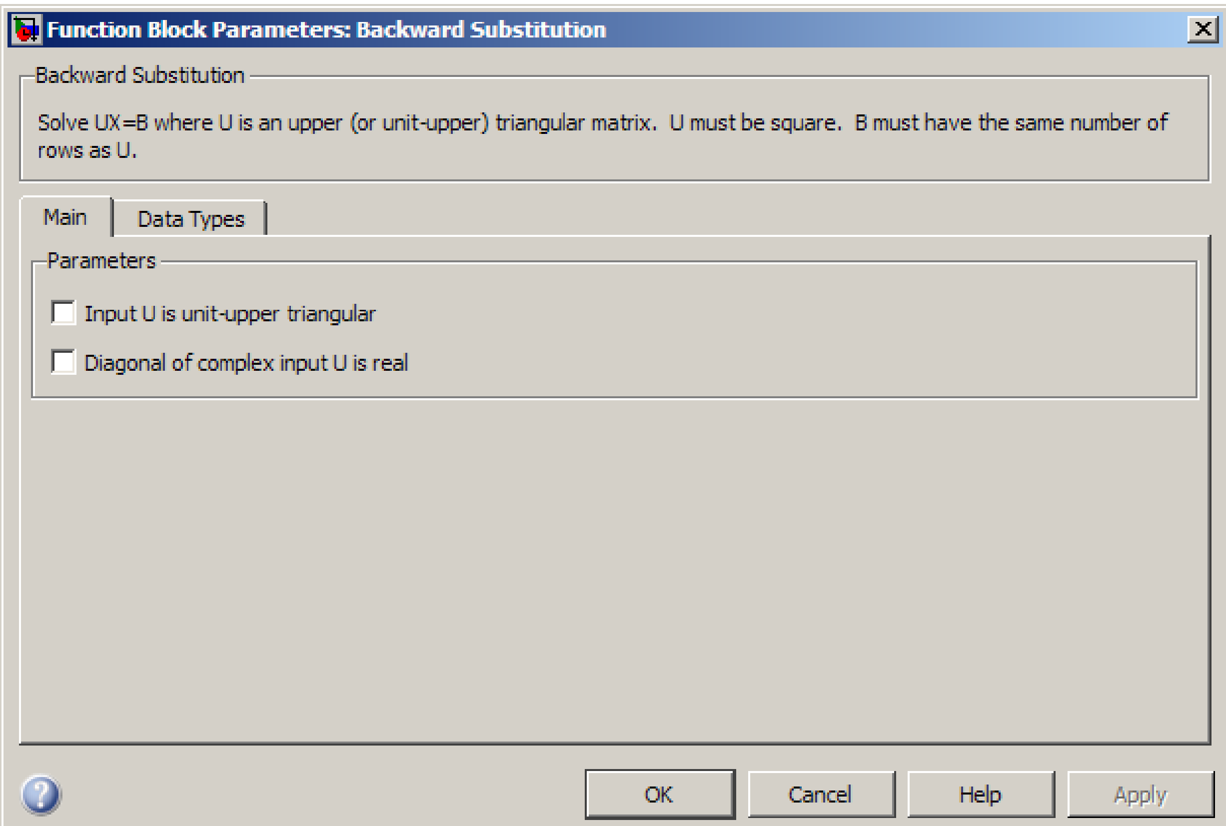


You can set the product output, accumulator, and output data types in the block dialog as discussed in the following section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

Dialog Box

The **Main** pane of the Backward Substitution block dialog box appears as follows.



Input U is unit-upper triangular

Select this check box only when all elements on the diagonal of *U* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary divide operation.

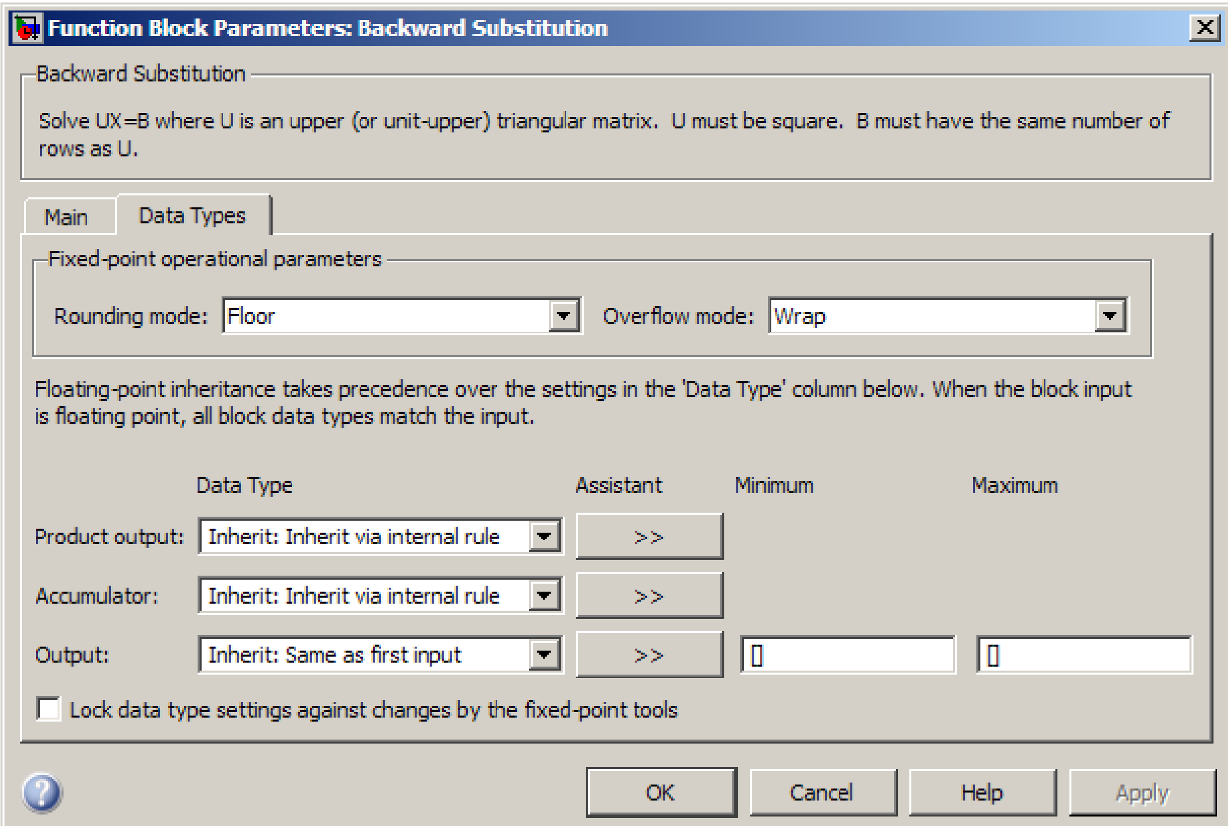
Do not select this check box if there are any elements on the diagonal of *U* that do not have a value of 1. When you clear the **Input U is unit-upper triangular** check box, the block always performs the necessary divide operation.

Diagonal of complex input U is real

Select to optimize simulation speed when the diagonal elements of complex input U are real. This parameter is only visible when **Input U is unit-upper triangular** is not selected.

Note: When U is a complex fixed-point signal, you must select either **Input U is unit-upper triangular** or **Diagonal of complex input U is real**. In such a case, any imaginary part of the diagonal of U is ignored.

The **Data Types** pane of the Backward Substitution block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-112 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-112 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-112 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
U	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
X	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

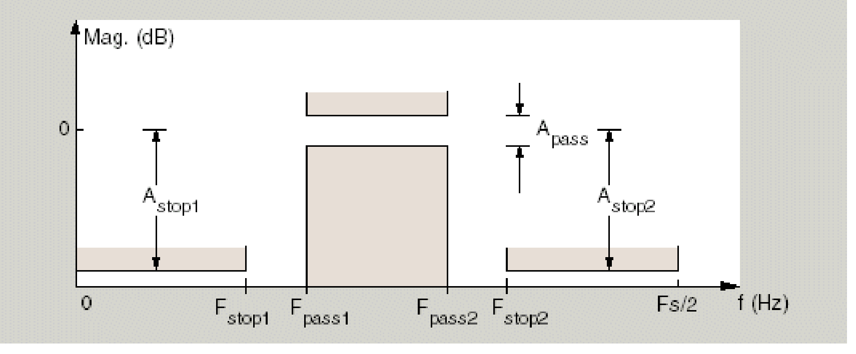
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, regions between specification values such as Fstop1 and Fpass1 represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- `3 dB points` — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- `3 dB points and passband width` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- `3 dB points and stopband widths` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- `6 dB points` — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you selected for **Frequency units**.

Fpass2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB1

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the lower-frequency 3 dB point.

F3dB2

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the higher-frequency 3 dB point.

F6dB1

When **Frequency constraints** is `6 dB points`, specify the lower-frequency 6 dB point.

F6dB2

When **Frequency constraints** is `6 dB points`, specify the higher-frequency 6 dB point.

Passband width

When **Frequency constraints** is `3 dB points and passband width`, specify the width of the passband, in units corresponding to the **Frequency units** parameter.

Stopband width

When **Frequency constraints** is `3 dB points and stopband width`, specify the width of the stopband, in units corresponding to the **Frequency units** parameter.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. When you set the **Frequency constraints** parameter to `Unconstrained`, **Magnitude constraints** must also be set to `Unconstrained`. When **Frequency constraints** is not set to `Unconstrained`, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, `Passband ripple`, `Passband ripple and stopband attenuation` or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications.

From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in dB (decibels). This is the default setting.
- `Squared` — Specify the magnitude in squared units.

Astop1

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Note: Generally, **Minimum order** designs are not available for IIR filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

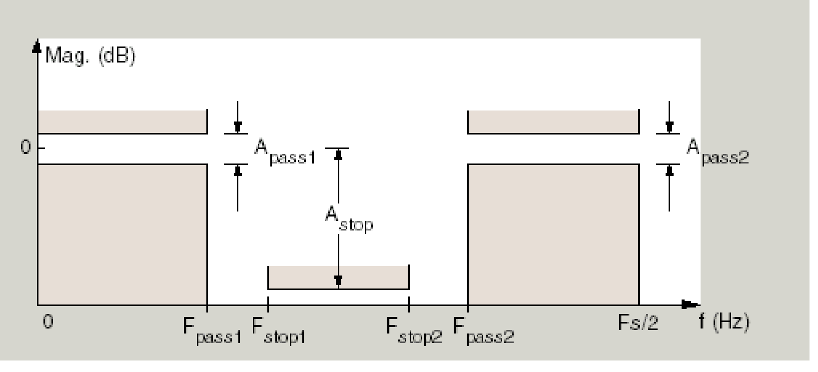
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- `3 dB points` — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- `3 dB points and passband width` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- `3 dB points and stopband widths` — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- `6 dB points` — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

When you design an interpolator, Fs represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is `interpolator`.

Fpass1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB1

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the lower-frequency 3 dB point.

F3dB2

When **Frequency constraints** is `3 dB points`, `3 dB points and passband width`, or `3 dB points and stopband width`, specify the higher-frequency 3 dB point.

F6dB1

When **Frequency constraints** is `6 dB points`, specify the lower-frequency 6 dB point.

F6dB2

When **Frequency constraints** is `6 dB points`, specify the higher-frequency 6 dB point.

Passband width

When **Frequency constraints** is `3 dB points and passband width`, specify the width of the passband, in units corresponding to the **Frequency units** parameter.

Stopband width

When **Frequency constraints** is `3 dB points and stopband width`, specify the width of the stopband, in units corresponding to the **Frequency units** parameter.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. Depending on the value of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, `Passband ripple and stopband attenuation`, or `Constrained bands`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

Apass2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2006b

Binary File Reader

Read data from binary files
Library: DSP System Toolbox / Sources

Description

The Binary File Reader block reads multichannel signal data from a binary file. The block reads the header that precedes the data. The **File header** parameter specifies the structure of the header. You can specify the type, size, and complexity of the data through the block parameters. You can also export the header to the base workspace by clicking on the **Export header to base workspace** button.

The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of the file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the `Binary File Writer` block.

Ports

Output

`data` — Binary file data

column vector | row vector | matrix

The reader block reads the binary data from the file specified in the **File name** parameter. The data output from the block has dimensions **Samples per frame**-by-**Number of channels**. The block can read floating-point data and integer data. The input data can be real or complex. When the data is complex, the block reads the data as interleaved real and imaginary components. The reader assumes the default endianness of the host machine.

This port is unnamed until you select the **Output end-of-file indicator** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`EOF` — End-of-file indicator
boolean scalar

When the block reaches the end of the file, the port outputs a `1`. Otherwise, the port outputs a `0`.

This port is unnamed until you select the **Output end-of-file indicator** parameter.

Data Types: `Boolean`

Parameters

`File name` — Name of the file
`'Untitled.bin'` (default) | character vector

Name of the file from which the block reads the data. If the file is not on the MATLAB path, then specify the full path for the file.

`File header` — Size of the header
`struct([])` (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if **File header** is set to `struct('field1',1:10,'field2',single(1))`, the block assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this parameter to an empty structure, `struct([])`.

`Export header to base workspace` — Retrieve the header
button

To retrieve the file header, click **Export header to base workspace**. The block exports the file header to the base workspace.

`Storage data type` — Storage class of data in file
`'double'` (default) | `'single'` | `'int8'` | `'int16'` | `'int32'` | `'int64'` | `'uint8'` | `'uint16'` | `'uint32'` | `'uint64'`

Storage class of data in file, specified as a character vector. This parameter defines the data type of the matrix the block outputs.

`Samples per frame` — Number of samples per output frame
`1024` (default) | positive integer

Samples per frame specifies the number of rows of the output matrix that the block outputs. The output matrix has dimensions **Samples per frame**-by-**Number of channels**. Once the end of the file is reached, the block returns zeros of the specified data type, size, and complexity.

`Data is complex` — Specify data complexity
off (default) | on

When you select this parameter, the reader treats the data as complex data. The block reads the data as interleaved real and imaginary components. Configure the block to read the data as a 2-by-2 matrix. The block reads `[1 5 2 6 3 7 4 8]` as `[1 2; 3 4]+1j*[5 6; 7 8]`. When you do not select this parameter, the block reads the data as `[1 5; 2 6]`.

`Number of channels` — Number of channels
`1` (default) | positive integer

Number of channels specifies the number of columns of the output matrix that the block outputs. This parameter defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is **Samples per frame**-by-**Number of channels**. Once the end of the file is reached, if the output matrix is not full, the block fills the matrix with zeros to make it a full-sized matrix.

`Output end-of-file indicator` — End-of-file indicator
off (default) | on

When you select this parameter, an additional output port named **EOF** appears on the block. When the block reaches the end of the file, the port outputs a `1`. Otherwise, the port outputs a `0`.

`Sample time (s)` — Sample time
1 (default) | numeric and nonnegative or -1

Sample time (s) controls the sample time at the output port of the block. This value represents $1/F_s$, where F_s is the sampling rate of the signal data. The Simulink sample time at the output port is **Samples per frame** × **Sample time (s)**.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation` — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Binary File Writer

Write data to binary files

Library: DSP System Toolbox / Sources

Description

The Binary File Writer block writes multichannel signal data to a binary file. The block specifies the name of the file and the structure of the header that precedes the signal data. If there is no header to write, the block specifies an empty structure, `struct([])`. The first time you write to the file, the block writes the header, followed by the data. On subsequent calls, the block writes the remaining data. If the header is empty, then no header is written.

The block writes the data in a row-major format. For example, if the input array is [`1 2 4 5; 8 7 9 2`], the block writes the data as [`1 2 4 5 8 7 9 2`].

Ports

Input

`Port_1` — Data to write

column vector | row vector | matrix

The writer block writes the data to the file specified in the **File name** parameter. If the **File header** structure is not empty, then the writer writes the header before writing the data. The block can write floating-point data and integer data. The input data can be real or complex. When the data is complex, the block writes the data as interleaved real and imaginary components. The writer assumes the default endianness of the host machine.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

Parameters

`File name` — Name of the file

`'Untitled.bin'` (default) | character vector

Name of the file to which the block writes the data.

`File header` — Size of the header

`struct([])` (default) | structure

The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if **File header** is set to `struct('field1',1:10,'field2',single(1))`, the block writes a header formed by 10 double-precision values, `(1:10)`, followed by 1 single precision value, `single(1)`. If there is no header to write, set this parameter to an empty structure, `struct([])`.

`Simulate using` — Type of simulation to run

`Code generation` (default) | `Interpreted execution`

- `Code generation` — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Biquad Filter

Model biquadratic IIR (SOS) filters

Library

Filtering / Filter Implementations

`dsparch4`

Description

The Biquad Filter block independently filters each channel of the input signal with the specified biquadratic IIR filter. When you specify the filter coefficients in the dialog box, the block implements static filters with fixed coefficients. When you provide the filter coefficients through an input port, you can tune the coefficients during simulation.

The block filters an M-by-N input matrix as follows:

- When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column as a separate channel. In this mode, the block creates M instances of the same filter, each with its own independent state buffer. Each of the M filters process N input samples at every Simulink time step.
- When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element as a separate channel. In this mode, the block creates $M*N$ instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

This block supports variable-size input. It means that while the block is simulating, the frame size (number of rows) can change. The output dimensions always equal the dimensions of the input signal. The outputs of this block numerically match the outputs of the dsp.BiquadFilter System object™.

The Biquad Filter block supports the Simulink state logging feature. See “States” (Simulink) for more information.

Coefficient Source and Filter Structures

The Biquad Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box. If you select:

- **Dialog parameters** — Enter information about the filter such as structure and coefficients in the block mask. In this mode, you can choose the following filter structures in the **Filter structure** parameter:
  - `Direct form I`
  - `Direct form I transposed`
  - `Direct form II`
  - `Direct form II transposed`
- **Input port(s)** — Enter information about the filter structure in the block mask using the **Filter structure** parameter. The filter coefficients come into the block via input ports. The following additional ports appear on the block icon:
  - `Num` — Specify numerator coefficients
  - `Den` — Specify denominator coefficients
  - `g` — Specify scale values

  `Num` must be a 3–by–N numeric matrix, `Den` must be a 2–by–N numeric matrix, and `g` must be a 1–by–(N+1) numeric vector, where N is the number of biquad filter sections. The object assumes the first denominator coefficients of each section to be 1. This configuration is applicable when the `SOSMatrixSource` property is 'Input port' and the `ScaleValuesInputPort` property is true. The reason you would need to specify `Num` and `Den` instead of the `SOSMatrix`, is that in Fixed-Point operation, the numerators, and denominators can have different fraction lengths. Therefore, there is a need to be able to pass the data of the numerator with a fixed-point type different from that of the denominator.
- **Filter object** — Specify the filter using a dsp.BiquadFilter System object.

Specifying the SOS Matrix and Scale Values

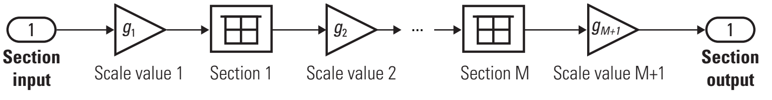
The **SOS matrix (Mx6)** is an M-by-6 matrix, where M is the number of sections in the second-order section filter. Each row of the SOS matrix contains the numerator and denominator coefficients (b_{ik} and a_{ik}) of the corresponding section in the filter.

$$\begin{bmatrix} b_{01} & b_{11} & b_{21} & a_{01} & a_{11} & a_{21} \\ b_{02} & b_{12} & b_{22} & a_{02} & a_{12} & a_{22} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{0M} & b_{1M} & b_{2M} & a_{0M} & a_{1M} & a_{2M} \end{bmatrix}$$

`ss2sos` and `tf2sos` functions from Signal Processing Toolbox convert a state-space or transfer function description of your filter into the second-order section description used by this block.

The **Scale values** parameter specifies the scale values the block uses between each SOS section. You can specify a real-valued scalar or a vector of length M+**1**.

- If you enter a scalar, the value specifies the gain value before the first section of the second-order filter. The rest of the gain values default to `1`.
- If you enter a vector of M+1 values, each value specifies a separate section of the filter. For example, the first element is the first gain value, the second element is the second gain value, and so on.



Select the **Optimize unity scale values** check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases, when there are unity scale values, selecting this parameter also omits certain casts. Refer to “Filter Structure Diagrams” on page 2-170 for more information.

Specifying Initial Conditions

The Biquad Filter block initializes the internal filter states to zero by default. Optionally, use the **Initial conditions** or **Initial conditions on zeros side** and **Initial conditions on poles side** parameters to specify nonzero initial states for the filter delays.

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

Valid Initial Conditions

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. Where *M* is the number of sections and *N* is the number of input channels: • The vector length must equal the number of delay elements in the filter, *M**2. • The matrix must have the same number of rows as the number of delay elements in the filter (*M**2)**N*. The matrix must also have one column for each channel of the input signal.

Fixed-Point Data Types

See the “Filter Structure Diagrams” on page 2-170 section for diagrams showing the data types the biquad filter block uses when processing fixed-point signals.

Examples

Open an example model by typing `ex_biquad_filter_ref` at the MATLAB command line.

Dialog Box

Coefficient Source

The Biquad Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box. If you select:

- **Dialog parameters** — Enter information about the filter such as structure and coefficients in the block mask. In this mode, you can choose the following filter structures in the **Filter structure** parameter:
  - `Direct form I`

  - `Direct form I transposed`
  - `Direct form II`
  - `Direct form II transposed`
- **Input port(s)** — Enter information about the filter structure in the block mask using the **Filter structure** parameter. The filter coefficients come into the block via input ports. The following additional ports appear on the block icon:
  - `Num` — Specify numerator coefficients
  - `Den` — Specify denominator coefficients
  - `g` — Specify scale values

  `Num` must be a 3–by–N numeric matrix, `Den` must be a 2–by–N numeric matrix, and `g` must be a 1–by–(N+1) numeric vector, where N is the number of biquad filter sections. The object assumes the first denominator coefficients of each section to be 1. This configuration is applicable when the `SOSMatrixSource` property is 'Input port' and the `ScaleValuesInputPort` property is true. The reason you would need to specify `Num` and `Den` instead of the `SOSMatrix`, is that in Fixed-Point operation, the numerators, and denominators can have different fraction lengths. Therefore, there is a need to be able to pass the data of the numerator with a fixed-point type different from that of the denominator.
- **Filter object** — Specify the filter using a dsp.BiquadFilter System object.

Specify Filter Characteristics in Dialog

The **Main** pane of the Biquad Filter block dialog appears as follows when **Dialog parameters** is selected in the **Coefficient source** group box.

Filter structure

Select the filter structure.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected.

SOS Matrix

Specify an M-by-6 matrix, where M is the number of sections in the second-order section filter. Each row of the SOS matrix contains the numerator and denominator coefficients (b_{ik} and a_{ik}) of the corresponding section in the filter.

$$\begin{bmatrix} b_{01} & b_{11} & b_{21} & a_{01} & a_{11} & a_{21} \\ b_{02} & b_{12} & b_{22} & a_{02} & a_{12} & a_{22} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{0M} & b_{1M} & b_{2M} & a_{0M} & a_{1M} & a_{2M} \end{bmatrix}$$

This parameter is only visible when **Dialog parameters** is selected.

Scale values

The **Scale values** parameter specifies the scalar or vector of M+1 scale values to be used between SOS sections.

- When you enter a scalar, the value specifies the gain value before the first section of the second-order filter. The rest of the gain values default to 1.
- When you enter a vector of M+1 values, each value specifies a separate section of the filter. For example, the first element is the first gain value, the second element is the second gain value, and so on.

  This parameter is only visible when **Dialog parameters** is selected.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-149.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form II` or `Direct form II transposed`.

Initial conditions on zeros side

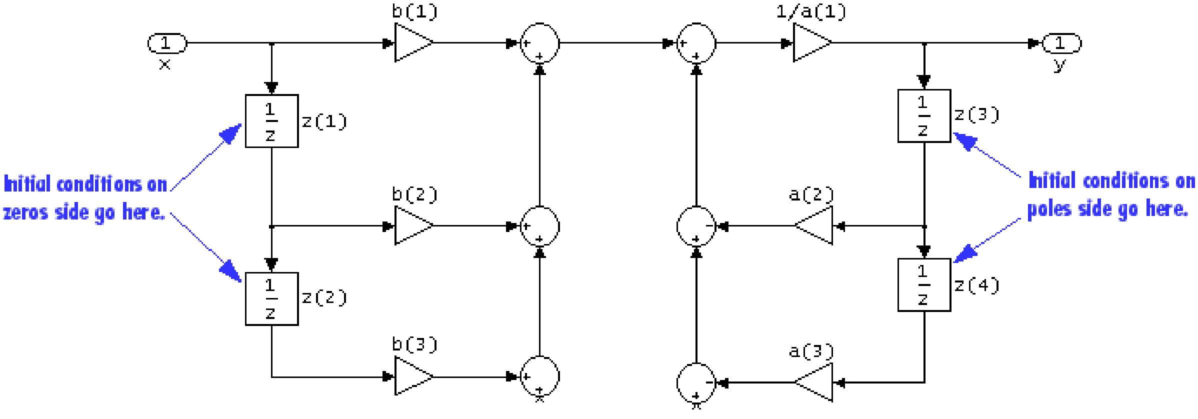
Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1,b_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 2-149.

Initial conditions on poles side

Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1,a_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 2-149.



Action when the a0 values of the SOS matrix are not one

Specify the action the block should perform when the SOS matrix a_{0j} values do not equal one; `None`, `Error`, or `Warn`.

This parameter is only visible when **Dialog parameters** is selected.

Optimize unity scale values

Select this check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. Refer to "Filter Structure Diagrams" on page 2-170 for more information.

This parameter is only visible when **Dialog parameters** is selected.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter specified in the dialog. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the Biquad Filter block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; instead, they always round to `Nearest`.

Overflow mode

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; instead, they are always saturated.

Multiplicand

Choose how you specify the word and fraction lengths of the multiplicand data type of a `Direct form I transposed` filter structure. See "Fixed-Point Data Types" on page 2-150 and the "Direct Form I Transposed" on page 2-173 filter structure diagram for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the **Filter structure** parameter is set to `Direct form I transposed`. When you select:

- `Same as output` — Word length and fraction length characteristics of **Multiplicand** data type match with those of the output of the block.
- `Binary point scaling` — Enter the word length and the fraction length of the multiplicand, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the multiplicand. This block requires power-of-two slope and a bias of zero.

Section input

Choose how you specify the word and fraction lengths of the fixed-point data type going into each section of a biquadratic filter. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the section input data type in this block. When you select:

- `Same as input` — Word length and fraction length characteristics of **Section input** data type match with those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section input, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the section input. This block requires power-of-two slope and a bias of zero.

Section output

Choose how you specify the word and fraction lengths of the fixed-point data type coming out of each section of a biquadratic filter. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the section output data type in this block. When you select:

- `Same as section input` — Word length and fraction length characteristics of **Section output** data type match with those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section output, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the section output. This block requires power-of-two slope and a bias of zero.

Coefficients

Choose how you specify the word and fraction lengths of the filter coefficients (numerator, denominator, and scale value) when **Dialog parameters** is selected in the **Coefficient source** group box. See “Fixed-Point Data Types” on page 2-150 for illustrations depicting the use of the coefficient data types in this block. When you select:

- `Same word length as input` — Word length of the filter coefficients matches with that of the input to the block. In this mode, the block automatically sets the fraction length of the coefficients to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- `Specify word length` — Enter the word length of the coefficients, in bits. In this mode, the block automatically sets the fraction length of the coefficients to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- `Binary point scaling` — Enter the word length and the fraction length of the coefficients, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator coefficients.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the coefficients. If applicable, you can enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Fixed-Point Data Types” on page 2-150 and

"Multiplication Data Types" for illustrations depicting the use of the product output data type in this block. When you select:

- `Same as input` (default) — **Product output** word length and fraction length characteristics match those of the input to the block.
- `Inherit via internal rule` — **Product output** word length and fraction lengths are computed based on full-precision rules. These rules prevent quantization from occurring within the block. Bits are added, as needed, so that no roundoff or overflow occurs. For more details, see "Inherit via Internal Rule".
- `Binary point scaling` — Enter the word length and the fraction length of the product output, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator product output data type
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the product output. If applicable, you can enter separate slopes for the numerator and denominator product output data type. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Fixed-Point Data Types" on page 2-150 and "Multiplication Data Types" for illustrations depicting the use of the accumulator data type in this block. When you select:

- `Same as input` — **Accumulator** word and fraction length characteristics match those of the input to the block.
- `Same as product output` — **Accumulator** word and fraction length characteristics match those of the product output.
- `Binary point scaling` — Enter the word length and the fraction length of the accumulator, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator accumulator data type.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the accumulator. If applicable, you can enter separate slopes for the numerator and denominator accumulator data type. This block requires power-of-two slope and a bias of zero.

State

Use this parameter to specify how you would like to designate the state word and fraction lengths when **Dialog parameters** is selected in the **Coefficient source** group box. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for `Direct form I` and `Direct form I transposed filter` structures. When you select:

- `Same as input` — **State** word and fraction length characteristics match those of the input to the block.
- `Same as accumulator` — **State** word and fraction length characteristics match those of the accumulator.
- `Binary point scaling` — Enter the word length and the fraction length of the state, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator state data type.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the state. If applicable, you can enter separate slopes for the numerator and denominator state data type. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the output data type in this block. When you select:

- `Same as input` — **Output** word and fraction length characteristics match those of the input to the block.
- `Same as accumulator` — **Output** word and fraction length characteristics match those of the accumulator.
- `Binary point scaling` — Enter the word length and the fraction length of the output, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Filter Characteristics Via Input Port

The **Main** pane of the Biquad Filter block dialog appears as follows when **Input port(s)** is selected in the **Coefficient source** group box.

Filter structure

Select the filter structure.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected in the **Coefficient source** group box.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-149.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form II` or `Direct form II transposed`.

Initial conditions on zeros side

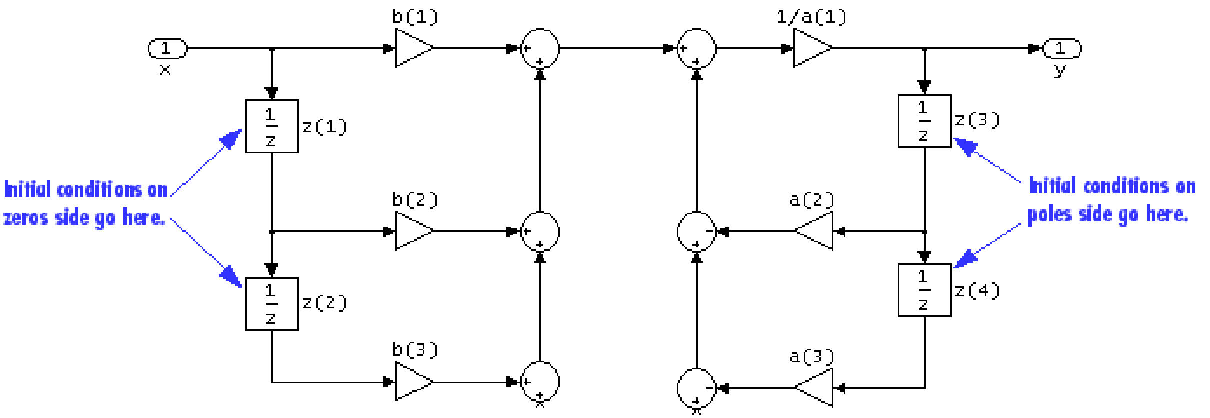
Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1,b_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-149.

Initial conditions on poles side

Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1,a_2, ...); see the next diagram.

This parameter is only visible when **Dialog parameters** or **Input port(s)** is selected and the filter structure is `Direct form I` or `Direct form I transposed`. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-149.



Scale values mode

Choose how to specify the scale values to use between filter sections. When you select `Specify via input port (g)`, you enter the scale values as a 2-D vector at port g. When you select `Assume all are unity and optimize`, all scale values are removed and treated like Simulink lines or wires.

This parameter is only visible when **Input port(s)** is selected.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

The **Data Types** pane of the Biquad Filter block dialog appears as follows when you select **Input port(s)** in the **Coefficient source** group box.

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; instead, they always round to `Nearest`.

Overflow mode

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; instead, they are always saturated.

Multiplicand

Choose how you specify the word and fraction lengths of the multiplicand data type of a `Direct form I transposed` filter structure. See "Fixed-Point Data Types" on page 2-150 and the "Direct Form I Transposed" on page 2-173 filter structure diagram for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the **Filter structure** parameter is set to `Direct form I transposed`. When you select:

- `Same as output` — Word length and fraction length characteristics of **Multiplicand** data type match with those of the output of the block.
- `Binary point scaling` — Enter the word length and the fraction length of the multiplicand, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the multiplicand. This block requires power-of-two slope and a bias of zero.

Section input

Choose how you specify the word and fraction lengths of the fixed-point data type going into each section of a biquadratic filter. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the section input data type in this block. When you select:

- `Same as input` — Word length and fraction length characteristics of **Section input** data type match with those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section input, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the section input. This block requires power-of-two slope and a bias of zero.

Section output

Choose how you specify the word and fraction lengths of the fixed-point data type coming out of each section of a biquadratic filter. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the section output data type in this block. When you select:

- `Same as section input` — Word length and fraction length characteristics of **Section output** data type match with those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section output, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the section output. This block requires power-of-two slope and a bias of zero.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Fixed-Point Data Types” on page 2-150 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. When you select:

- `Same as input` (default) — **Product output** word length and fraction length characteristics match those of the input to the block.
- `Inherit via internal rule` — **Product output** word length and fraction lengths are computed based on full-precision rules. These rules prevent quantization from occurring within the block. Bits are added, as needed, so that no roundoff or overflow occurs. For more details, see “Inherit via Internal Rule”.
- `Binary point scaling` — Enter the word length and the fraction length of the product output, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator product output data type.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the product output. If applicable, you can enter separate slopes for the numerator and denominator product output data type. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Fixed-Point Data Types” on page 2-150 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block. When you select:

- `Same as input` — **Accumulator** word and fraction length characteristics match those of the input to the block.

- `Same as product output` — **Accumulator** word and fraction length characteristics match those of the product output.
- `Binary point scaling` — Enter the word length and the fraction length of the accumulator, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator accumulator data type.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the accumulator. If applicable, you can enter separate slopes for the numerator and denominator accumulator data type. This block requires power-of-two slope and a bias of zero.

State

Use this parameter to specify how you would like to designate the state word and fraction lengths. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for `Direct form I` structure. When you select:

- `Same as input` — **State** word and fraction length characteristics match those of the input to the block.
- `Same as accumulator` — **State** word and fraction length characteristics match those of the accumulator.
- `Binary point scaling` — Enter the word length and the fraction length of the state, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator state data type.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the state. If applicable, you can enter separate slopes for the numerator and denominator state data type. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length. See "Fixed-Point Data Types" on page 2-150 for illustrations depicting the use of the output data type in this block. When you select:

- `Same as input` — **Output** word and fraction length characteristics match those of the input to the block.
- `Same as accumulator` — **Output** word and fraction length characteristics match those of the accumulator.

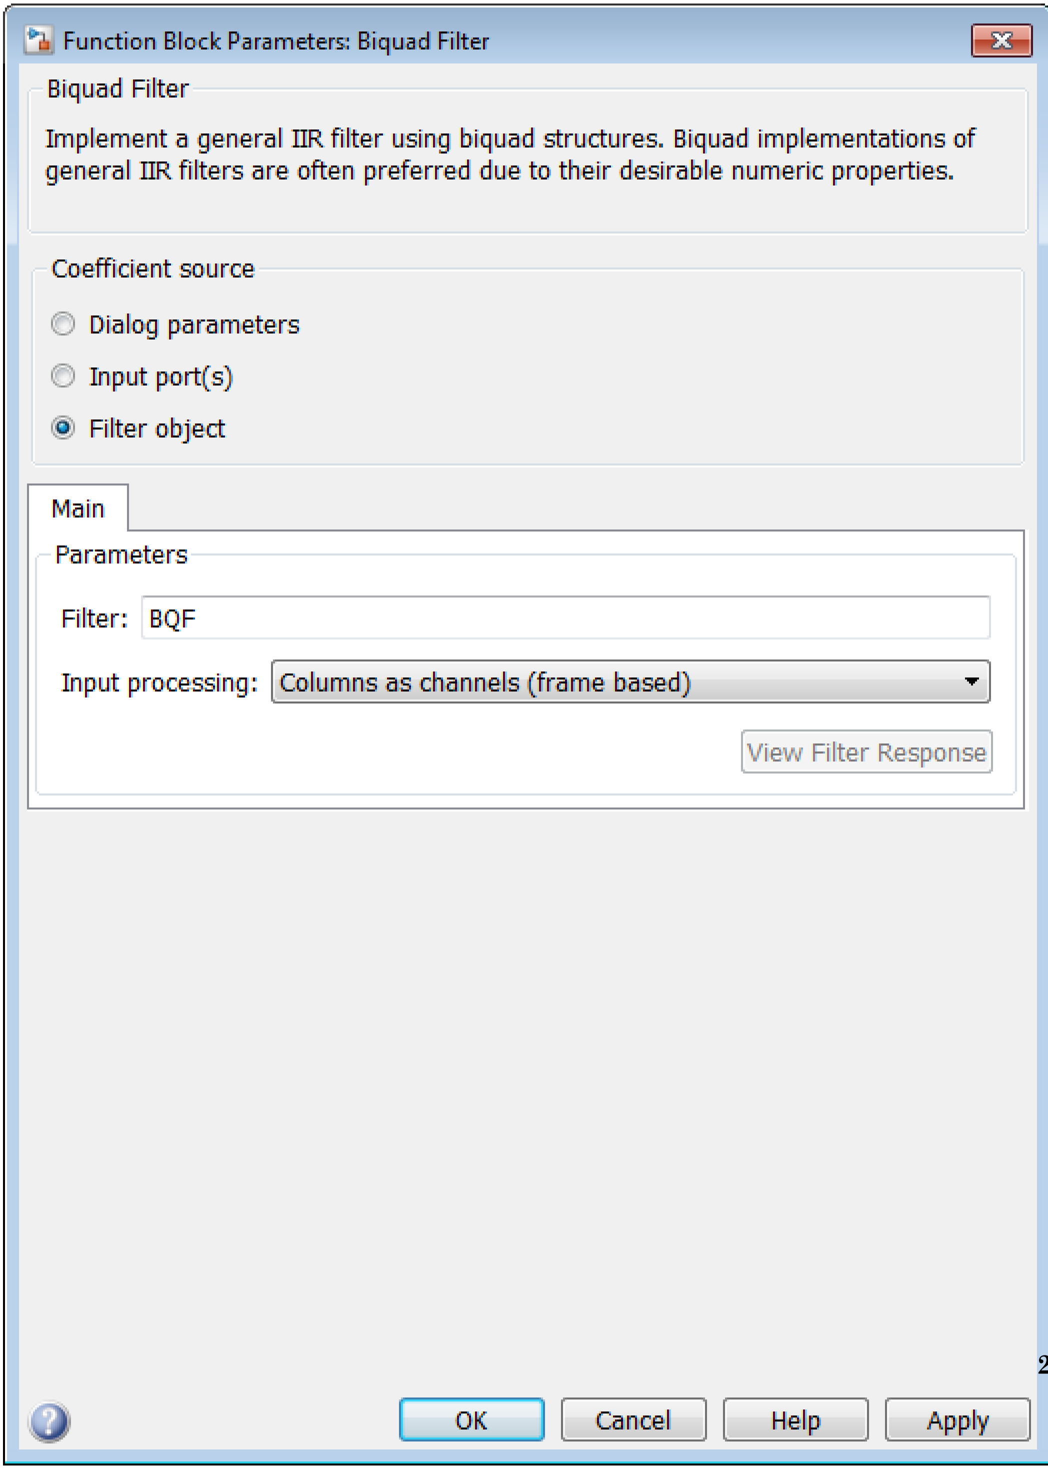
- `Binary point scaling` — Enter the word length and the fraction length of the output, in bits.
- `Slope and bias scaling` — Enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Discrete-Time Filter Object

The **Main** pane of the Biquad Filter block dialog appears as follows when **Filter object** is selected in the **Coefficient source** group box.



Function Block Parameters: Biquad Filter
Biquad Filter
Implement a general IIR filter using biquad structures. Biquad implementations of general IIR filters are often preferred due to their desirable numeric properties.
Coefficient source
Dialog parameters
Input port(s)
Filter object

Filter

Specify the name of the discrete-time filter object that you want the block to implement. You must specify the filter as a dsp.BiquadFilter System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects” (MATLAB).

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter object specified in the **Filter object** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter object** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

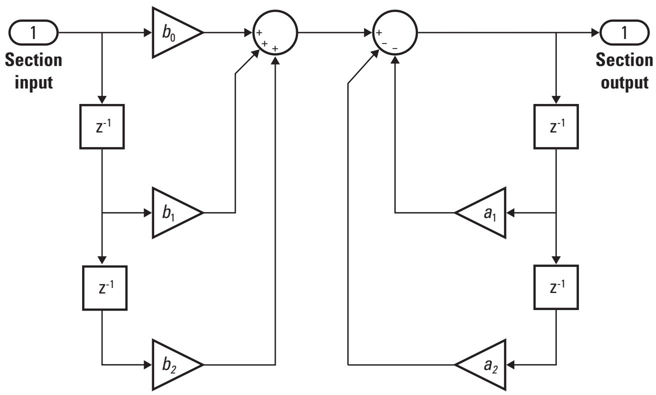
Filter Structure Diagrams

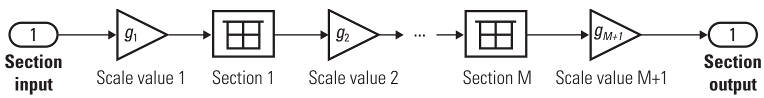
The diagrams in the following sections show the filter structures supported by the Biquad Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the data types shown in these diagrams in the block dialog box. This is discussed in “Dialog Box” on page 2-150.

- “Direct Form I” on page 2-171
- “Direct Form I Transposed” on page 2-173
- “Direct Form II” on page 2-176

- "Direct Form II Transposed" on page 2-179

Direct Form I





The following diagram shows the data types for one section of the filter for fixed-point signals.

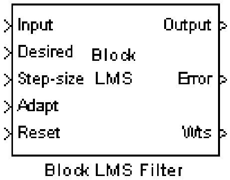
Block LMS Filter

Compute output, error, and weights using LMS adaptive algorithm



Library

Filtering / Adaptive Filters

`dspadpt3`

Description

The Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of filter weights occurs once for every block of samples. The block estimates the filter weights, or coefficients, needed to minimize the error, $e(n)$, between the output signal, $y(n)$, and the desired signal, $d(n)$. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the `Desired` port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The `Output` port outputs the filtered input signal. The `Error` port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS adaptive filter algorithm. This algorithm is defined by the following equations.

$$
\begin{aligned}
n &= kN + i \\
y(n) &= \mathbf{w}^T(k-1)\mathbf{u}(n) \\
e(n) &= d(n) - y(n) \\
\mathbf{w}(k) &= \mathbf{w}(k-1) + f(\mathbf{u}(n), e(n), \mu)
\end{aligned}
$$

The weight update function for the Block LMS adaptive filter algorithm is defined as

$$f(\mathbf{u}(n), e(n), \mu) = \mu \sum_{i=0}^{N-1} \mathbf{u}^*(kN+i)e(kN+i)$$

The variables are as follows.

Variable	Description
n	The current time index
i	The iteration variable in each block, $0 \le i \le N-1$
k	The block number
N	The block size
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at time n
$d(n)$	The desired response at time n
μ	The adaptation step size

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size** parameter.

The adaptation **Step-size (mu)** parameter corresponds to μ in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor, $0 < 1 - \mu\alpha \le 1$, in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k-1) + f(\mathbf{u}(n), e(n), \mu)$$

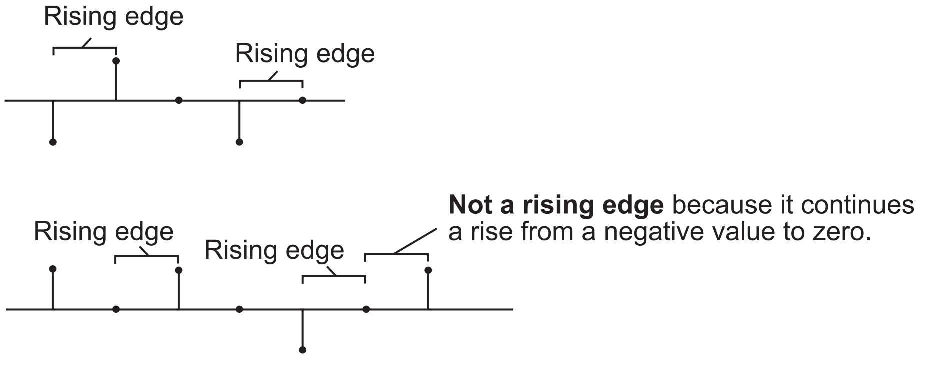
Enter the initial filter weights as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value

When you select the **Adapt port** check box, an `Adapt` port appears on the block. When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

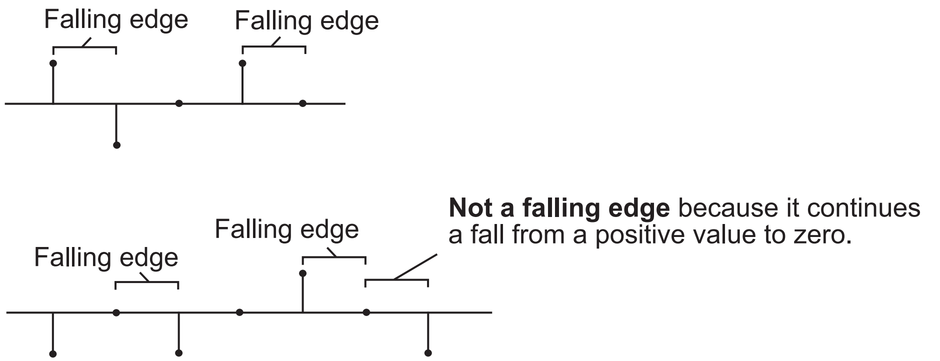
When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).



- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a `Wts` port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Parameters

Filter length

Enter the length of the FIR filter weights vector.

Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**.

Specify step-size via

Select `Dialog` to enter a value for mu in the Block parameters: LMS Filter dialog box. Select `Input port` to specify mu using the Step-size input port.

Step-size (mu)

Enter the step-size. Tunable (Simulink).

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

Reset port

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

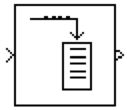
Buffer

Buffer input sequence to smaller or larger frame size



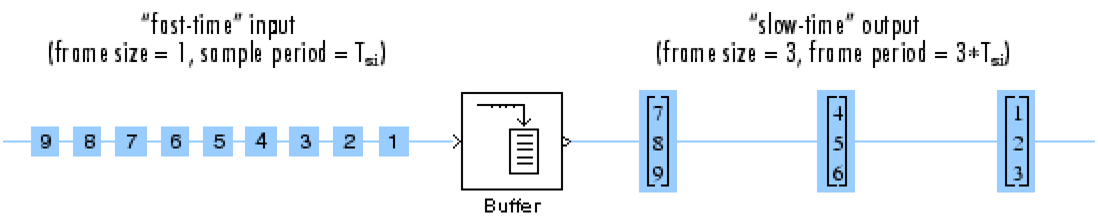
Library

Signal Management / Buffers

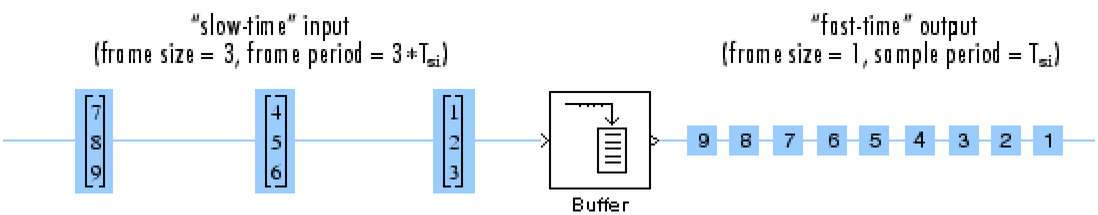
`dspbuff3`

Description

The Buffer block always performs frame-based processing. The block redistributes the data in each column of the input to produce an output with a different frame size. Buffering a signal to a larger frame size yields an output with a *slower* frame rate than the input. For example, consider the following illustration for scalar input.



Buffering a signal to a smaller frame size yields an output with a *faster* frame rate than the input. For example, consider the following illustration of scalar output.



The block coordinates the output *frame size* and *frame rate* of nonoverlapping buffers such that the sample period of the signal is the same at both the input and output: $T_{so} = T_{si}$.

This block supports triggered subsystems when the block input and output rates are the same.

Buffering Single Channel Signals

The following table shows the output dimensions of the Buffer block when the input is a single-channel signal. M_o is the value of the **Output buffer size** parameter.

Input Dimensions	Output Dimensions
1-by-1 (scalar)	M_o-by-1
M_i-by-1 (column vector)	M_o-by-1

The input frame period is $M_i \cdot T_{si}$, where M_i is the input frame size and T_{si} is the input sample period. The output frame period is $(M_o - L)T_{si}$, where L is the value of the **Buffer overlap** parameter and T_{si} is the input sample period. When you set the **Buffer overlap** parameter to $M_o - 1$, the output frame period equals the input sample period.

Buffering Multichannel Signals

The following table shows the output dimensions of the Buffer block when the input is a multichannel signal. M_o is the value of the **Output buffer size** parameter and can be greater or less than the input frame size, M_i. The block buffers each of the N input channels independently.

Input Dimensions	Output Dimensions
1-by-N (row vector)	M_o-by-N
M_i-by-N (matrix)	M_o-by-N

The input frame period is $M_i \cdot T_{si}$, where M_i is the input frame size and T_{si} is the input sample period. The output frame period is $(M_o - L)T_{si}$, which equals the sequence sample period when the **Buffer overlap** is $M_o - 1$. Thus, the output sample period is related to the input sample period by

$$T_{so} = \frac{(M_o - L)T_{si}}{M_i}$$

Buffering with Overlap or Underlap

The **Buffer overlap** parameter, L, specifies the amount of overlap or underlap in each successive output frame. To overlap the data in the buffer, specify a value of L in the range $0 \le L < M_o$, where M_o is the value of the **Output buffer size** parameter. The block takes L samples (rows) from the current output and repeats them in the next output. In cases of overlap, the block acquires $M_o - L$ *new* input samples before propagating the buffered data to the output.

When $L < 0$, you are buffering the signal with underlap. The block discards L input samples after the buffer fills and outputs the buffer with period $(M_o - L)T_{si}$, which is longer than in the zero-overlap case.

The output frame period is $(M_o - L)T_{si}$, which equals the input sequence sample period, T_{si}, when the **Buffer overlap** is $M_o - 1$.

Latency

Zero-tasking latency means that the first input sample, received at $t = 0$, appears as the first output sample. In the Simulink single-tasking mode, the Buffer block has zero-tasking latency for the following special cases:

- Scalar input and output ($M_o = M_i = 1$) with zero or negative **Buffer overlap** ($L \le 0$)
- Input frame size is an integer multiple of the output frame size

  $$M_i = kM_o$$

  where k is an integer with zero **Buffer overlap** ($L = 0$); notable cases of this include

- Any input frame size M_i with scalar output ($M_o = 1$) and zero **Buffer overlap** ($L = 0$)
- Equal input and output frame sizes ($M_o = M_i$) with zero **Buffer overlap** ($L = 0$)

For all cases of single-tasking operation other than those listed above, the Buffer block's buffer is initialized to the value(s) specified by the **Initial conditions** parameter. The block reads from this buffer to generate the first D output samples, where

$$D = \begin{cases} M_o + L & (L \geq 0) \\ M_o & (L < 0) \end{cases}$$

The dimensions of the **Initial conditions** parameter depend on the **Buffer overlap**, L, and whether the input is single-channel or multichannel:

- When $L \neq 0$, the **Initial conditions** parameter must be a scalar.
- When $L = 0$, the **Initial conditions** parameter can be a scalar, or it can be a vector with the following constraints:
  - For single-channel inputs, the **Initial conditions** parameter can be a vector of length M_o if M_i is 1, or a vector of length M_i if M_o is 1.
  - For multichannel inputs, the **Initial conditions** parameter can be a vector of length $M_o * N$ if M_i is 1, or a vector of length $M_i * N$ if M_o is 1.

For all *multitasking* operations, use the `rebuffer_delay` function to compute the exact delay, in samples, that the Buffer block introduces for a given combination of buffer size and buffer overlap.

For general buffering between arbitrary frame sizes, the **Initial conditions** parameter must be a scalar value, which is then repeated across all elements of the initial output(s). However, in the special case where the input is a 1-by-N row vector, and the output of the block is an M_o-by-N matrix, **Initial conditions** can be

- An M_o-by-N matrix
- A length-M_o vector to be repeated across all columns of the initial output(s)
- A scalar to be repeated across all elements of the initial output(s)

In the special case where the output is a 1-by-N row vector, which is the result of unbuffering an M_i-by-N matrix, the **Initial conditions** can be

- A vector containing M_i samples to output sequentially for each channel during the first M_i sample times
- A scalar to be repeated across all elements of the initial output(s)

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Behavior in Enabled Subsystems

The Buffer block cannot be used in an enabled subsystem under the following conditions:

- In a multirate multitasking environment
- When the **Buffer overlap** parameter is set to a negative value

The Buffer block has an internal reservoir that temporarily stores data. When the Buffer block is used in an enabled subsystem, there is the possibility that the reservoir can overrun or underrun. The block implements safeguards against these occurrences.

Overrun occurs when more data enters into the buffer than it can hold. For example, consider buffering a scalar input to a frame of size three with a buffer that accepts input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled every three seconds at t = 3s, t = 6s, and so on, the buffer accumulates data in its internal reservoir without being able to empty it. This condition results in overrun.

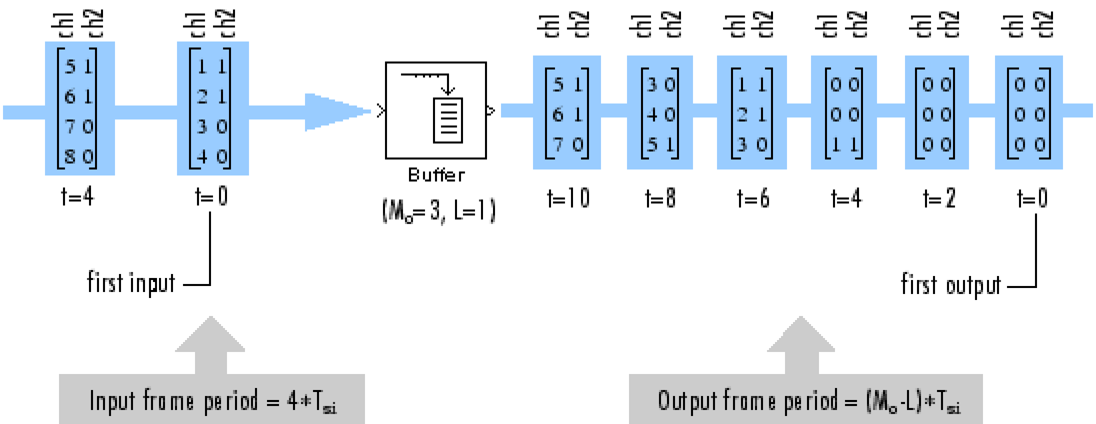
Underrun occurs when the buffer runs out of data to output. For example, again consider buffering a scalar input to a frame size of three with a buffer that accepts input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled at t = 10s, t = 11s, t = 13s, t = 14s, t = 16s, and t = 17s, its internal reservoir becomes drained, and there is no data to output at t = 18s. This condition results in underrun.

To protect from overrun and underrun, the Buffer block keeps a record of the amount of data in its internal reservoir. When the Buffer block reads data, the amount of data in its reservoir goes up. When data is output from the Buffer block, the amount of data in its reservoir goes down. To protect from overrun, the oldest samples in the reservoir are discarded whenever amount of data in the reservoir is larger than the actual buffer size. To protect from underrun, the most recent samples are repeated whenever an output is due and there is no data in the reservoir.

Examples

Buffering a two-channel input with overlap

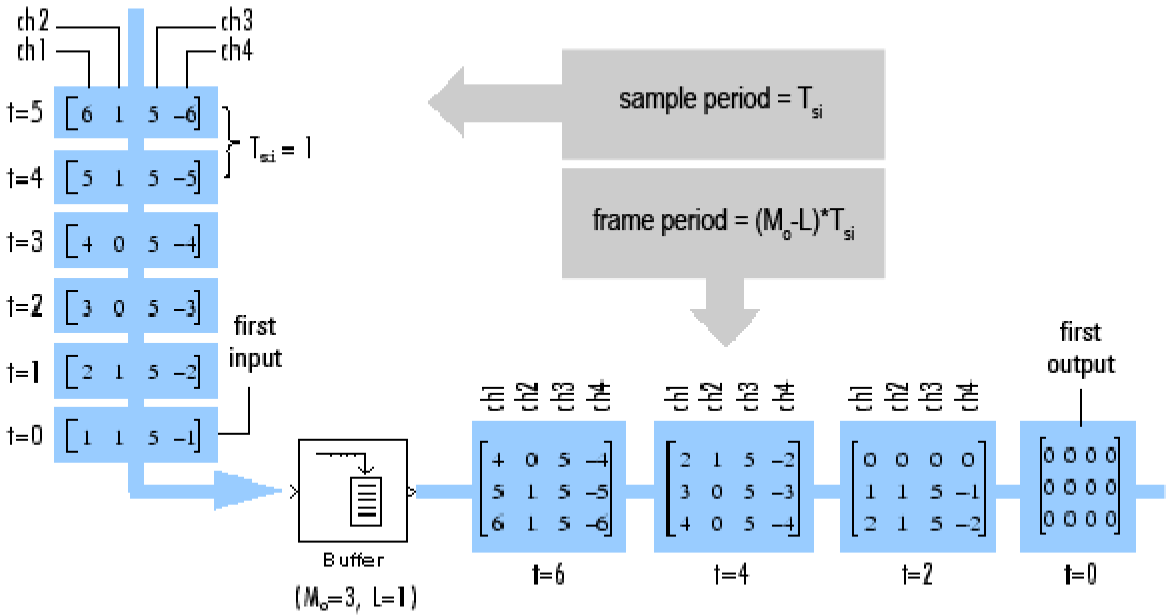
The ex_buffer_tut4 model buffers a two-channel input using an **Output buffer size** of three and a **Buffer overlap** of one. The following diagram illustrates the inputs and outputs of the Buffer block.



Notice that the output is delayed by eight samples. This is latency occurs because of the parameter settings in this model, and because the model is running in Simulink multitasking mode. The first eight output samples therefore adopt the value specified for the **Initial conditions** parameter, which in this case is set to zero. You can use the `rebuffer_delay` function to determine the latency of the Buffer block for any combination of frame size and overlap values.

Buffering a four-channel input with overlap

The ex_buffer_tut3 buffers a four-channel input using a **Output buffer size** of three and a **Buffer overlap** of one. The following diagram illustrates the inputs and outputs of the Buffer block.



Notice that the input vectors do not begin appearing at the output until the second row of the second matrix. This is due to latency in the Buffer block. The first output matrix (all zeros in this example) reflects the value of the **Initial conditions** parameter, while the first row of zeros in the second output is a result of the one-sample overlap between consecutive output frames.

You can use the `rebuffer_delay` function with a frame size of 1 to precisely compute the delay (in samples). For the previous example,

```
d = rebuffer_delay(1,3,1)
d =
     4
```

This agrees with the four samples of delay (zeros) per channel shown in the previous figure.

Parameters

Output buffer size

Specify the number of consecutive samples, M_o, from each channel to buffer into the output frame.

Buffer overlap

Specify the number of samples, L, by which consecutive output frames overlap.

Initial conditions

Specify the value of the block's initial output for cases of nonzero latency; a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

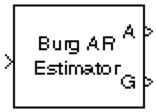
Introduced before R2006a

Burg AR Estimator

Compute estimate of autoregressive (AR) model parameters using Burg method



Library

Estimation / Parametric Estimation

`dspparest3`

Description

The Burg AR Estimator block uses the Burg method to fit an autoregressive (AR) model to the input data by minimizing (least squares) the forward and backward prediction errors while constraining the AR parameters to satisfy the Levinson-Durbin recursion.

The input must be a column vector or an unoriented vector, which is assumed to be the output of an AR system driven by white noise. This input represents a frame of consecutive time samples from a single-channel signal. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

When you select the **Inherit estimation order from input dimensions** parameter, the order, p, of the all-pole model is one less than the length of the input vector. Otherwise, the order is the value specified by the **Estimation order** parameter.

The **Output(s)** parameter allows you to select between two realizations of the AR process:

- A — The top output, A, is a column vector of length p+1 with the same frame status as the input, and contains the normalized estimate of the AR model polynomial coefficients in descending powers of z.

```
[1 a(2) ... a(p+1)]
```

- `K` — The top output, K, is a column vector of length p with the same frame status as the input, and contains the reflection coefficients (which are a secondary result of the Levinson recursion).
- `A and K` — The block outputs both realizations.

The scalar gain, G, is provided at the bottom output (`G`).

The following table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

	Burg AR Estimator	Covariance AR Estimator	Modified Covariance AR Estimator	Yule-Walker AR Estimator
Characteristics	Does not apply window to data	Does not apply window to data	Does not apply window to data	Applies window to data
	Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion	Minimizes the forward prediction error in the least squares sense	Minimizes the forward and backward prediction errors in the least squares sense	Minimizes the forward prediction error in the least squares sense (also called “autocorrelation method”)
Advantages	Always produces a stable model			Always produces a stable model
Disadvantages		May produce unstable models	May produce unstable models	Performs relatively poorly for short data records
Conditions for Nonsingularity		Order must be less than or equal to half the input frame size	Order must be less than or equal to 2/3 the input frame size	Because of the biased estimate, the autocorrelation matrix is

	Burg AR Estimator	Covariance AR Estimator	Modified Covariance AR Estimator	Yule-Walker AR Estimator
				guaranteed to positive-definite, hence nonsingular

Parameters

Output(s)

The realization to output, model coefficients, reflection coefficients, or both.

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of the input vector.

Estimation order

The order of the AR model, p. This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

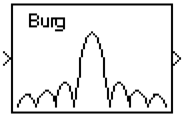
Burg Method

Power spectral density estimate using Burg method



Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Burg Method block estimates the power spectral density (PSD) of the input frame using the Burg method. This method fits an autoregressive (AR) model to the signal by minimizing (least squares) the forward and backward prediction errors. Such minimization occurs with the AR parameters constrained to satisfy the Levinson-Durbin recursion.

The input must be a column vector or an unoriented vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

When you select the **Inherit estimation order from input dimensions** parameter, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter specifies the order. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box, allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT. The output is always sample based.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

The Burg Method and Yule-Walker Method blocks return similar results for large frame sizes. The following table compares the features of the Burg Method block to the Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

	Burg	Covariance	Modified Covariance	Yule-Walker
Characteristics	Does not apply window to data	Does not apply window to data	Does not apply window to data	Applies window to data
	Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion	Minimizes the forward prediction error in the least squares sense	Minimizes the forward and backward prediction errors in the least squares sense	Minimizes the forward prediction error in the least squares sense (also called *autocorrelation method*)
Advantages	High resolution for short data records	Better resolution than Y-W for short data records (more accurate estimates)	High resolution for short data records	Performs as well as other methods for large data records
	Always produces a stable model	Able to extract frequencies from	Able to extract frequencies from	Always produces a stable model

	Burg	Covariance	Modified Covariance	Yule-Walker
		data consisting of p or more pure sinusoids	data consisting of p or more pure sinusoids	
			Does not suffer spectral line-splitting	
Disadvantages	Peak locations highly dependent on initial phase	May produce unstable models	May produce unstable models	Performs relatively poorly for short data records
	May suffer spectral line-splitting for sinusoids in noise, or when order is very large	Frequency bias for estimates of sinusoids in noise	Peak locations slightly dependent on initial phase	Frequency bias for estimates of sinusoids in noise
	Frequency bias for estimates of sinusoids in noise		Minor frequency bias for estimates of sinusoids in noise	
Conditions for Nonsingularity		Order must be less than or equal to half the input frame size	Order must be less than or equal to 2/3 the input frame size	Because of the biased estimate, the autocorrelation matrix is guaranteed to be positive-definite, hence nonsingular

Examples

The dspsacomp example compares the Burg method with several other spectral estimation methods.

Parameters

Inherit estimation order from input dimensions

Selecting this check box sets the estimation order to one less than the length of the input vector.

Estimation order

The order of the AR model. This parameter becomes visible only when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When selected, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".
- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Channelizer

Polyphase FFT analysis filter bank
Library: DSP System Toolbox / Filtering / Multirate Filters

Description

The Channelizer block separates a broadband input signal into multiple narrow subbands using an FFT-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.

This block accepts variable-size inputs. That is, during the simulation, you can change the size of each input channel. The number of channels cannot change.

Ports

Input

`Port_1` — Broadband signal

L-by-1 column vector | L-by-N matrix

Input broadband signal, which the channelizer splits into multiple narrow bands. The number of rows in the input signal must be a multiple of the number of frequency bands of the filter bank. Each column of the input corresponds to a separate channel.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Multiple narrowband signals

L/M-by-M | L/M-by-M-by-N array

Multiple narrow subbands of the input broadband signal. Each narrow band signal forms a column in the output.

If the input is one of the following:

- L-by-1 column vector — The output is a L/M-by-M matrix. M is the number of frequency bands.
- L-by-N matrix — The output is a L/M-by-M-by-N matrix.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

`Number of frequency bands` — Number of frequency bands
`8` (default) | positive integer greater than 1

Number of frequency bands into which the block separates the input broadband signal. This parameter indicates the FFT length and the decimation factor used by the algorithm.

`Polyphase filter specification` — Filter design parameters or coefficients
`Number of taps per band and stopband attenuation` (default) | `Coefficients`

- `Number of taps per band and stopband attenuation` — Specify the filter design parameters through the **Number of filter taps per frequency band** and **Stopband attenuation (dB)** parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.
- `Coefficients` — Specify the filter coefficients directly using the **Prototype lowpass filter coefficients** parameter.

`Number of filter taps per frequency band` — Number of filter coefficients per frequency band
`12` (default) | positive integer

Number of filter coefficients that each polyphase branch uses. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by **Number of frequency bands** × **Number of filter taps per frequency band**. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band, at the expense of increased computation.

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Number of taps per band and stopband attenuation`.

`Stopband attenuation (dB)` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation of the lowpass filter, in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Number of taps per band and stopband attenuation`.

`Prototype lowpass filter coefficients` — Coefficients of the prototype lowpass filter

`rcosdesign(0.25,6,8,'sqrt')` (default) | row vector

Coefficients of the prototype lowpass filter. The default value is the coefficients vector `rcosdesign(0.25,6,8,'sqrt')` returns. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

Tunable: Yes

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Coefficients`.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

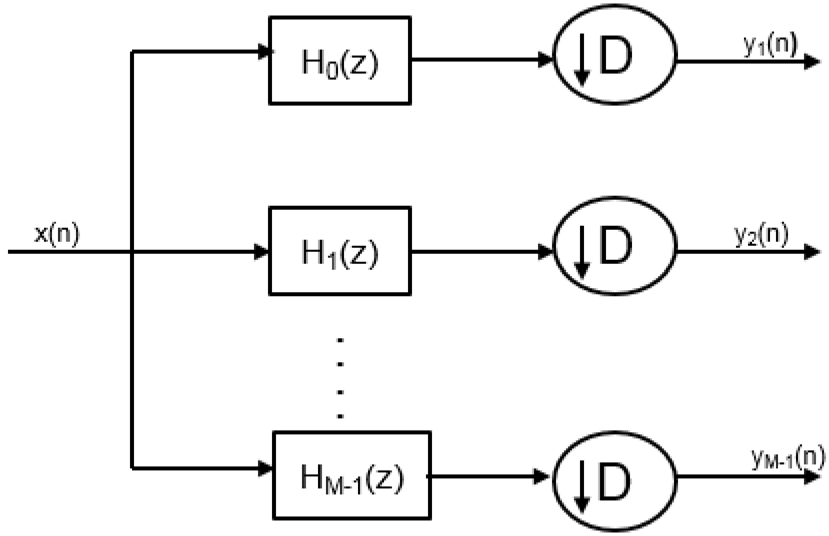
  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Model Examples

Definitions

Analysis Filter Bank

The analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, x(n), into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.



Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter. This filter has an impulse response of h[n], a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M. M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

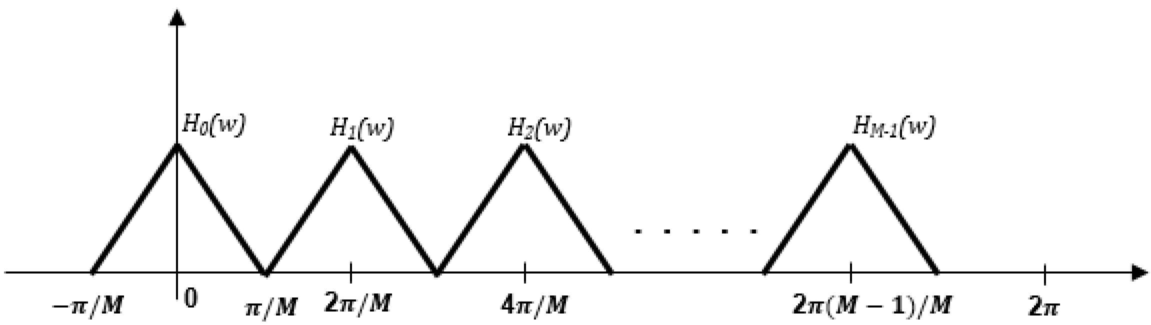
The prototype lowpass filter models the first branch of the filter bank. The other $M-1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{-jw_k n}, \quad w_k = 2\pi k / M, \quad k = 0, 1, \ldots, M-1$.

Using Prototype Lowpass Filter

The transfer function of the modulated kth bandpass filter is given by:

$$H_k(z) = H_0(ze^{-jw_k}), \quad w_k = 2\pi k / M, \quad k = 1, 2, \ldots, M-1$$

This figure shows the frequency response of M filters.

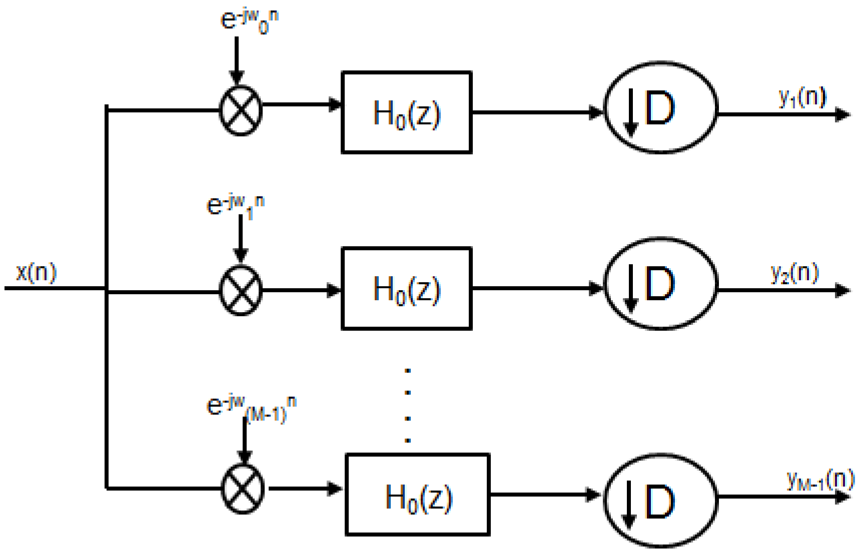


To obtain the frequency response characteristics of the filter $H_k(z)$, where $k = 1,...,M-1$, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of $2\pi/M$. Each subband filter, $H_k(z)$, $\{k = 1,...,M-1\}$, is derived from the prototype filter.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, $x(n)$, are translated in frequency to baseband by multiplying $x(n)$ with the complex exponentials, $e^{-jw_k n}$, *where* $w_k = 2\pi k / M$, *and* $k = 1,2,..,M-1$, where, $w_k = 2\pi k / M$, and $k = 1,2,\dots,M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \le M$, the number of branches of the analysis filter bank.

The figure shows an analysis filter bank that uses the prototype lowpass filter.



$y_1(n)$, $y_2(n)$, ..., $y_{M-1}(n)$ are narrow subband signals translated into baseband.

Algorithm

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \ldots + b_N z^{-N}$$

N+1 is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{matrix} \left(b_0 + b_M z^{-M} + b_{2M} z^{-2M} + .. + b_{N-M+1} z^{-(N-M+1)}\right) + \\ z^{-1}\left(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + .. + b_{N-M+2} z^{-(N-M+1)}\right) + \\ \vdots \\ z^{-(M-1)}\left(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + .. + b_N z^{-(N-M+1)}\right) \end{matrix}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \ldots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$, ..., $E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, H_0(z).

The other filters in the filter bank, H_k(z), where k = 1, ..., M-1, are modulated versions of this prototype filter.

You can write the transfer function of the kth modulated bandpass filter as $H_k(z) = H_0(ze^{-jw_k})$. Replacing z with ze^{-jw_k},

$$H_k(z) = h_0 + h_1 e^{-jwk} z^{-1} + h_2 e^{-j2wk} z^{-2} \ldots + h_N e^{-jNwk} z^{-N}$$

N+1 is the length of the kth filter.

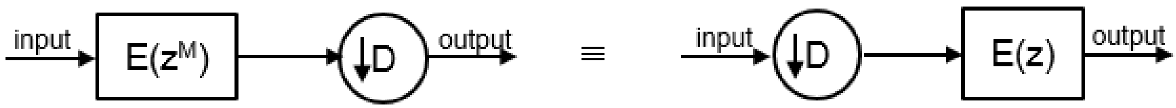
In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \ldots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

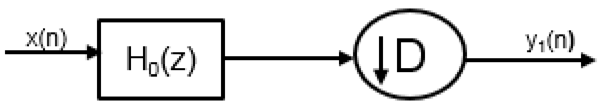
For all M channels in the filter bank, the MIMO transfer function, H(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

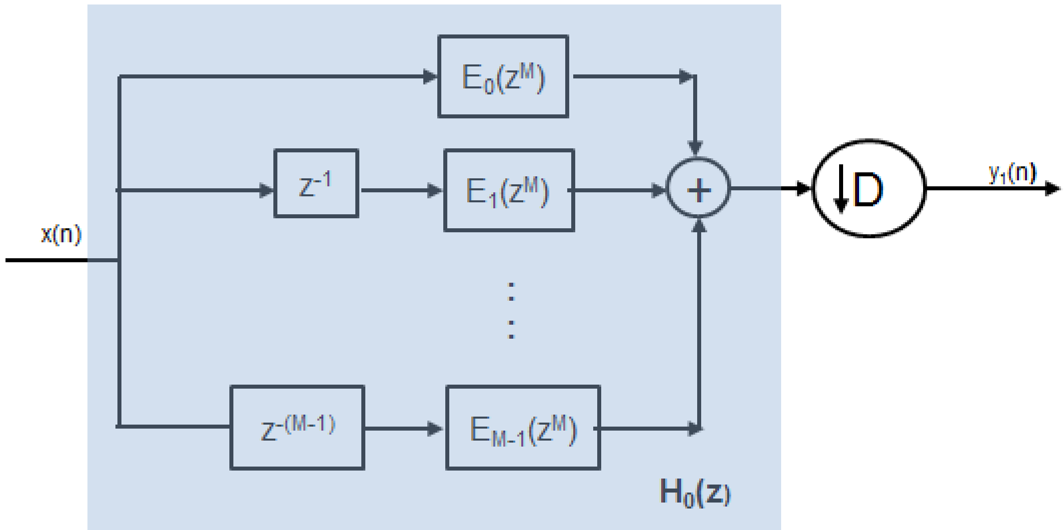
Here is the multirate noble identity for decimation.



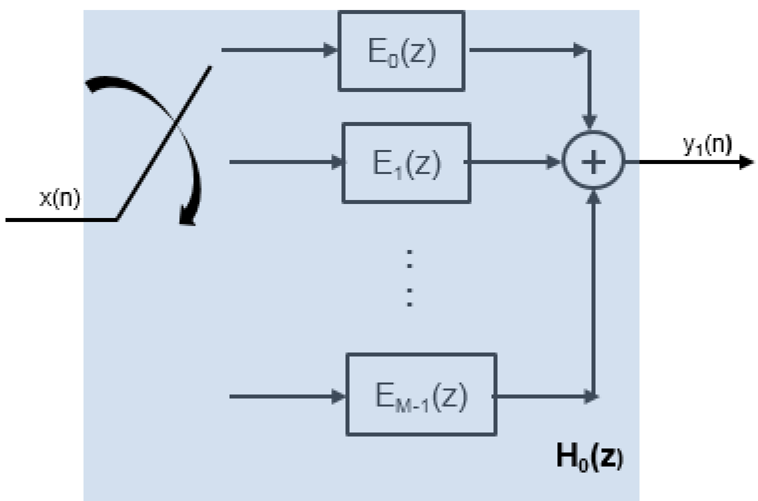
For illustration, consider the first branch of the filter bank that contains the lowpass filter.



Replace H_0(z) with its polyphase representation.



After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch.



For all *M* channels in the filter bank, the MIMO transfer function, *H*(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a DFT matrix. With the DFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

Channel Synthesizer

Polyphase FFT synthesis filter bank

Library: DSP System Toolbox / Filtering / Multirate Filters

Description

The Channel Syntheiszer block merges multiple narrowband signals into a broadband signal by using an FFT-based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.

This block also accepts variable-size inputs. That is, during the simulation, you can change the size of each input channel. The number of channels cannot change.

Ports

Input

`Port_1` — Input narrowband signals

L-by-M matrix | L-by-M-by-N array

Input narrowband signals, which the channel synthesizer merges to form the broadband signal. Each narrowband signal forms a column in the input signal. The number of columns in the input correspond to the number of frequency bands of the filter bank. If the input is three-dimensional, each matrix corresponds to a separate channel.

Data Types: `single` | `double`

Complex Number Support: Yes

Output

`Port_1` — Broadband signal

$L \times M$-by-1 vector | $L \times M$-by-N matrix

Broadband signal the channel synthesizer forms from the multiple input narrow subbands.

If the input is one of the following:

- L-by-M matrix — The output is a $L \times M$-by-1 vector. M is the number of frequency bands.
- L-by-M-by-N matrix — The output is a $L \times M$-by-N matrix.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

`Polyphase filter specification` — Filter design parameters or coefficients

`Number of taps per band and stopband attenuation` (default) | `Coefficients`

- `Number of taps per band and stopband attenuation` — Specify the filter design parameters through the **Number of filter taps per frequency band** and **Stopband attenuation (dB)** parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.
- `Coefficients` — Specify the filter coefficients directly using the **Prototype lowpass filter coefficients** parameter.

`Number of filter taps per frequency band` — Number of filter coefficients per frequency band

`12` (default) | positive integer

Number of filter coefficients that each polyphase branch uses. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by the product of the number of frequency bands and the number of filter taps per frequency band. The number of frequency bands equals the number of columns in the input. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band, at the expense of increased computation.

This parameter appears when you set **Polyphase filter specification** to `Number of taps per band and stopband attenuation`.

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Number of taps per band and stopband attenuation`.

`Stopband attenuation (dB)` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation of the lowpass filter, in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Number of taps per band and stopband attenuation`.

`Prototype lowpass filter coefficients` — Coefficients of the prototype lowpass filter

`rcosdesign(0.25,6,8,'sqrt')` (default) | row vector

This parameter specifies the coefficients of the prototype lowpass filter. The default value is the coefficients vector `rcosdesign(0.25,6,8,'sqrt')` returns. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

Tunable: Yes

Dependencies

To enable this parameter, set **Polyphase filter specification** to `Coefficients`.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

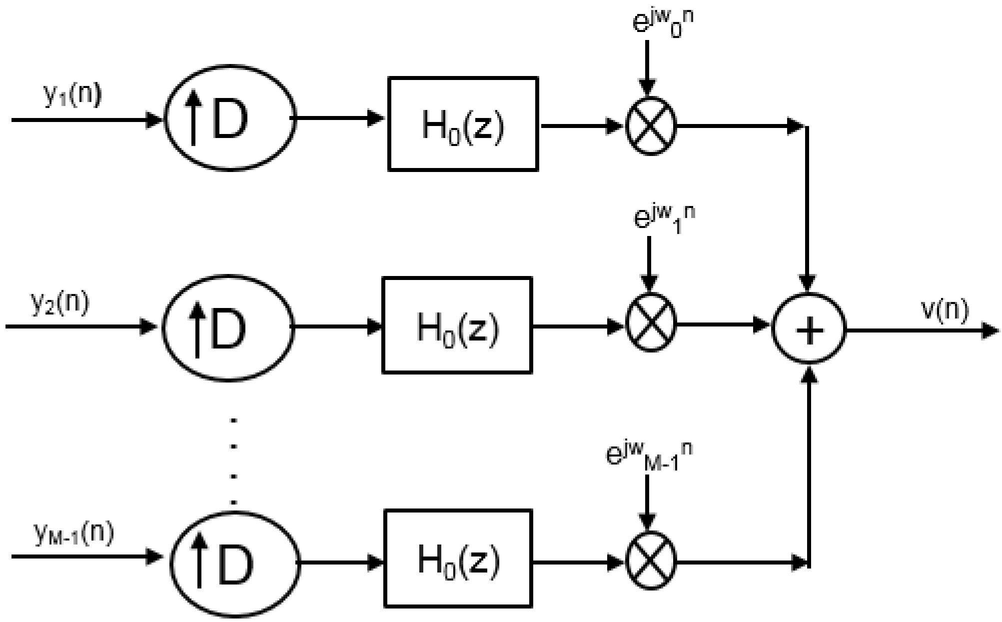
  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Model Examples

Definitions

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, y_1(n), y_2(n),..., y_{M-1}(n) into a single broadband signal, *v(n)*. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around w_k.



Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of h[n], a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M. M is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M-1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{jw_k n}, \quad w_k = 2\pi k / M, \quad k = 0,1,\ldots,M-1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, $v(n)$.

Algorithm

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \ldots + b_N z^{-N}$$

N+1 is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned} H_0(z) = \; & \left(b_0 + b_M z^{-M} + b_{2M} z^{-2M} + .. + b_{N-M+1} z^{-(N-M+1)}\right) + \\ & z^{-1}\left(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + .. + b_{N-M+2} z^{-(N-M+1)}\right) + \\ & \vdots \\ & z^{-(M-1)}\left(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + .. + b_N z^{-(N-M+1)}\right) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \ldots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$,..., $E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, H_0(z).

The other filters in the filter bank, H_k(z), where k = 1, ..., M-1, are modulated versions of this prototype filter.

You can write the transfer function of the kth modulated bandpass filter as $H_k(z) = H_0(ze^{jw_k})$. Replacing z with ze^{jw_k},

$$H_k(z) = h_0 + h_1 e^{jwk} z^{-1} + h_2 e^{j2wk} z^{-2} \ldots + h_N e^{jNwk} z^{-N}$$

N+1 is the length of the kth filter.

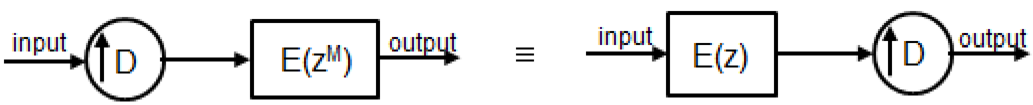
In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \ldots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

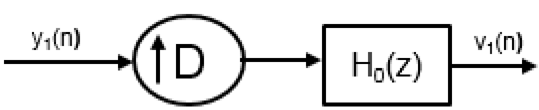
For all M channels in the filter bank, the MIMO transfer function, H(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \ldots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \ldots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \ldots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

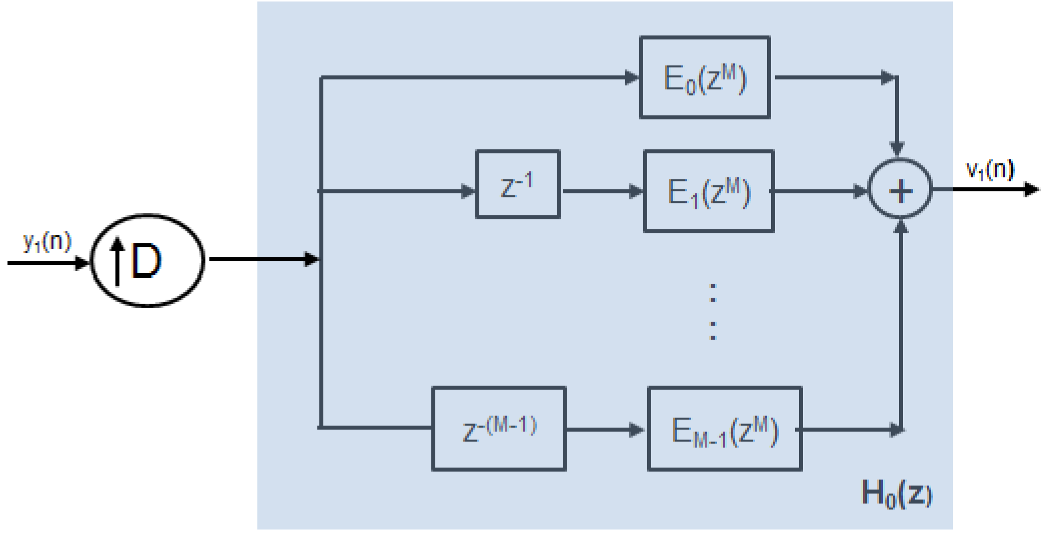
Here is the multirate noble identity for interpolation:



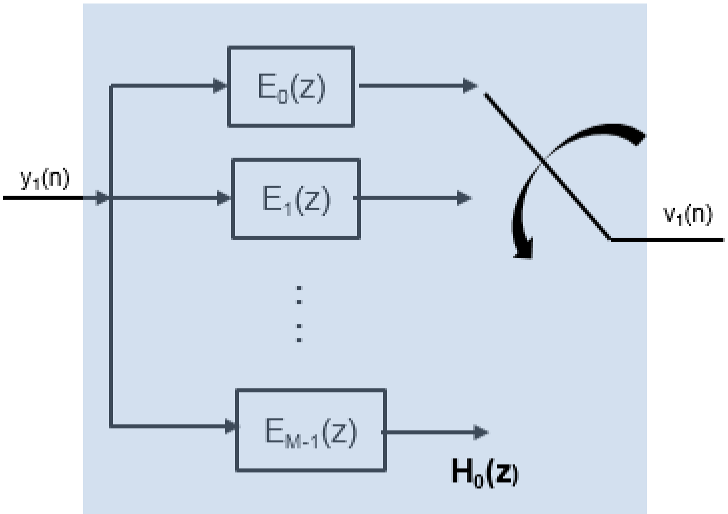
For illustration, consider the first branch of the filter bank that contains the lowpass filter.



Replace H_0(z) with its polyphase representation.



After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.



For all the M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

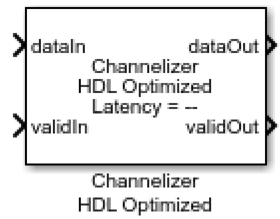
Channelizer HDL Optimized

Polyphase filter bank and fast Fourier transform—optimized for HDL code generation

Library: DSP System Toolbox / Filtering / Multirate Filters
DSP System Toolbox HDL Support / Filtering



Description

The Channelizer HDL Optimized block separates a broadband input signal into multiple narrowband output signals. It provides hardware speed and area optimization for streaming data applications. The block accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput using vector input. The block implements a polyphase filter, with one subfilter per input vector element. The hardware implementation interleaves the subfilters, which results in sharing each filter multiplier (*FFT Length* / *Input Size*) times. The FFT implementation uses the same pipelined Radix 2^2 FFT algorithm as the `FFT HDL Optimized` block.

Ports

Input

`dataIn` — Input data

scalar or column vector of real or complex values

The vector size must be a power of 2 that is from 1 to 64, and is not greater than the number of channels (FFT length). `double` and `single` input data are allowed for simulation but not for HDL code generation.

The block does not accept `uint64` data.

Data Types: `fixed_point` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`
Complex Number Support: Yes

`validIn` — Indicates valid input data
scalar

When **validIn** is `true`, the block captures the value on **dataIn**.

Data Types: `Boolean`

`reset` — Reset control signal (optional)
scalar

When **reset** is `true`, the block stops the current calculation and clears internal state.

Dependencies

To enable this port, select **Enable reset input port**.

Data Types: `Boolean`

Output

`dataOut` — Frequency channel output data
vector

- If you set **Output vector size** to `Same as number of frequency bands` (default), the output data is a 1-by-*M* vector where *M* is the FFT length. The output order is bit natural.
- If you set **Output vector size** to `Same as input size`, the output data is an *M*-by-1 vector where *M* is the input vector size. The output order is bit reversed.

The output data type is a result of the **Filter output data type** and the bit growth in the FFT necessary to avoid overflow.

`validOut` — Indicates valid output data
scalar

The block sets **validOut** to `true` with each valid sample on **dataOut**.

Data Types: `Boolean`

`startOut` — Indicates the first valid cycle of output data (optional)
scalar

The block sets **startOut** to `true` during the first valid sample on **dataOut**.

Dependencies

To enable this port, select **Enable start output port**.

Data Types: `Boolean`

`endOut` — Indicates the last valid cycle of output data (optional)
scalar

The block sets **endOut** to `true` during the last valid sample on **dataOut**.

Dependencies

To enable this port, select **Enable end output port**.

Data Types: `Boolean`

Parameters

Main

`Number of frequency bands (FFT length)` — FFT length
`8` (default) | integer power of two

For HDL code generation, the FFT length must be a power of 2 from 2^3 to 2^{16}.

`Filter coefficients` — Polyphase filter coefficients
`[ -0.032, 0.121, 0.318, 0.482, 0.546, 0.482, 0.318, 0.121, -0.032 ]` (default) | vector of numeric values

If the number of coefficients is not a multiple of **Number of frequency bands (FFT length)**, the block pads this vector with zeros. The default filter specification is a raised-cosine FIR filter, `rcosdesign(0.25,2,4,'sqrt')`. You can specify a vector of coefficients or a call to a filter design function that returns the coefficient values.

Complex coefficients are not supported. By default, the block casts the coefficients to the same data type as the input.

`Complex multiplication` — HDL implementation of complex multipliers

`Use 3 multipliers and 5 adders` (default) | `Use 4 multipliers and 2 adders`

Each multiplication is implemented with either 4 multipliers and 2 adders, or 3 multipliers and 5 adders. Which option is faster or smaller depends on your synthesis tool and target device.

`Output vector size` — Size and order of output data

`Same as number of frequency bands` (default) | `Same as input size`

The output data is a row vector of M-by-1 channels.

- `Same as number of frequency bands` — Output data is a 1-by-M vector, where M is the FFT length. The output order is bit natural.
- `Same as input size` — Output data is an M-by-1 vector, where M is the input vector size. The output order is bit reversed.

`Divide butterfly outputs by two` — FFT scaling

on (default) | off

When you select this parameter, the FFT implements an overall $1/N$ scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input. If scaling is disabled, the FFT avoids overflow by increasing the word length by 1 bit at each stage.

Data Types

`Rounding mode` — Rounding method used for internal fixed-point calculations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Zero`

See “Rounding Modes”. The block uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. Each FFT stage rounds after the twiddle factor multiplication but before the butterflies. Rounding can also occur when casting the coefficients and the output of the polyphase filter to the data types you specify.

`Overflow mode` — Overflow handling for internal fixed-point calculations

`Wrap` (default) | `Saturate`

See “Overflow Handling”. The block uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. This option applies to casting the coefficients and the output of the polyphase filter to the data types you specify.

The FFT algorithm avoids overflow by either scaling the output of each stage (`Normalize` enabled), or by increasing the word length by 1 bit at each stage (`Normalize` disabled).

`Coefficient data type` — Data type of the filter coefficients

`Inherit: Same word length as input` (default) | data type expression

The block casts the polyphase filter coefficients to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the block selects the binary point using `fi()` best-precision rules.

`Filter output data type` — Data type of the output of the polyphase filter

`Inherit: Same word length as input` (default) | data type expression

The block casts the output of the polyphase filter (the input to the FFT) to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the block selects a best-precision binary point by considering the values of your filter coefficients and the range of your input data type.

By default, the FFT logic does not modify the data type. When you disable **Divide butterfly outputs by two**, the FFT increases the word length by 1 bit at each stage to avoid overflow.

Control Ports

`Enable reset input port` — Optional reset signal

off (default) | on

When you select this parameter, the **reset** port shows on the block icon. When the **reset** input is `true`, the block stops calculation and clears all internal state.

`Enable start output port` — Optional control signal indicating start of data

off (default) | on

When you select this parameter, the **startOut** port shows on the block icon. The **startOut** signal is true for the first cycle of output data in a frame.

`Enable end output port` — Optional control signal indicating end of data
off (default) | on

When you select this parameter, the **endOut** port shows on the block icon. The **endOut** signal is true for the last cycle of output data in a frame.

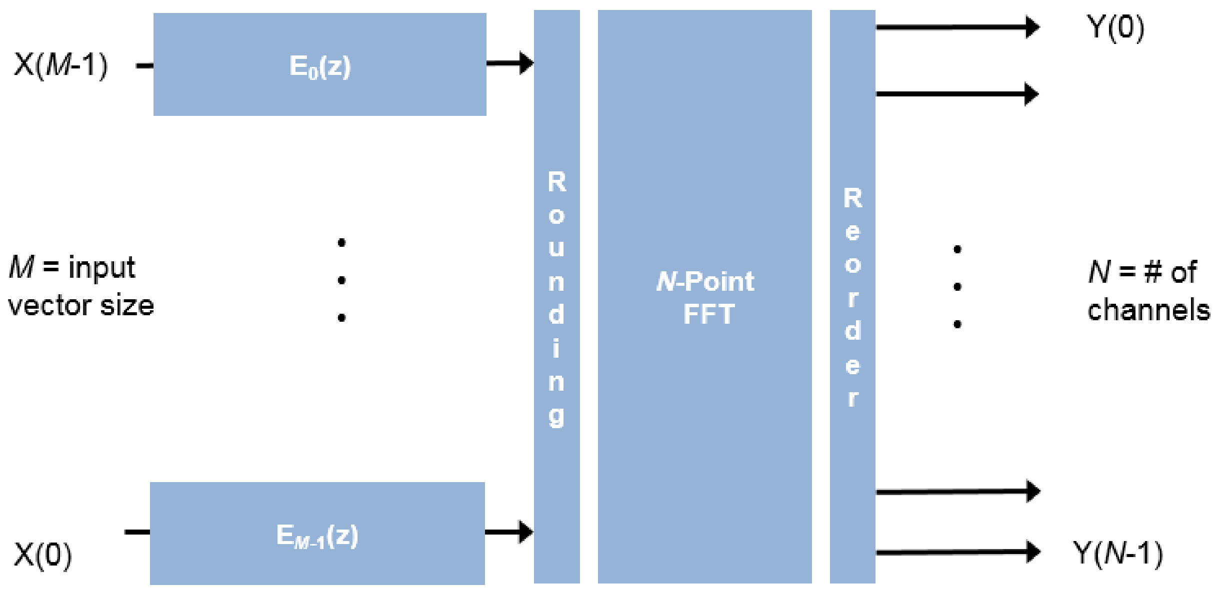
Model Examples

Algorithm

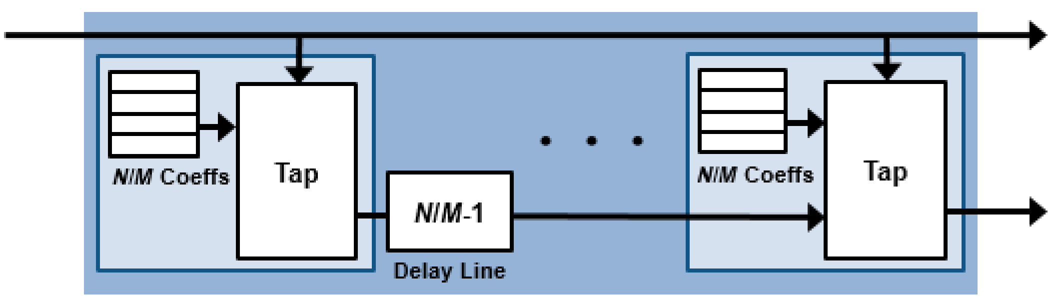
The polyphase filter algorithm requires a subfilter for each FFT channel. For more detail on the polyphase filter architecture, refer to [1], and to the `Channelizer` block reference page.

Note: The output of the Channelizer HDL Optimized block does not match the output from the Channelizer block sample-for-sample. This mismatch is because the blocks apply the input samples to the subfilters in different orders. The Channelizer HDL Optimized block applies input X(0) to subfilter $E_{M-1}(z)$, X(1) to subfilter $E_{M-2}(z)$, ..., X(M-1) to subfilter $E_0(z)$. The channels detected by both blocks match, when analyzed over multiple frames.

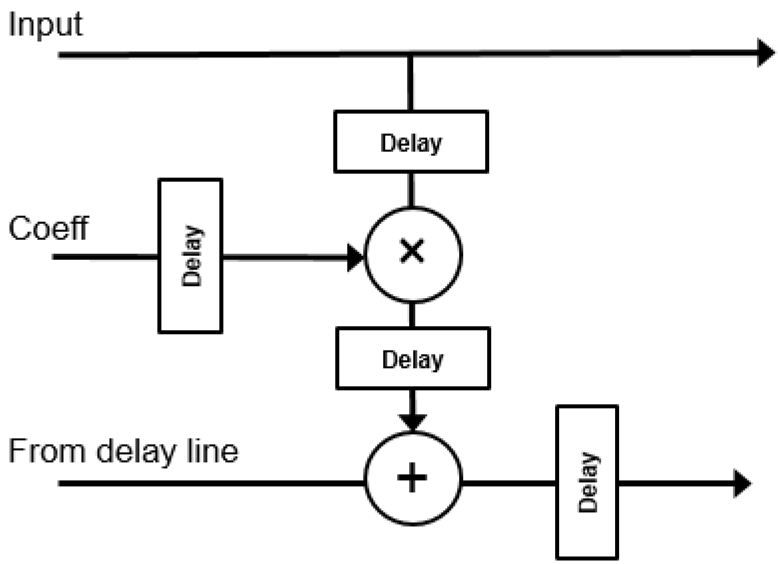
If the input vector size, M, is the same as the FFT length, N, then the block implements N subfilters in the hardware. Each subfilter is a direct-form transposed FIR filter with $NumCoeffs/N$ taps.



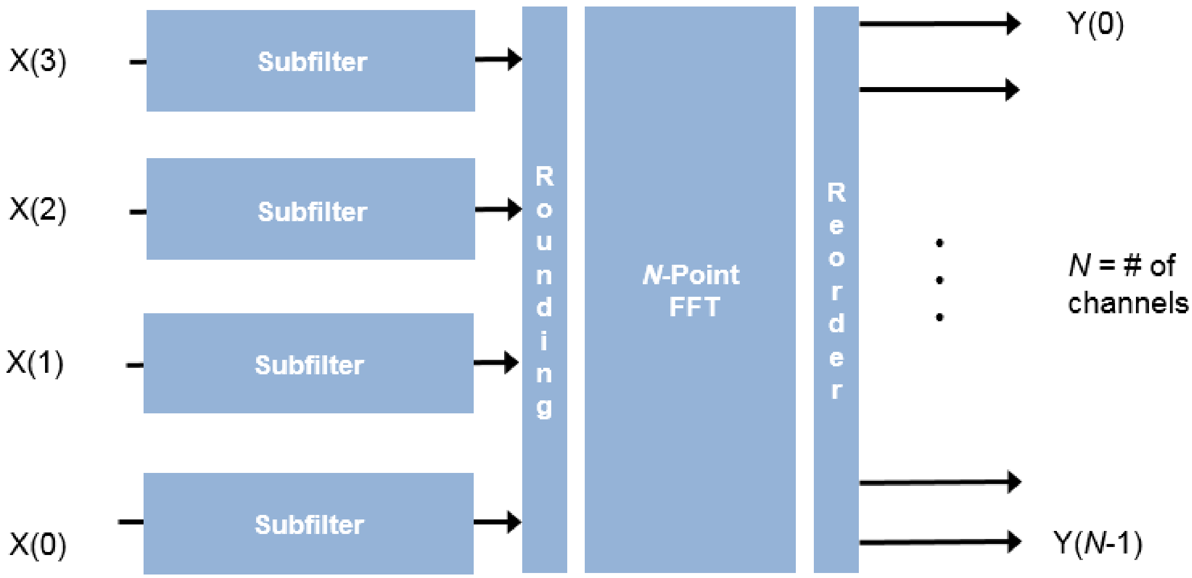
If the vector size is less than *N*, the block implements one subfilter for each input vector element. The subfilter multipliers are shared as necessary to implement *N* channel filters. The shared multiplier taps have a lookup table for *N*/*M* filter coefficients. Each tap is followed by a delay line of *N*/*M*–1 cycles.



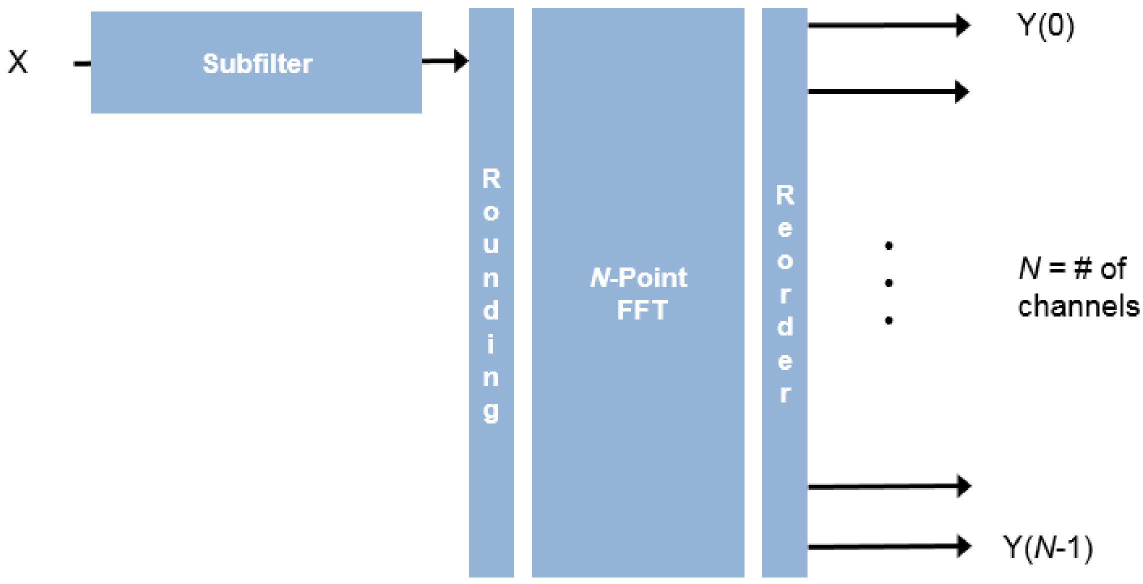
The output of the subfilters is cast to the specified **Filter output data type**, using the rounding and overflow settings you chose. Each filter tap in the subfilter is pipelined to target the DSP sections of an FPGA.



For instance, for an FFT length of 8, and an input vector size of 4, the block implements four filters. Each multiplier is shared *N*/*M* times, or twice. Each tap applies two coefficients, and the delay line is *N*/*M*–1 cycles.



For scalar input, the block implements one filter. Each multiplier is shared N times. Each tap applies N coefficients, and the delay line is N–1 cycles.



Latency

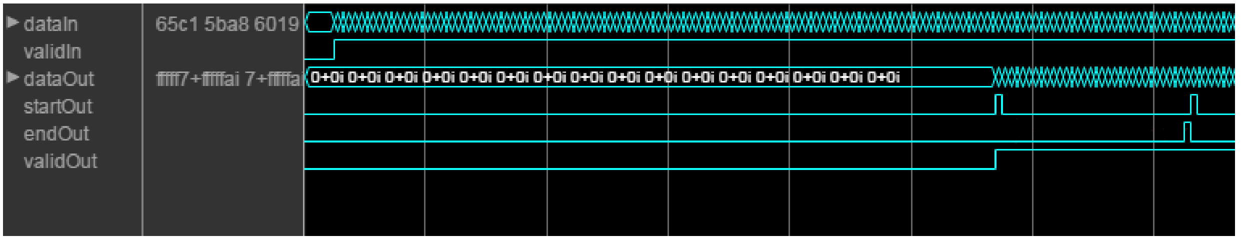
The latency varies with FFT length and vector size. After you update the model, the latency is displayed on the block icon. The displayed latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The filter coefficients do not affect the latency. Setting the output size equal to the input size reduces the latency, because the samples are not saved and reordered.

Control Signals

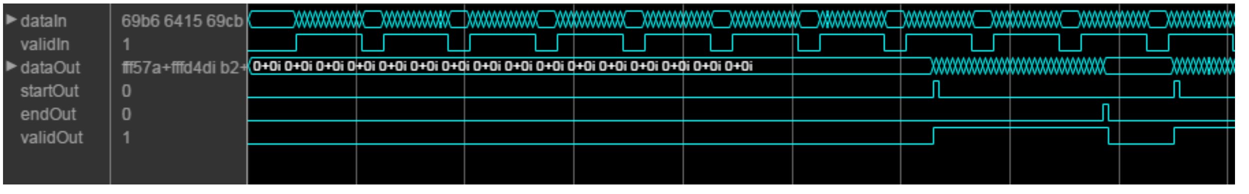
This diagram shows `validIn` and `validOut` signals for contiguous input data with a vector size of 16 and an FFT length of 512.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames, the output will also be continuous, after the initial latency.



The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is stored until a frame is filled, and output in a contiguous frame of *N* (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16 samples.



Performance

These resource and performance data are the place-and-route results from the generated HDL targeted to a Xilinx® Virtex® 6 (XC6VLX240-1ff784) FPGA. The three examples in the tables use this configuration:

- FFT length — 8
- Filter length — 96 coefficients
- 16-bit complex input data
- Coefficient and filter output data types same word length as input data (default)
- Complex multiplication (default) — 4 multipliers, 2 adders
- Output scaling — Enabled
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options.

For scalar input, the design achieves a clock frequency of 346 MHz. The latency is 53 cycles. The subfilters share each multiplier eight (*N*) times. The design uses these resources.

Resource	Uses
LUT	1591
FFS	2681
Xilinx LogiCORE® DSP48	16

For four-sample vector input, the design achieves a clock frequency of 333 MHz. The latency is 31 cycles. The subfilters share each multiplier twice (*N*/*M*). The design uses these resources.

Resource	Uses
LUT	1912
FFS	3986
Xilinx LogiCORE DSP48	56

For eight-sample vector input, the design achieves a clock frequency of 292 MHz. The latency is 20 cycles. When the input size is the same as the FFT length, the subfilters do not share any multipliers. The design uses these resources.

Resource	Uses
LUT	1388
FFS	2302
Xilinx LogiCORE DSP48	110

Check Signal Attributes

Error when input signal does or does not match selected attributes exactly

Library

Signal Management / Signal Attributes

`dspsigattribs`

Description

The Check Signal Attributes block terminates the simulation with an error when the input characteristics differ from the characteristics you specify in the block parameters.

When you set **Error when input** to `Does not match attributes exactly`, the block generates an error when the input fails to match *any* of the specified attributes. Only signals that possess *all* of the specified attributes propagate to the output unaltered and do not cause the block to generate an error.

When you set **Error when input** to `Matches attributes exactly`, the block generates an error only when the input possesses *all* specified attributes. Signals that do not possess *all* of the specified attributes propagate to the output unaltered, and do not cause the block to generate an error.

Signal Attributes

The Check Signal Attributes block can test for up to five different signal attributes, as specified by the following parameters. When you select `Ignore` for any parameter, the block does not check the signal for the corresponding attribute. For example, when you set **Complexity** to `Ignore`, neither real nor complex inputs cause the block to generate an error. The attributes are:

- **Complexity**

Check whether the input is real or complex. You can display this information in a model by attaching a Probe block with **Probe complex signal** selected. Alternatively, you can select **Port Data Types** from the **Display** > **Signals & Ports** menu.

- **Dimensionality**

  Check the dimensionality of the input for compliance or noncompliance with the attributes in the subordinate **Dimension** menu. See the following table. *M* and *N* are positive integers unless otherwise indicated.

Dimensions	Is...	Is not...
1-D	1-D vector, 1-D scalar	*M*-by-*N* matrix, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)
2-D	*M*-by-*N* matrix, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)	1-D vector, 1-D scalar
Scalar (1-D or 2-D)	1-D scalar, 1-by-1 matrix (2-D scalar)	1-D vector with length>1, *M*-by-*N* matrix with *M*>1 and/or *N*>1
Vector (1-D or 2-D)	1-D vector, 1-D scalar, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar) Vector (1-D or 2-D) or scalar	*M*-by-*N* matrix with *M*>1 and *N*>1
Row Vector (2-D)	1-by-*N* matrix (row vector), 1-by-1 matrix (2-D scalar) Row vector (2-D) or scalar	1-D vector, 1-D scalar, *M*-by-*N* matrix with *M*>1
Column Vector (2-D)	*M*-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar) Column vector (2-D) or scalar	1-D vector, 1-D scalar, *M*-by-*N* matrix with *N*>1
Full matrix	*M*-by-*N* matrix with *M*>1 and *N*>1	1-D vector, 1-D scalar, 1-by-*N* matrix (row vector),

Dimensions	Is...	Is not...
		M-by-1 matrix (column vector), 1-by-1 matrix (2-D scalar)
Square matrix	*M*-by-*N* matrix with *M*=*N*, 1-D scalar, 1-by-1 matrix (2-D scalar	*M*-by-*N* matrix with *M*≠*N*, 1-D vector, 1-by-*N* matrix (row vector), *M*-by-1 matrix (column vector)

When you select **Signal Dimensions** from the **Display** > **Signals & Ports** menu, Simulink displays the size of a 1-D vector signal as an unbracketed integer, and displays the dimension of a 2-D signal as a pair of bracketed integers, `[MxN]`. Simulink *does not display* any size information for a 1-D or 2-D scalar signal. You can also display dimension information for a signal in a model by attaching a Probe block with **Probe signal dimensions** selected.

- **Data type**

  Check the signal data type for compliance `(Is...)` or noncompliance `(Is not...)` with the attributes in the subordinate **General data type** menu. See the following table. You can individually select any of the specific data types listed in the `(Is...)` column from the subordinate **Specific data type** menu.

General Data Type	Is...	Is not...
Boolean	`boolean`	`single, double, uint8, int8, uint16, int16, uint32, int32`, fixed point, enumerated
Enumerated	A user-defined enumerated data type. See “Data Types” (Simulink) in the Simulink documentation.	`boolean, single, double, uint8, int8, uint16, int16, uint32, int32`, fixed point
Floating point	`single, double`	`boolean, uint8, int8, uint16, int16, uint32, int32`, fixed point, enumerated
Floating point or Boolean	`single, double, boolean`	`uint8, int8, uint16, int16, uint32, int32`, fixed point, enumerated

General Data Type	Is...	Is not...
Fixed point	fixed point, `uint8, int8, uint16, int16, uint32, int32`	`boolean, single, double`, enumerated
Integer	Signed integer `int8`, `int16`, `int32` Unsigned integer `uint8`, `uint16`, `uint32`	`boolean, single, double`, fixed point, enumerated

To display data type information, in your model window, from the **Display** menu, point to **Signals & Ports** and select **Port Data Types**.

- **Sample time**

  Check whether the signal is discrete time or continuous time. When you select **Colors** from the **Display** > **Sample Time** menu, Simulink displays continuous-time signal lines in black or grey and discrete-time signal lines in colors corresponding to the relative rate.

  When you attach a Probe block with **Probe sample time** enabled to a continuous-time signal, the block icon displays `Ts:[0 To]`, where `To` is the sample time offset. Valid values of `To` for continuous-time signals are `0` and `1`. When `To` is `0`, updates occur at every major and minor time step. When `To` is `1`, updates occur only at major time steps and the sample time is *fixed in minor time step*.

  When you attach a Probe block with **Probe sample time** enabled to a discrete-time signal, the block icon displays `Ts:[Ts To]` for sample-based signals, and `Tf:[Tf To]` for frame-based signals. `Ts` and `Tf` are the positive sample period and frame period, respectively. `To` is the offset, such that 0 ≤ *`offset`* < *`period`*. Frame-based signals are almost always discrete time.

Parameters

Error when input

Specify whether the block generates an error when the input *does* or *does not* possess *all* of the required attributes.

Complexity

Specify the complexity for which you want to check the input, `Real` or `Complex`. When you select `Ignore` from the list, the block does not check the complexity of the input.

Dimensionality

Specify whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **Dimensions** menu. When you select `Ignore` from the list, the block does not check the dimensionality of the input.

Dimensions

Specify the dimensions for which you want to check the input. This parameter is only visible when you set the **Dimensionality** parameter to `Is...` or `Is not...`.

Data type

Specifies whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **General data type** menu. When you select `Ignore` from the list, the block does not check the input data type.

General data type

Specify the general data type for which you want to check the input. This parameter is only visible when you set the **Data type** to `Is...` or `Is not...`.

Specific floating-point

Specify the floating-point data type for which you want to check the input. This parameter is only visible when you set the **General data type** to `Floating-point` or `Floating-point or boolean`.

Specific fixed-point

Specify the fixed-point data type for which you want to check the input. This parameter is only visible when you set the **General data type** to `Fixed-point`.

Specific integer

Specify the integer data type for which you want to check the input. This parameter is only visible when you set the **General data type** to `Integer`.

Sample time

Specify the sample time for which you want to check the input, `Discrete` or `Continuous`. When you select `Ignore` from the list, the block does not check the sample time of the input.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8, 16, and 32-bit signed integers • 8, 16, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8, 16, and 32-bit signed integers • 8, 16, and 32-bit unsigned integers • Enumerated

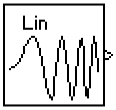
Chirp

Generate swept-frequency cosine (chirp) signal



Library

Sources

`dspsrcs4`

Description

The Chirp block outputs a swept-frequency cosine (chirp) signal with unity amplitude and continuous phase. To specify the desired output chirp signal, you must define its instantaneous frequency function, also known as the output frequency sweep. The frequency sweep can be linear, quadratic, or logarithmic, and repeats once every **Sweep time** by default. See other sections of this reference page for more details about the block.

Variables Used in This Reference Page

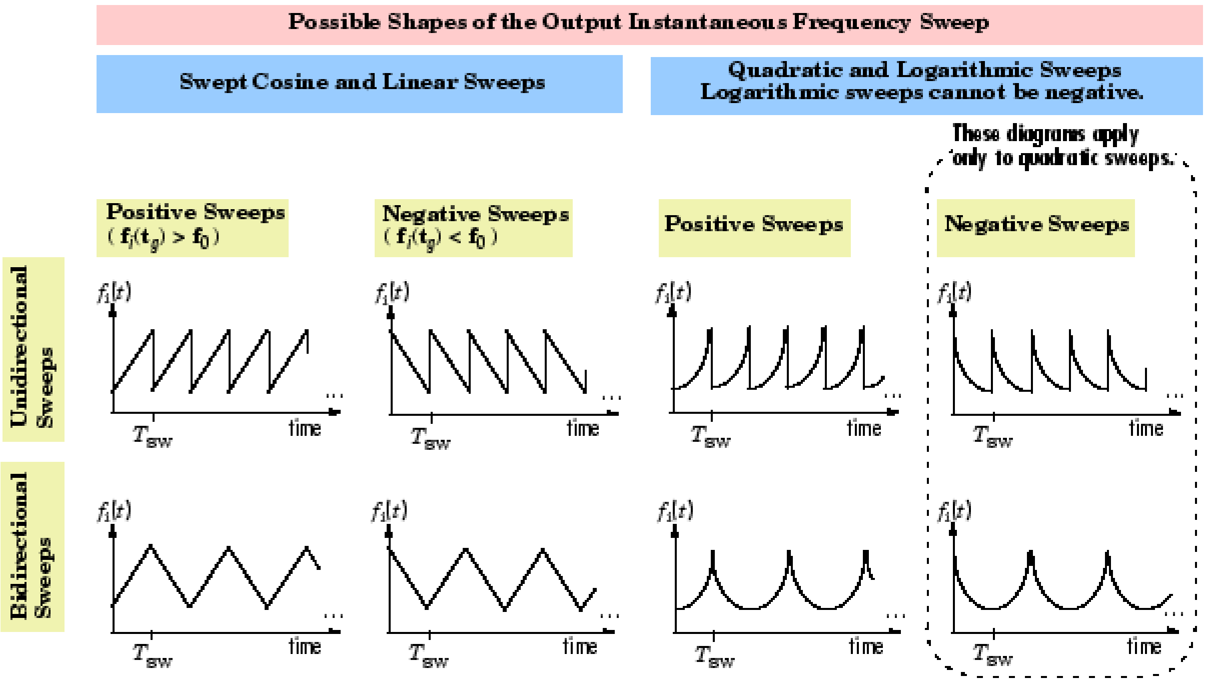
f_0	**Initial frequency** parameter (Hz)
$f_i(t_g)$	**Target frequency** parameter (Hz)
t_g	**Target time** parameter (seconds)
T_{sw}	**Sweep time** parameter (seconds)
ϕ_0	**Initial phase** parameter (radians)
$\psi(t)$	Phase of the chirp signal (radians)
$f_i(t)$	User-specified output instantaneous frequency function (Hz); user-specified sweep
$f_{i(actual)}(t)$	Actual output instantaneous frequency function (Hz); actual output sweep
$y_{chirp}(t)$	Output chirp function

Shaping the Frequency Sweep by Setting Frequency Sweep and Sweep Mode

The basic shape of the output instantaneous frequency sweep, $f_i(t)$, is set by the **Frequency sweep** and **Sweep mode** parameters, described in the following table.

Parameters for Setting Sweep Shape	Possible Setting	Parameter Description
Frequency sweep	Linear Quadratic Logarithmic Swept cosine	Determines whether the sweep frequencies vary linearly, quadratically, or logarithmically. Linear and swept cosine sweeps both vary linearly.
Sweep mode	Unidirectional Bidirectional	Determines whether the sweep is unidirectional or bidirectional. For details, see "Unidirectional and Bidirectional Sweep Modes" on page 2-253

The following diagram illustrates the possible shapes of the frequency sweep that you can obtain by setting the **Frequency sweep** and **Sweep mode** parameters.



For information on how to set the frequency values in your sweep, see "Setting Instantaneous Frequency Sweep Values" on page 2-254.

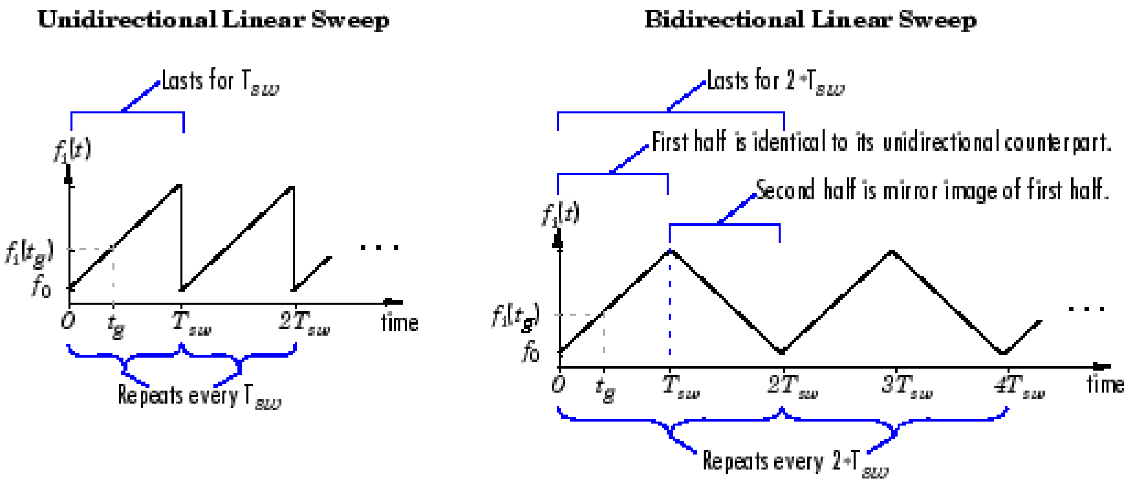
Unidirectional and Bidirectional Sweep Modes

The **Sweep mode** parameter determines whether your sweep is unidirectional or bidirectional, which affects the shape of your output frequency sweep (see "Shaping the Frequency Sweep by Setting Frequency Sweep and Sweep Mode" on page 2-252). The following table describes the characteristics of unidirectional and bidirectional sweeps.

Sweep Mode Parameter Settings	Sweep Characteristics
`Unidirectional`	• Lasts for one **Sweep time**, T_{sw} • Repeats once every T_{sw}
`Bidirectional`	• Lasts for twice the **Sweep time**, $2*T_{sw}$ • Repeats once every $2*T_{sw}$

Sweep Mode Parameter Settings	Sweep Characteristics
	• First half is identical to its unidirectional counterpart. • Second half is a mirror image of the first half.

The following diagram illustrates a linear sweep in both sweep modes. For information on setting the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 2-254.



Setting Instantaneous Frequency Sweep Values

Set the following parameters to tune the frequency values of your output frequency sweep.

- **Initial frequency** (Hz), f_0
- **Target frequency** (Hz), $f_i(t_g)$
- **Target time** (seconds), t_g

The following table summarizes the sweep values at specific times for all **Frequency sweep** settings. For information on the formulas used to compute sweep values at other times, see “Block Computation Methods” on page 2-255.

Instantaneous Frequency Sweep Values

Frequency Sweep	Sweep Value at $t = 0$	Sweep Value at $t = t_g$	Time when Sweep Value Is Target Frequency, $f_i(t_g)$
Linear	f_0	$f_i(t_g)$	t_g
Quadratic	f_0	$f_i(t_g)$	t_g
Logarithmic	f_0	$f_i(t_g)$	t_g
Swept cosine	f_0	$2f_i(t_g)$ - f_0	$t_g/2$

Block Computation Methods

The Chirp block uses one of two formulas to compute the block output, depending on the **Frequency Sweep** parameter setting. For details, see the following sections:

- "Equations for Output Computation" on page 2-255
- "Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps" on page 2-256
- "Output Computation Method for Swept Cosine Frequency Sweep" on page 2-257

Equations for Output Computation

The following table shows the equations used by the block to compute the user-specified output frequency sweep, $f_i(t)$, the block output, $y_{chirp}(t)$, and the actual output frequency sweep, $f_{i(actual)}(t)$. The only time the user-specified sweep is not the actual output sweep is when the **Frequency sweep** parameter is set to `Swept cosine`.

Note The following equations apply only to unidirectional sweeps in which $f_i(0) < f_i(t_g)$. To derive equations for other cases, you might find it helpful to examine the following table and the diagram in "Shaping the Frequency Sweep by Setting Frequency Sweep and Sweep Mode" on page 2-252.

The table below contains the following variables:

- $f_i(t)$ — the user-specified frequency sweep
- $f_{i(actual)}(t)$ — the actual output frequency sweep, usually equal to $f_i(t)$

- $y(t)$ — the Chirp block output
- $\psi(t)$ — the phase of the chirp signal, where $\psi(0) = 0$, and $2\pi f_i(t)$ is the derivative of the phase

  $$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

- ϕ_0 — the **Initial phase** parameter value, where $y_{chirp}(0) = \cos(\phi_0)$

Equations Used by the Chirp Block for Unidirectional Positive Sweeps

Frequency Sweep	Block Output Chirp Signal	User-Specified Frequency Sweep, $f_i(t)$	β	Actual Frequency Sweep, $f_{i(actual)}(t)$
`Linear`	$y(t) = \cos(\psi(t) + \phi_0)$	$f_i(t) = f_0 + \beta t$	$\beta = \frac{f_i(t_g) - f_0}{t_g}$	$f_{i(actual)}{}^{(t)} = f_i^{(t)}$
`Quadratic`	Same as `Linear`	$f_i(t) = f_0 + \beta t^2$	$\beta = \frac{f_i(t_g) - f_0}{t_g^2}$	$f_{i(actual)}{}^{(t)} = f_i^{(t)}$
`Logarithmic`	Same as `Linear`	$F_i(t) = f_0 \left(\frac{f_i(t_g)}{f_0} \right)^{\frac{t}{t_g}}$ Where $f_i(t_g) > f_0 > 0$	N/A	$f_{i(actual)}(t) = f_i(t)$
`Swept cosine`	$y(t) = \cos(2\pi f_i(t)t + \phi_0)$	Same as `Linear`	Same as `Linear`	$f_{i(actual)}(t) = f_i(t) + \beta t$

Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps

The derivative of the phase of a chirp function gives the instantaneous frequency of the chirp function. The Chirp block uses this principle to calculate the chirp output when the **Frequency Sweep** parameter is set to `Linear`, `Quadratic`, or `Logarithmic`.

$y_{chirp}(t) = \cos(\psi(t) + \phi_0)$	Linear, quadratic, or logarithmic chirp signal with phase $\psi(t)$

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

Phase derivative is instantaneous frequency

For instance, if you want a chirp signal with a linear instantaneous frequency sweep, you should set the **Frequency Sweep** parameter to `Linear`, and tune the linear sweep values by setting other parameters appropriately. The block outputs a chirp signal, the phase derivative of which is the specified linear sweep. This ensures that the instantaneous frequency of the output is the linear sweep you desired. For equations describing the linear, quadratic, and logarithmic sweeps, see “Equations for Output Computation” on page 2-255.

Output Computation Method for Swept Cosine Frequency Sweep

To generate the swept cosine chirp signal, the block sets the swept cosine chirp output as follows.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0) = \cos(2\pi f_i(t)t + \phi_0)$$

Swept cosine chirp output (Instantaneous frequency equation, shown above, does not hold.)

Note that the instantaneous frequency equation, shown above, does not hold for the swept cosine chirp, so the user-defined frequency sweep, $f_i(t)$, is not the actual output frequency sweep, $f_{i(actual)}(t)$, of the swept cosine chirp. Thus, the swept cosine output might not behave as you expect. To learn more about swept cosine chirp behavior, see “Cautions Regarding the Swept Cosine Sweep” on page 2-257 and “Equations for Output Computation” on page 2-255.

Cautions Regarding the Swept Cosine Sweep

When you want a linearly swept chirp signal, we recommend you use a linear frequency sweep. Though a swept cosine frequency sweep also yields a linearly swept chirp signal, the output might have unexpected frequency content. For details, see the following two sections.

Swept Cosine Instantaneous Output Frequency at the Target Time is not the Target Frequency

The swept cosine sweep value at the **Target time** is not necessarily the **Target frequency**. This is because the user-specified sweep is not the actual frequency sweep of the swept cosine output, as noted in "Output Computation Method for Swept Cosine Frequency Sweep" on page 2-257. See the table Instantaneous Frequency Sweep Values for the actual value of the swept cosine sweep at the **Target time**.

Swept Cosine Output Frequency Content May Greatly Exceed Frequencies in the Sweep

In **Swept cosine** mode, you should not set the parameters so that $1/T\mathrm{sw}$ is very large compared to the values of the **Initial frequency** and **Target frequency** parameters. In such cases, the actual frequency content of the swept cosine sweep might be closer to $1/T\mathrm{sw}$, far exceeding the **Initial frequency** and **Target frequency** parameter values.

Parameters

Frequency sweep

The type of output instantaneous frequency sweep, $f_i(t)$: `Linear`, `Logarithmic`, `Quadratic`, or `Swept cosine`.

Sweep mode

The directionality of the chirp signal: `Unidirectional` or `Bidirectional`.

Initial frequency (Hz)

For `Linear`, `Quadratic`, and `Swept cosine` sweeps, the initial frequency, f_0, of the output chirp signal. For `Logarithmic` sweeps, **Initial frequency** is one less than the actual initial frequency of the sweep. Also, when the sweep is `Logarithmic`, you must set the **Initial frequency** to be less than the **Target frequency**. Tunable (Simulink).

Target frequency (Hz)

For `Linear`, `Quadratic`, and `Logarithmic` sweeps, the instantaneous frequency, $f_i(t_g)$, of the output at the **Target time**, t_g. For a `Swept cosine` sweep, **Target frequency** is the instantaneous frequency of the output at half the **Target time**,

$t_g/2$. When **Frequency sweep** is `Logarithmic`, you must set the **Target frequency** to be greater than the **Initial frequency**. Tunable (Simulink).

Target time (s)

For `Linear`, `Quadratic`, and `Logarithmic` sweeps, the time, t_g, at which the **Target frequency**, $f_i(t_g)$, is reached by the sweep. For a `Swept cosine` sweep, **Target time** is the time at which the sweep reaches $2f_i(t_g) - f_0$. You must set **Target time** to be *no greater than* **Sweep time** , $T_{sw} \geq t_g$. Tunable (Simulink).

Sweep time (s)

In `Unidirectional` **Sweep mode**, the **Sweep time**, T_{sw}, is the period of the output frequency sweep. In `Bidirectional` **Sweep mode**, the **Sweep time** is half the period of the output frequency sweep. You must set **Sweep time** to be no less than **Target time**, $T_{sw} \geq t_g$. Tunable (Simulink).

Initial phase (rad)

The phase, ϕ_0 , of the cosine output at t=0; $y_{chirp}(t) = \cos(\phi_0)$. Tunable (Simulink).

Sample time

The sample period, T_s, of the output. The output frame period is $M_o{*}T_s$.

Samples per frame

The number of samples, M_o, to buffer into each output frame.

Output data type

The data type of the output, single-precision or double-precision.

Examples

The first few examples demonstrate how to use the Chirp block's main parameters, how to view the output in the time domain, and how to view the output spectrogram:

- “Example 1: Setting a Final Frequency Value for Unidirectional Sweeps” on page 2-260
- “Example 2: Bidirectional Sweeps” on page 2-263
- “Example 3: When Sweep Time is Greater Than Target Time” on page 2-264

Examples 4 and 5 illustrate Chirp block settings that might produce unexpected outputs:

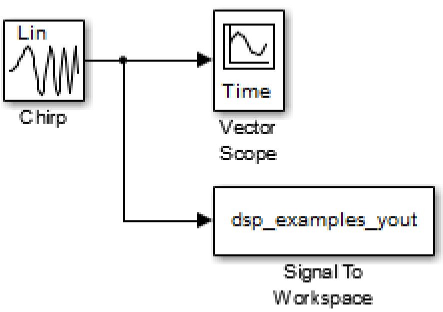
- "Example 4: Output Sweep with Negative Frequencies" on page 2-266
- "Example 5: Output Sweep with Frequencies Greater Than Half the Sampling Frequency" on page 2-267

Example 1: Setting a Final Frequency Value for Unidirectional Sweeps

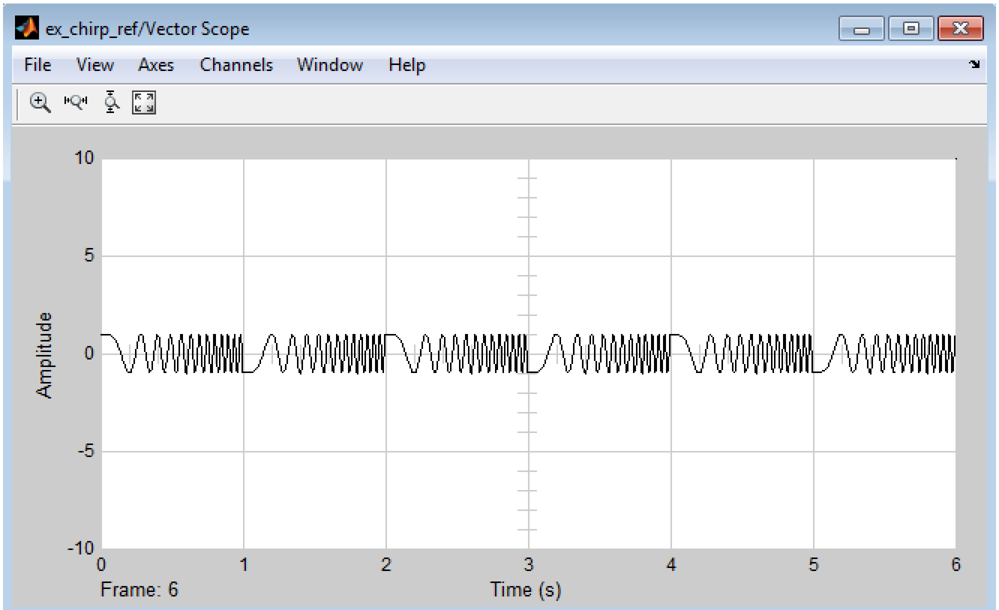
Often times, you might want a unidirectional sweep for which you know the initial and final frequency values. You can specify the final frequency of a unidirectional sweep by setting **Target time** equal to **Sweep time**, in which case the **Target frequency** becomes the final frequency in the sweep. The following model demonstrates this method.

This technique might not work for swept cosine sweeps. For details, see "Cautions Regarding the Swept Cosine Sweep" on page 2-257.

Open the Example 1 model by typing ex_chirp_ref at the MATLAB command line. You can also rebuild the model yourself; see the following list for model parameter settings (leave unlisted parameters in their default states).

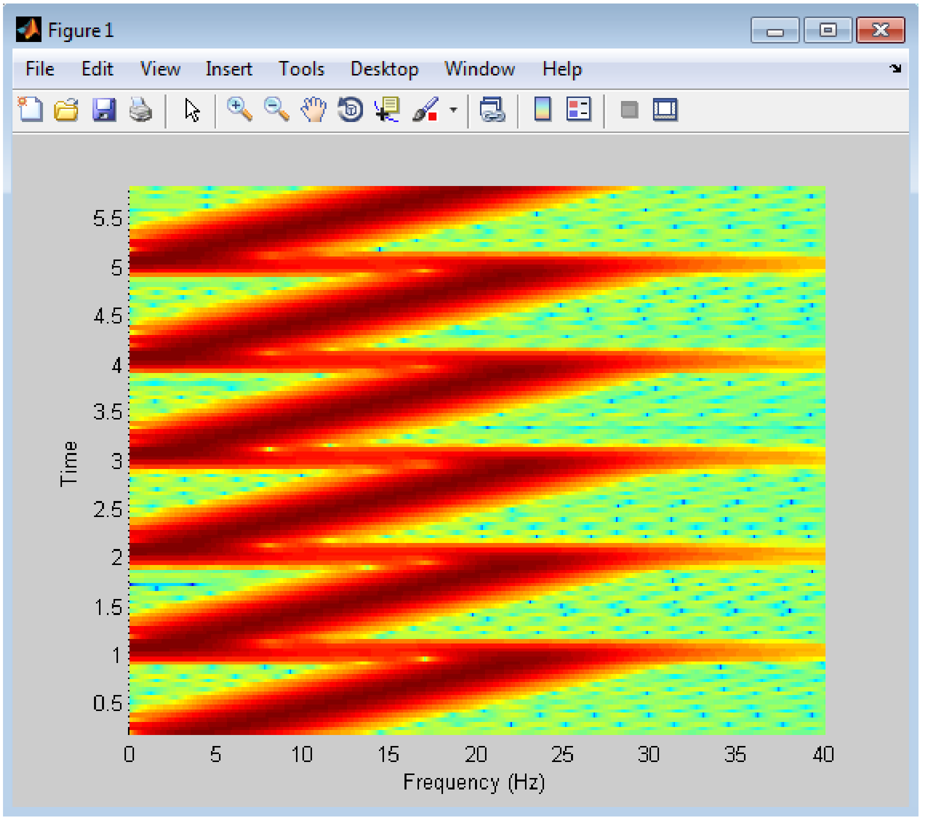


Since **Target time** is set to equal **Sweep time** (1 second), the **Target frequency** (25 Hz) is the final frequency of the unidirectional sweep. Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(128),...
      110,[0:.01:40],400)
```



Chirp Block Parameters for Example 1	
Frequency sweep	`Linear`
Sweep mode	`Unidirectional`
Initial frequency	0
Target frequency	25
Target time	1
Sweep time	1
Initial phase	0
Sample time	1/400
Samples per frame	400

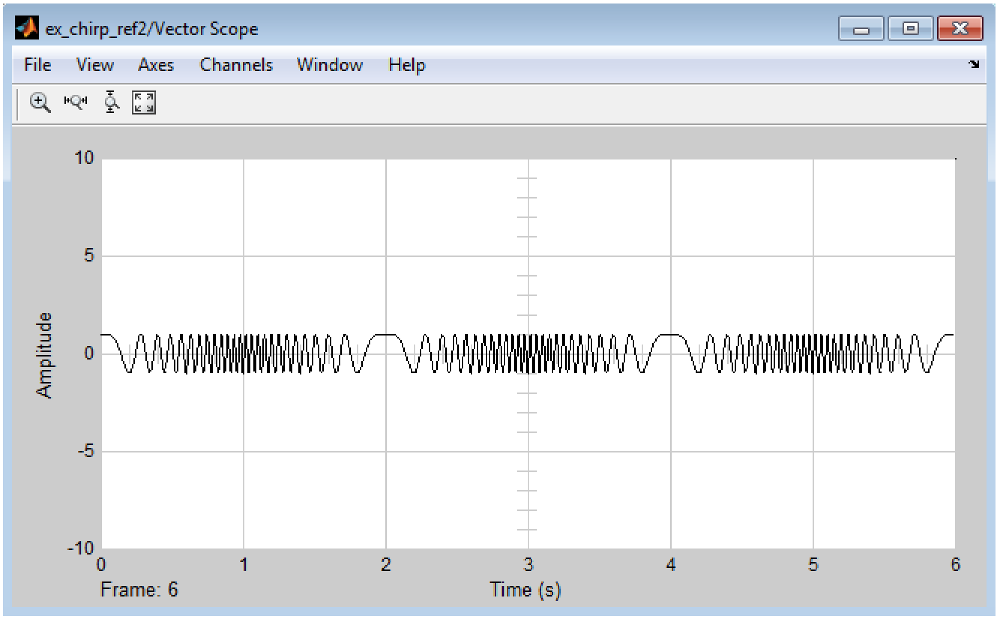
Vector Scope Block Parameters for Example 1	
Input domain	`Time`
Time display span	6
Signal To Workspace Block Parameters for Example 1	
Variable name	`dsp_examples_yout`
Configuration Dialog Parameters for Example 1	
Stop time	5

Example 2: Bidirectional Sweeps

Change the **Sweep mode** parameter in the Example 1 model to `Bidirectional`, and leave all other parameters the same to view the following bidirectional chirp. Note that in the bidirectional sweep, the period of the sweep is twice the **Sweep time** (2 seconds), whereas it was one **Sweep time** (1 second) for the unidirectional sweep in Example 1.

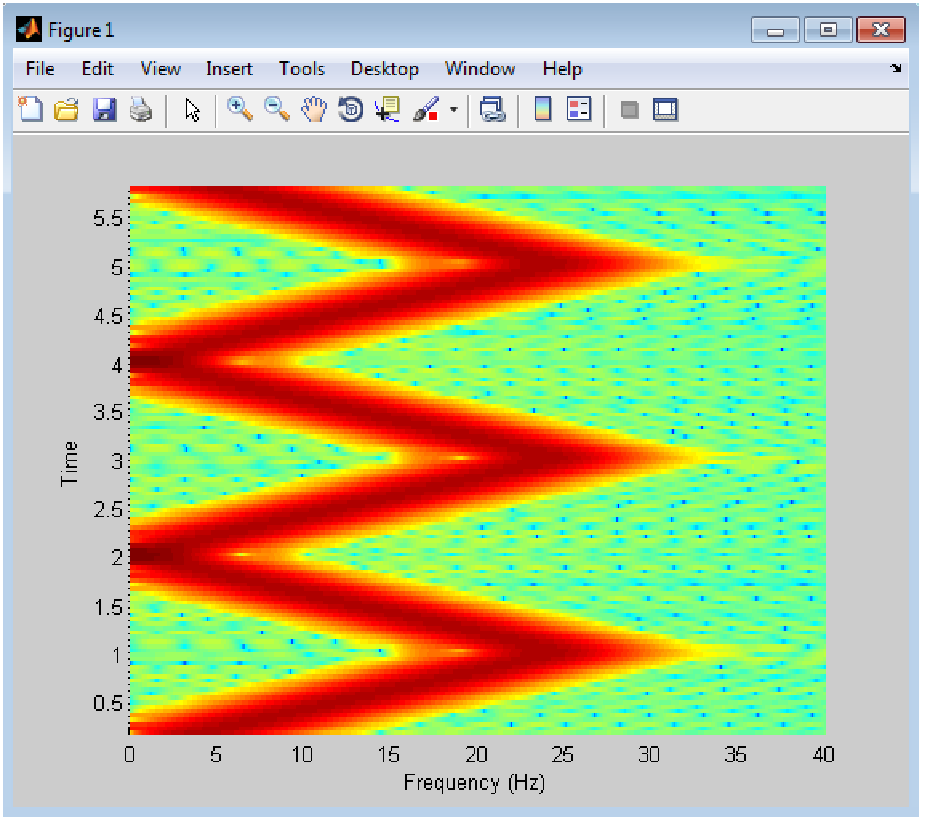
Open the Example 2 model by typing `ex_chirp_ref2` at the MATLAB command line.

Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(128),...
     110,[0:.01:40],400)
```



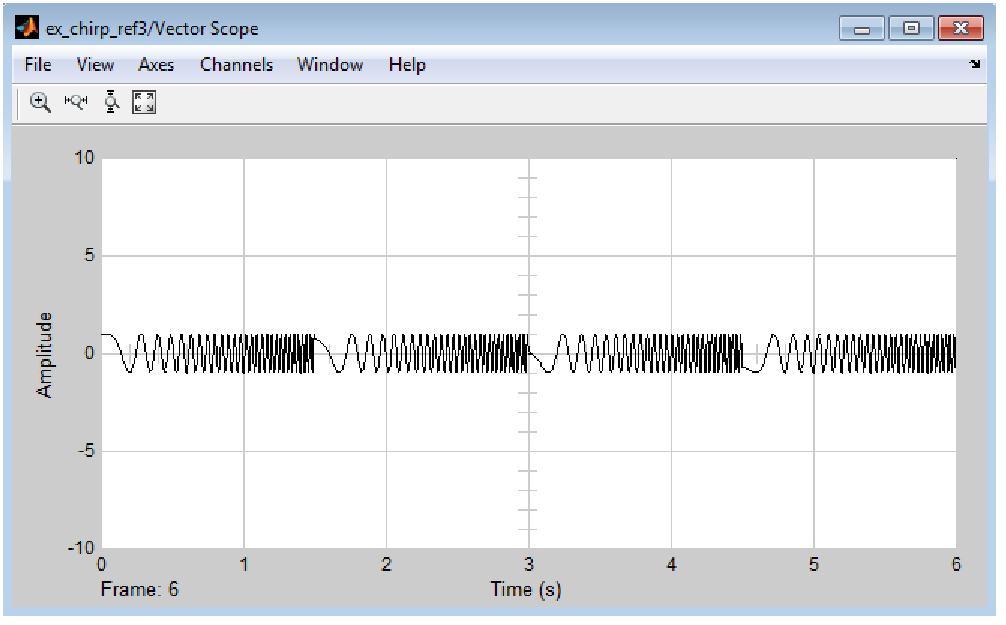
Example 3: When Sweep Time is Greater Than Target Time

Setting **Sweep time** to `1.5` and leaving the rest of the parameters as in the Example 1 model gives the following output. The sweep still reaches the **Target frequency** (25 Hz) at the **Target time** (1 second), but since **Sweep time** is greater than **Target time**, the sweep continues on its linear path until one **Sweep time** (1.5 seconds) is traversed.

Unexpected behavior might arise when you set **Sweep time** greater than **Target time**; see "Example 4: Output Sweep with Negative Frequencies" on page 2-266 for details.

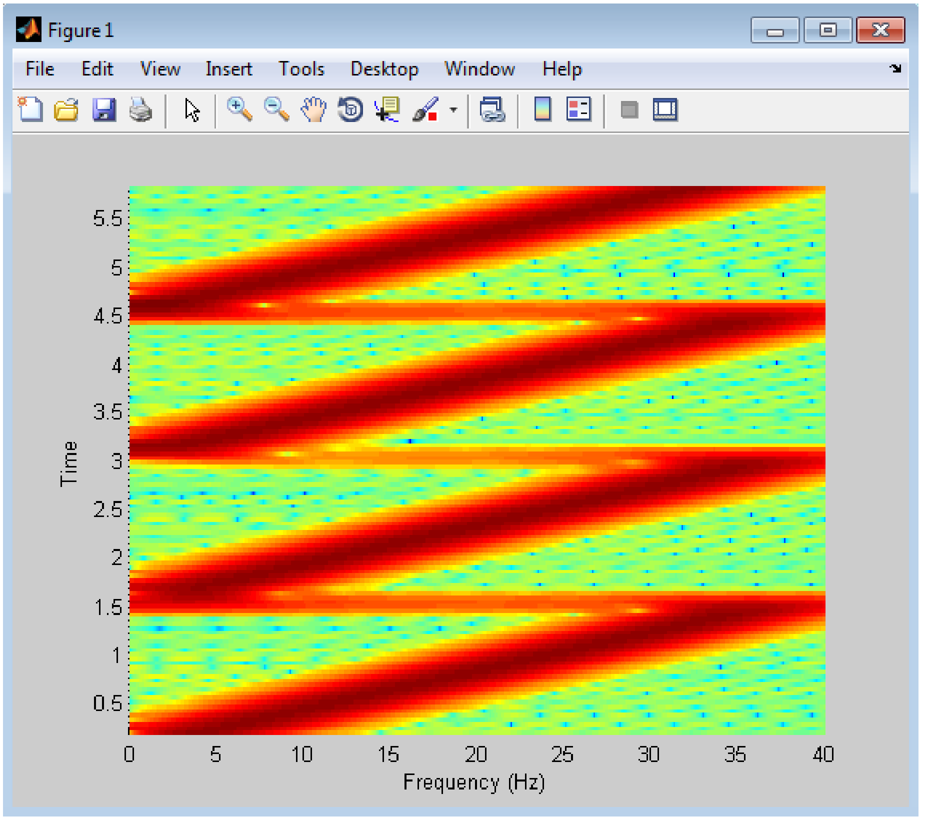
Open the Example 3 model by typing `ex_chirp_ref3` at the MATLAB command line.

Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(128),...
      110,[0:.01:40],400)
```

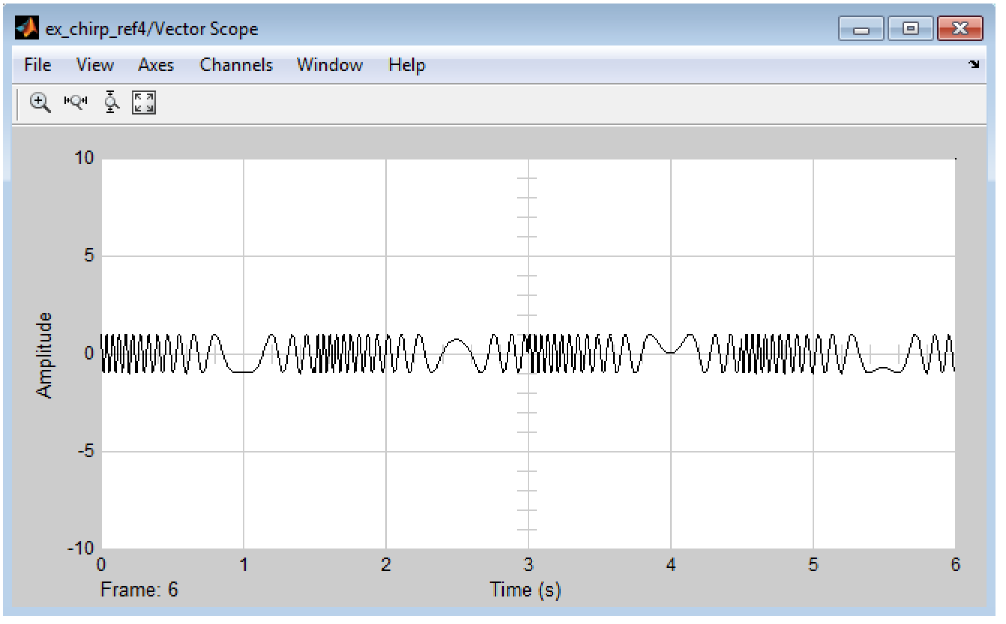


Example 4: Output Sweep with Negative Frequencies

Modify the Example 1 model by changing **Sweep time** to `1.5`, **Initial frequency** to `25`, and **Target frequency** to `0`. *The output chirp of this example might not behave as you expect* because the sweep contains negative frequencies between 1 and 1.5 seconds. The sweep reaches the **Target frequency** of 0 Hz at one second, then continues on its negative slope, taking on negative frequency values until it traverses one **Sweep time** (1.5 seconds).

Open the Example 4 model by typing `ex_chirp_ref4` at the MATLAB command line.

Run your model to see the time domain output:

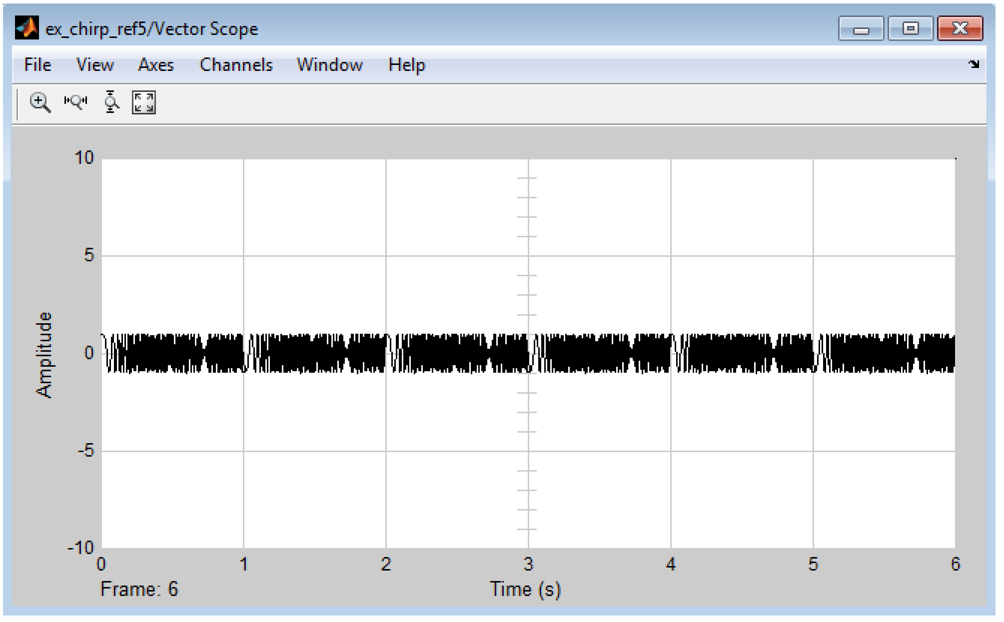


Example 5: Output Sweep with Frequencies Greater Than Half the Sampling Frequency

Modify the Example 1 model by changing the **Target frequency** parameter to `275`. *The output chirp of this model might not behave as you expect* because the sweep contains frequencies greater than half the sampling frequency (`200` Hz), which causes aliasing. If you unexpectedly get a chirp output with a spectrogram resembling the one following, your chirp's sweep might contain frequencies greater than half the sampling frequency.

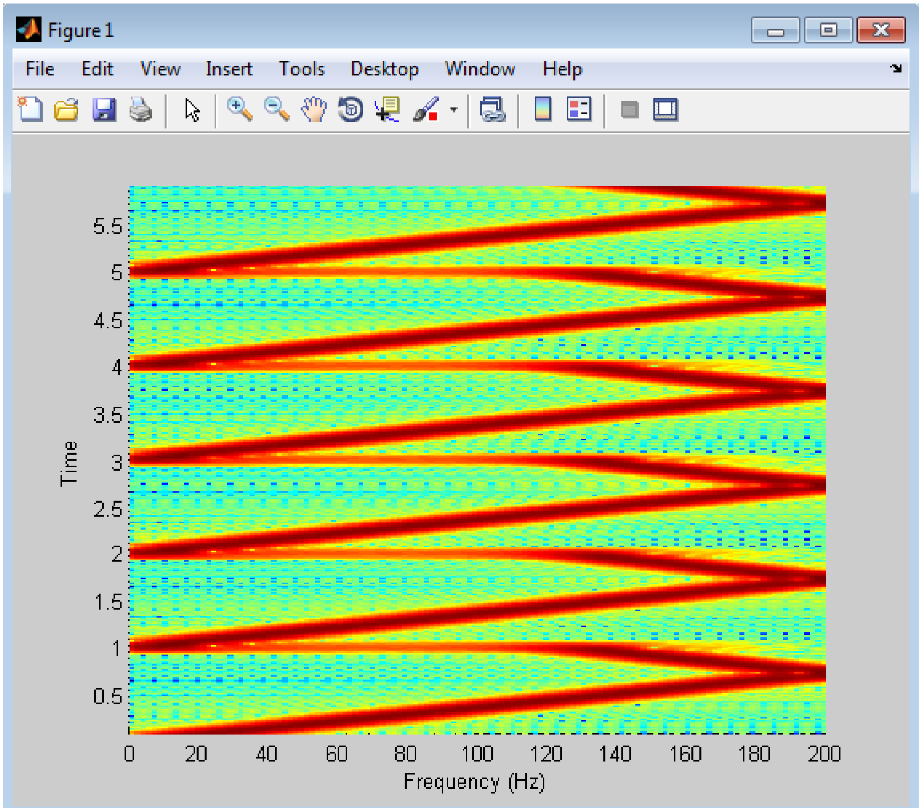
Open the Example 5 model by typing `ex_chirp_ref5` at the MATLAB command line.

Run your model to see the time domain output:



Type the following command to view the chirp output spectrogram:

```
spectrogram(dsp_examples_yout,hamming(64),...
       60,256,400)
```



Supported Data Types

- Double-precision floating point
- Single-precision floating point

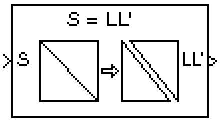
Cholesky Factorization

Factor square Hermitian positive definite matrix into triangular components



Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`

Description

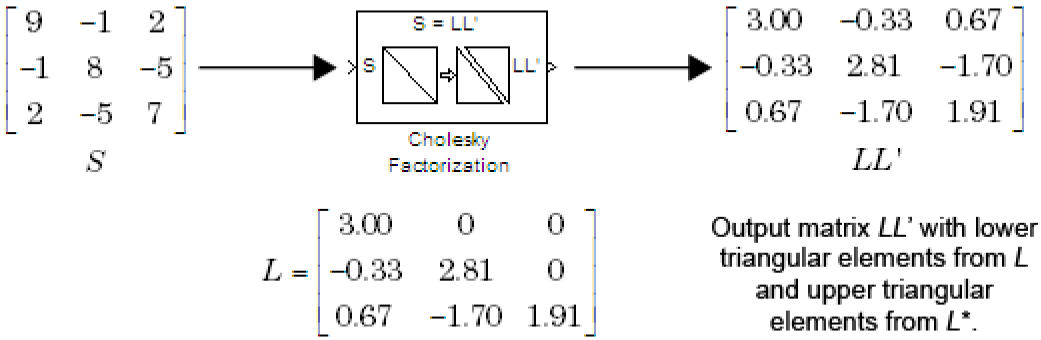
The Cholesky Factorization block uniquely factors the square Hermitian positive definite input matrix S as

$$S = LL^*$$

where L is a lower triangular square matrix with positive diagonal elements and L^* is the Hermitian (complex conjugate) transpose of L. The block outputs a matrix with lower triangle elements from L and upper triangle elements from L^*. The output is not in the same form as the output of the MATLAB `chol` function. In order to convert the output of the Cholesky Factorization block to the MATLAB form, use the following equation:

```
R = triu(LL');
```

Here, `LL'` is the output of the Cholesky Factorization block. Due to roundoff error, these equations do not produce a result that is exactly the same as the MATLAB result.



Block Output Composed of L and L[*]

Input Requirements for Valid Output

The block output is valid only when its input has the following characteristics:

- Hermitian — The block does *not* check whether the input is Hermitian; it uses only the diagonal and upper triangle of the input to compute the output.
- Real-valued diagonal entries — The block disregards any imaginary component of the input's diagonal entries.
- Positive definite — Set the block to notify you when the input is not positive definite as described in “Response to Nonpositive Definite Input” on page 2-272.

Response to Nonpositive Definite Input

To generate a valid output, the block algorithm requires a positive definite input (see “Input Requirements for Valid Output” on page 2-272). Set the **Non-positive definite input** parameter to determine how the block responds to a nonpositive definite input:

- `Ignore` — Proceed with the computation and *do not* issue an alert. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- `Error` — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to `Ignore` in the code generated for this block by Simulink Coder™ code generation software.

Performance Comparisons with Other Blocks

Note that L and L^* share the same diagonal in the output matrix. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs: `Ignore`, `Warning`, or `Error`. See “Response to Nonpositive Definite Input” on page 2-272.

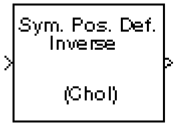
Cholesky Inverse

Compute inverse of Hermitian positive definite matrix using Cholesky factorization



Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

`dspinverses`

Description

The Cholesky Inverse block computes the inverse of the Hermitian positive definite input matrix S by performing Cholesky factorization.

$$S^{-1} = (LL^{*})^{-1}$$

L is a lower triangular square matrix with positive diagonal elements and L^{*} is the Hermitian (complex conjugate) transpose of L. Only the diagonal and upper triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

Response to Nonpositive Definite Input

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and *do not* issue an alert. The output is *not* a valid inverse.

- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid inverse.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs: `Ignore`, `Warning`, or `Error`. See "Response to Nonpositive Definite Input" on page 2-275.

References

Golub, G. H., and C. F. Van Loan. *Matrix Computations*. 3rd ed. Baltimore, MD: Johns Hopkins University Press, 1996.

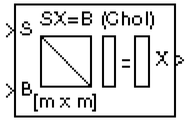
Cholesky Solver

Solve *S*X=*B* for X when *S* is square Hermitian positive definite matrix



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The Cholesky Solver block solves the linear system *S*X=*B* by applying Cholesky factorization to input matrix at the `S` port, which must be square (*M*-by-*M*) and Hermitian positive definite. Only the diagonal and upper triangle of the matrix are used, and any imaginary component of the diagonal entries is disregarded. The input to the `B` port is the right side *M*-by-*N* matrix, *B*. The *M*-by-*N* output matrix X is the unique solution of the equations.

A length-*M* vector input for right side *B* is treated as an *M*-by-1 matrix.

Response to Nonpositive Definite Input

When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and *do not* issue an alert. The output is *not* a valid solution.
- `Warning` — Proceed with the computation and display a warning message in the MATLAB Command Window. The output is *not* a valid solution.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Algorithm

Cholesky factorization uniquely factors the Hermitian positive definite input matrix S as

$$S = LL^*$$

where L is a lower triangular square matrix with positive diagonal elements.

The equation $SX=B$ then becomes

$$LL^*X = B$$

which is solved for X by making the substitution $Y = L^*X$, and solving the following two triangular systems by forward and backward substitution, respectively.

$$LY = B$$

$$L^*X = Y$$

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs: `Ignore`, `Warning`, or `Error`. See "Response to Nonpositive Definite Input" on page 2-278.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

CIC Compensator

Design CIC compensator

Note: The CIC Compensator block has been removed from the DSP System Toolbox block library. Existing instances of the CIC Compensator block will continue to operate. For new models, use the `CIC Compensation Decimator` and `CIC Compensation Interpolator` blocks. These blocks replace the functionality of the CIC Compensator block, when **FilterType** is set to `Decimator` and `Interpolator`, respectively.

Library

Filtering / Filter Designs

`dspfdesign`

Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

See "CIC Compensator Design — Main Pane" on page 5-733 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Compensator block allows the adder's numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

Filter Specifications

In this group, you specify your filter format, such as the filter order mode and the filter type.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

Differential Delay

Specify the differential delay of your target CIC filter. The default value is `1`. Most CIC filters use 1 or 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency Specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, the filter uses direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

CIC Compensation Interpolator

Compensate for CIC filter using FIR interpolator

Library

Filtering/Filter Designs

`dspfdesign`

Description

The CIC Compensation Interpolator block uses an FIR polyphase interpolator as the compensation filter. CIC compensation interpolators are multirate FIR filters that can be cascaded with CIC interpolators to mitigate the drawbacks of the CIC filters.

CIC interpolation filters are used in areas that require high interpolation. These filters are popular in ASICs and FPGAs, since they do not have any multipliers. CIC filters have two drawbacks:

- CIC filters have a magnitude response that causes a droop in the passband region. This magnitude response is:

$$abs\left(\frac{\sin\left(M\frac{\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right)^{n}$$

  - M — Differential delay
  - n — Number of stages
  - ω — Normalized angular frequency

- CIC filters have a wide transition region.

The compensation interpolator filters have an inverse sinc passband response to correct for the CIC droop, and they have a narrow transition width.

This block brings the capabilities of the dsp.CICCompensationInterpolator System object to the Simulink environment.

Rate change factor

Rate change factor for the CIC filter to be compensated, specified as a positive scalar integer. The default is 2.

Number of sections

Number of integrator and comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is 2.

Differential delay

Delay value used in each of the comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is 1.

Filter parameters

Interpolation factor

Interpolation factor of the compensator, specified as a positive scalar integer. The default value is 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the specifications for passband frequency, stopband frequency, passband ripple, and stopband attenuation. When you clear this check box, the block designs filters with the order that you specify in **Filter order**.

By default, this check box is selected.

Filter order

Order of the compensation filter, specified as a positive scalar integer. The default is 12.

Passband edge frequency (Hz)

Passband edge frequency of the compensation filter, specified as a real positive scalar in Hz. **Passband edge frequency (Hz)** must be less than $F_s/2$, where F_s is the output sample rate. The default is 100000.

Stopband edge frequency (Hz)

Stopband edge frequency of the compensation filter, specified as a real positive scalar in hertz. **Stopband edge frequency (Hz)** must be less than $F_s/2$, where F_s is the output sample rate. The default is 400000.

Passband ripple (dB)

Passband ripple of compensation filter, specified as a real positive scalar in dB. The default is 0.1.

Stopband attenuation (dB)

Stopband attenuation of compensation filter, specified as a real positive scalar in dB. The default is 60.

Inherit sample rate from input

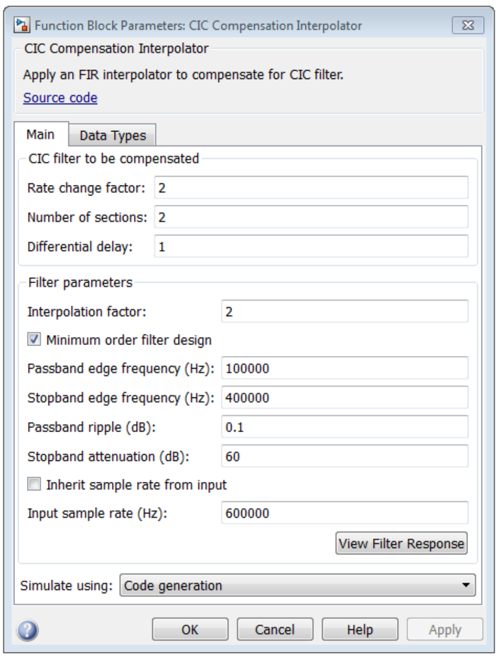
When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you must specify the sample rate in **Input sample rate (Hz)**.

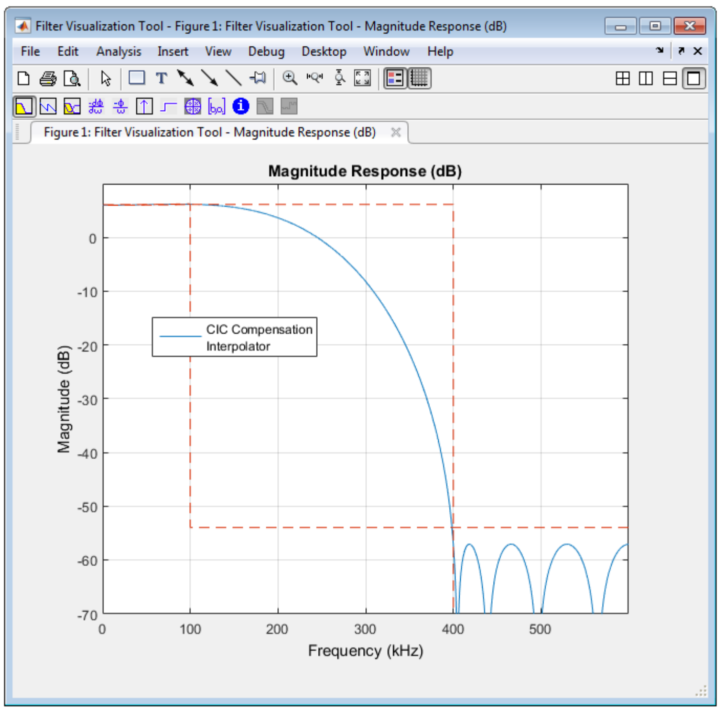
Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 600000.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the CIC Compensation Interpolator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

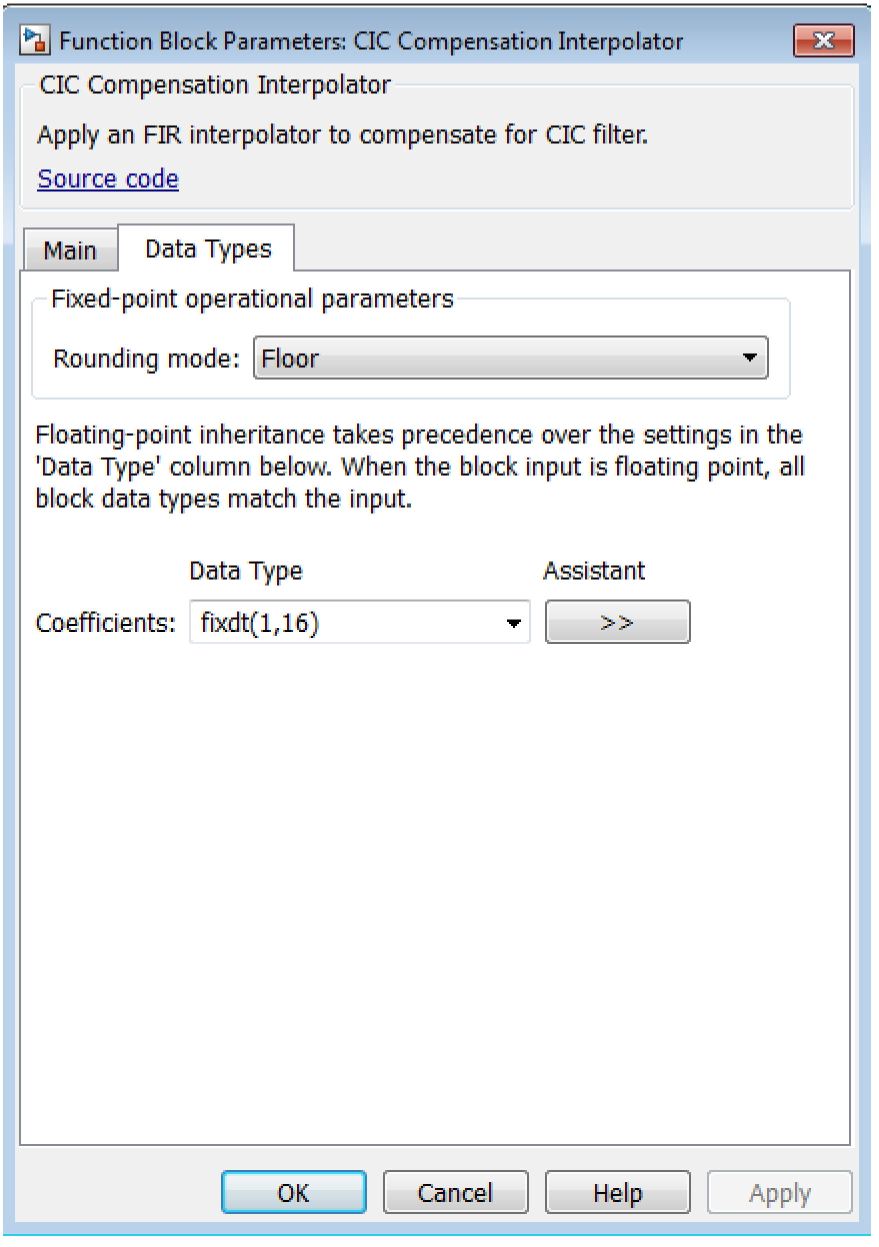
- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients data type

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16`, fraction length `0`. You can change the fraction length to any other integer value.
- <data type expression> — Specify the coefficients data type by using the expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16, 15)`, to specify the coefficients data type. Specify the sign mode of this data type as `[ ]` or true.
- `Refresh Data Type` — Refreshes to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned) • 8-, 16-, 32-, and 64-bit signed integers
Output	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point (signed only) • 8-, 16-, 32-, and 64-bit signed integers

CIC Compensation Decimator

Compensate for CIC filter using FIR decimator

Library

Filtering/Filter Designs

`dspfdesign`

Description

The CIC Compensation Decimator block uses an FIR polyphase decimator as the compensation filter. CIC compensation decimators are multirate FIR filters that can be cascaded with CIC decimators to mitigate the drawbacks of the CIC filters.

CIC decimation filters are used in areas that require high decimation. These filters are popular in ASICs and FPGAs, since they do not have any multipliers. CIC filters have two drawbacks:

- CIC filters have a magnitude response that causes a droop in the passband region. This magnitude response is:

$$abs\left(\frac{\sin\left(M\frac{\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right)^n$$

  - M — Differential delay
  - n — Number of stages
  - ω — Normalized angular frequency

- CIC filters have a wide transition region.

The compensation decimator filters have an inverse passband response to correct for the CIC droop, and they have a narrow transition width.

This block brings the capabilities of the dsp.CICCompensationDecimator System object to the Simulink environment.

Rate change factor

Rate change factor for the CIC filter to be compensated, specified as a positive scalar integer. The default is `2`.

Number of sections

Number of decimator and comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is `2`.

Differential delay

Delay value used in each of the comb sections of the CIC filter to be compensated, specified as a positive scalar integer. The default is `1`.

Decimation factor

Decimation factor of the compensator, specified as a positive scalar integer. The default is `2`.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the specifications passband frequency, stopband frequency, passband ripple, and stopband attenuation. When you clear this check box, the block designs filters with the order that you specify in **Filter order**.

By default, this check box is selected.

Filter order

Order of compensation filter, specified as a positive scalar integer. The default is `12`.

Passband edge frequency (Hz)

Passband edge frequency of the compensation filter, specified as a real positive scalar in Hz. **Passband edge frequency (Hz)** must be less than $F_s/2$, where F_s is the input sample rate. The default value is `100000`.

Stopband edge frequency (Hz)

Stopband edge frequency of the compensation filter, specified as a real positive scalar in Hz. **Stopband edge frequency (Hz)** must be less than $F_s/2$, where F_s is the input sample rate. This parameter applies when you select the **Minimum order filter design** check box. The default is `400000`.

Passband ripple (dB)

Passband ripple of the compensation filter, specified as a real positive scalar in dB. The default is `0.1`.

Stopband attenuation (dB)

Stopband attenuation of the compensation filter, specified as a real positive scalar in dB. The default is 60.

Inherit sample rate from input

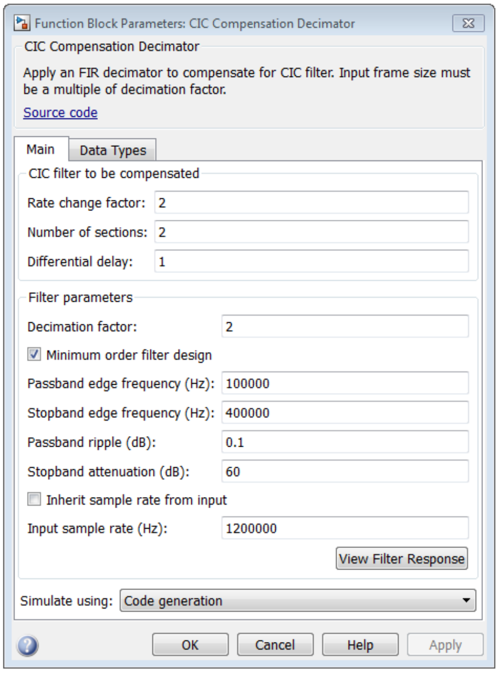
When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you must specify the sample rate in **Input sample rate (Hz)**.

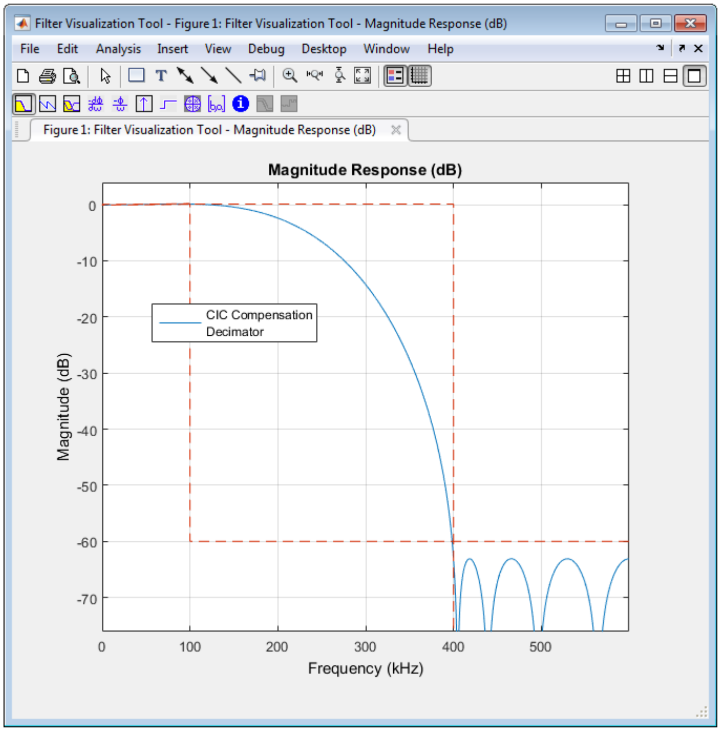
Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is 1200000.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the CIC Compensation Decimator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

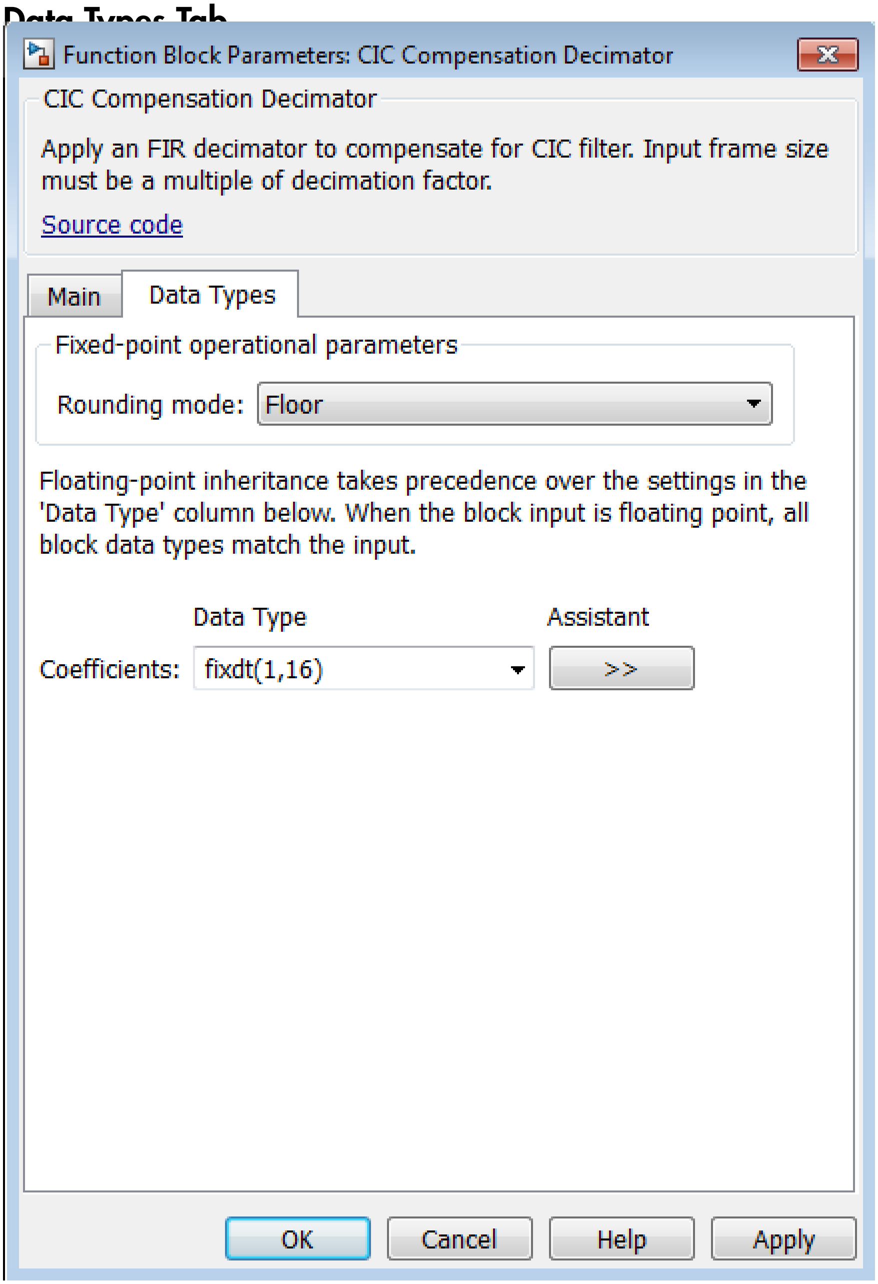
- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients data type

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16`, fraction length `0`. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using an expression that evaluates to a data type object, for example, numeric type (fixdt(`[ ]`,`16`, `15`)), to specify the coefficients data type. Specify the sign mode of this data type as `[ ]` or true.
- `Refresh Data Type` — Refresh to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

CIC Decimation

Decimate signal using Cascaded Integrator-Comb filter

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The CIC Decimation block performs a sample rate decrease (decimation) on an input signal by an integer factor. Cascaded Integrator-Comb (CIC) filters are a class of linear phase FIR filters comprised of a comb part and an integrator part.

The transfer function of a CIC decimation filter is

$$H(z) = H_I{}^N(z)H_c{}^N(z) = \frac{\left(1 - z^{-RM}\right)^N}{\left(1 - z^{-1}\right)^N} = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N$$

where

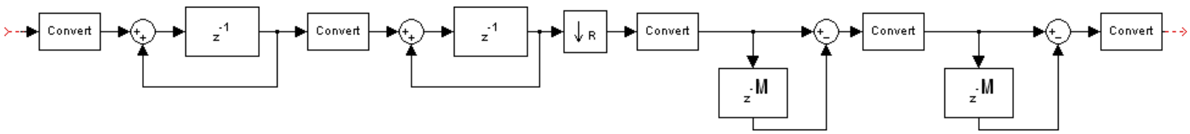
- H_I is the transfer function of the integrator part of the filter.
- H_C is the transfer function of the comb part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

The CIC Decimation block requires a Fixed-Point Designer™ license.

The block supports real and complex fixed-point inputs. In its normal mode of operation, the CIC Decimation block allows the adder's numeric values to overflow and wrap around [1] [3]. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

CIC Filter Structure

The CIC Decimation block has the following CIC filter structure. The structure consists of N sections of cascaded integrators, followed by a rate change by a factor R, followed by N sections of cascaded comb filters [1] .



The unit delay in the integrator portion of the CIC Filter can be located in either the feed-forward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feed forward path of the integrator since it is a preferred configuration for HDL implementation.

Examples

See GSM Digital Down Converter for an example using the CIC Decimation block.

Dialog Box

Coefficient Source

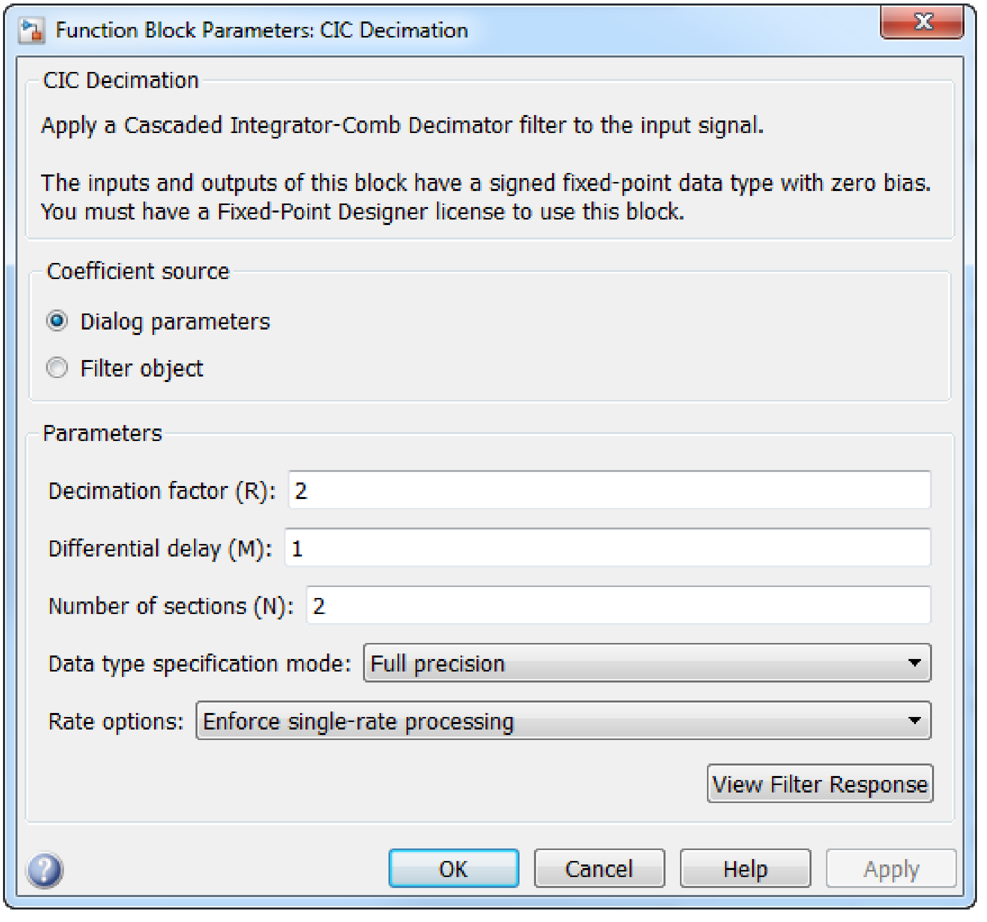
The CIC Decimation block can operate in two different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as **Decimation factor (R)**, **Differential delay (M)** and **Number of sections (N)** in the block mask.
- **Filter object** — Specify the filter using a dsp.CICDecimator System object.

Different items appear on the CIC Decimation block dialog depending on whether you select **Dialog parameters** or **Filter object** in the **Coefficient source** group box. See the following sections for details:

Specify Filter Characteristics in Dialog

The **Main** pane of the CIC Decimation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Decimation factor (R)

Specify the decimation factor of the filter.

Differential delay (M)

Specify the differential delay of the comb part of the filter, `M`, as shown in the diagram in "CIC Filter Structure" on page 2-309.

Number of sections (N)

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

Data type specification mode

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output.

- `Full precision` — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. All word lengths are set to

$$\text{word length} = \text{ceil}(N * \log_2(M * R)) + I$$

  where

  - I = input word length
  - M = differential delay
  - N = number of sections
  - R = decimation factor

  All fraction lengths are set to the input fraction length.

- `Minimum section word lengths` — In this mode, you specify the word length of the filter output in the **Output word length** parameter. The block automatically selects the word lengths of the filter sections and all fraction lengths such that each of the section word lengths is as small as possible. The precision of each filter section is less than in `Full precision` mode, but the range of each section is preserved.
- `Specify word lengths` — In this mode you specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The block automatically selects fraction lengths for the filter sections and output such that the range of each section is preserved when the least significant bits are discarded.

- `Binary point scaling` — In this mode you fully specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

Section word lengths

Specify the word length, in bits, of the filter sections.

This parameter is only visible if `Specify word lengths` or `Binary point scaling` is selected for the **Data type specification mode** parameter.

Section fraction lengths

Specify the fraction length of the filter sections.

This parameter is only visible if `Binary point scaling` is selected for the **Data type specification mode** parameter.

Output word length

Specify the word length, in bits, of the filter output.

This parameter is only visible if you select `Minimum section word lengths`, `Specify word lengths`, or `Binary point scaling` for the **Data type specification mode** parameter.

Output fraction length

Specify the fraction length of the filter output.

This parameter is only visible if `Binary point scaling` is selected for the **Data type specification mode** parameter.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

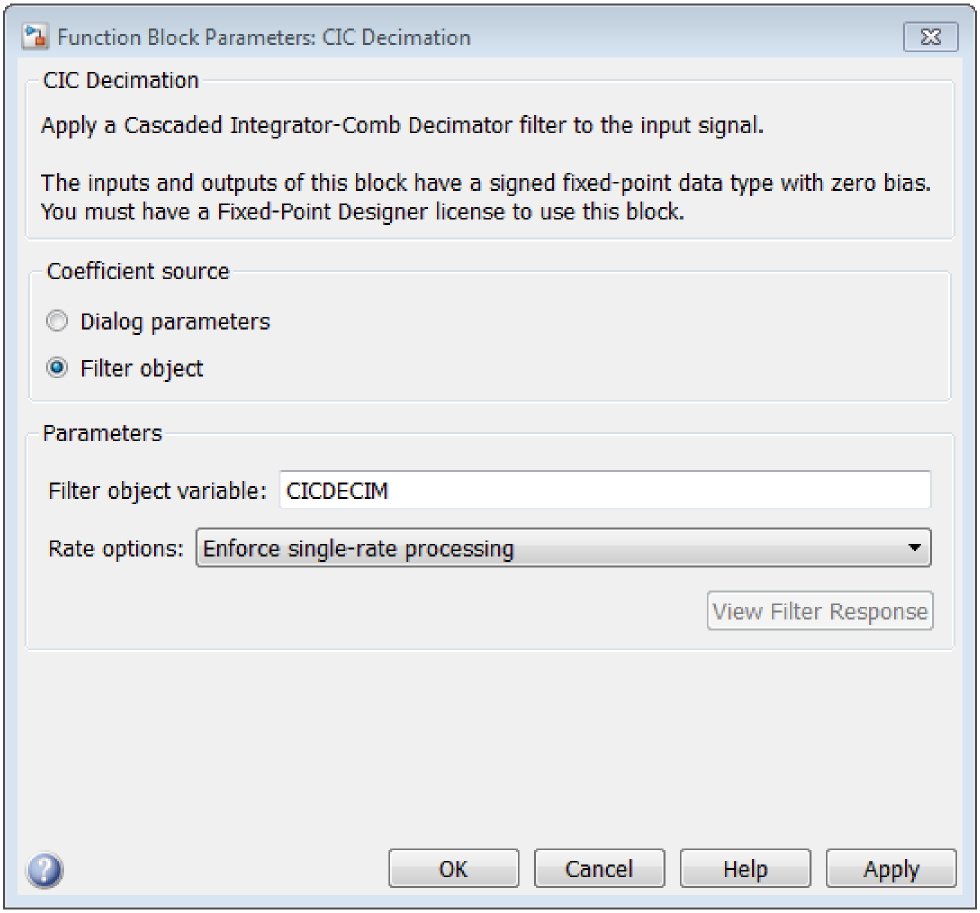
- `Enforce single-rate processing` — When you select this option, the block performs frame-based processing and produces an output that has the same sample rate as the input. To decimate the signal while maintaining the input sample rate, the block decreases the output frame size. In this mode, the input column size must be a multiple of the decimation factor, `R`.
- `Allow multirate processing` — When you select this option, the block performs sample-based processing. In this mode, the block produces an output with a sample rate that is `R` times slower than the input sample rate.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Specify Multirate Filter Object

The **Main** pane of the CIC Decimation block dialog appears as follows when you select **Filter object** in the **Coefficient source** group box.



Multirate filter variable

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.CICDecimator System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects” (MATLAB).

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block performs frame-based processing and produces an output that has the same sample rate as the input. To decimate the signal while maintaining the input sample rate, the block decreases the output frame size. In this mode, the input column size must be a multiple of the decimation factor, `R`.
- `Allow multirate processing` — When you select this option, the block performs sample-based processing and produces an output with a sample rate that is `R` times slower than the input sample rate.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the System object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see CIC Decimation.

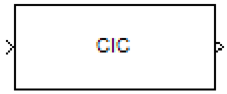
CIC Filter

Design Cascaded Integrator-Comb (CIC) Filter



Library

Filtering / Filter Designs

`dspfdesign`

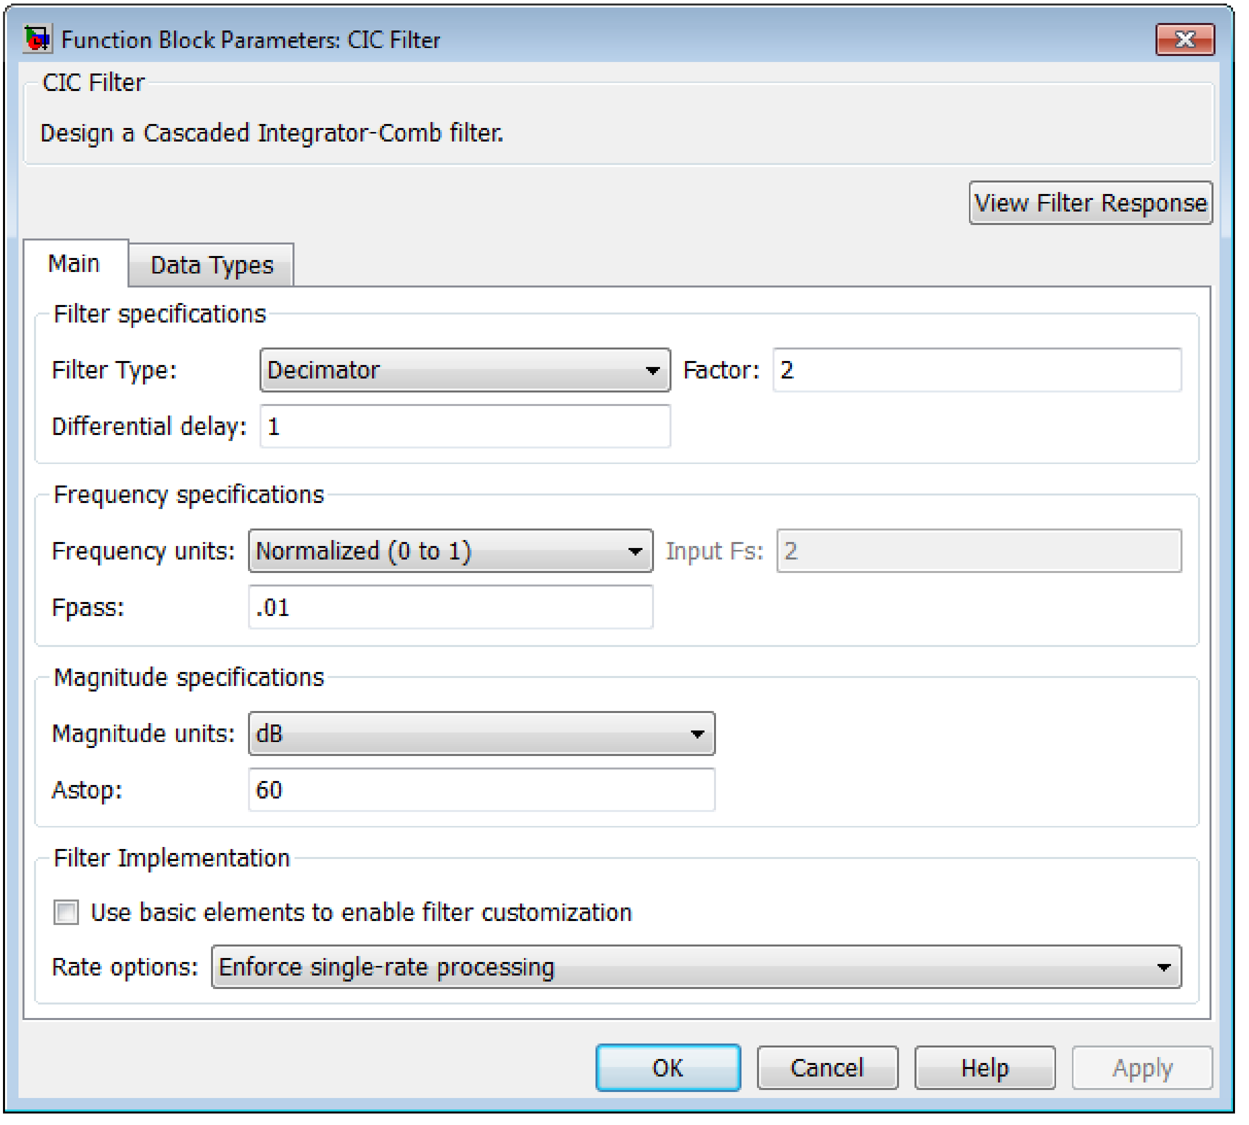
Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

Main Pane

See "CIC Filter Design — Main Pane" on page 5-730 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.



View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Filter block allows the adder's numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

Filter Specifications

In this group, you specify your CIC filter format, such as the filter type and the differential delay.

Filter type

Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output Fs** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

Differential delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Filter Implementation

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

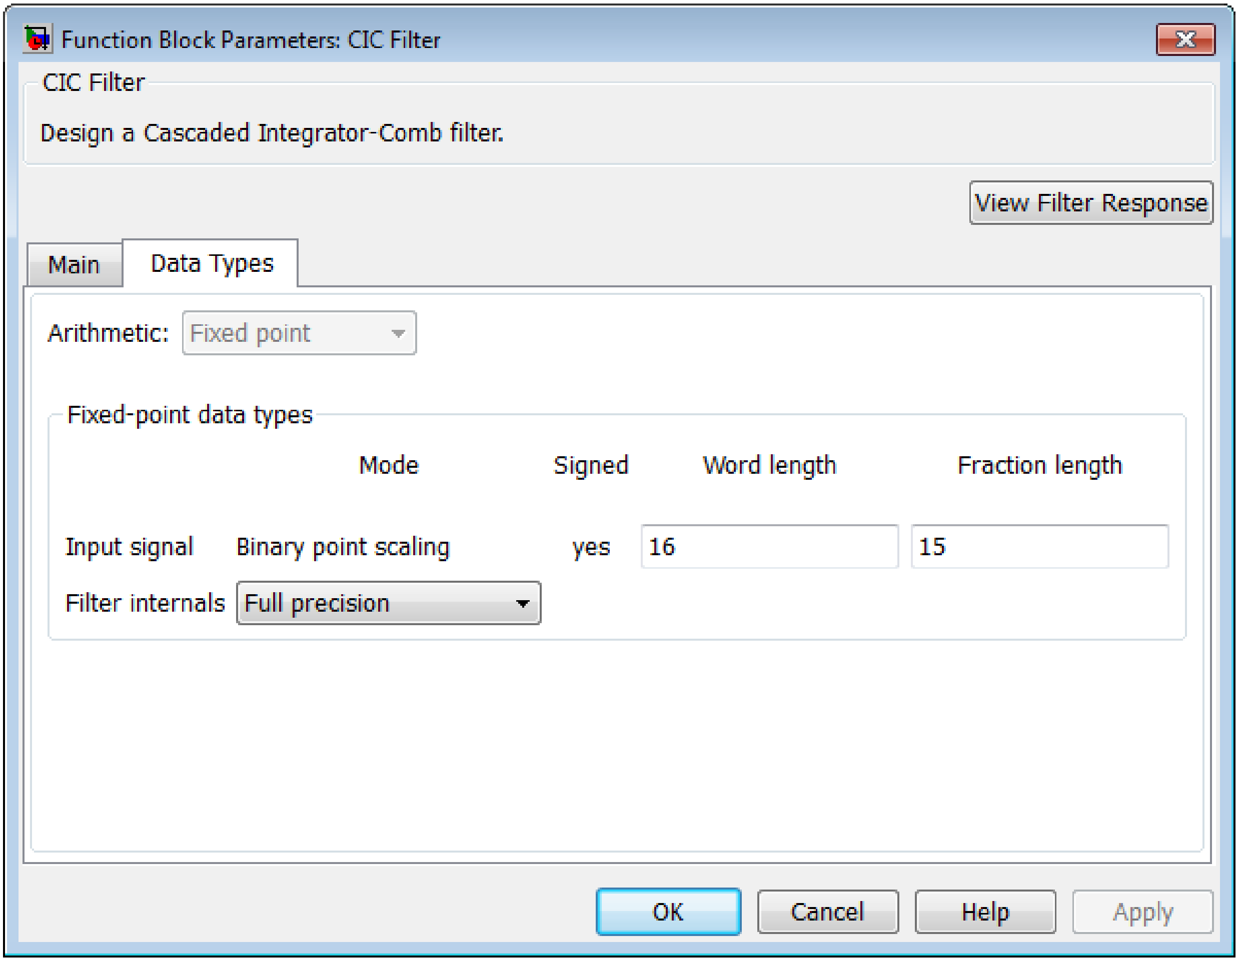
The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Data Types Pane



See the Data Types Pane subsection of the `filterBuilder` function reference page for more information about specifying data type parameters.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Fixed point

Introduced in R2007b

CIC Interpolation

Interpolate signal using Cascaded Integrator-Comb filter

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The CIC Interpolation block performs a sample rate increase (interpolation) on an input signal by an integer factor. Cascaded Integrator-Comb (CIC) filters are a class of linear phase FIR filters that consist of a comb part and an integrator part.

The transfer function of a CIC interpolator filter is

$$H(z) = {H_I}^N(z){H_C}^N(z) = \frac{(1-z^{-RM})^N}{(1-z^{-1})^N} = \left[\sum_{k=0}^{RM-1} z^{-k}\right]^N$$

where

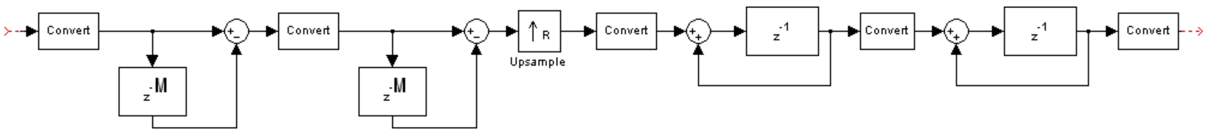
- H_I is the transfer function of the integrator part of the filter.
- H_C is the transfer function of the comb part of the filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the interpolation factor.
- M is the differential delay.

The CIC Interpolation block requires a Fixed-Point Designer license.

The block supports real and complex fixed-point inputs. In its normal mode of operation, the CIC Interpolation block allows the adder's numeric values to overflow and wrap around [1] [3]. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

CIC Filter Structure

The CIC Interpolation block has the following CIC filter structure. The structure consists of *N* sections of cascaded comb filters, followed by a rate change by a factor *R*, followed by *N* sections of cascaded integrators [1] .



The unit delay in the integrator portion of the CIC Filter can be located in either the feed-forward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feed forward path of the integrator since it is a preferred configuration for HDL implementation.

Dialog Box

Coefficient Source

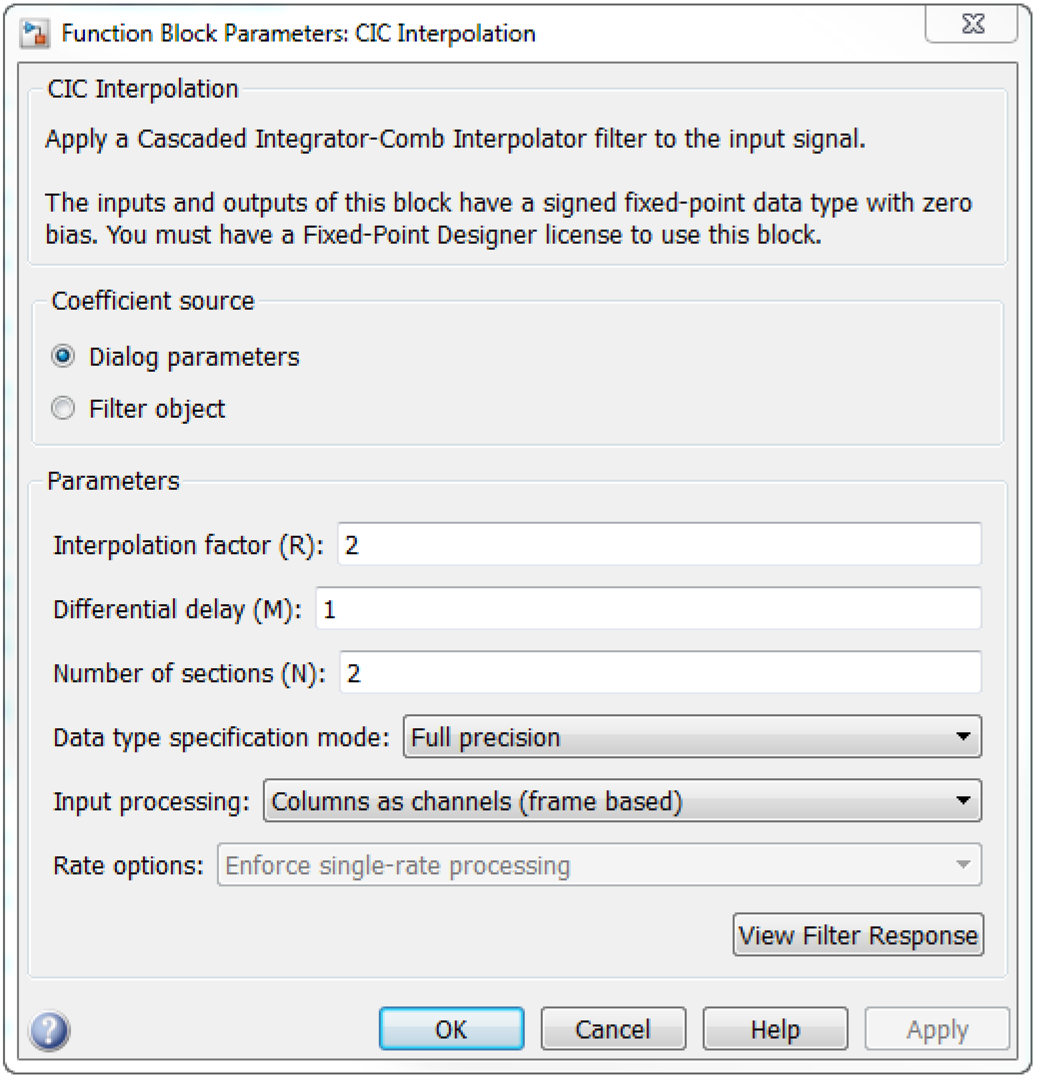
The CIC Interpolation block can operate in two different modes. Select the mode in the **Coefficient source** group box. If you select:

- **Dialog parameters** — Enter information about the filter, such as **Interpolation factor (R)**, **Differential delay (M)** and **Number of sections (N)** in the block mask.
- **Filter object** — Specify the filter using a dsp.CICInterpolator System object.

Different items appear on the CIC Interpolation block dialog depending on whether you select **Dialog parameters** or **Filter object** in the **Coefficient source** group box. See the following sections for details:

Specify Filter Characteristics in Dialog

The **Main** pane of the CIC Interpolation block dialog appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Interpolation factor (R)

Specify the interpolation factor of the filter.

Differential delay (M)

Specify the differential delay of the comb portion of the filter, `M`, as shown in the diagram in "CIC Filter Structure" on page 2-325.

Number of sections (N)

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or in the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

Data type specification mode

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output.

- `Full precision` — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to

$$\text{word length} = \text{ceil}(\log_2(\frac{(R*M)^N}{R})) + I$$

  where

  - I = input word length
  - M = differential delay
  - N = number of sections
  - R = interpolation factor

  The other section word lengths are set is such a way as to accommodate the bit growth, as described in Hogenauer's paper [1]. All fraction lengths are set to the input fraction length.

- `Minimum section word lengths` — In this mode, you specify the word length of the filter output in the **Output word length** parameter. The word lengths of the filter sections are set in the same way as in `Full precision` mode.

  The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.

- `Specify word lengths` — In this mode you specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- `Binary point scaling` — In this mode you fully specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

Section word lengths

Specify the word length, in bits, of the filter sections.

This parameter is only visible if you select `Specify word lengths` or `Binary point scaling` for the **Data type specification mode** parameter.

Section fraction lengths

Specify the fraction length of the filter sections.

This parameter is only visible if you select `Binary point scaling` for the **Data type specification mode** parameter.

Output word length

Specify the word length, in bits, of the filter output.

This parameter is only visible if you select `Minimum section word lengths`, `Specify word lengths` or `Binary point scaling` for the **Data type specification mode** parameter.

Output fraction length

Specify the fraction length of the filter output.

This parameter is only visible if you select `Binary point scaling` for the **Data type specification mode** parameter.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block always performs single-rate processing.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the input to the block must be a scalar or a vector. You can use the **Rate options** parameter to specify whether the block performs single-rate or multirate processing.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

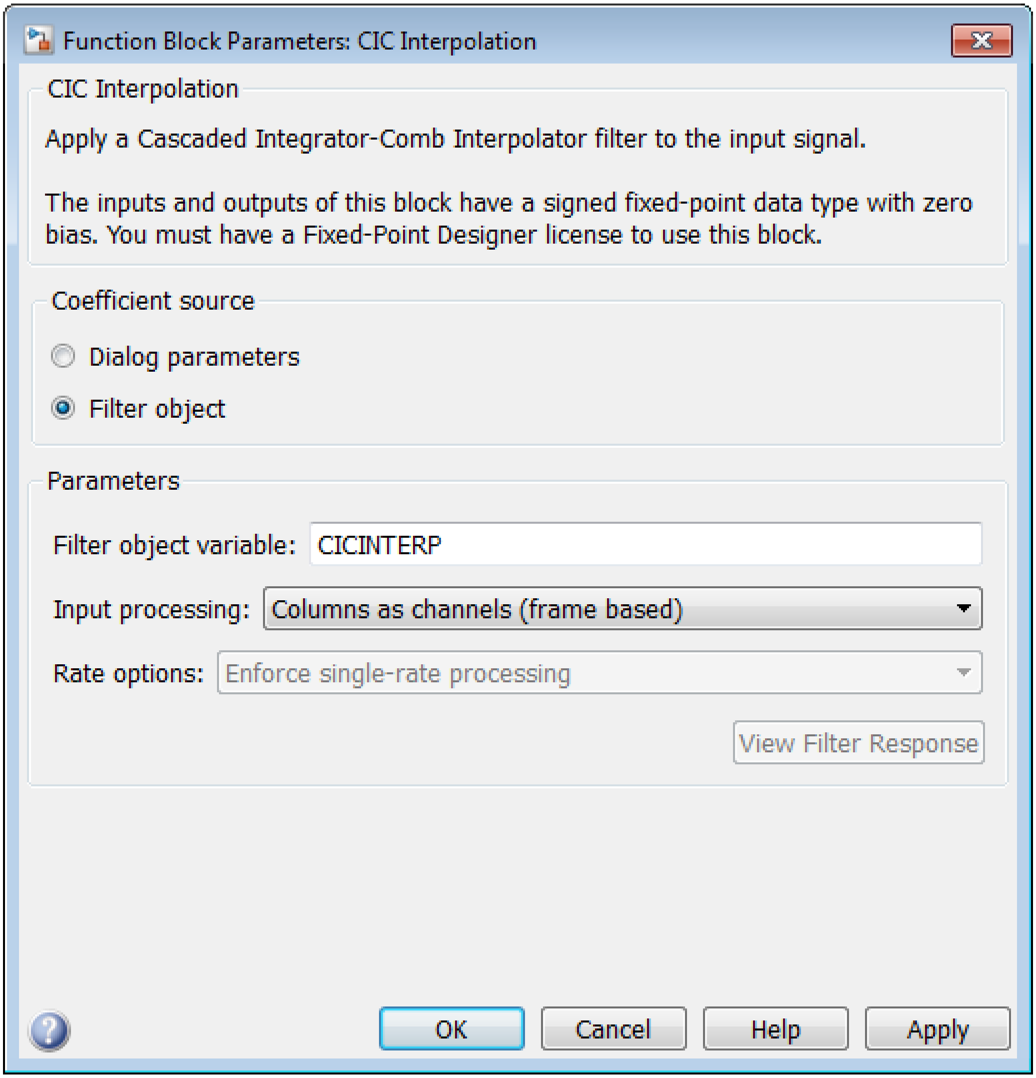
- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block produces an output with a sample rate that is `R` times faster than the input sample rate. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Specify Multirate Filter Object

The **Main** pane of the CIC Interpolation block dialog appears as follows when you specify **Filter object** in the **Coefficient source** group box.



Multirate filter variable

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.CICInterpolator System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects” (MATLAB).

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block always performs single-rate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the input to the block must be a scalar or a vector. You can use the **Rate options** parameter to specify whether the block performs single-rate or multirate processing.

Rate options

Specify the rate processing rule for the block. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block produces an output with a sample rate that is `R` times faster than the input sample rate. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the System object specified in the **Multirate filter variable** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Multirate filter variable** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see CIC Interpolation in the HDL Coder documentation.

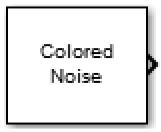
Colored Noise

Generate colored noise signal



Library

Sources

`dspsrcs4`

Description

The Colored Noise block generates a colored noise signal with a power spectral density of $1/|f|^{\alpha}$ over its entire frequency range. The inverse power spectral density component, α, can be any value in the interval `[-2 2]`. The type of colored noise the block generates depends on the **Noise color** option you choose in the block dialog box. When you set **Noise color** to `custom`, you can specify the power density of the noise through the **Power of inverse frequency** parameter.

The size and data type properties of the generated signal are determined by the parameters set in the block dialog box.

Algorithms

This block brings the capabilities of the dsp.ColoredNoise System object to the Simulink environment.

For information on the various colored noise processes, see the “Definitions” on page 4-424 section of `dsp.ColoredNoise`. For information on the algorithm used by this block, see the “Algorithms” on page 4-423 section of `dsp.ColoredNoise`.

Parameters

Noise color

Color of the noise the block generates. You can set this parameter to:

- pink (default) — Generates pink noise. This option is equivalent to setting **Power of inverse frequency** to 1.
- white — Generates white noise (flat power spectral density). This option is equivalent to setting **Power of inverse frequency** to 0.
- brown — Generates brown noise. This option is equivalent to setting **Power of inverse frequency** to 2.
- blue — Generates blue noise. This option is equivalent to setting **Power of inverse frequency** to -1.
- purple — Generates violet (purple) noise. This option is equivalent to setting **Power of inverse frequency** to -2.
- custom — Specify the power density of the noise through **Power of inverse frequency**.

Power of inverse frequency

Inverse power spectral density component, a, specified as a real scalar in the interval [-2 2]. The inverse exponent defines the power spectral density of the random process by $1/|f|^{\alpha}$. The default value of this property is 1. When **Power of inverse frequency** is greater than 0, the block generates lowpass noise, with a singularity (pole) at $f = 0$. These processes exhibit long memory. When **Power of inverse frequency** is less than 0, the block generates highpass noise with negatively correlated increments. These processes are referred to as antipersistent. In a log-log plot of power as a function of frequency, processes generated by the Colored Noise block exhibit an approximate linear relationship, with the slope equal to $–a$.

This parameter applies when you set **Noise color** to custom.

Number of output channels

Number of output channels, specified as a positive integer scalar. This parameter defines the number of columns in the generated signal. The default is 1. This parameter is nontunable.

Output data type

Data type of the output. You can set this parameter to:

- `double` (default)
- `single`

This parameter is nontunable.

Number of samples per output channel

Number of samples in each frame of the output signal, specified as a positive integer scalar. This parameter defines the number of rows in the generated signal. The default is `1024`. This parameter is nontunable.

Output sample time (s)

Sample time of the output signal, specified as a positive scalar in seconds. The default is `1`. This parameter is nontunable.

Initial seed

Initial seed of the random number generator algorithm, specified as a real positive integer scalar. The default is `67`. This parameter is nontunable.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time.
- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify the type of comb filter and the number of peaks or notches.

Comb Type

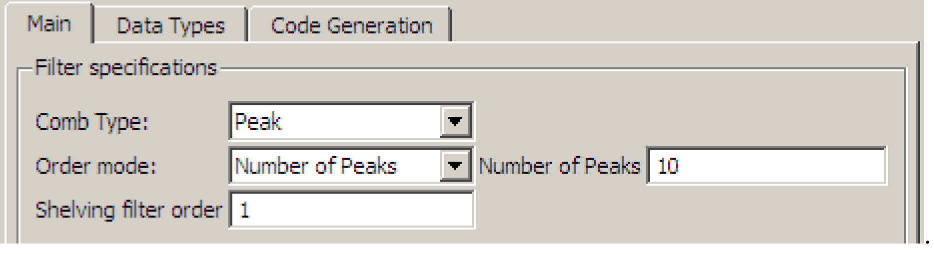
Select either `Notch` or `Peak` from the drop-down list. `Notch` creates a comb filter that attenuates a set of harmonically related frequencies. `Peak` creates a comb filter that amplifies a set of harmonically related frequencies.

Order mode

Select either `Order` or `Number of Peaks/Notches` from the drop-down menu.

Select `Order` to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of 2/`Order` in normalized frequency units.

Select `Number of Peaks` or `Number of Notches` to specify the number of peaks or notches and the `Shelving filter order`



.

Shelving filter order

The `Shelving filter order` is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

Frequency specifications

In this group, you specify the frequency constraints and frequency units.

Frequency specifications

Select either `Quality factor` or `Bandwidth`.

`Quality factor` is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the –3 dB point.

`Bandwidth` specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the –3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input Fs** dialog box.

Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Bandwidth gain — Specify the gain at which the bandwidth is measured. The default is –3 dB.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

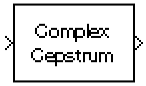
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2010a

Complex Cepstrum

Compute complex cepstrum of input



Library

Transforms

`dspxfrm3`

Description

The Complex Cepstrum block computes the complex cepstrum of each column in the real-valued M-by-N input matrix, u. The block treats each column of the input as an independent channel containing M consecutive samples. The block *always* processes unoriented vector inputs as a single channel, and returns the result as a length-M column vector. The block does not accept complex-valued inputs.

The input is altered by the application of a linear phase term so that there is no phase discontinuity at ±π radians. That is, each input channel is independently zero padded and circularly shifted to have zero phase at π radians.

The output is a real M_o-by-N matrix, where M_o is specified by the **FFT length** parameter. Each output column contains the length-M_o complex cepstrum of the corresponding input column.

```
y = cceps(u,Mo)     % Equivalent MATLAB code
```

When you select the **Inherit FFT length from input port dimensions** check box, the output frame size matches the input frame size ($M_o = M$).

The output port rate is the same as the input port rate.

Parameters

Inherit FFT length from input port dimensions

When you select this check box, the output frame size matches the input frame size.

FFT length

The number of frequency points at which to compute the FFT, which is also the output frame size, M_o. This parameter is visible only when you clear the **Inherit FFT length from input port dimensions** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Constant

Generate constant value

Library

Sources

`dspsrcs4`

Description

The Constant block is an implementation of the Simulink Constant block. See Constant for more information.

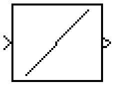
HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Constant.

Introduced in R2008b

Constant Ramp

Generate ramp signal with length based on input dimensions



Library

Signal Operations

`dspsigops`

Description

The Constant Ramp block generates the constant ramp signal

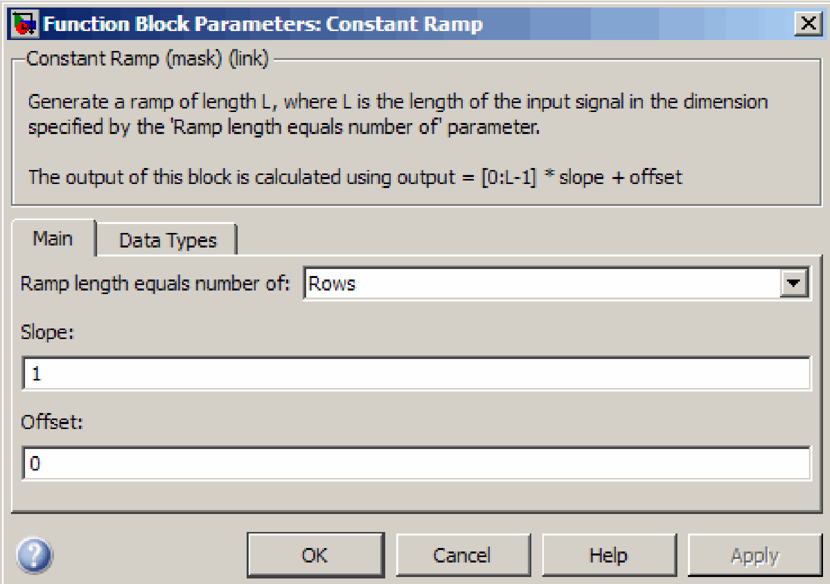
```
y = (0:L-1)*m + b
```

where m is the slope specified by the scalar **Slope** parameter, and b is the y-intercept specified by the scalar **Offset** parameter.

For an unoriented vector input, L is equal to the length of the input vector. For an N-D input array, the length L of the output ramp is equal to the length of the input in the dimension specified by the **Ramp length equals number of** or **Dimension** parameter. The output, y, is always an unoriented vector.

Dialog Box

The **Main** pane of the Constant Ramp block dialog appears as follows.



Ramp length equals number of

Specify whether the length of the output ramp is the number of rows, number of columns, or the length of the specified dimension of the input.

Dimension

Specify the one-based dimension of the input array that determines the length of the output ramp.

This parameter is only visible when you select `Elements in specified dimension` for the **Ramp length equals number of** parameter.

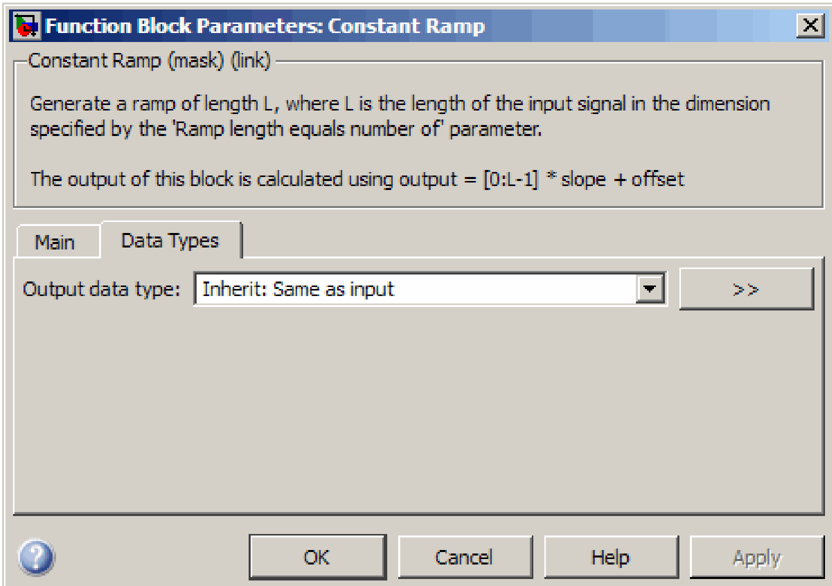
Slope

Specify the scalar slope of the ramp.

Offset

Specify the scalar *y*-intercept of the ramp.

The **Data Types** pane of the Constant Ramp block dialog appears as follows.



Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

This block differs from other DSP System Toolbox blocks in that unless you choose `Same as input` for the **Output data type** parameter, the data types of the input and the output do not need to be the same.

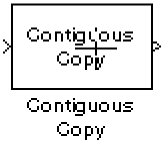
Introduced before R2006a

Contiguous Copy (Obsolete)

Create discontiguous input in contiguous block of memory



Library

`dspobslib`

Description

Note The Contiguous Copy block is still supported but is likely to be obsoleted in a future release.

The Contiguous Copy block copies the input to a contiguous block of memory, and passes this new copy to the output. The output is identical to the input, but is guaranteed to reside in a contiguous section of memory.

Because Simulink software employs an efficient copy-by-reference method for propagating data in a model, some operations produce outputs with discontiguous memory locations.

Although this does not present a problem during simulation, blocks linked to versions of DSP Blockset prior to 4.0 may require contiguous inputs for code generation with the Simulink Coder product. When such blocks are used in a model intended for code generation, they should be preceded by the Contiguous Copy block to ensure that their inputs are contiguous.

Supported Data Types

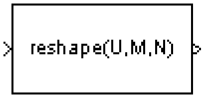
- Double-precision floating point

- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Introduced in R2008b

Convert 1-D to 2-D

Reshape 1-D or 2-D input to 2-D matrix with specified dimensions



Library

Signal Management / Signal Attributes

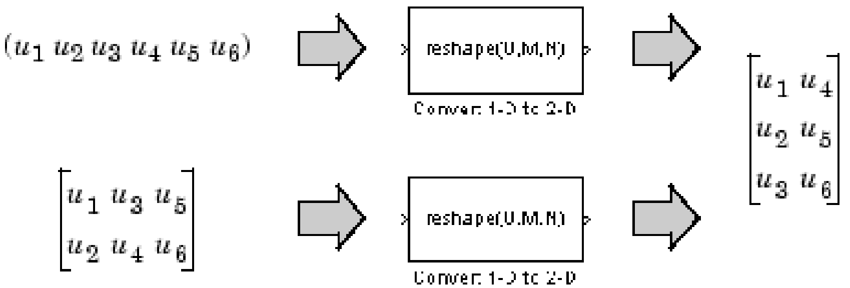
`dspsigattribs`

Description

The Convert 1-D to 2-D block reshapes a length-M_i 1-D vector or an M_i-by-N_i matrix to an M_o-by-N_o matrix, where M_o is specified by the **Number of output rows** parameter, and N_o is specified by the **Number of output columns** parameter.

```
y = reshape(u,Mo,No)        % Equivalent MATLAB code
```

The input is reshaped *columnwise*, as shown in the two cases below. The length-6 vector and the 2-by-3 matrix are both reshaped to the same 3-by-2 output matrix.



An error is generated when $(M_o*N_o) \neq (M_i*N_i)$. That is, the total number of input elements must be conserved in the output.

The output is frame based when you select the **Frame-based output** check box; otherwise, the output is sample based.

Parameters

Number of output rows

The number of rows, M_o, in the output matrix.

Number of output columns

The number of rows, N_o, in the output matrix.

Frame-based output

Creates a frame-based output when selected.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Convert 1-D to 2-D in the HDL Coder documentation.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

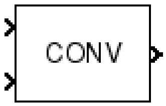
Convolution

Convolution of two inputs



Library

Signal Operations

`dspsigops`

Description

The Convolution block convolves the first dimension of an N-D input array *u*, with the first dimension of an N-D input array *v*. The block can also independently convolve a column vector with the first-dimension of an N-D input array.

Convolution with DSP System Toolbox Blocks

The general equation for convolution is

$$y(k) = \sum_{n} u(n-k)h(k)$$

There are two DSP System Toolbox blocks that can be used for this purpose:

- Convolution
- `Discrete FIR Filter`

The Convolution block assumes that all of u and h are available at each Simulink time step, and computes the entire convolution at every one.

The Discrete FIR Filter block can be used for convolving signals in situations where all of h is available at each time step, but u is a sequence that comes in over the life of the simulation. When you use the Discrete FIR Filter block, the convolution is computed only once.

Use the following questions to help you determine which block best fits your needs:

Question	Answer	Recommended Block(s)
How many convolutions do you intend to perform?	Many convolutions, one at each time step	• Convolution block
	One convolution over the life of the simulation	• Convolution block • Discrete FIR Filter block
How long are your input sequences?	Both sequences have a finite length	• Convolution block • Discrete FIR Filter block
	One sequence has an infinite (not predetermined) length	• Discrete FIR Filter block
How many of the inputs are scalar streams?	None	• Convolution block • Discrete FIR Filter block
	One or both	• Buffer block followed by the Convolution block • Discrete FIR Filter block

Convolving Two N-D Arrays

The block always computes the convolution of two N-D input arrays along the first dimension. When both inputs are N-D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when u is an M_u-by-N-by-P array, and v is an M_v-by-N-by-P array, the output is an (M_u+M_v-1)-by-N-by-P array.

When the input to the Convolution block is a M_u-by-N matrix u and an M_v-by-N matrix v, the output, y, is a (M_u+M_v-1)-by-N matrix whose jth column has the following elements

$$y_{i,j} = \sum_{k=0}^{\max(M_u,M_v)-1} u_{k,j} v_{(i-k),j} \quad 0 \le i \le (M_u + M_v - 2)$$

Inputs u and v are zero when indexed outside of their valid ranges. When both inputs are real, the output is real; when one or both inputs are complex, the output is complex.

Convolving a Column Vector with an N-D Array

When one input is a column vector and the other is an N-D array, the block independently convolves the vector with the first dimension of the N-D input array. For example, when u is a M_u-by-1 column vector and v is an M_v-by-N matrix, the output is an (M_u+M_v-1)-by-N matrix whose jth column has the following elements

$$y_{i,j} = \sum_{k=0}^{\max(M_u,M_v)-1} u_k v_{(i-k),j} \quad 0 \le i \le (M_u + M_v - 2)$$

Convolving Two Column Vectors

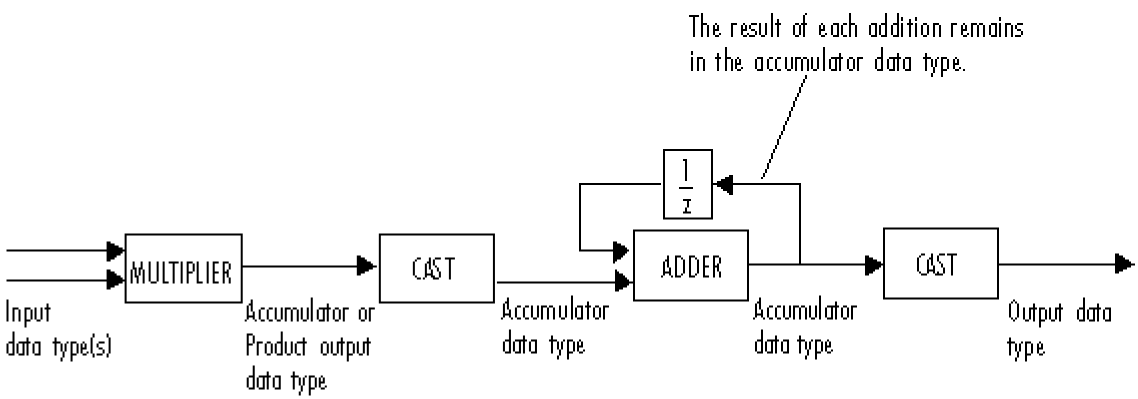
The Convolution block also accepts two column vector inputs. When u and v are column vectors with lengths M_u and M_v, the Convolution block performs the vector convolution

$$y_i = \sum_{k=0}^{\max(M_u,M_v)-1} u_k v_{(i-k)} \quad 0 \le i \le (M_u + M_v - 2)$$

The output is a (M_u+M_v-1)-by-1 column vector.

Fixed-Point Data Types

The following diagram shows the data types used within the Convolution block for fixed-point signals (time domain only).



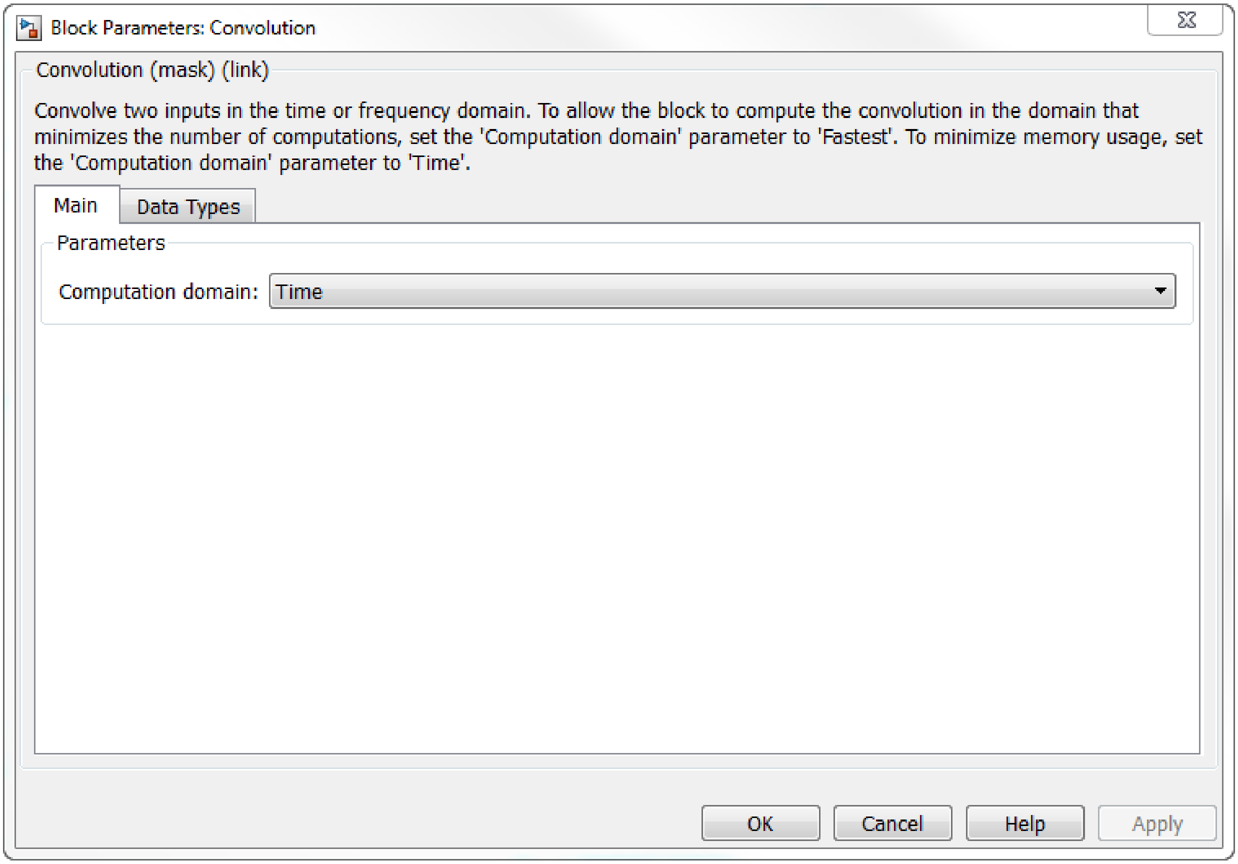
You can set the product output, accumulator, and output data types in the block dialog as discussed in the next section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. The internal block data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

Dialog Box

The **Main** pane of the Convolution block dialog appears as follows.

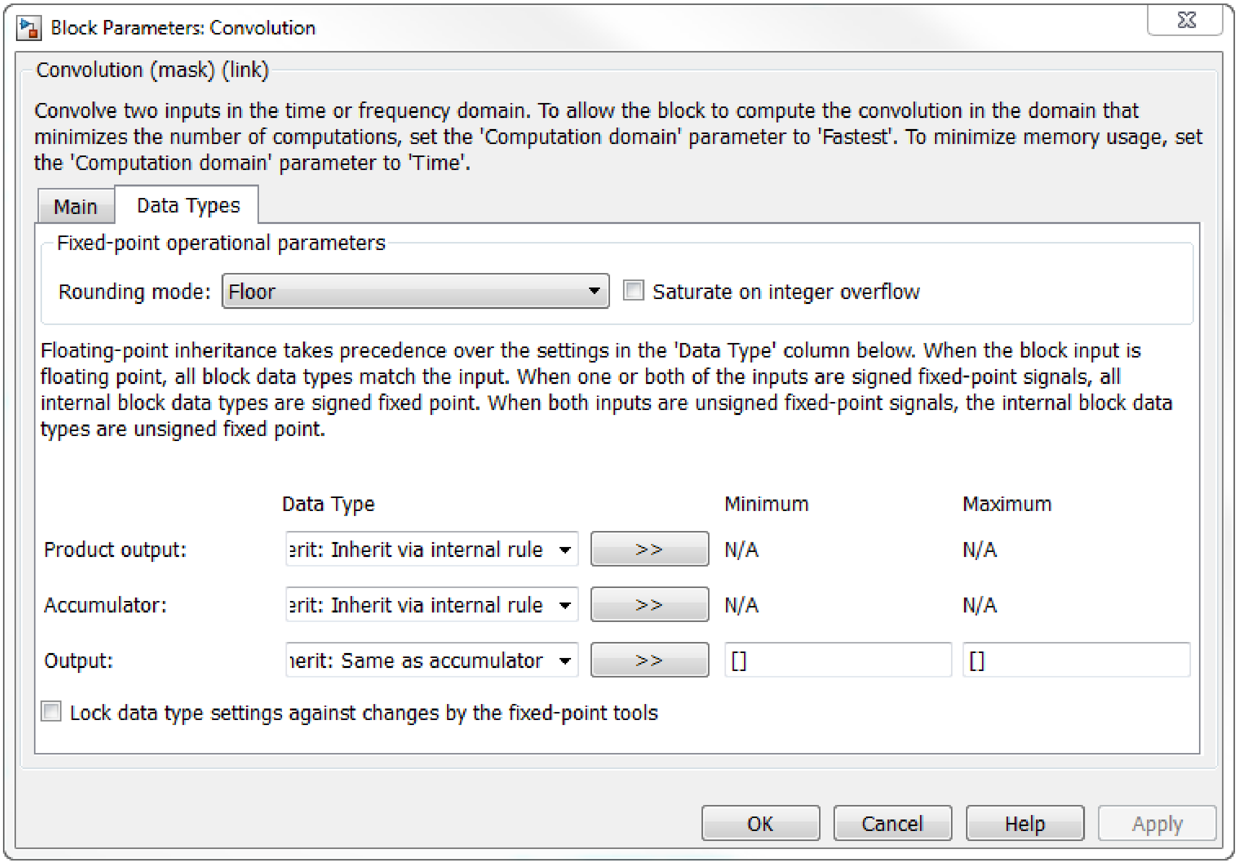


Computation domain

Set the domain in which the block computes convolutions:

- `Time` — The block computes in the time domain, which minimizes memory use.
- `Frequency` — The block computes in the frequency domain, which might require fewer computations than computing in the time domain, depending on the input length.
- `Fastest` — The block computes in the domain, which minimizes the number of computations.

The **Data Types** pane of the Convolution block dialog appears as follows.



Note: Fixed-point signals are only supported for the time domain. To use the parameters on this pane, make sure `Time` is selected for the **Computation domain** parameter on the **Main** pane.

Rounding mode

Select the rounding mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-360 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-360 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-360 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Functions
`conv`

Blocks
`Correlation` | `Discrete FIR Filter`

Introduced before R2006a

Correlation

Cross-correlation of two *N*-D arrays
Library: DSP System Toolbox / Statistics

Description

The Correlation block computes the cross-correlation of two *N*-D input arrays along the first-dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the **Computation domain** parameter. In the time domain, the block convolves the first input signal, u, with the time-reversed complex conjugate of the second input signal, v. In the frequency domain, to compute the cross-correlation, the block:

1. Takes the Fourier transform of both input signals, U and V.
2. Multiplies U and V^*, where * denotes the complex conjugate.
3. Computes the inverse Fourier transform of the product.

If you set **Computation domain** to `Fastest`, the block chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 2-373.

Ports

Input

`Port_1` — First data input signal

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to `Time`. When one or both of the input signals are complex, the output signal is also complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

`Port_2` — Second data input signal
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to `Time`. When one or both of the input signals are complex, the output signal is also complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

Output

`Port_1` — Cross-correlated output
vector | matrix | *N*-D array

Cross-correlated output of the data input.

When the inputs are *N*-D arrays, the block outputs an *N*-D array, where all the dimensions, except for the first dimension, match with the input array. For example,

- When the inputs u and v have dimensions M_u-by-N-by-P and M_v-by-N-by-P, respectively, the Correlation block outputs an $(M_u + M_v - 1)$-by-N-by-P array.
- When the inputs u and v have the dimensions M_u-by-N and M_v-by-N, the block outputs an $(M_u + M_v - 1)$-by-N matrix.

If one input is a column vector and the other input is an *N*-D array, the Correlation block computes the cross-correlation of the vector with each column in the *N*-D array. For example,

- When the input u is an M_u-by-1 column vector and v is an M_v-by-N matrix, the block outputs an $(M_u + M_v - 1)$-by-N matrix.
- Similarly, when u and v are column vectors with lengths M_u and M_v, respectively, the block performs the vector cross-correlation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

Complex Number Support: Yes

Parameters

Main Tab

`Computation domain` — Domain in which the block computes the cross-correlation

`Time` (default) | `Frequency` | `Fastest`

- `Time` — Computes the cross-correlation in the time domain, which minimizes the memory usage.
- `Frequency` — Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 2-373.
- `Fastest` — Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this parameter to `Time`.

Data Types Tab

Note Fixed-point signals are supported for the time domain only. To use these parameters, on the **Main** tab, set **Computation domain** to `Time`.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.
- **Output** data type is `Inherit: Same as accumulator`.

With these data type settings, the block operates in full-precision mode.

`Saturate on integer overflow` — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

`Product output` — Product output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the Correlation block. For more information on the product output data type, see "Multiplication Data Types" and the 'Fixed-Point Conversion' section in "Extended Capabilities" on page 2- .

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see "Inherit via Internal Rule".
- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt([],16,0)`

Accumulator specifies the data type of output of an accumulation operation in the Correlation block. For illustrations on how to use the accumulator data type in this block, see the 'Fixed-Point Conversion' section in "Extended Capabilities" on page 2- .

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Output` — Output data type

`Inherit: Same as accumulator` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt([],16,0)`

Output specifies the data type of the output of the Correlation block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2- .

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Output Minimum` — Minimum value block can output
[ ] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See "Signal Ranges" (Simulink).
- Automatic scaling of fixed-point data types.

`Output Maximum` — Maximum value the block can output
[ ] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See "Signal Ranges" (Simulink).
- Automatic scaling of fixed-point data types.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Definitions

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length N deterministic inputs, or realizations of jointly WSS random processes, x and y, the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \le h \le N-1 \\ r_{yx}^*(h) & -(N-1) \le h \le 0 \end{cases}$$

where h is the lag and * denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where E{ } is the expectation operator.

Algorithms

Time domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i,j)} = \sum_{k=0}^{\max(M_u,M_v)-1} u^*_{k,j} v_{(k+i),j} \qquad 0 \le i < M_v$$

$$y_{uv(i,j)} = y^*_{vu(-i,j)} \qquad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u-by-N input matrix.
- v is an M_v-by-N input matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$-by-N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i,j)} = \sum_{k=0}^{\max(M_u,M_v)-1} \overset{*}{u_k} v_{(k+i),j} \qquad 0 \le i < M_v$$

$$y_{uv(i,j)} = \overset{*}{y}_{vu(-i,j)} \qquad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u-by-1 column vector.
- v is an M_v-by-N matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$-by-N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i)} = \sum_{k=0}^{\max(M_u,M_v)-1} \overset{*}{u_k} v_{(k+i)} \qquad 0 \le i < M_v$$

$$y_{uv(i)} = \overset{*}{y}_{vu(-i)} \qquad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u-by-1 column vector.
- v is an M_v-by-1 column vector.
- $y_{u,v}$ is an $(M_u + M_v - 1)$-by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

1. Takes the Fourier transform of both input signals, U and V.
2. Multiplies U and V^*, where * denotes the complex conjugate.
3. Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

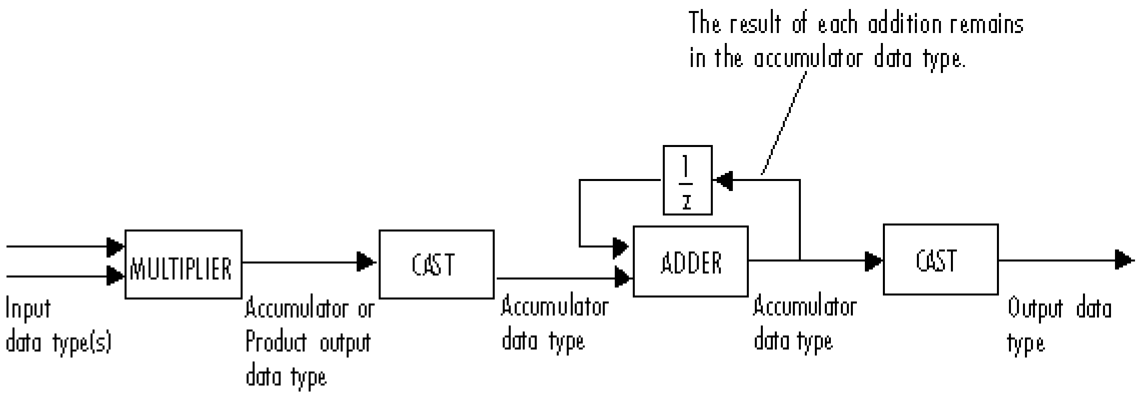
C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The following diagram shows the data types the Correlation block uses for fixed-point signals (time domain only).



You can set the product output, accumulator, and output data types on the **Data Types** tab of the block.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplier is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. The internal block data types are unsigned fixed point only when both inputs are unsigned fixed-point signals.

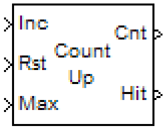
Blocks
`Autocorrelation`

Introduced before R2006a

Counter

Count up or down through specified range of numbers



Library

Signal Management / Switches and Counters

`dspswit3`

Description

The Counter block counts up or down through a specified range of numbers. The block enables the Inc (increment) port when you set the **Count direction** parameter to `Up`. When you set the **Count direction** parameter to `Down`, the block enables the Dec (decrement) port. If you set the **Count event** parameter to `Free running`, the block disables the Inc or Dec port, and counts at a constant time interval. For all other settings of the **Count event** parameter, the block increments or decrements the counter each time a trigger event occurs at the Inc or Dec input port. When a trigger event occurs at the optional Rst port, the block resets the counter to its initial state.

The Counter block accepts single-channel inputs. The Inc and Dec ports accept real-valued scalars or vectors. If the input to the Inc or Dec port is a vector, the block treats the vector as a frame. The Rst port only accepts real-valued scalars. The Rst port must have the same port sample time as the Inc or Dec input port. If you enable the optional Max input port, you must provide an unsigned integer input that the **Count data type** can represent.

See the following topics for more information:

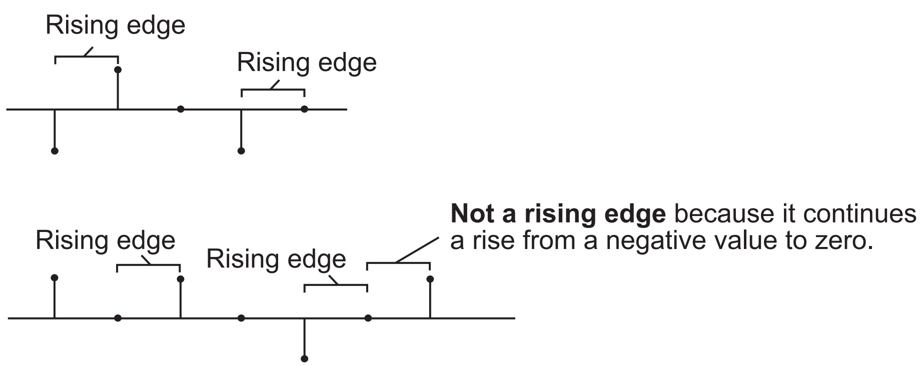
- "Setting the Count Event Parameter" on page 2-378
- "Setting the Counter Size and Initial Count Parameters" on page 2-379

- “Scalar Input Operation” on page 2-380
- “Vector Input Operation” on page 2-381
- “Free-Running Operation” on page 2-381

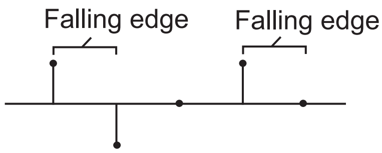
Setting the Count Event Parameter

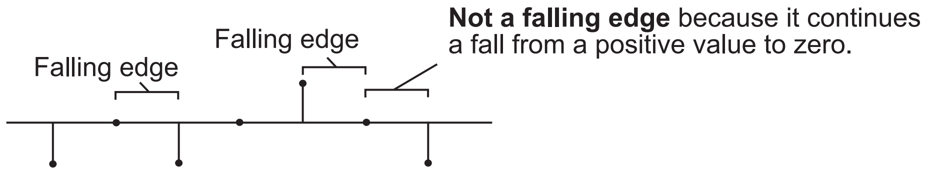
Specify the trigger event for the Inc/Dec and Rst ports by setting the **Count event** parameter to one of the following values:

- `Rising edge` — Triggers a count or reset operation when the input to the Inc/Dec or Rst port behaves in one of the following ways:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).



- `Falling edge` — Triggers a count or reset operation when the input to the Inc/Dec or Rst port behaves in one of the following ways:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure).





- `Either edge` — Triggers a count or reset operation when the input to the Inc/Dec or Rst port is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a count or reset operation at each sample time when the input to the Inc/Dec or Rst port is not zero.
- `Free running` — Disables the Inc/Dec port and enables the **Samples per output frame** and **Sample time** block parameters. The block increments or decrements the counter at a constant interval, T_s, which you specify using the **Sample time** parameter. For more information, see "Free-Running Operation" on page 2-381. In this mode, the block resets the counter whenever it receives a non-zero sample at the Rst port.

Setting the Counter Size and Initial Count Parameters

At the start of the simulation, the block sets the counter to the value you specify in the **Initial count** parameter. The **Initial count** can be any unsigned integer in the range defined by the **Counter size** parameter.

The **Counter size** parameter allows you to specify the range of integer values the block counts through. When the block counts through the entire counter range, the next time a trigger event occurs at the Inc/Dec port, the block resets the counter as follows:

- When you set the **Count direction** parameter to `Up` and the counter reaches the upper-limit of the counter range, the block restarts the counter at zero.
- When you set the **Count direction** parameter to `Down` and the counter reaches zero, the block restarts the counter at the upper-limit of the counter range.

You can set the **Counter size** parameter to one of the following options:

- `8 bits` — Specifies a counter with a range of `0` to `255`.
- `16 bits` — Specifies a counter with a range of `0` to `65535`.
- `32 bits` — Specifies a counter with a range of `0` to $2^{32}-1$.
- `User defined` — Enables the **Maximum count** parameter, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from `0` to the value of the **Maximum count** parameter.
- `Specify via input port` — Enables the Max input port, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from `0` to the value you specify as an input to the Max port.

Scalar Input Operation

When you set the **Count direction** parameter to `Up`, a trigger event at the Inc (increment) input port causes the block to increase the counter by one. Assuming no reset events occur, the block continues increasing the counter value when triggered, until the counter value reaches the upper-count limit. The next time a trigger event occurs at the Inc port, the block restarts the counter at `0` and resumes increasing the counter by one for each subsequent trigger event at the Inc port.

When you set the **Count direction** parameter to `Down`, a trigger event at the Dec (decrement) input port causes the block to decrease the counter by one. Assuming no reset events occur, the block continues decreasing the counter value when triggered until the counter value reaches zero. The next time a trigger event occurs at the Dec port, the block restarts the counter at the upper-count limit and resumes decreasing the counter by one for each subsequent trigger event at the Dec port.

Between triggering events, the block holds the output at its most recent value. The block resets the counter to its initial state when the trigger event specified by the **Count event** parameter occurs at the optional Rst input port. When the Inc/Dec and Rst ports receive trigger events simultaneously, the block first resets the counter, and then increments or decrements the counter appropriately. If you do not need to reset the counter during simulation, you can disable the Rst port by clearing the **Reset input** check box.

The **Output** parameter allows you to specify which values the block outputs.

- `Count` enables a Cnt output port on the block, which provides the current value of the counter as a scalar value. The Cnt output port has the same port sample time as the Inc/Dec input port.
- `Hit` enables a Hit output port on the block. The Hit port produces zeros while the value of the counter does not equal any of the integers you specify for the **Hit values** parameter. You can specify an integer or a vector of integers for the **Hit values** parameter. When the counter value does equal one or more of the values you specify for the **Hit values** parameter, the block outputs a value of `1` at the Hit output port. The Hit output port has the same port sample time as the Inc/Dec input port.
- `Count and Hit` enables both the Cnt and Hit output ports.

Vector Input Operation

The block treats vector inputs to the Inc/Dec port as a frame. Vector operation is the same as scalar operation, except that the block increments or decrements the counter by the total number of trigger events contained in the Inc/Dec input vector. Thus, the counter may change multiple times during the processing of a single Inc/Dec input vector.

When the block has a Hit port, the block outputs a value of `1` if any of the **Hit values** match any of the counter values during the processing of the Inc/Dec input vector.

When a trigger event splits across two consecutive vectors, that event is counted in the vector that contains the conclusion of the event. When the Rst port receives a trigger event at the same time as the Inc/Dec port, the block first resets the counter. The block then increments or decrements the counter by the number of trigger events contained in the Inc/Dec input vector.

When the input to the Inc/Dec port is a length N vector, the port sample time of the Inc/Dec input port is equal to the frame period of the input, or N times the sample time of the input signal. The port sample time of the Cnt and Hit output ports equals that of the Inc/Dec input port.

Free-Running Operation

The block operates in free-running mode when you select `Free running` for the **Count event** parameter.

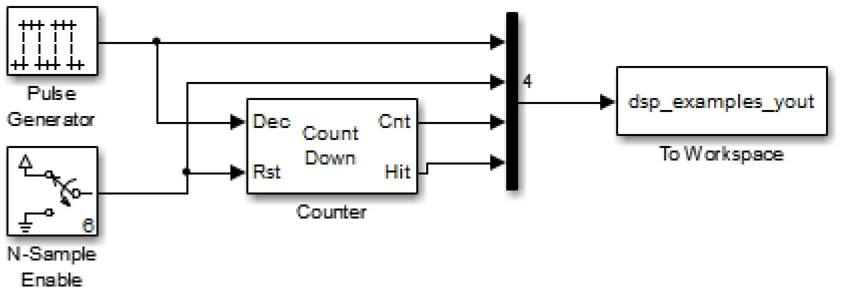
The Inc/Dec input port is disabled in this mode, and the block simply increments or decrements the counter at the constant interval, T_s, which you specify using the **Sample time** parameter.

In this mode, the Rst port always behaves as if the **Count event** parameter were set to `Non-zero sample`. Thus, the block triggers a reset event at each sample time that the Rst input is not zero.

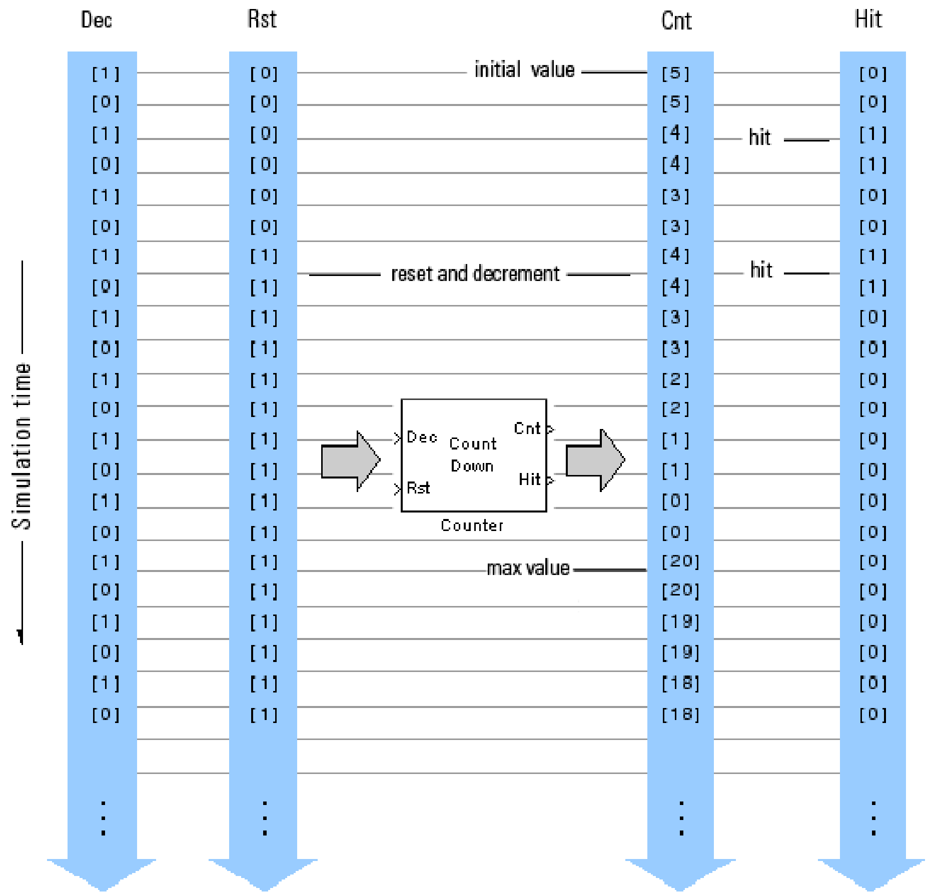
In this mode, the Cnt output is an M-by-`1` vector containing the count value at each of M consecutive sample times, where M is the value you specify for the **Samples per output frame** parameter. The Hit output is an M-by-`1` vector containing the hit status (`0` or `1`) at each of those M consecutive sample times. Both the Cnt and Hit output ports have a port sample time of $M*T_s$.

Examples

In the following model, ex_counter_ref, the Simulink Pulse Generator block drives the Dec port of the Counter block, and the `N-Sample Enable` block triggers the Rst port. All inputs to and outputs from the Counter block are multiplexed into a single To Workspace block using a 4-port Mux block.



The following figure shows the first 22 samples of the model's four-column output, `yout`.



You can see that the seventh input sample to both the Dec and Rst ports of the Counter block represent trigger events (rising edges). When this occurs, the block first resets the counter to its initial value of 5, and then immediately decrements the counter to 4. When the counter reaches its minimum value of 0, the block restarts the counter at its maximum value of 20 the next time a trigger event occurs at the Dec port.

Parameters

Count direction

Specify whether to count `Up` or `Down`. The port label on the block icon changes to Inc (increment) or Dec (decrement) based on the value of this parameter.

- When you set the **Count direction** parameter to `Up` and the counter reaches the upper-limit of the counter range, the block restarts the counter at zero the next time a trigger event occurs at the Inc port.
- When you set the **Count direction** parameter to `Down` and the counter reaches zero, the block restarts the counter at the upper-limit of the counter range the next time a trigger event occurs at the Dec port.

This parameter is tunable (Simulink) in Simulink Normal mode.

Count event

Specify the type of event that triggers the block to increment, decrement, or reset the counter when received at the Inc/Dec or Rst ports. When you set this parameter to `Free running`, the block disables the Inc/Dec port and counts at the constant interval specified by the **Sample time** parameter. For more information on all the possible settings of this parameter, see “Setting the Count Event Parameter” on page 2-378.

Counter size

Specify the range of integer values the block counts through. For more information about the valid values of this parameter, see “Setting the Counter Size and Initial Count Parameters” on page 2-379.

Maximum count

Specify the maximum value of the counter as any unsigned integer representable by the data type you specify for the **Counter data type** parameter. This parameter appears only when you set the **Counter size** parameter to `User defined`. Tunable (Simulink) in Simulink Normal mode.

Initial count

Specify the initial value of the counter. The block uses the initial value of the counter at the start of simulation and resets the counter back to that initial value each time a trigger event occurs at the Rst port. Tunable (Simulink).

Output

Select the output ports to enable. You can choose to enable the `Count`, `Hit`, or `Count and Hit` ports.

Hit values

Specify an integer or vector of integers whose occurrence in the count should be flagged by a `1` at the (optional) Hit output port. This parameter appears only when you set the **Output** parameter to `Hit` or `Count and Hit`. Tunable (Simulink).

Reset input

Select this check box to enable the Rst input port. When you enable the Rst port, the block resets the counter to its initial value each time a trigger event occurs at the Rst port. To specify the type of event that triggers a reset of the counter, set the **Count event** parameter. When you clear the **Reset input** check box, you cannot reset the counter during simulation.

Samples per output frame

Specify the number of samples, M, in each output vector. This parameter appears only when you set the **Count event** parameter to `Free running`.

Sample time

Specify the constant interval, T_s, at which the block increments or decrements the counter when in free-running mode. For example, to have the block increment the counter every `5` seconds, set the **Count direction** parameter to `Up`, the **Count event** parameter to `Free running`, and specify a value of `5` for the **Sample time** parameter. In free running mode, the sample time of the output ports is always $M*T_s$.

This parameter appears only when you set the **Count event** parameter to `Free running`.

Count data type

Specify the data type of the output at the Cnt port. This parameter appears only when you set the **Output** parameter to `Count` or `Count and Hit`.

Hit data type

Specify the data type of the output at the Hit port. This parameter appears only when you set the **Output** parameter to `Hit` or set it to `Count and Hit` with the **Count data type** parameter set to `Double`.

Supported Data Types

Port	Supported Data Types
Inc/Dec	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Rst	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Max	• 8-, 16-, and 32-bit unsigned integers
Cnt	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Hit	• Logical • Boolean — The block might output Boolean values from the `Hit` output port depending on the setting of the **Hit data type** parameter.

Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using covariance method

Library

Estimation / Parametric Estimation

`dspparest3`

Description

The Covariance AR Estimator block uses the covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward prediction error in the least squares sense.

The input must be a column vector or an unoriented vector, which is assumed to be the output of an AR system driven by white noise. This input represents a frame of consecutive time samples from a single-channel signal. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

The order, p, of the all-pole model is specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be less than or equal to half the input vector length.

The top output, A, is a column vector of length p+1 with the same frame status as the input, and contains the normalized estimate of the AR model coefficients in descending powers of z.

```
[1 a(2) ... a(p+1)]
```

The scalar gain, G, is provided at the bottom output (`G`).

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Estimation order

The order of the AR model, p. To guarantee a nonsingular output, you must set p to be less than or equal to half the input length. Otherwise, the output might be singular.

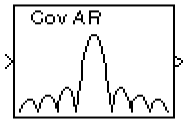
Covariance Method

Power spectral density estimate using covariance method



Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Covariance Method block estimates the power spectral density (PSD) of the input using the covariance method. This method fits an autoregressive (AR) model to the signal by minimizing the forward prediction error in the least squares sense. The **Estimation order** parameter specifies the order of the all-pole model. The block computes the spectrum from the FFT of the estimated AR model parameters. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length.

The input must be a column vector or an unoriented vector. It represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

Selecting **Inherit FFT length from estimation order**, specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the `Burg Method` block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

Parameters

Estimation order

The order of the AR model. To guarantee a nonsingular output, the value of this parameter must be less than or equal to half the input length.

Inherit FFT length from estimation order

When selected, this option specifies that the FFT length is one greater than the estimation order.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from estimation order** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

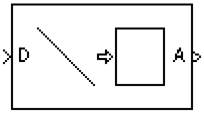
Create Diagonal Matrix

Create square diagonal matrix from diagonal elements



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Create Diagonal Matrix block populates the diagonal of the M-by-M matrix output with the elements contained in the length-M vector input, D. The elements off the diagonal are zero.

```
A = diag(D)     Equivalent MATLAB code
```

Supported Data Types

Port	Supported Data Types
D	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

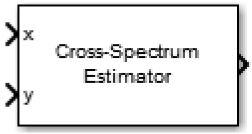
Cross-Spectrum Estimator

Estimate cross-power spectrum density



Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Cross Spectrum Estimator block outputs the frequency cross-power spectrum density of two real or complex input signals, *x* and *y*, via Welch's method of averaged modified periodograms. The input signals must be of the same size and data type.

The Cross Spectrum Estimator block computes the current power spectrum estimate by averaging the last *N* power spectrum estimates, where *N* is the number of spectral averages defined in **Number of spectral averages**. The block buffers the input data into overlapping segments. You can set the length of the data segment and the amount of data overlap through the parameters set in the block dialog box. The block computes the power spectrum based on the parameters set in the block dialog box.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

Algorithms

This block brings the capabilities of the dsp.CrossSpectrumEstimator System object to the Simulink environment.

For information on the algorithm used by the Cross Spectrum Estimator block, see the “Algorithms” on page 4-486 section of `dsp.CrossSpectrumEstimator`.

Parameters

Window length source

Source of the window length value. You can set this parameter to:

- `Same as input frame length` (default) — Window length is set to the frame size of the input.
- `Specify on dialog` — Window length is the value specified in **Window length**.

This parameter is nontunable.

Window length

Length of the window, in samples, used to compute the spectrum estimate, specified as a positive integer scalar greater than `2`. This parameter applies when you set **Window length source** to `Specify on dialog`. The default is `1024`. This parameter is nontunable.

Window Overlap (%)

Percentage of overlap between successive data windows, specified as a scalar in the range [`0, 100`). The default is `0`. This parameter is nontunable.

Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The cross-spectrum estimator computes the current power spectrum estimate by averaging the last *N* power spectrum estimates, where *N* is the number of spectral averages defined in **Number of spectral averages**. The default is `1`. This parameter is nontunable.

FFT length source

Source of the FFT length value. You can set this parameter to:

- `Auto` (default) — FFT length is set to the frame size of the input.
- `Property` — FFT length is the value specified in **FFT length**.

This parameter is nontunable.

FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **FFT length source** to `Property`. The default is `1024`. This parameter is nontunable.

Window function

Window function for the cross-spectrum estimator, specified as one of `Chebyshev | Flat Top | Hamming | Hann | Kaiser | Rectangular`. The default is `Hann`. This parameter is nontunable.

Sidelobe attenuation of window (dB)

Side lobe attenuation of the window, specified as real positive scalar. This parameter applies when you set **Window function** to `Chebyshev` or `Kaiser`. The default is `60`. This parameter is nontunable.

Frequency range

Frequency range of the cross-spectrum estimator. You can set this parameter to:

- `centered` (default) — The cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals, *x* and *y*. The length of the cross-spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range `[-SampleRate/2 SampleRate/2]` when the FFT length is even and `[-SampleRate/2 SampleRate/2]` when FFT length is odd.
- `onesided` — The cross-spectrum estimator computes the one-sided spectrum of real input signals, *x* and *y*. When the FFT length, *NFFT* is even, length of the cross-spectrum estimate is (*NFFT*/ `2`) + `1`, and is computed over the frequency range `[0 SampleRate/2]`. When the FFT length, *NFFT* is odd, length of the cross-spectrum estimate is (*NFFT* + 1)/ `2`, and is computed over the frequency range `[0 SampleRate/2]`.
- `twosided` — The cross-spectrum estimator computes the two-sided spectrum of complex or real input signals, *x* and *y*. The length of the cross-spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range `[0 SampleRate]`, where `SampleRate` is the sample rate of the input signal.

This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block's sample rate is computed as *N*/*Ts*, where *N* is the frame size of the input signal, and *Ts* is the sample time of the input signal. When you clear this check box, the block sample rate is the value specified in **Sample rate (Hz)**. By default, this check box is selected.

Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

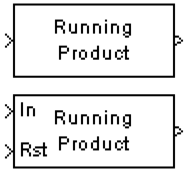
Introduced in R2015a

Cumulative Product

Cumulative product of channel, column, or row elements



Library

Math Functions / Math Operations

`dspmathops`

Description

The Cumulative Product block computes the cumulative product along the specified dimension of the input or across time (running product).

The input can be a vector or matrix. The output always has the same dimensions, rate, data type, and complexity as the input.

Input and Output Characteristics

Valid Input

The Cumulative Product block accepts vector or matrix inputs containing real or complex values.

Valid Reset Signal

The optional reset port, `Rst`, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time.

Output Characteristics

The output always has the same dimensions, rate, data type, and complexity as the data signal input.

Computing the Running Product Along Channels of the Input

When you set the **Multiply input along** parameter to `Channels (running product)`, the block computes the cumulative product of the elements in each input channel. The running product of the current input takes into account the running product of all previous inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block computes the running product along each column of the current input. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block computes a running product for each element of the input across time. See the following sections for more information:

-
-
-

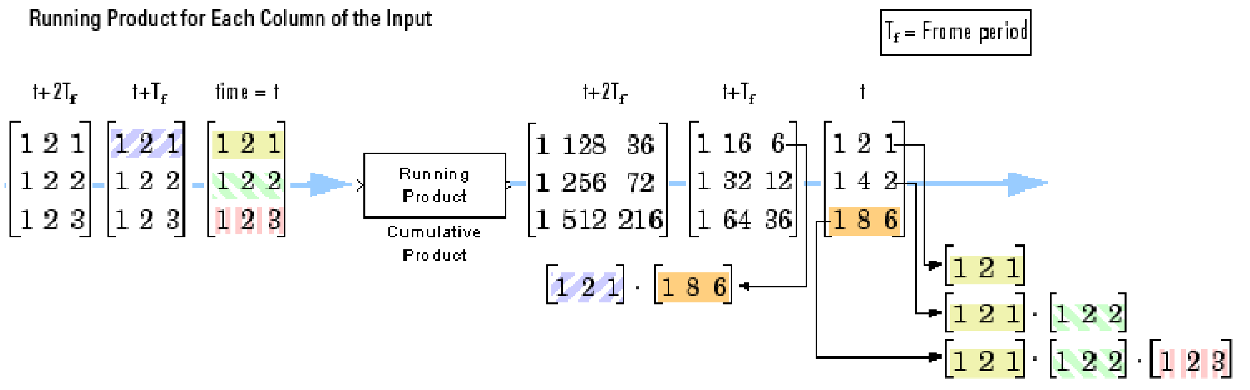
Computing the Running Product for Each Column of the Input

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the element-wise product of the first row of the current input (time t), and the last row of the previous output (time t - T_f, where T_f is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M-by-N matrix input, u, the output, y, is an M-by-N matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) \cdot y_{M,j}\left(t - T_f\right)$$



Computing the Running Product for Each Element of the Input

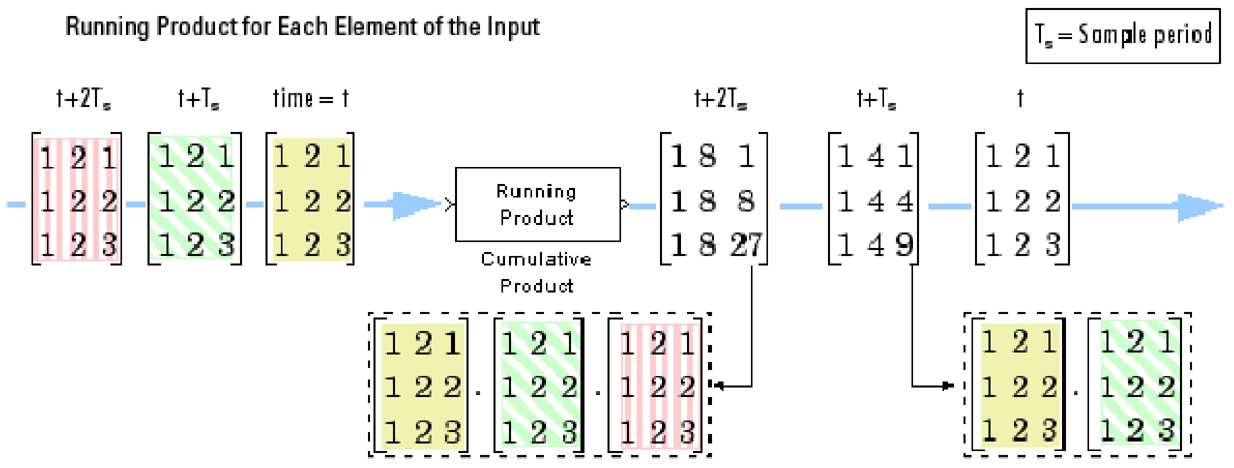
When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first output is the same as the first input.
- Each subsequent output is the element-wise product of the current input (time t) and the previous output (time t - T_s, where T_s is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M-by-N matrix input, u, the output, y, is an M-by-N matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) \cdot y_{i,j}(t - T_s) \quad \begin{array}{l} 1 \le i \le M \\ 1 \le j \le N \end{array}$$

For convenience, the block treats length-M unoriented vector inputs as M-by-1 column vectors when multiplying along channels. In such cases, the output is a length-M unoriented vector.



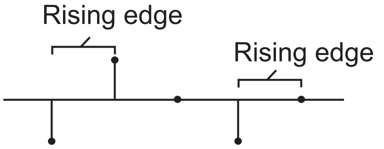
Resetting the Running Product

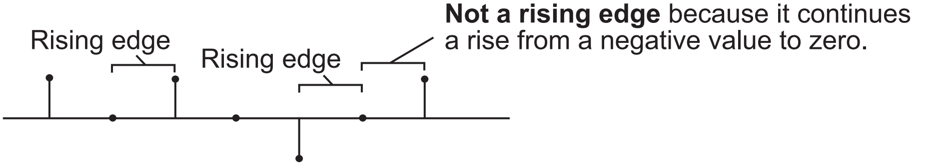
When you are computing the running product, you can configure the block to reset the running product whenever it detects a reset event at the optional `Rst` port. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. The input to the `Rst` port can be of the Boolean data type.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

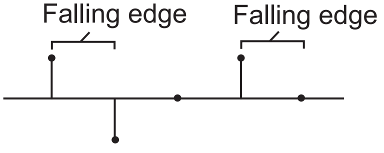
The **Reset port** parameter specifies the reset event, which can be one of the following:

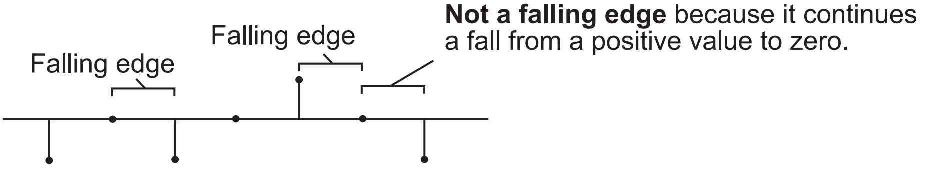
- `None` disables the `Rst` port.
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)





- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

---

Note: When you run simulations in Simulink `MultiTasking` mode, reset signals have a one-sample latency. Thus, when the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Multiplying Along Columns

When you set the **Multiply input along** parameter to `Columns`, the block computes the cumulative product of each column of the input. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

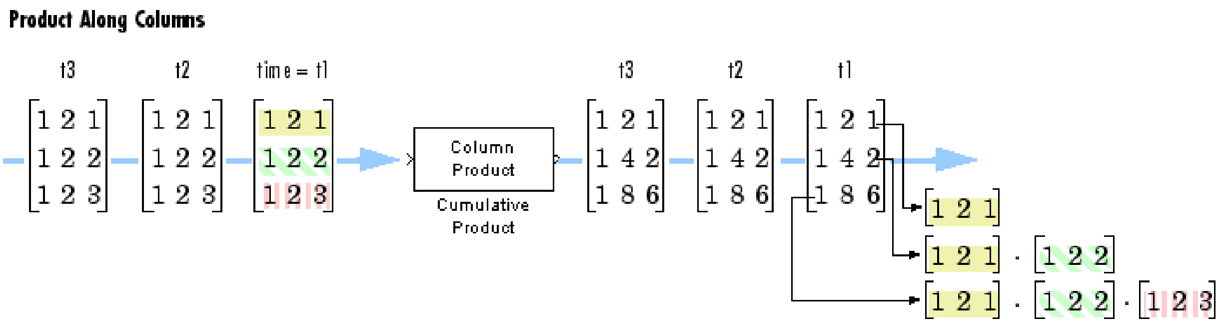
```
y = cumprod(u)      % Equivalent MATLAB code
```

The output has the same size, dimension, data type, and complexity as the input. The mth output row is the element-wise product of the first m input rows.

Given an M-by-N input, u, the output, y, is an M-by-N matrix whose jth column has elements

$$y_{i,j} = \prod_{k=1}^{i} u_{k,j} \qquad 1 \le i \le M$$

When multiplying along columns, the block treats length-M unoriented vector inputs as M-by-1 column vectors.



Multiplying Along Rows

When you set the **Multiply input along** parameter to `Rows`, the block computes the cumulative product of the row elements. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u,2)      % Equivalent MATLAB code
```

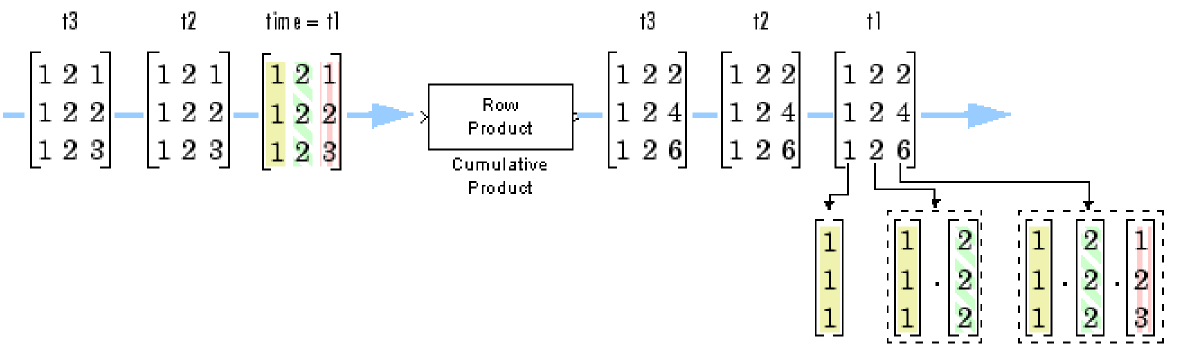
The output has the same size, dimension, and data type as the input. The nth output column is the element-wise product of the first n input columns.

Given an M-by-N matrix input, u, the output, y, is an M-by-N matrix whose ith row has elements

$$y_{i,j} = \prod_{k=1}^{j} u_{i,k} \qquad 1 \le j \le N$$

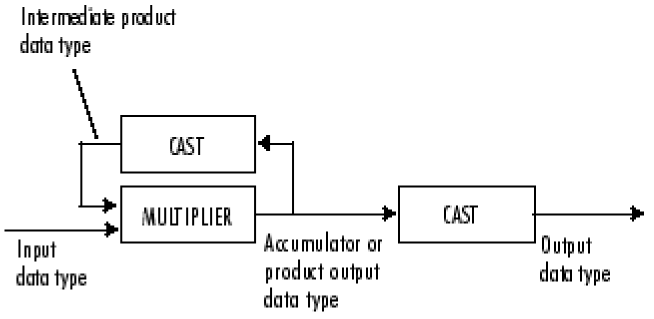
When you multiply along rows, the block treats length-N unoriented vector inputs as 1-by-N row vectors.

Product Along Rows



Fixed-Point Data Types

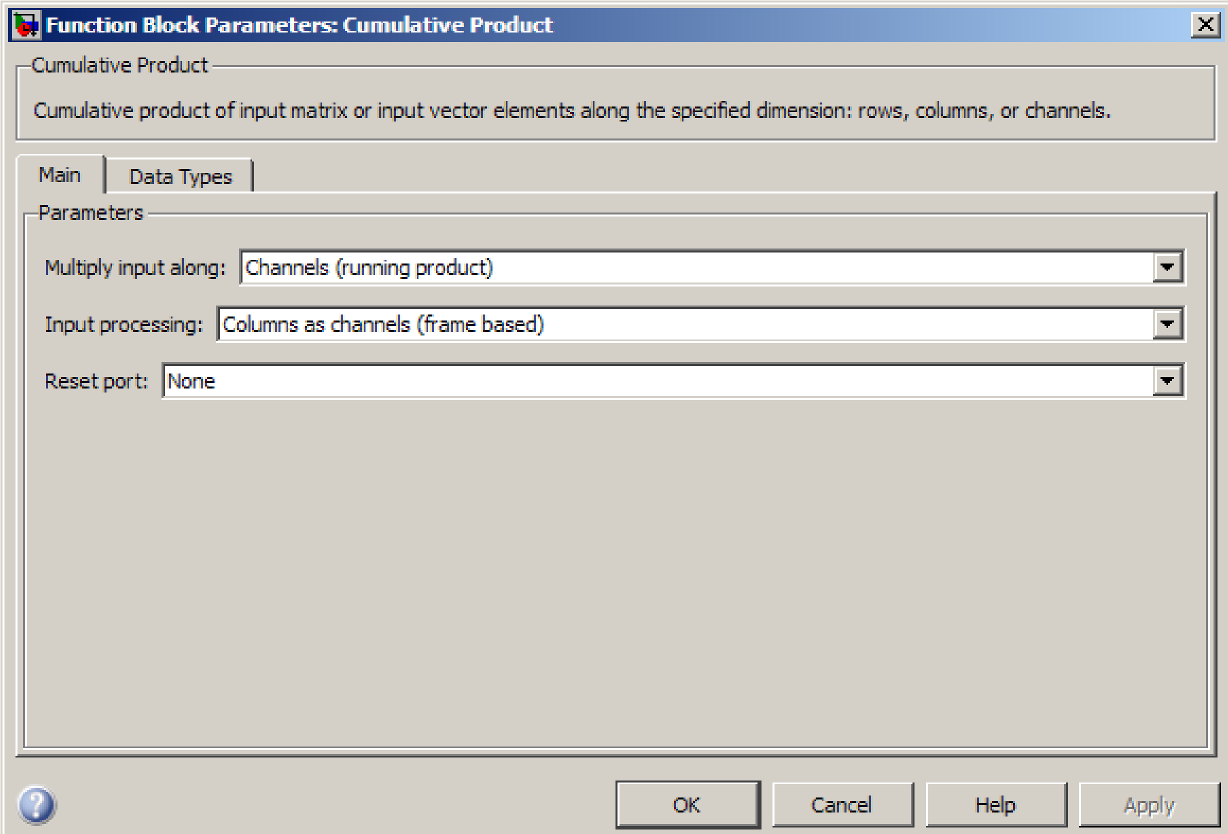
The following diagram shows the data types used within the Cumulative Product block for fixed-point signals.



The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types". You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in "Dialog Box" on page 2-408.

Dialog Box

The **Main** pane of the Cumulative Product block dialog appears as follows.



Multiply input along

Specify the dimension along which to compute the cumulative product. You can choose to multiply along `Channels (running product)`, `Columns`, or `Rows`. For more information, see the following sections:

- "Computing the Running Product Along Channels of the Input" on page 2-402
- "Multiplying Along Columns" on page 2-406
- "Multiplying Along Rows" on page 2-406

Input processing

Specify how the block should process the input when computing the running product along the channels of the input. You can set this parameter to one of the following options:

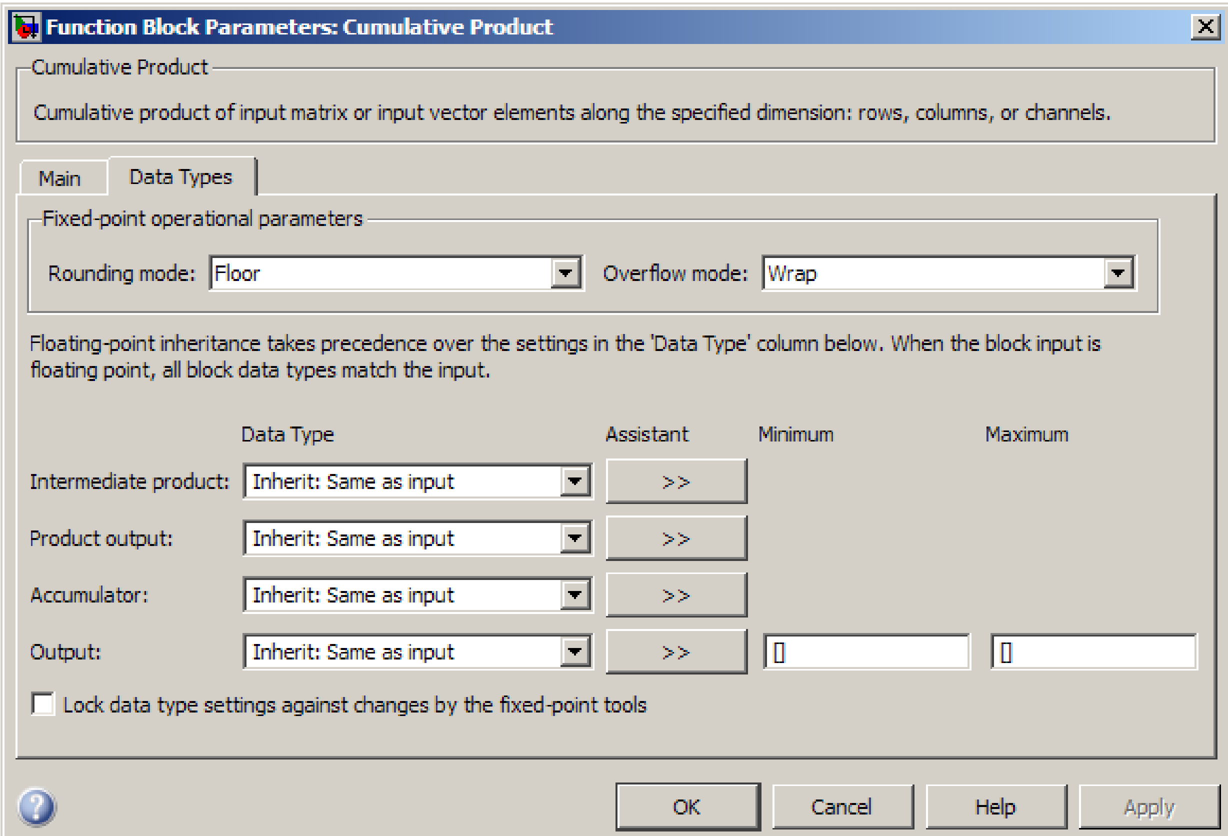
- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter is available only when you set the **Multiply input along** parameter to `Channels (running product)`.

Reset port

Determines the reset event that causes the block to reset the product along channels. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Multiply input along** parameter to `Channels (running product)`. For more information, see .

The **Data Types** pane of the Cumulative Product block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-407, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-407 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-407 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-407 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Input and Output Ports	Supported Data Types
Data input port, `In`	• Double-precision floating point • Single-precision floating point

Input and Output Ports	Supported Data Types
	• Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset input port, `Rst`	All built-in Simulink data types: • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output port	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

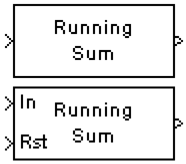
`Cumulative Sum`	DSP System Toolbox
`Matrix Product`	DSP System Toolbox
`cumprod`	MATLAB

Introduced before R2006a

Cumulative Sum

Cumulative sum of channel, column, or row elements



Library

Math Functions / Math Operations

`dspmathops`

Description

The Cumulative Sum block computes the cumulative sum along the specified dimension of the input or across time (running sum).

The inputs can be a vector or a matrix. The output always has the same dimensions, rate, data type, and complexity as the input.

Input and Output Characteristics

Valid Input

The Cumulative Sum block accepts vector or matrix inputs containing real or complex values.

Valid Reset Signal

The optional reset port, `Rst`, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time.

Output Characteristics

The output always has the same dimensions, rate, data type, and complexity as the data signal input.

Computing the Running Sum Along Channels of the Input

When you set the **Sum input along** parameter to `Channels (running sum)`, the block computes the cumulative sum of the elements in each input channel. The running sum of the current input takes into account the running sum of all previous inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block computes the running sum along each column of the current input. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block computes a running sum for each element of the input across time. See the following sections for more information:

-
-
-

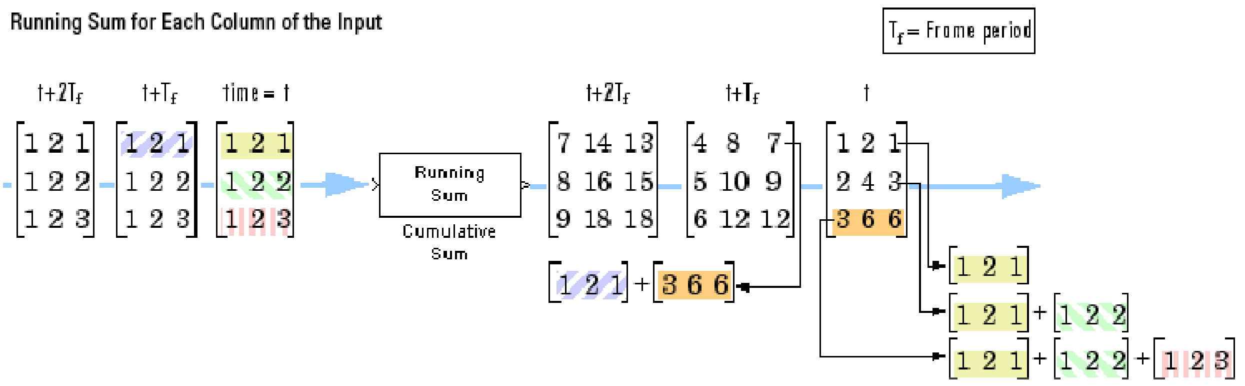
Computing the Running Sum for Each Column of the Input

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the sum of the first row of the current input (time t), and the last row of the previous output (time t - T_f, where T_f is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M-by-N matrix input, u, the output, y, is an M-by-N matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) + y_{M,j}(t - T_f)$$



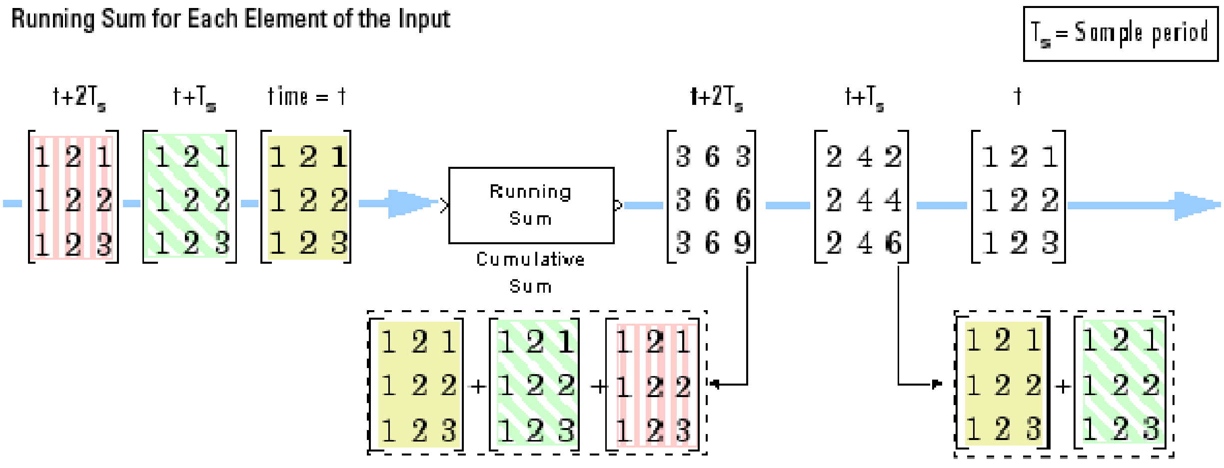
Computing the Running Sum for Each Element of the Input

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first output is the same as the first input.
- Each subsequent output is the sum of the current input (time t) and the previous output (time t - T_s, where T_s is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an M-by-N matrix input, u, the output, y, is an M-by-N matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) + y_{i,j}(t - T_s) \qquad \begin{array}{l} 1 \le i \le M \\ 1 \le j \le N \end{array}$$



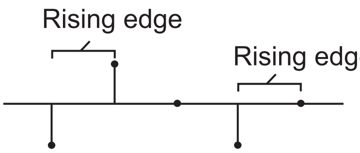
Resetting the Running Sum

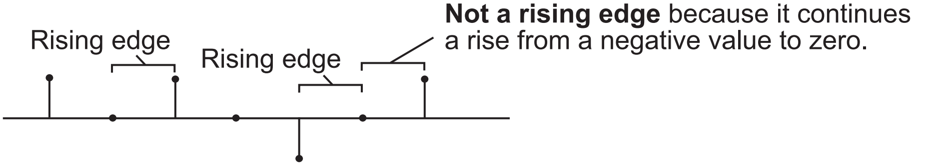
When you are computing the running sum, you can configure the block to reset the running sum whenever it detects a reset event at the optional `Rst` port. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. The reset sample time must be a positive integer multiple of the input sample time. The input to the `Rst` port can be of the `boolean` data type.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

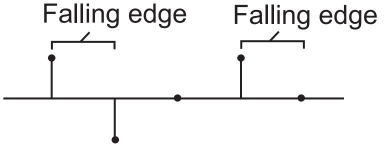
The **Reset port** parameter specifies the reset event, which can be one of the following:

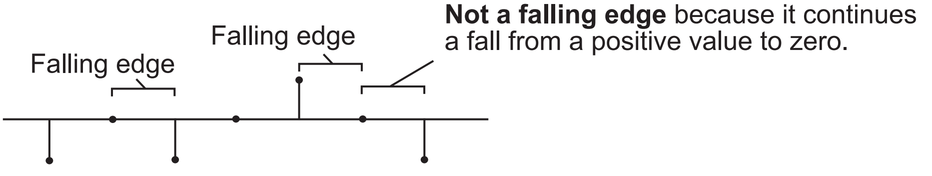
- `None` disables the `Rst` port.
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)





- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero

---

Note: When you run simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Thus, when the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Summing Along Columns

When you set the **Sum input along** parameter to `Columns`, the block computes the cumulative sum of each column of the input. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

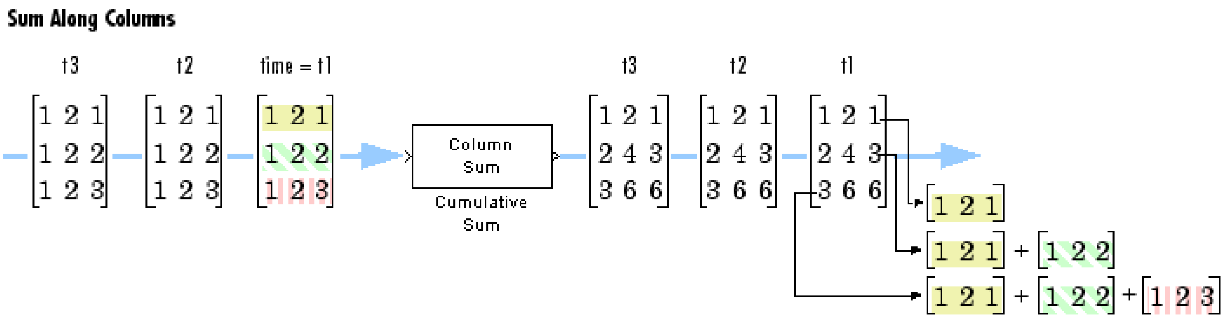
```
y = cumsum(u)      % Equivalent MATLAB code
```

The output has the same size, dimension, data type, and complexity as the input. The mth output row is the sum of the first m input rows.

Given an M-by-N input, u, the output, y, is an M-by-N matrix whose jth column has elements

$$y_{i,j} = \sum_{k=1}^{j} u_{k,j} \qquad 1 \le i \le M$$

The block treats length-M unoriented vector inputs as M-by-1 column vectors when summing along columns.



Summing Along Rows

When you set the **Sum input along** parameter to `Rows`, the block computes the cumulative sum of the row elements. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

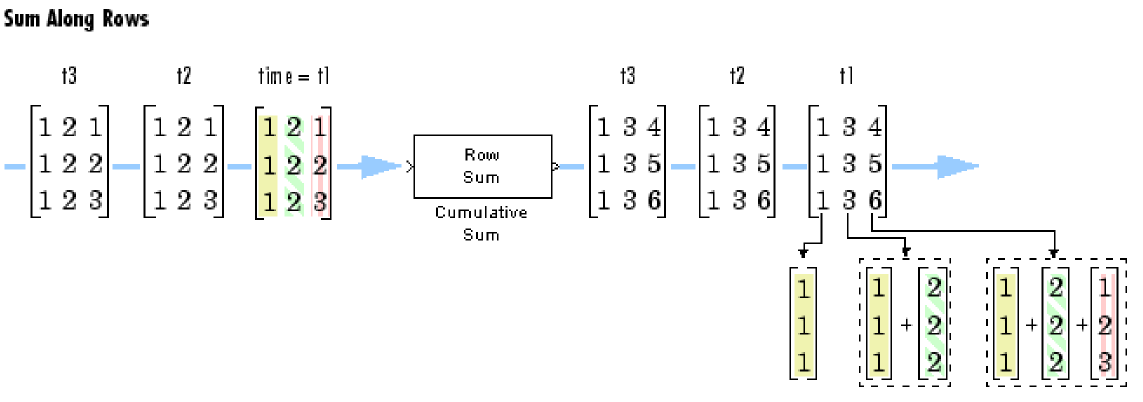
```
y = cumsum(u,2)      % Equivalent MATLAB code
```

The output has the same size, dimension, and data type as the input. The *n*th output column is the sum of the first *n* input columns.

Given an *M*-by-*N* input, *u*, the output, *y*, is an *M*-by-*N* matrix whose *i*th row has elements

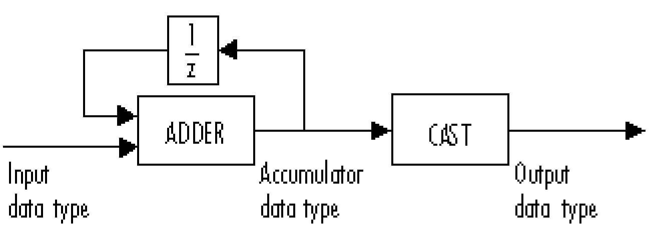
$$y_{i,j} = \sum_{k=1}^{j} u_{i,k} \qquad 1 \le j \le N$$

When you sum along rows, the block treats length-*N* unoriented vector inputs as 1-by-*N* row vectors.



Fixed-Point Data Types

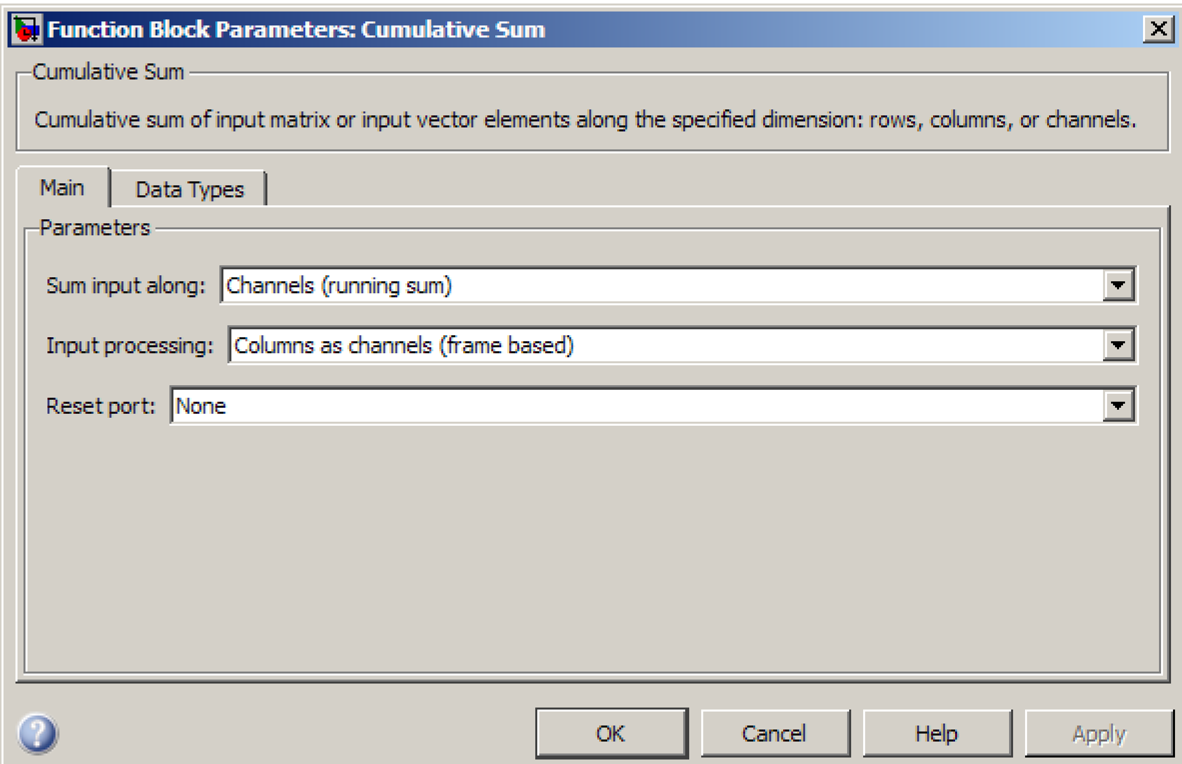
The following diagram shows the data types used within the Cumulative Sum block for fixed-point signals.



You can set the accumulator and output data types in the block dialog as discussed in "Dialog Box" on page 2-422.

Dialog Box

The **Main** pane of the Cumulative Sum block dialog appears as follows.



Sum input along

Specify the dimension along which to compute the cumulative summations. You can choose to sum along `Channels (running sum)`, `Columns`, or `Rows`. For more information, see the following sections:

- "Computing the Running Sum Along Channels of the Input" on page 2-416

- "Summing Along Columns" on page 2-420
- "Summing Along Rows" on page 2-420

Input processing

Specify how the block should process the input when computing the running sum along the channels of the input. You can set this parameter to one of the following options:

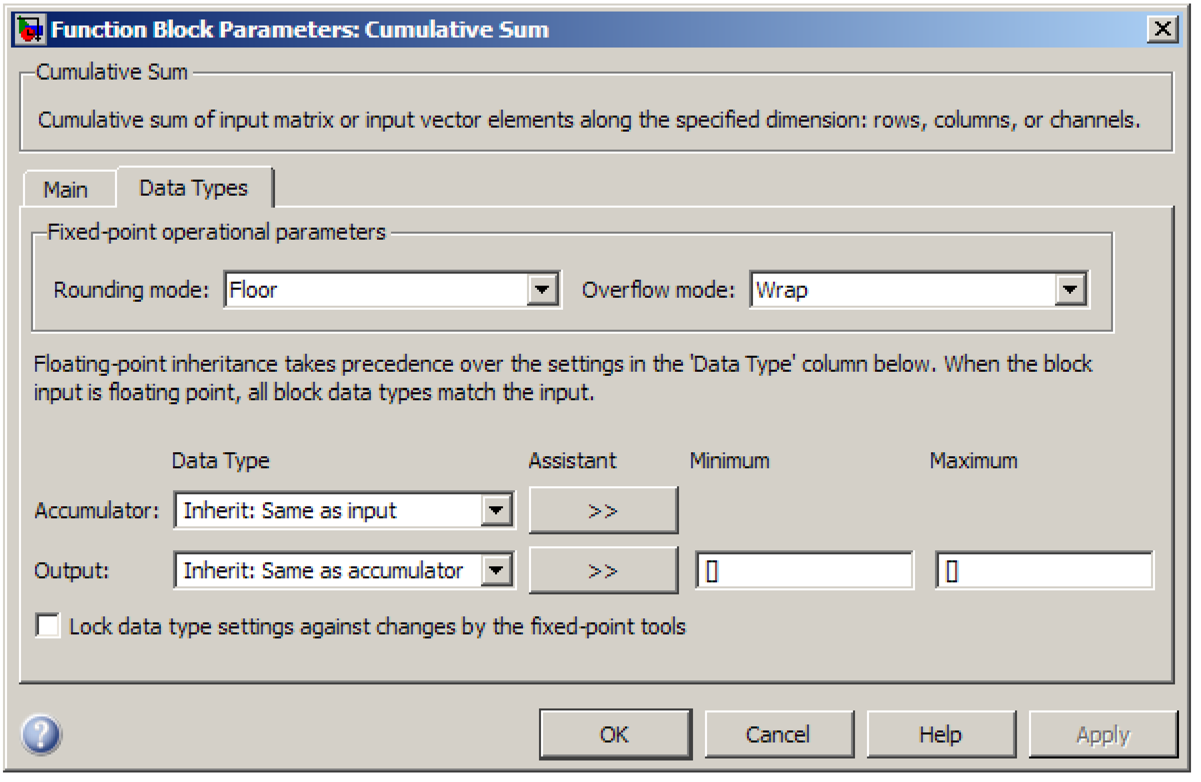
- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

This parameter is available only when you set the **Sum input along** parameter to `Channels (running sum)`.

Reset port

Determines the reset event that causes the block to reset the sum along channels. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Sum input along** parameter to `Channels (running sum)`. For more information, see .

The **Data Types** pane of the Cumulative Sum block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-421 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button `>>` to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-421 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button `>>` to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Input and Output Ports	Supported Data Types
Data input port, `In`	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset input port, `Rst`	All built-in Simulink data types: • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output port	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Introduced before R2006a

Data Type Conversion

Convert input signal to specified data type

Library

Signal Management / Signal Attributes

`dspsigattribs`

Description

The Data Type Conversion block is an implementation of the Simulink Data Type Conversion block. See Data Type Conversion for more information.

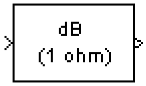
HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Data Type Conversion.

Introduced in R2008a

dB Conversion

Convert magnitude data to decibels (dB or dBm)



Library

Math Functions / Math Operations

`dspmathops`

Description

The dB Conversion block converts a linearly scaled power or amplitude input to dB or dBm. The reference power is 1 Watt for conversions to dB and 1 mWatt for conversions to dBm. The **Input signal** parameter specifies whether the input is a power signal or a voltage signal, and the **Convert to** parameter controls the scaling of the output. When selected, the **Add eps to input to protect against "log(0) = -inf"** parameter adds a value of `eps` to all power and voltage inputs. When this option is not enabled, zero-valued inputs produce `-inf` at the output.

The output is the same size as the input.

Power Inputs

Select `Power` as the **Input signal** parameter when the input, `u`, is a real, nonnegative, power signal (units of watts). When the **Convert to** parameter is set to `dB`, the block performs the dB conversion

```
y = 10*log10(u)       % Equivalent MATLAB code
```

When the **Convert to** parameter is set to `dBm`, the block performs the dBm conversion

```
y = 10*log10(u) + 30
```

The dBm conversion is equivalent to performing the dB operation *after* converting the input to milliwatts.

Voltage Inputs

Select `Amplitude` as the **Input signal** parameter when the input, `u`, is a real voltage signal (units of volts). The block uses the scale factor specified in ohms by the **Load resistance** parameter, `R`, to convert the voltage input to units of power (watts) before converting to dB or dBm.

When the **Convert to** parameter is set to `dB`, the block performs the dB conversion

```
y = 10*log10(abs(u)^2/R)
```

When the **Convert to** parameter is set to `dBm`, the block performs the dBm conversion

```
y = 10*log10(abs(u)^2/R) + 30
```

The dBm conversion is equivalent to performing the dB operation *after* converting the `(abs(u)^2/R)` result to milliwatts.

Parameters

Convert to

The logarithmic scaling to which the input is converted, `dB` or `dBm`. The reference power is 1 W for conversions to dB and 1 mW for conversions to dBm. Tunable (Simulink).

Input signal

The type of input signal, `Power` or `Amplitude`.

Load resistance

The scale factor used to convert voltage inputs to units of power. Tunable (Simulink).

Add eps to input to protect against "log(0) = -inf"

When selected, adds `eps` to all input values (power or voltage). Tunable (Simulink).

Supported Data Types

- Double-precision floating point
- Single-precision floating point

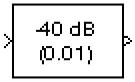
`log10`	MATLAB

Introduced before R2006a

dB Gain

Apply decibel gain



Library

Math Functions / Math Operations

`dspmathops`

Description

The dB Gain block multiplies the input by the decibel values specified in the **Gain** parameter. For an M-by-N input matrix u with elements u_{ij}, the **Gain** parameter can be a real M-by-N matrix with elements g_{ij} to be multiplied element-wise with the input, or a real scalar.

$$y_{ij} = u_{ij} 10^{(g_{ij}/k)}$$

The value of k is 10 for power signals (select `Power` as the **Input signal** parameter) and 20 for voltage signals (select `Amplitude` as the **Input signal** parameter).

The value of the equivalent linear gain

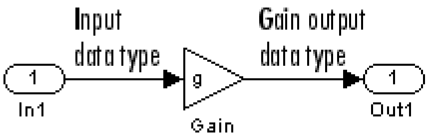
$$g_{ij}^{lin} = 10^{(g_{ij}/k)}$$

is displayed in the block icon below the dB gain value. The output is the same size as the input.

The dB Gain block supports real and complex floating-point and fixed-point data types.

Fixed-Point Data Types

The following diagram shows the data types used within the dB Gain subsystem block for fixed-point signals.



The settings for the fixed-point parameters of the Gain block in the diagram above are as follows:

- Integer rounding mode: `Floor`
- Saturate on integer overflow — unselected
- Parameter data type mode — `Inherit via internal rule`
- Output data type mode — `Inherit via internal rule`

See the Gain reference page for more information.

Parameters

Gain

The dB gain to apply to the input, a scalar or a real *M*-by-*N* matrix. Tunable (Simulink).

Input signal

The type of input signal: `Power` or `Amplitude`. Tunable (Simulink).

Note: This block does not support tunability in generated code.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)

- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

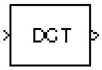
DCT

Discrete cosine transform (DCT) of input



Library

Transforms

`dspxfrm3`

Description

The DCT block computes the unitary discrete cosine transform (DCT) of each channel in the M-by-N input matrix, u.

```
y = dct(u)     % Equivalent MATLAB code
```

For all N-D input arrays, the block computes the DCT across the first dimension. The size of the first dimension (frame size), must be a power of two. To work with other frame sizes, use the `Pad` block to pad or truncate the frame size to a power-of-two length.

When the input to the DCT block is an M-by-N matrix, the block treats each input column as an independent channel containing M consecutive samples. The block outputs an M-by-N matrix whose lth column contains the length-M DCT of the corresponding input column.

$$y(k,l) = w(k) \sum_{m=1}^{M} u(m,l) \cos \frac{\pi(2m-1)(k-1)}{2M}, \quad k = 1,\ldots,M$$

where

$$w(k) = \begin{cases} \dfrac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\dfrac{2}{M}}, & 2 \le k \le M \end{cases}$$

The **Sine and cosine computation** parameter determines how the block computes the necessary sine and cosine values. This parameter has two settings, each with its advantages and disadvantages, as described in the following table.

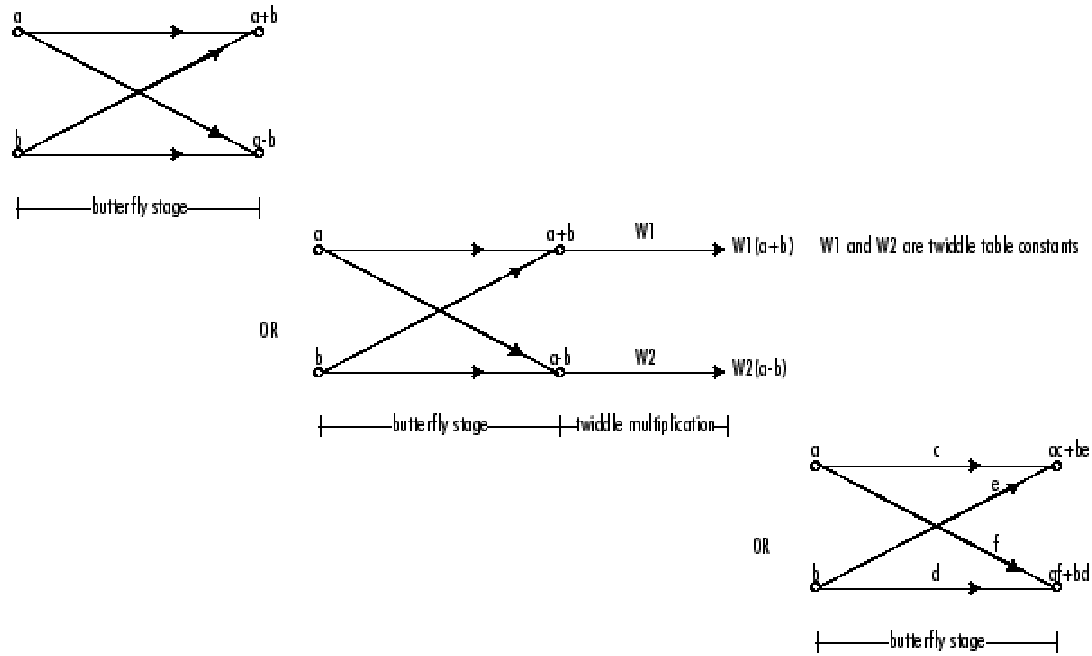
Sine and Cosine Computation Parameter Setting	Sine and Cosine Computation Method	Effect on Block Performance
`Table lookup`	The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.	The block usually runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.
`Trigonometric fcn`	The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.	The block usually runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

This block supports Simulink virtual buses.

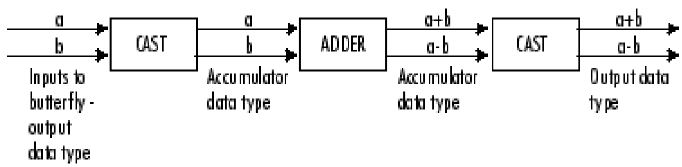
Fixed-Point Data Types

The following diagrams show the data types used within the DCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the DCT block dialog as discussed in “Dialog Box” on page 2-437.

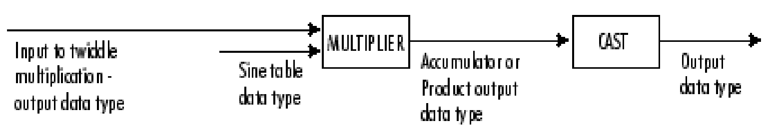
Inputs to the DCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.



Butterfly Stage Data Types



Twiddle Multiplication Data Types

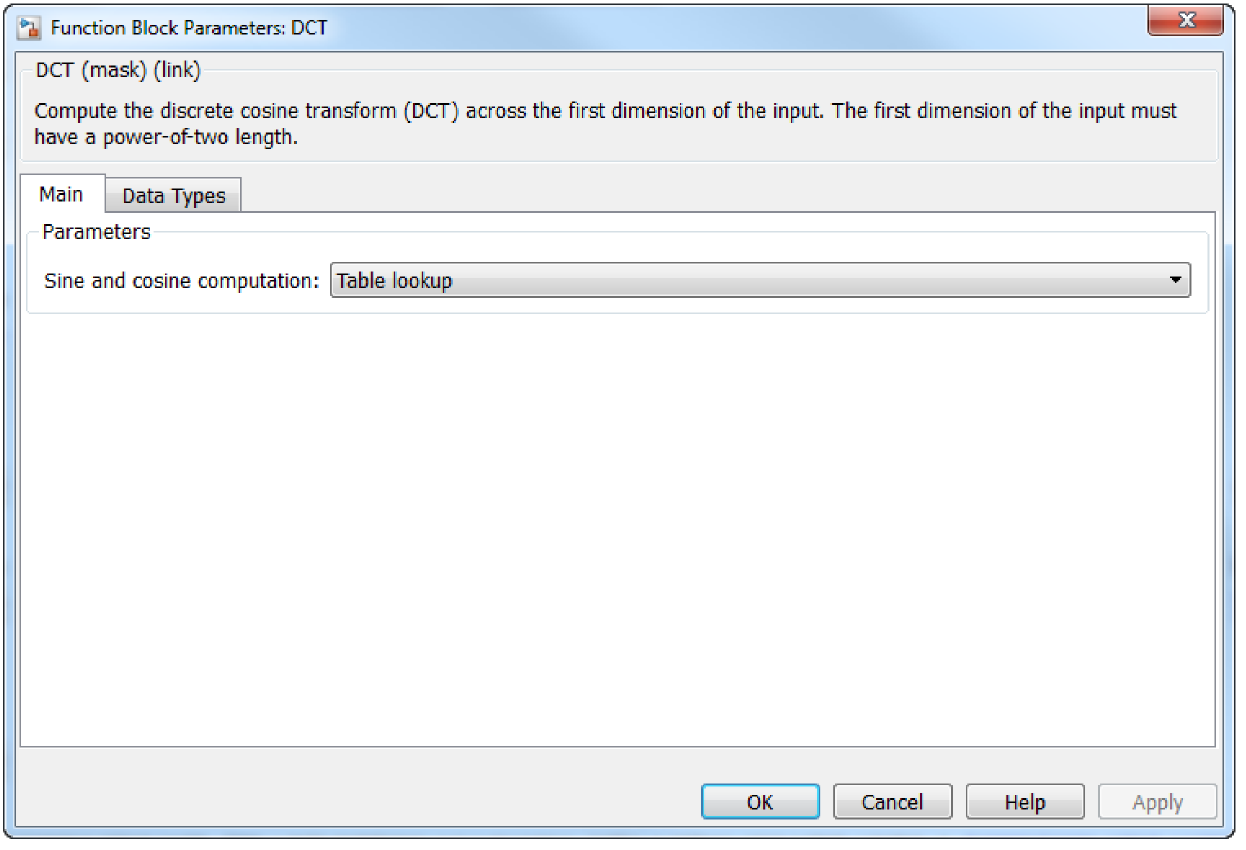


The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

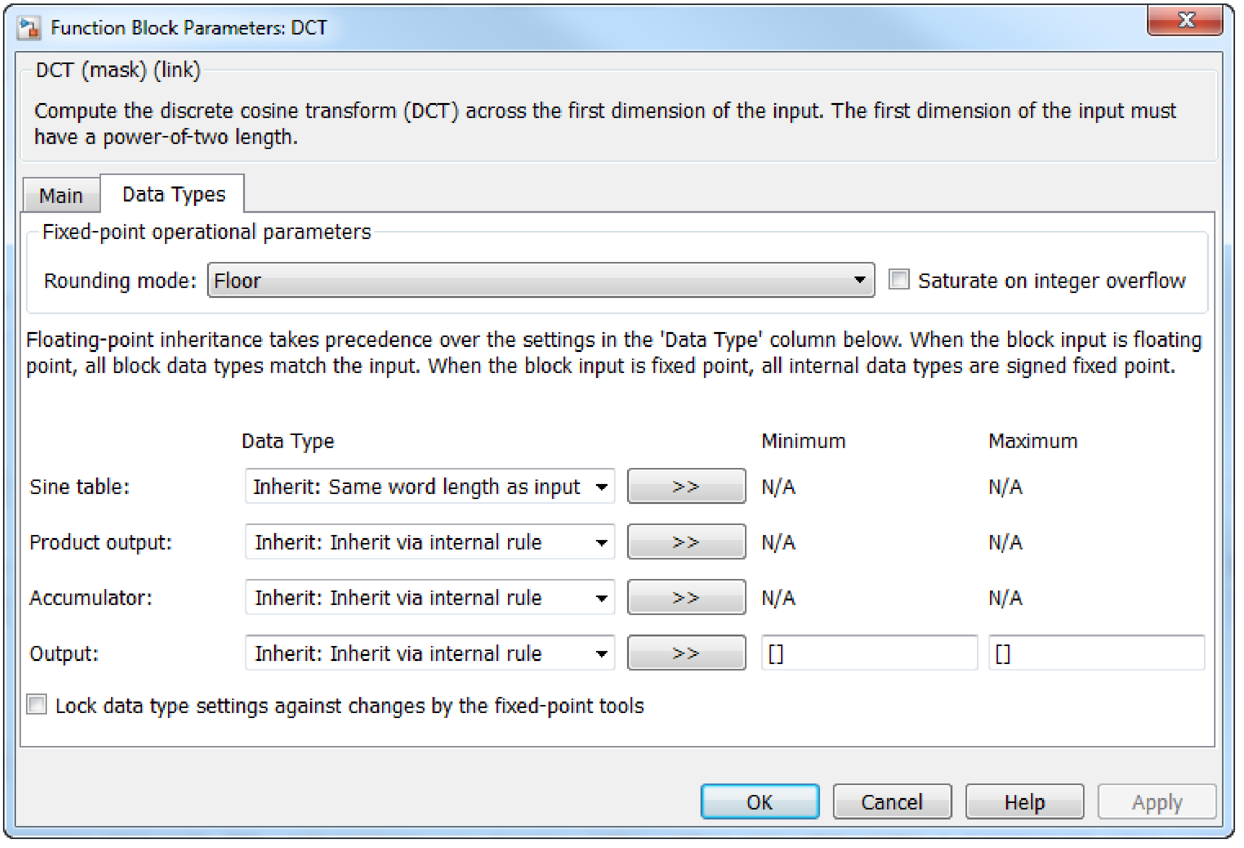
The **Main** pane of the DCT block dialog appears as follows.



Sine and cosine computation

Sets the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (`Table lookup`), or by making sine and cosine function calls (`Trigonometric fcn`). See the table in the "Description" on page 2-434 section.

The **Data Types** pane of the DCT block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; they always round to `Nearest`.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-435 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-435 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-435 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(DCT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

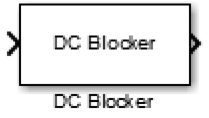
DC Blocker

Block DC component



Library

Signal Operations

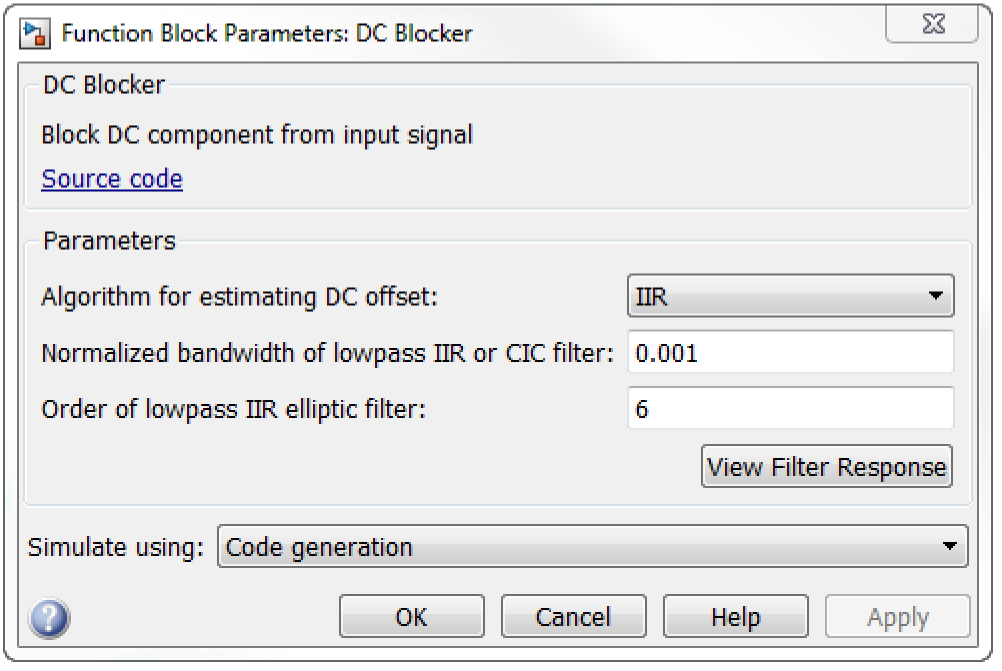
`dspsigops`

Description

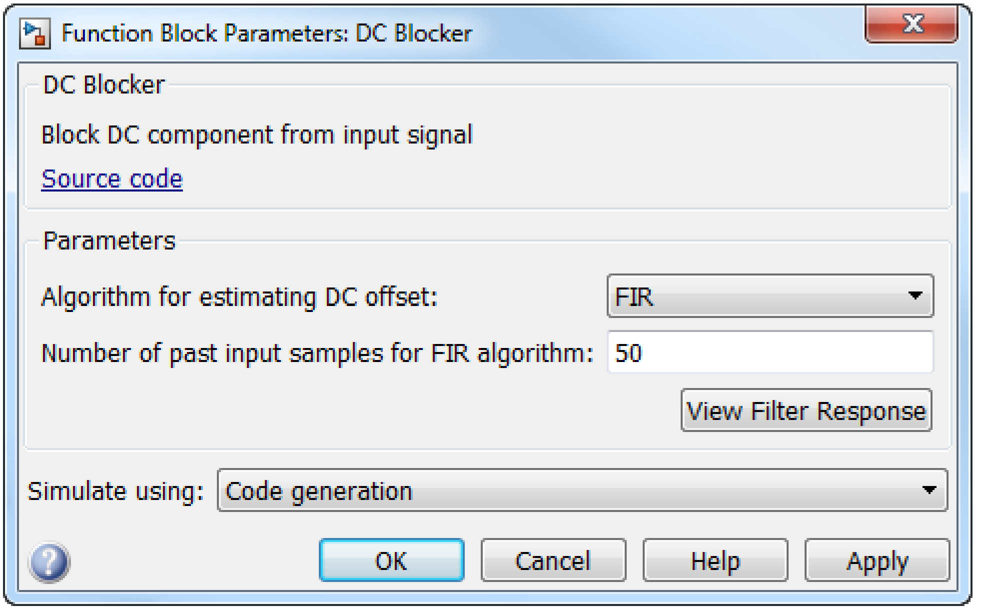
The DC Blocker block removes the DC component of the input signal.

Dialog Box

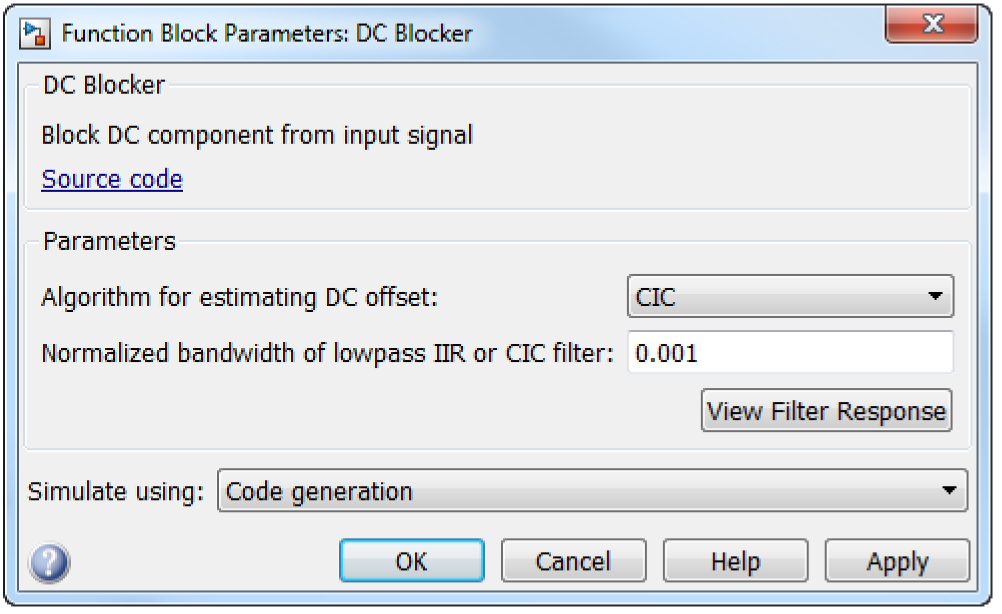
The DC Blocker dialog box changes based on how the DC offset is estimated. The dialog box for the `IIR` method is shown below.



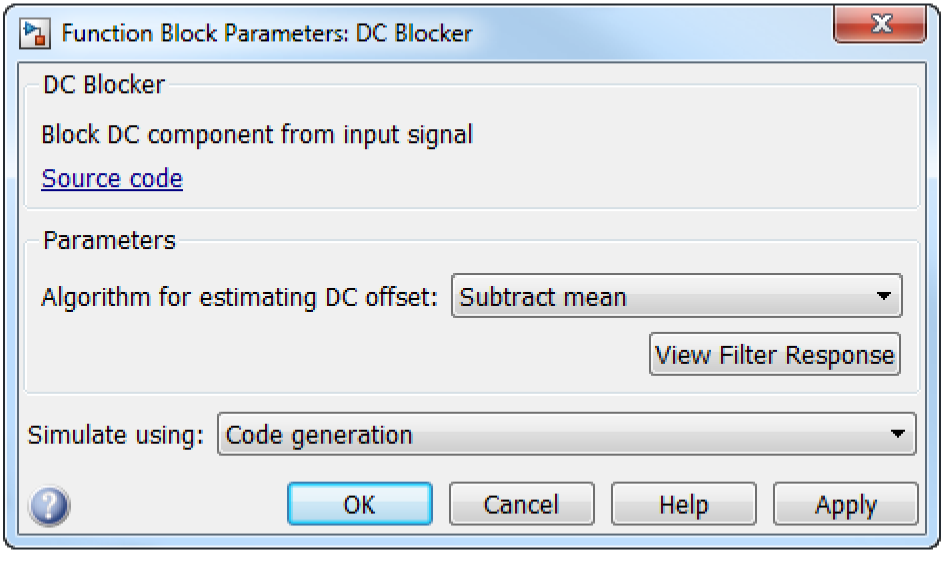
The dialog box for the `FIR` method is shown below.



The dialog box for the `CIC` method is shown below.



The dialog box for the `Subtract mean` method is shown below.



Algorithm for estimating DC offset

Specify the algorithm used for estimating the DC offset. Select from the following:

- `IIR` uses a recursive estimate based on a narrow, lowpass elliptic filter. This algorithm typically uses less memory than FIR and is more efficient.
- `FIR` uses a nonrecursive, moving-average estimate. This algorithm typically uses more memory than IIR and is less efficient.
- `CIC` uses a lowpass filter that does not employ any multipliers. If the algorithm is `CIC`, then fixed-point data must be input to the DC Blocker.
- `Subtract mean` computes the means of the columns of the input matrix and subtracts the means from the input. This method does not retain state between inputs. For example, if the input is `[1 2 3 4; 3 4 5 6]`, then the DC Blocker block in `Subtract mean` mode outputs `[-1 -1 -1 -1; 1 1 1 1]`.

Normalized bandwidth of lowpass IIR or CIC filter

Specify the normalized filter bandwidth as a real scalar greater than 0 and less than 1. The DC Blocker uses this parameter only when the estimation algorithm is set to `IIR` or `CIC`.

Order of lowpass IIR elliptic filter

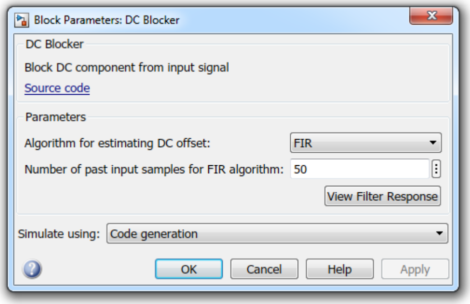
Specify the filter order as an integer greater than 3. The DC Blocker uses this parameter only when the estimation algorithm is set to `IIR`.

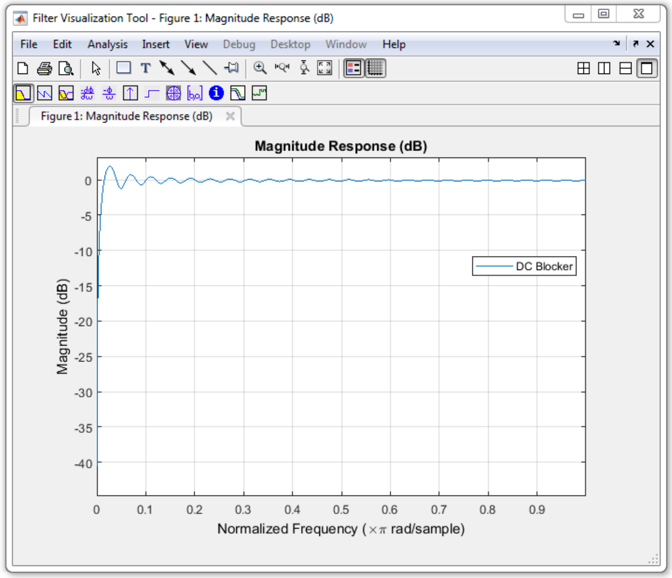
Number of past input samples for FIR algorithm

Specify, as a positive integer, the number of samples to use when the estimation algorithm is set to `FIR`.

View Filter Response

Opens the `fvtool` and displays the magnitude response of the DC Blocker. The response is based on the block parameters. Changes made to these parameters update `fvtool`.





To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

Simulate using

Select the simulation type from the following:

- `Code generation` (default)
- `Interpreted execution`

Examples

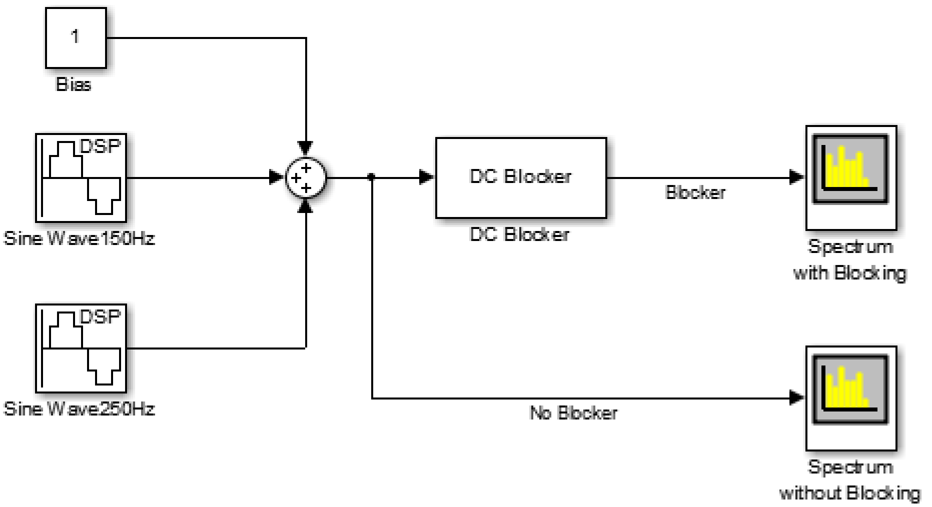
Use DC Blocker to Remove DC Component of Signal

This example shows how to use the DC Blocker to remove the DC component of a signal.

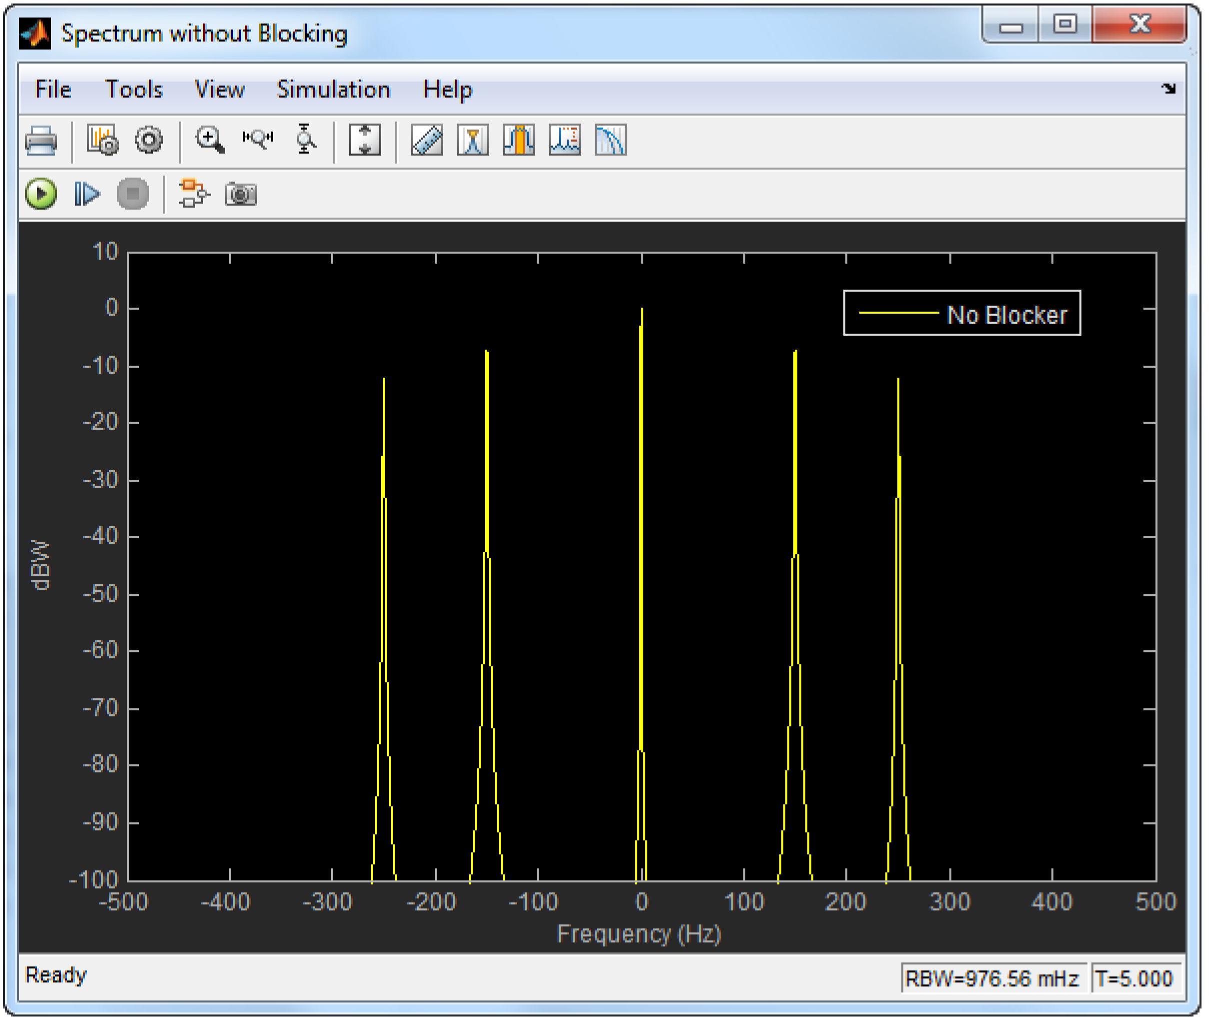
Load the DC Blocker example by typing `ex_dc_blocker` in the MATLAB command prompt.

The spectral output from the DC Blocker is displayed in Spectrum with Blocking, while the spectrum of the input signal is displayed in Spectrum without Blocking.

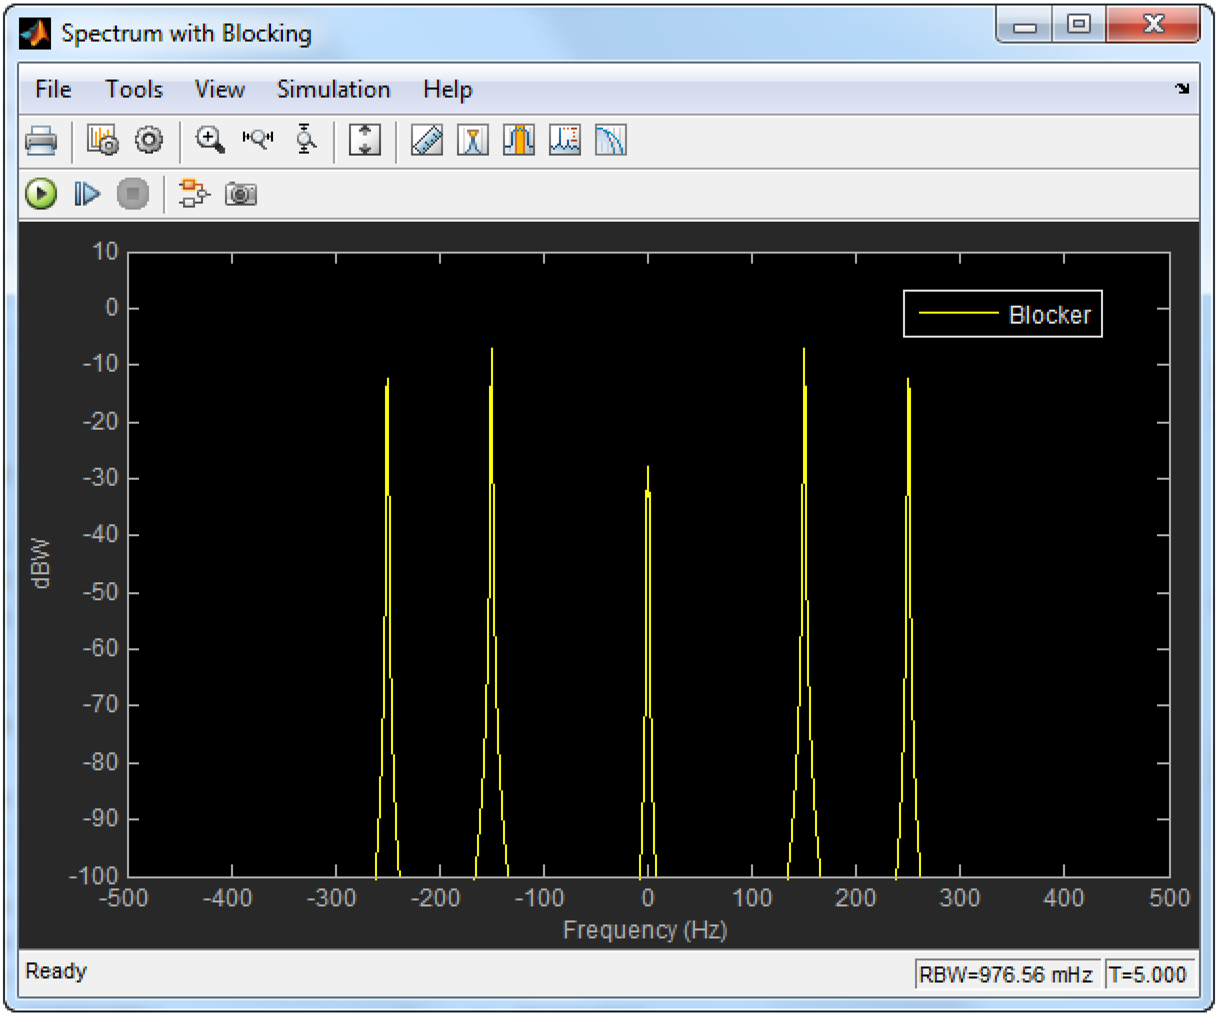
The two sine wave sources are set to use 1000 samples per frame because the `Subtract mean` estimation algorithm requires a statistically significant number of samples to calculate a valid mean.



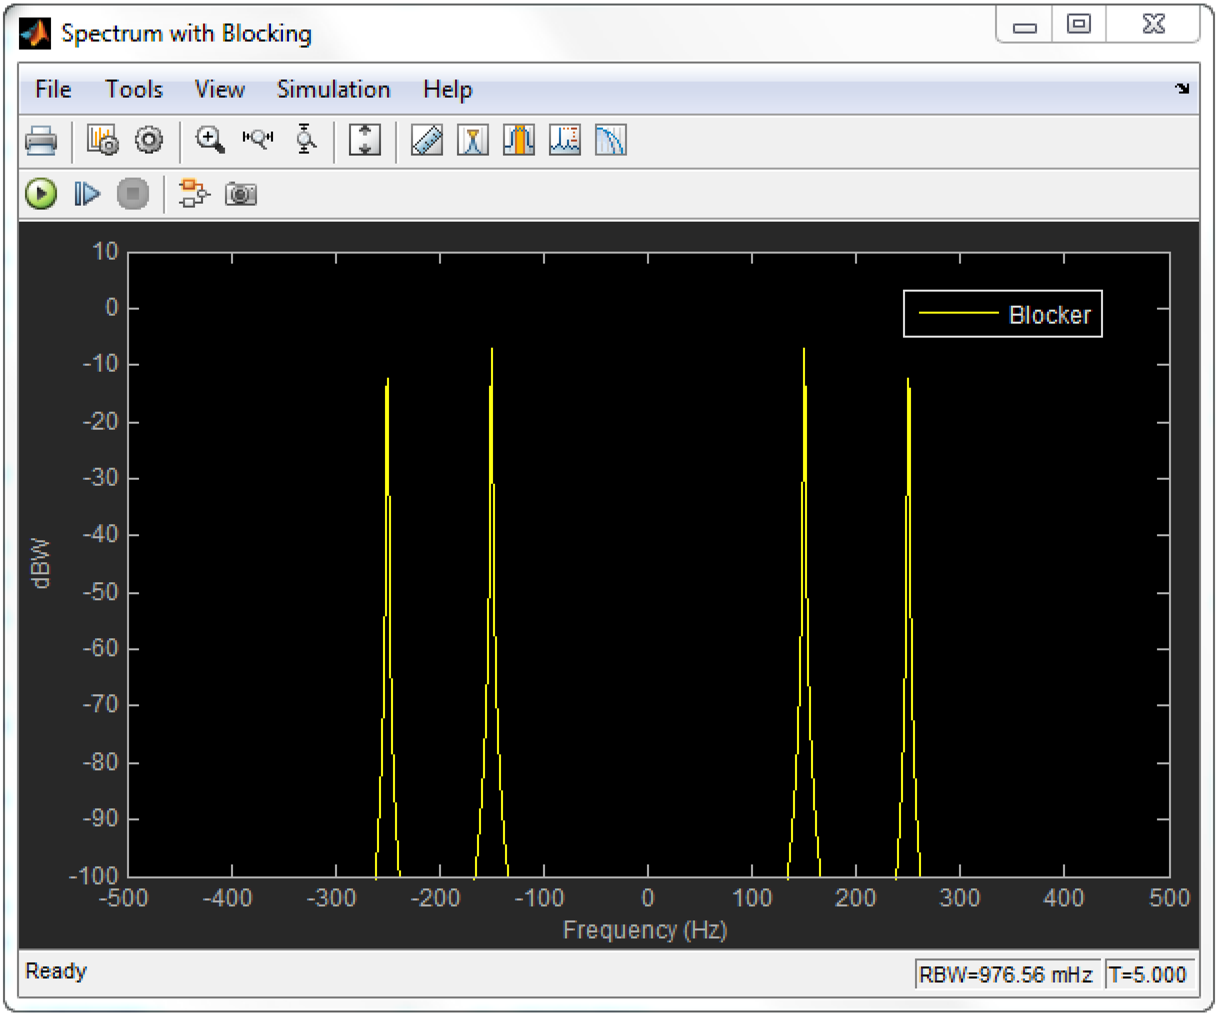
In the model, run the simulation. The spectrum of the input signal shows tones at 150 Hz and 250 Hz and a significant (0 dBW) DC component.



Using the default `IIR` setting for the DC Blocker estimation algorithm, the tones at 150 Hz and 250 Hz are unaffected while the DC component has been attenuated by 30 dB.



Select the DC Blocker block by double-clicking on it and change the algorithm type from `IIR` to `Subtract mean`. Rerun the simulation. The spectral output from the DC Blocker shows that the `Subtract mean` estimation method results in a DC component of less than −100 dBW.



Try all three estimation methods. Modify the `IIR` and `FIR` parameters to illustrate the performance of the DC Blocker using the various estimation techniques.

DC Blocker with Fixed Point Data

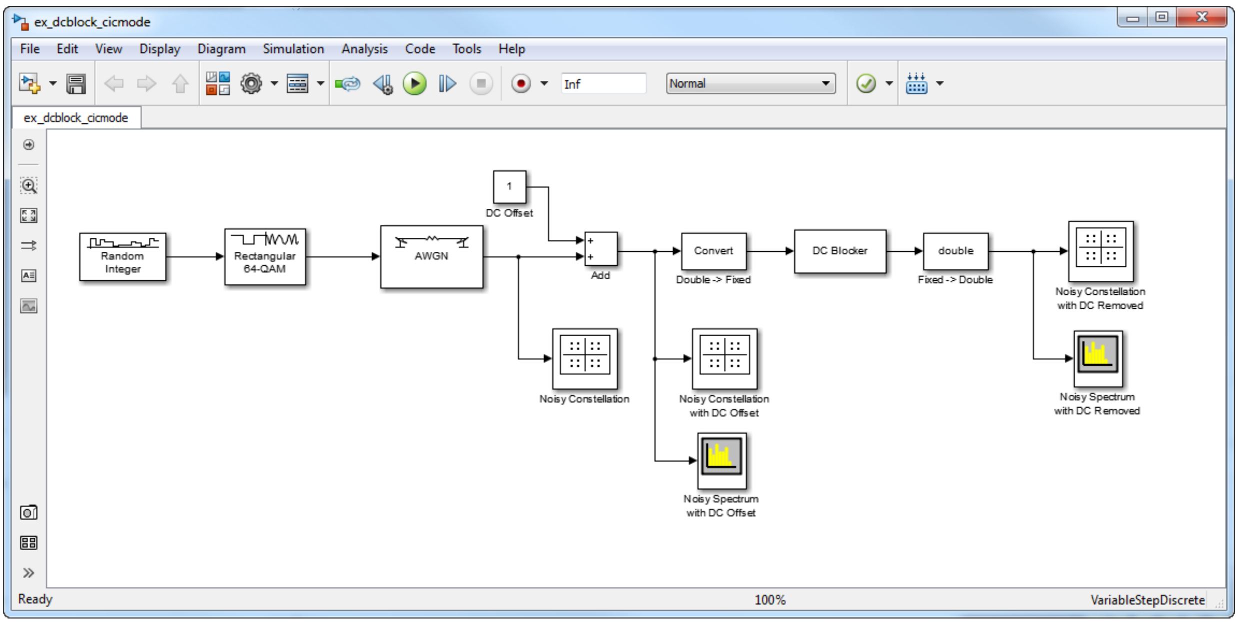
This example shows how to use the DC Blocker to remove a DC offset from fixed point data.

Load the DC Blocker example by typing `ex_dcblock_cicmode` in the MATLAB command prompt.

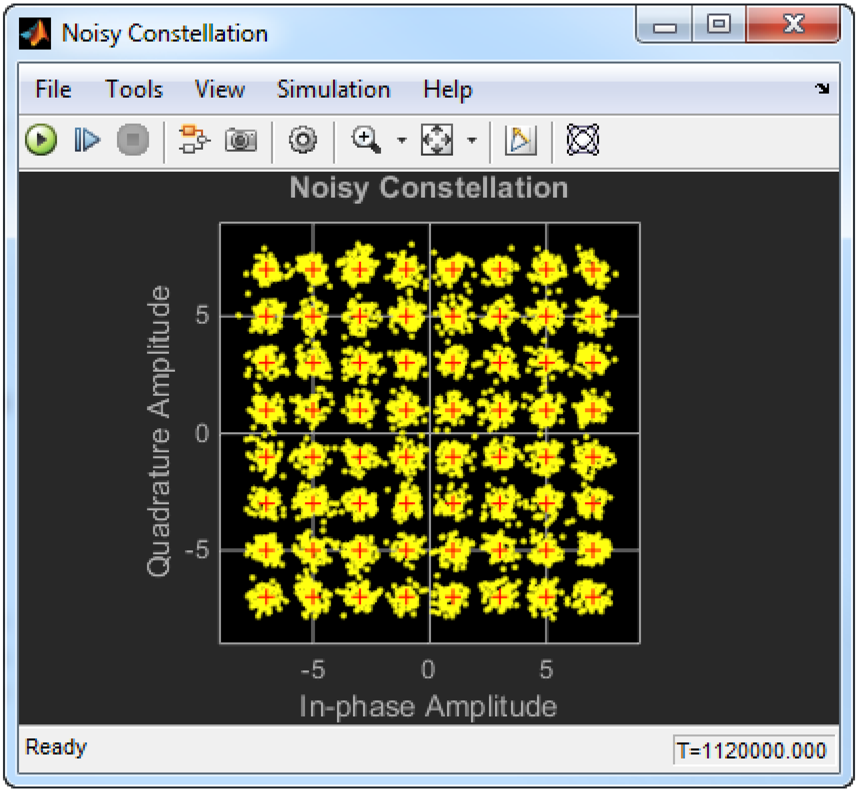
In the model:

- 64-QAM data passes through an AWGN channel.
- A DC offset of 1 is added to the signal .
- The Double -> Fixed block converts the data to 16-bit fixed point.
- The fixed-point data passes through the DC Blocker, which has the CIC algorithm selected, to remove the DC offset.
- The Fixed -> Double block converts the data back to floating point.

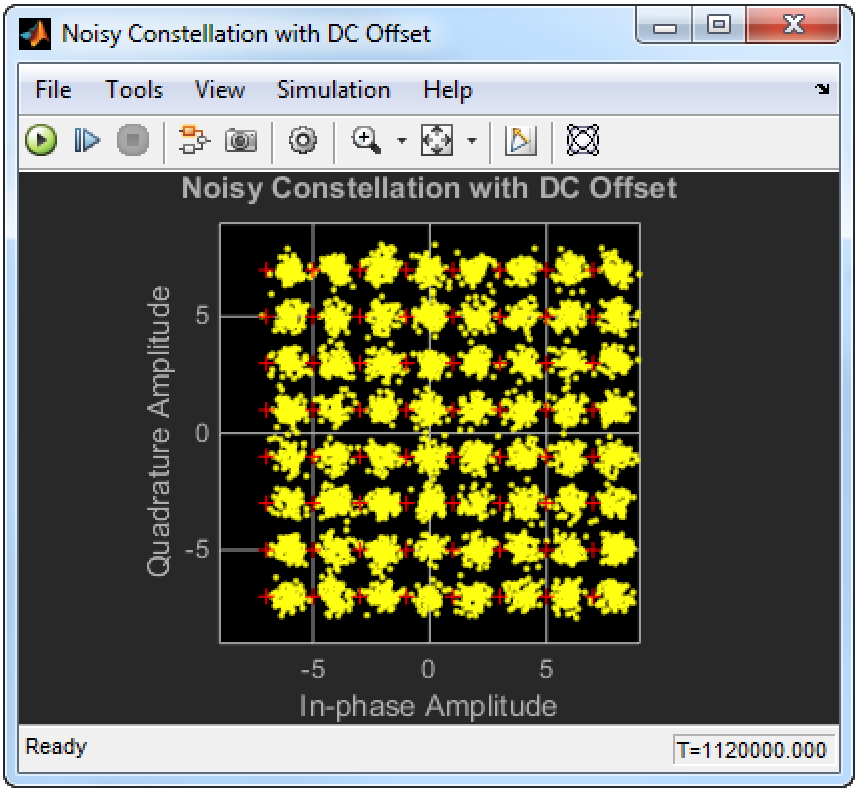
Constellation diagrams and spectrum analyzers are used to show the improvements from the DC Blocker.



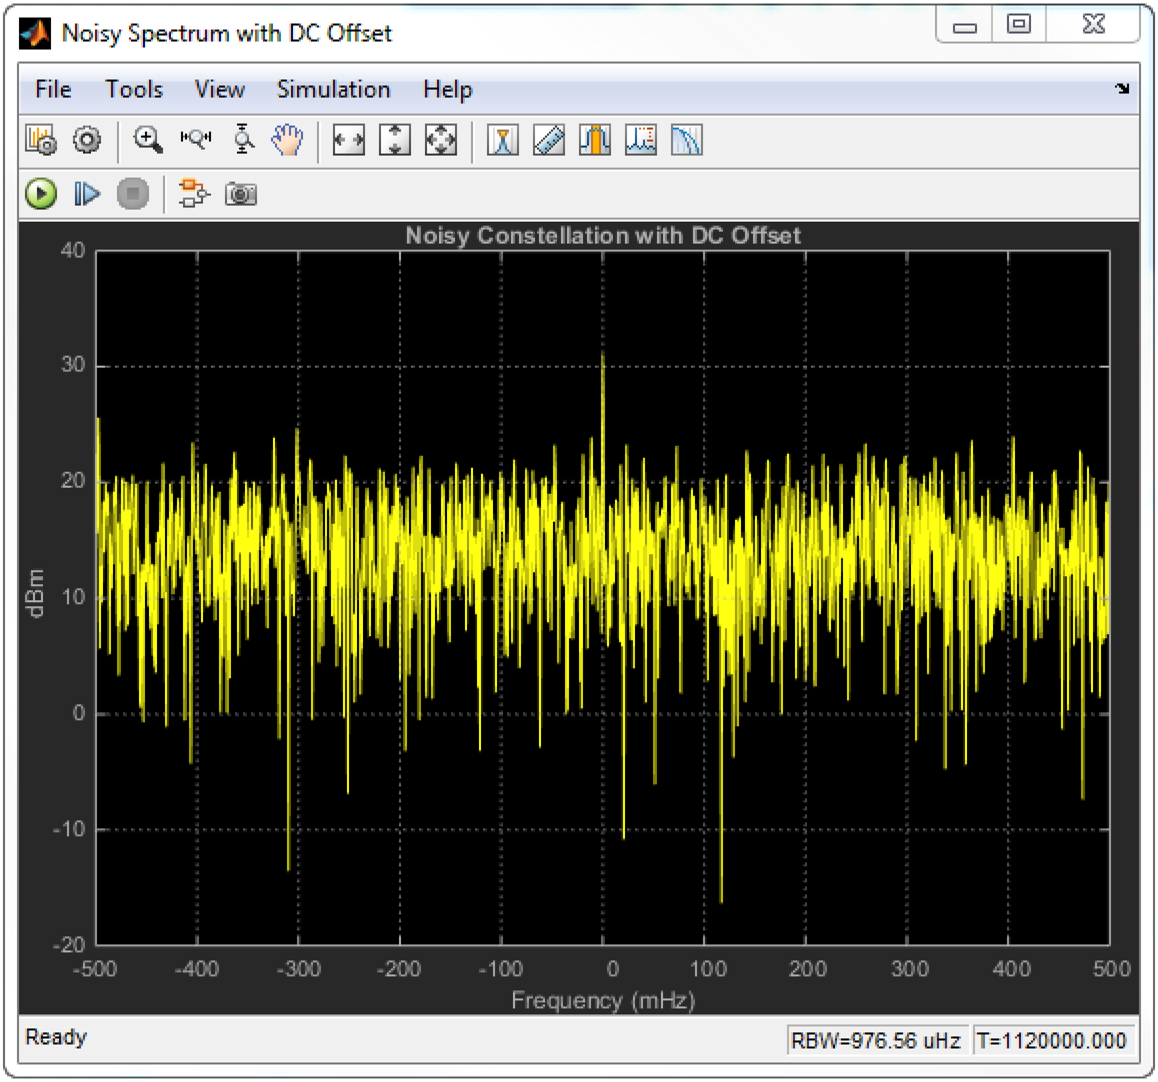
Run the simulation. The first constellation diagram, Noisy Constellation, shows a 64-QAM signal with white noise.



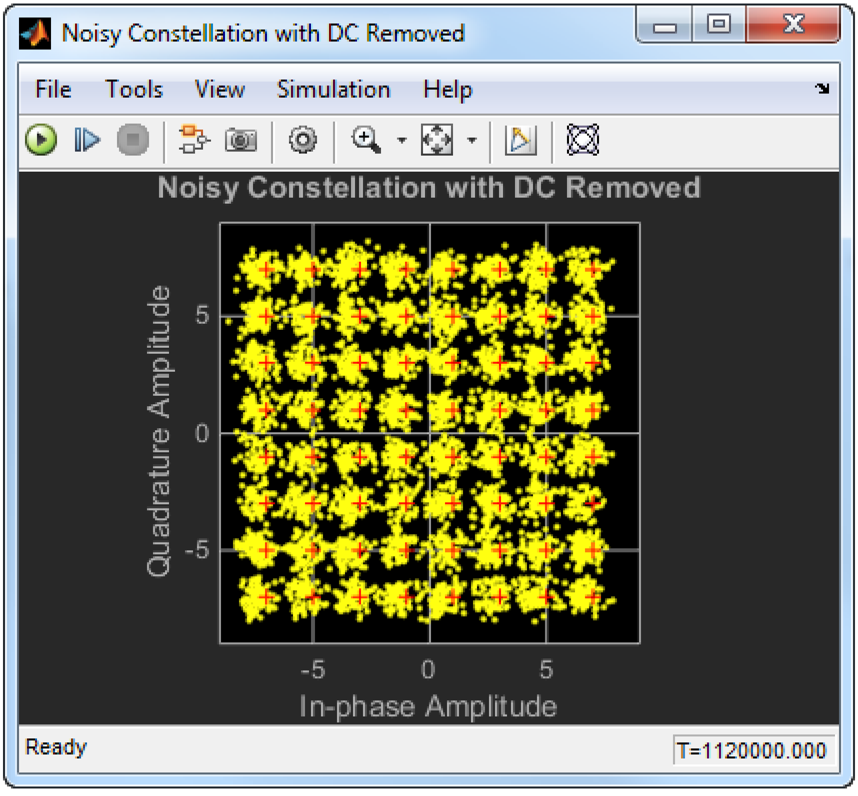
Observe the constellation diagram of the signal after the DC offset of 1 has been applied. The signal, represented by the yellow data points, has shifted one unit to the right.



Look at the spectrum of the noisy signal with the DC offset. Notice that the signal has a peak at 0 Hz.



Observe the noisy constellation after the DC offset is removed. The signal has shifted back to the left so that the data clusters are aligned with their corresponding reference points.



Observe the spectrum of the noisy signal after the DC Blocker removes the offset. The spectral peak at 0 Hz has been removed.

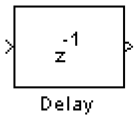
Introduced in R2014a

Delay

Delay discrete-time input by specified number of samples or frames



Note: The Delay block from the `dspsigops` library has been replaced by the Delay block from the Discrete library in Simulink. Existing instances of the `dspsigops` Delay block will be replaced with Simulink Delay block when there is an exact match in functionality between the two blocks. For new models, use the Delay block from the Discrete library in Simulink.

Library

Signal Operations

`dspsigops`

Description

The Delay block delays a discrete-time input by the number of samples or frames specified in the **Delay units** and **Delay** parameters. The **Delay** value must be an integer value greater than or equal to zero. When you enter a value of zero for the **Delay** parameter, any initial conditions you might have entered have no effect on the output.

The Delay block allows you to set the initial conditions of the signal that is being delayed. The initial conditions must be numeric.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the M-by-N input matrix as an independent channel. The block delays each channel of the input as specified by the **Delay** parameter.

The **Delay** parameter can be a scalar integer by which the block equally delays all channels or a vector whose length is equal to the number of channels.

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. See the "Frame-Based Processing Examples" on page 2-463 section for more information.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the N-D input array as an independent channel. Thus, the total number of channels in the input is equal to the product of the input dimensions. The dimension of the output is the same as that of the input.

The **Delay** parameter can be a scalar integer by which to equally delay all channels or an N-D array of the same dimensions as the input array, containing nonnegative integers that specify the number of sample intervals to delay each channel of the input.

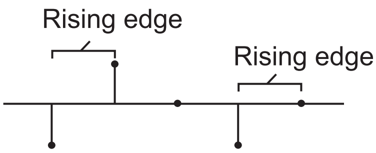
There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different within a channel. See the "Sample-Based Processing Examples" on page 2-467 section for more information.

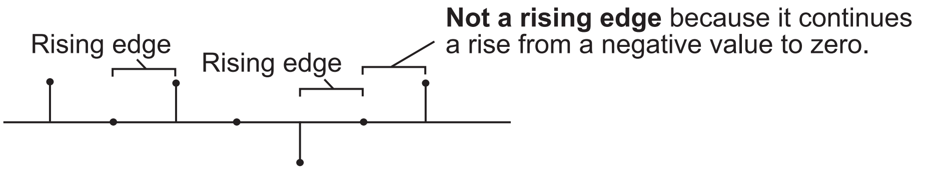
Resetting the Delay

The Delay block resets the delay whenever it detects a reset event at the optional `Rst` port. The reset sample time must be a positive integer multiple of the input sample time.

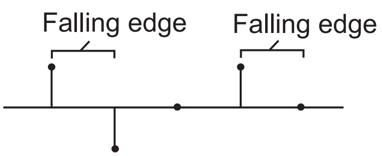
The reset event is specified by the **Reset port** parameter, and can be one of the following:

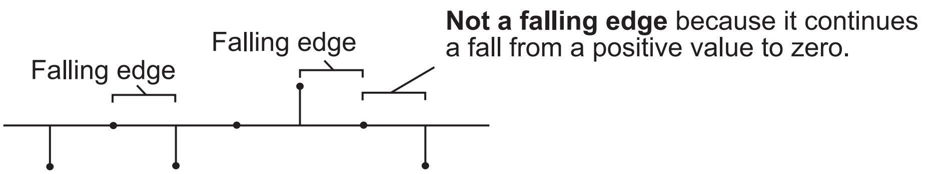
- `None` disables the `Rst` port.
- `Rising edge` triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)





- `Falling edge` triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





- `Either edge` triggers a reset operation when the `Rst` input is `Rising edge` or `Falling edge` (as described earlier).
- `Non-zero sample` triggers a reset operation at each sample time that the `Rst` input is not zero.

Note When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

This block supports Simulink virtual buses.

Examples

Frame-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. The next sections describe the behavior of the block for each of these four cases:

- "Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel" on page 2-463
- "Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel" on page 2-464
- "Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel" on page 2-465
- "Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel" on page 2-466

Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

You want the initial conditions of your three-channel signal to be identical and zero for the first frame:

1 Set the **Delay (frames)** parameter to `1`.
2 Clear the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
3 Set the **Initial conditions** parameter to a scalar value of `0`.

   The output of the delay block is

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

   `0`, the scalar initial condition value, is used across the channels and within the channels for the first frame. This frame is the output at sample time zero.

Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be a vector of length N, where $N \geq 1$. N is also equal to the number of channels in your signal. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

You want the initial conditions of your three-channel signal to be `[0 10 20]` for the first frame:

1 Set the **Delay (frames)** parameter to `1`.
2 Select the **Specify different initial conditions for each channel** check box.
3 Clear the **Specify different initial conditions within a channel** check box.

4 Set the **Initial conditions** parameter to `[0 10 20]`.

The output of the delay block is

$$\begin{bmatrix} 0 & 10 & 20 \\ 0 & 10 & 20 \\ 0 & 10 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

The initial condition vector expands to create the frame that is output at sample time zero. Different initial conditions are used for each channel, but the same initial condition value is used with a channel.

Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, the **Delay** parameter can be a scalar integer by which to equally delay all channels or a vector whose length is equal to the number of channels. All the values of this vector must be equal.

Enter the initial conditions as a vector. These values are used as the initial condition value along each of the channels to be delayed. The initial condition vector must have length equal to the value of the **Delay (frames)** parameter multiplied by the frame length. For example, if you want to delay your signal by two frames with frame length two and an initial condition value of 3, enter your initial condition vector as `[3 3 3 3]`.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

You want the initial conditions of your three-channel signal to be the same along each of the channels to be delayed:

1 Set the **Delay (frame)** parameter to `1`.

2 Clear the **Specify different initial conditions for each channel** check box.

3. Select the **Specify different initial conditions within a channel** check box.
4. Set the **Initial conditions** parameter to `[10 20 30]`.

   The output of the delay block is

$$\begin{bmatrix} 10 & 10 & 10 \\ 20 & 20 & 20 \\ 30 & 30 & 30 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

   The initial condition vector defines the initial condition values within each of the three channels. The same initial conditions are used for each channel, but different initial condition values are used with a channel.

Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. Or, when you have a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Columns as channels (frame based)`.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \ldots$$

You want the initial conditions of your three-channel signal to be different for each channel and along each channel.

1. Set the **Delay (frames)** parameter to `1`.
2. Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
3. Set the **Initial conditions** parameter to either `[10 20 30; 40 50 60; 70 80 90]` or `{[10 40 70];[20 50 80];[30 60 90]}`. Each cell of the cell array represents the delay along one channel.

   Regardless of whether you use a matrix or cell array, the output of the delay block is

$$\begin{bmatrix} 10 & 20 & 30 \\ 40 & 50 & 60 \\ 70 & 80 & 90 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix} \ldots$$

The initial condition matrix is the output at sample time zero. The elements of the initial condition cell array define the initial condition values within each channel. The first element, a vector, represents the initial conditions within channel 1. The second element, a vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

Sample-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different along each channel. The next sections describe the behavior of the block for each of these four cases:

- "Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel" on page 2-467
- "Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel" on page 2-468
- "Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel" on page 2-469
- "Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel" on page 2-470

Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

You want the initial conditions of your four-channel signal to be identical and zero for the first two samples:

1 Set the **Delay (samples)** parameter to 2.
2 Clear the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
3 Set the **Initial conditions** parameter to a scalar value of 0.

   The output of the delay block is

$$\begin{bmatrix}0 & 0\\0 & 0\end{bmatrix},\begin{bmatrix}0 & 0\\0 & 0\end{bmatrix},\begin{bmatrix}1 & 1\\1 & 1\end{bmatrix},\begin{bmatrix}2 & 2\\2 & 2\end{bmatrix},\begin{bmatrix}3 & 3\\3 & 3\end{bmatrix},\ldots$$

   0, the scalar initial condition value, is used for each channel and within the channels. It is the output at sample time zero and sample time one.

Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be an N-D array for N-D input. The initial conditions must have the same dimensions as the input data. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix}1 & 1\\1 & 1\end{bmatrix},\begin{bmatrix}2 & 2\\2 & 2\end{bmatrix},\begin{bmatrix}3 & 3\\3 & 3\end{bmatrix},\ldots$$

You want the initial conditions of your four-channel signal to be

$$\begin{bmatrix}7 & 9\\11 & 13\end{bmatrix}$$

for the first two samples:

1 Set the **Delay (samples)** parameter to 2.

2 Select the **Specify different initial conditions for each channel** check box.

3 Clear the **Specify different initial conditions within a channel** check box.

4 Set the **Initial conditions** parameter to `[7 9; 11 13]`.

The output of the delay block is

$$\begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

The initial condition matrix is the output at sample time zero and sample time one. Different initial conditions are used for each channel; the same initial condition value is used within a channel.

Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, for N-D sample-based inputs, the initial conditions parameter must be a vector whose length is equal to the delay value, specified by the **Delay** parameter. The values in this vector are used as the initial condition values along each of the channels to be delayed.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

You want the initial conditions of your four channel signal to be the same along each of the channels to be delayed:

1 Set the **Delay (samples)** parameter to `2`.

2 Clear the **Specify different initial conditions for each channel** check box.

3 Select the **Specify different initial conditions within a channel** check box.

4 Set the **Initial conditions** parameter to `[10 20]`.

The output of the delay block is

$$\begin{bmatrix}10 & 10\\10 & 10\end{bmatrix},\begin{bmatrix}20 & 20\\20 & 20\end{bmatrix},\begin{bmatrix}1 & 1\\1 & 1\end{bmatrix},\begin{bmatrix}2 & 2\\2 & 2\end{bmatrix},\begin{bmatrix}3 & 3\\3 & 3\end{bmatrix},\ldots$$

The first element of the initial conditions vector is the output, for all channels, at sample time zero. The second element of the initial conditions vector is the output, for all channels, at sample time one. The same initial conditions are used for each channel, but different initial condition values are used within a channel.

Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. The cell array must be the same size as your input signal. Each cell of the cell array represents the delay values for one channel, and must be a vector of size equal to the delay value. If you have a vector or scalar input and a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$[1\quad 1],\ \ [2\quad 2],\ \ [3\quad 3],\ldots$$

You want the initial conditions of your two channel signal to be different for each channel and along each channel:

1. Set the **Delay (samples)** parameter to `2`.
2. Select the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
3. Set the **Initial conditions** parameter to `[10 20; 30 40]`.

   The output of the delay block is

   $$[10\quad 20],\ \ [30\quad 40],\ \ [1\quad 1],\ \ [2\quad 2]\ldots$$

   The first row of the initial conditions vector is the output at sample time zero. The second row of the initial conditions vector is the output at sample time one. Different initial conditions are used for each channel and within the channels.

In addition, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \ldots$$

You want the initial conditions of your two-channel signal to be different for each channel and along each channel:

1. Set the **Delay (samples)** parameter to `2`.
2. Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
3. Set the **Initial conditions** parameter to `{[11 15] [12 16]; [13 17] [14 18]}`. The dimensions of the cell array match the dimensions of the input. Also, each element of the cell array represents the initial conditions within one channel.

   The output of the delay block is

   $$\begin{bmatrix} 11 & 12 \\ 13 & 14 \end{bmatrix}, \begin{bmatrix} 15 & 16 \\ 17 & 18 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \ldots$$

   Each element of the cell array represents the initial conditions within a channel. The first element, a vector, represents the initial conditions within channel 1. The second element, a vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The option `Inherit from input (this choice will be removed - see release notes)` will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Delay units

Select whether you want to delay your input by a specified number of `Samples` or `Frames`. This parameter appears only when you set the **Input processing** parameter to `Columns as channels (frame based)`.

Delay (samples) or Delay (frames)

See "Sample-Based Processing" on page 2-461 and "Frame-Based Processing" on page 2-460 for a description of what format to use for each configuration of the block dialog.

Specify different initial conditions for each channel

Select this check box when you want the initial conditions to vary across the channels. When you do not select this check box, the initial conditions are the same across the channels.

Specify different initial conditions within a channel

Select this check box when you want the initial conditions to vary within the channels. When you do not select this check box, the initial conditions are the same within the channels.

Initial conditions

Enter a scalar, vector, matrix, or cell array of initial condition values, depending on your choice for the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes. See "Sample-Based Processing" on page 2-461 and "Frame-Based Processing" on page 2-460 for a description of what format to use for each configuration of the block dialog.

Reset port

Determines the reset event that causes the block to reset the delay. For more information, see "Resetting the Delay" on page 2-461.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see Delay.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

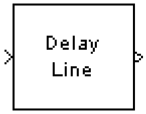
Introduced before R2006a

Delay Line

Rebuffer sequence of inputs



Library

Signal Management / Buffers

`dspbuff3`

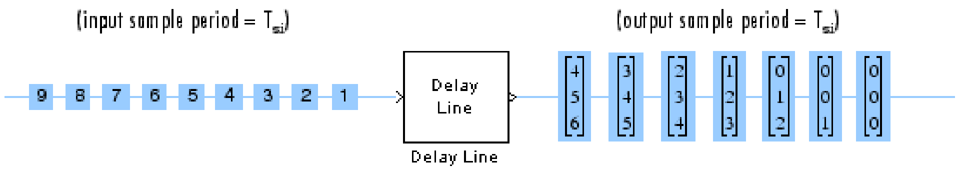
Description

The Delay Line block rebuffers a sequence of M_i-by-N matrix inputs into a sequence of M_o-by-N matrix outputs, where M_o is the output frame size you specify in the **Delay line size** parameter. Depending on whether M_o is greater than, less than, or equal to the input frame size, M_i, the output frames can be underlapped or overlapped. The block always performs frame-based processing and rebuffers each of the N input channels independently.

When $M_o > M_i$, the output frame overlap is the difference between the output and input frame size, M_o-M_i. When $M_o < M_i$, the output is underlapped; the Delay Line block discards the first M_i-M_o samples of each input frame so that only the last M_o samples are buffered into the corresponding output frame. When $M_o = M_i$, the output data is identical to the input data, but is delayed by the latency of the block. Due to the block's latency, the outputs are always delayed by one frame, the entries of which you specify in the **Initial conditions** parameter (see “Initial Conditions” on page 2-475).

The output frame period is equal to the input frame period (T_{fo}=T_{fi}). The output sample period, T_{so}, is therefore equal to T_{fi}/M_o, or equivalently, $T_{si}(M_i/M_o)$

In the most typical use, each output differs from the preceding output by only one sample, as illustrated below for scalar input.



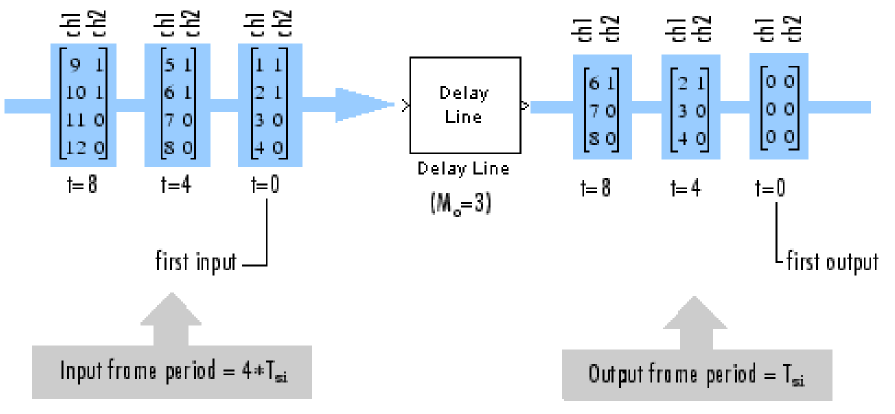
Note that the first output of the block in the example above is all zeros; this is because the **Initial Conditions** parameter is set to zero.

Initial Conditions

The Delay Line block's buffer is initialized to the value specified by the **Initial conditions** parameter. The block outputs this buffer at the first simulation step (t=0). When the block's output is a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

Examples

In the following ex_delayline_ref2 model, the block rebuffers a two-channel input with a **Delay line size** of 3.



The first output frame in this example is due to the latency of the Delay Line block; it is all zeros because the **Initial conditions** parameter is set to zero. Because the input frame size of 4 is larger than the output frame size of 3, only the last three samples in each input frame are propagated to the corresponding output frame. The frame periods of the input and output are the same, and the output sample period is $T_{si}(M_i/M_o)$, or 4/3 the input sample period.

Parameters

Delay line size

Specify the number of rows in output matrix, M_o.

Initial conditions

Specify the value of the block's initial output. When the block outputs a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all elements of the initial output. When the block outputs a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

Allow direct feedthrough

When you select this check box, the input data is not delayed by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output port of the block.

Show En_Out port for selectively enabling output

When you select this check box, the En_Out port appears on the block icon. This block uses a circular buffer internally even though the output is linear. This means that for valid output, data from the circular buffer has to be linearized. The En_Out port determines whether or not a valid output needs to be computed based on the value of its `Boolean` input. If the input value to the En_Out port is `1`, the block output is linearized, and thus is valid. Otherwise, the output is not linearized, and is invalid. This allows the block to be more efficient when the tapped Delay Line's output is not required at each sample time.

Note that when the input value to the En_Out port is `0`, the block can give different results depending on the state of the model. The results can appear to match valid results or can be invalid, and they cannot be predicted. You should ignore the block output in all cases when the input to the En_Out port is `0`.

Hold previous value when the output is disabled

This parameter only appears and applies when the **Show En_Out port for selectively enabling output** parameter is selected. Use this parameter to specify the block output at those time steps when the internal state buffer is not being linearized to output valid data.

When you do not select this check box, the block memory is free to be used by other parts of the model, and the signal on the output port is invalid. When you select this check box, the most recent valid value is held on the output port, and slightly more memory is used by the block.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

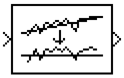
Detrend

Remove linear trend from vectors



Library

Statistics

`dspstat3`

Description

The Detrend block removes a linear trend from the length-M input vector, u, by subtracting the straight line that best fits the data in the least squares sense.

The least squares line, $\hat{u} = ax + b$, is the line with parameters a and b that minimizes the quantity

$$\sum_{i=1}^{M}(u_i - u_i)^2$$

for M evenly-spaced values of x, where u_i is the ith element in the input vector. The output, $y = u\text{-}\hat{u}$, is always an M-by-1 column vector.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

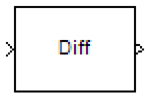
Difference

Compute element-to-element difference along specified dimension of input



Library

Math Functions / Math Operations

`dspmathops`

Description

The Difference block computes the difference between adjacent elements in rows, columns, or a specified dimension of the input array `u`. You can configure the block to compute the difference only within the current input, or across consecutive inputs (running difference).

Basic Operation

When you set the **Running difference** parameter to `No`, the block computes the difference between adjacent elements in the specified dimension of the current input. In this mode, the block can compute the difference along the columns, rows, or a specified dimension of the input.

Columnwise Differencing

When you set the **Difference along** parameter to `Columns`, the block computes differences between adjacent elements in each column of the input.

```
y = diff(u)      % Equivalent MATLAB code
```

For M-by-N inputs, the output is an (M-1)-by-N matrix whose jth column has the following elements:

$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 1 \le i \le (M-1)$$

Rowwise Differencing

When you set the **Difference along** parameter to `Rows`, the block computes differences between adjacent elements in each row of the input.

```
y = diff(u,[],2)      % Equivalent MATLAB code
```

The output is an M-by-(N-1) matrix whose ith row has the following elements:

$$y_{i,j} = u_{i,j+1} - u_{i,j} \quad 1 \le j \le (N-1)$$

Differencing Along Arbitrary Dimensions

When you set the **Difference along** parameter to `Specified dimension`, the behavior of the block is an extension of the rowwise differencing described earlier. The block computes differences between adjacent elements along the dimension you specify in the **Dimension** parameter.

```
y = diff(u,[],d) % Equivalent MATLAB code where d is the dimension
```

The output is an array whose length in the specified dimension is one less than that of the input, and whose lengths in other dimensions are unchanged. For example, consider an M-by-N-by-P-by-R input array with elements *u(i,j,k,l)* and assume that **Dimension** is `3`. The output of the block is an M-by-N-by-(P–1)-by-R array with the following elements:

$$y_{i,j,k,l} = u_{i,j,k+1,l} - u_{i,j,k,l} \quad 1 \le k \le (P-1)$$

Running Operation

When you set the **Running difference** parameter to `Yes`, the block computes the running difference along the columns of the input.

For an M-by-N input matrix, the output is an M-by-N matrix whose jth column has the following elements:

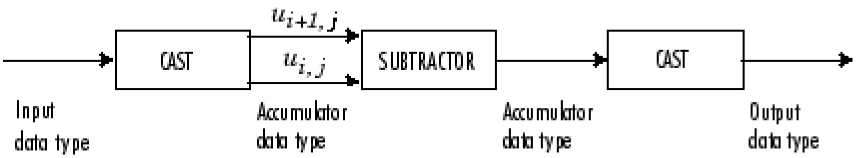
$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 2 \le i \le (M-1)$$

In running mode, the first element of the output for each column is the first input element minus the last input element of the previous frame. For the first frame, the block subtracts zero from the first input element.

$$y_{1,j}(t) = u_{1,j}(t) - u_{M,j}(t - T_f)$$

Fixed-Point Data Types

The following diagram shows the data types used within the Difference block for fixed-point signals.

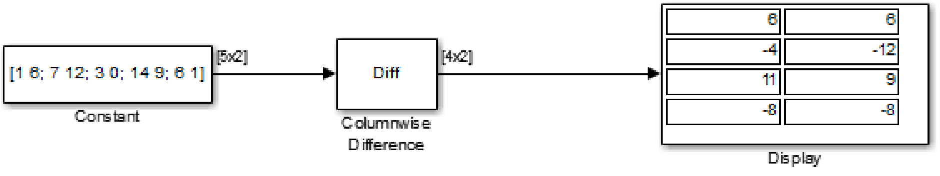


You can set the accumulator and output data types in the block dialog as discussed in “Dialog Box” on page 2-483 .

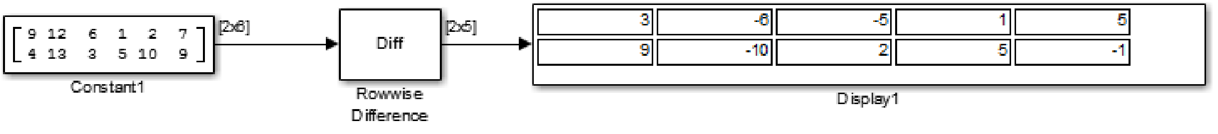
Examples

For an example showing the modes of the Difference block, open ex_difference.

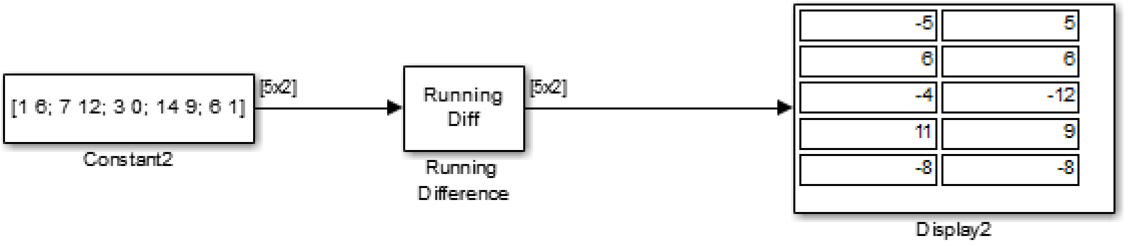
The following figure shows the output of the block when it is differencing along columns in nonrunning mode.



The following figure shows the output of the block when it is differencing along rows in nonrunning mode.

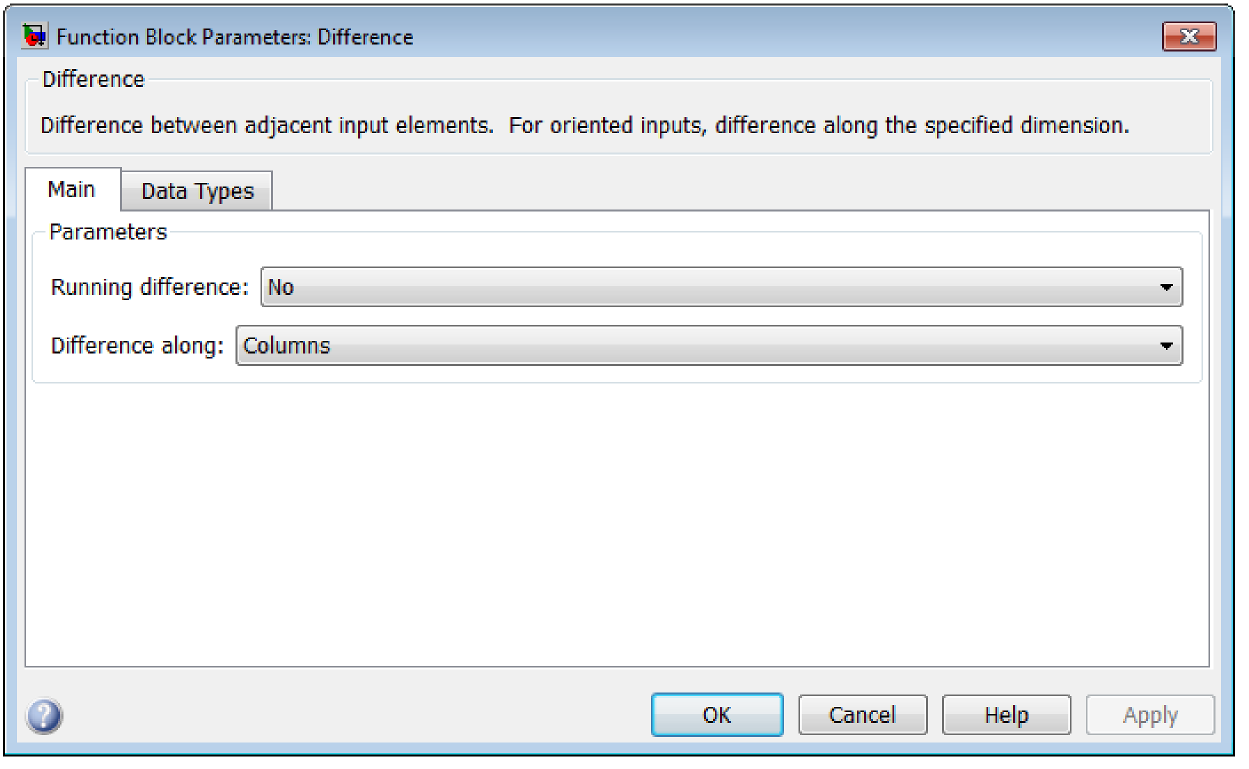


The following figure shows the second frame of block output when the block is computing the running difference.



Dialog Box

The **Main** pane of the Difference block appears as follows.



Running difference

Specify whether or not the block computes a running difference. When you select `No`, the block computes the difference between adjacent elements in the current input. When you select `Yes`, the block computes the running difference across consecutive inputs. In running mode, the block always computes the difference along the columns of the input. See "Running Operation" on page 2-481 for more information.

Difference along

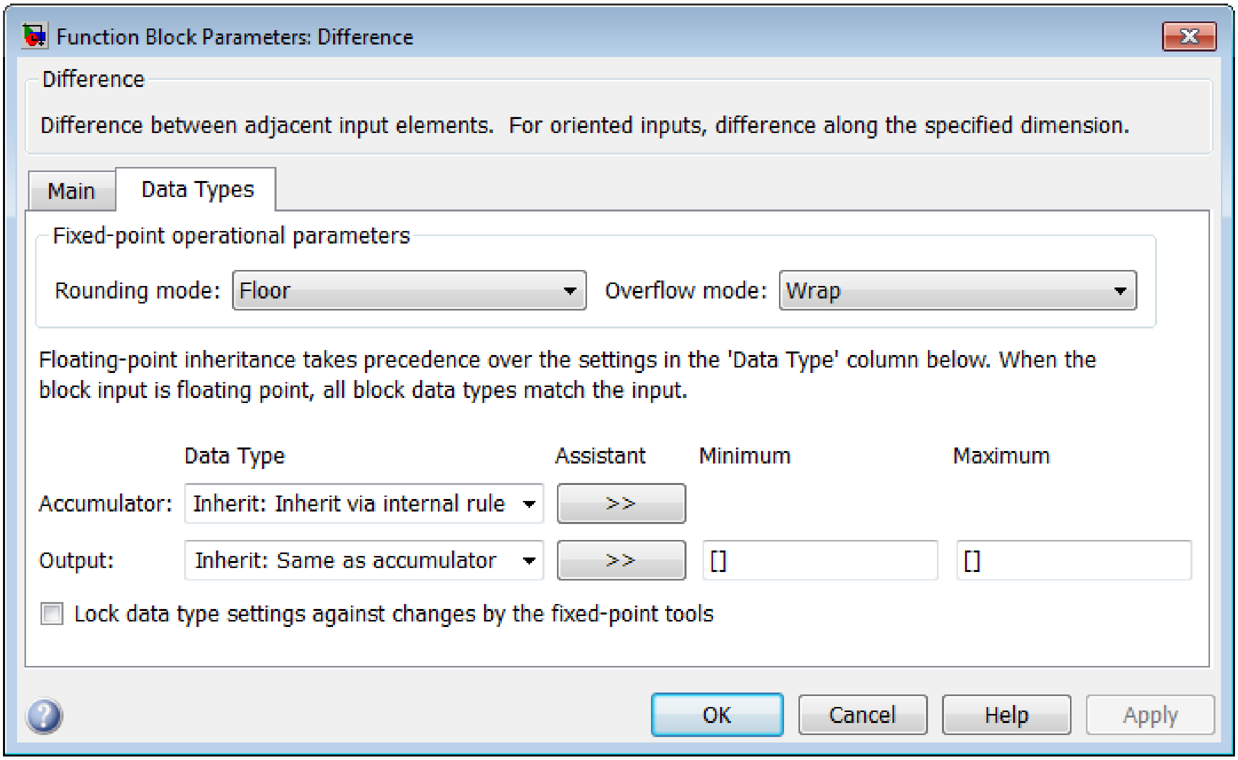
Specify whether the block computes the difference along the columns, rows, or specified dimension of the input.

Dimension

Specify the one-based dimension along which to compute element-to-element differences.

This parameter is only visible when you select `Specified dimension` for the **Difference along** parameter.

The **Data Types** pane of the Difference block appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-482 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-482 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

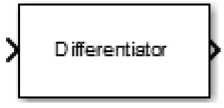
Differentiator Filter

Direct form FIR fullband differentiator filter



Library

Filtering / Filter Designs

`dspfdesign`

Description

The Differentiator Filter block applies a fullband differentiator filter on the input signal to differentiate all its frequency components. The block uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is $D(\omega) = j\omega$ for $-\pi \leq \omega \leq \pi$.

You can design the filter with minimum order or with a specifies order.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

This block supports variable-size input, enabling you to change the channel length during simulation. The output port properties, such as data type, complexity, and dimension, are identical to the input port properties. The block supports fixed-point operations.

Examples

- “Group Delay Estimation”

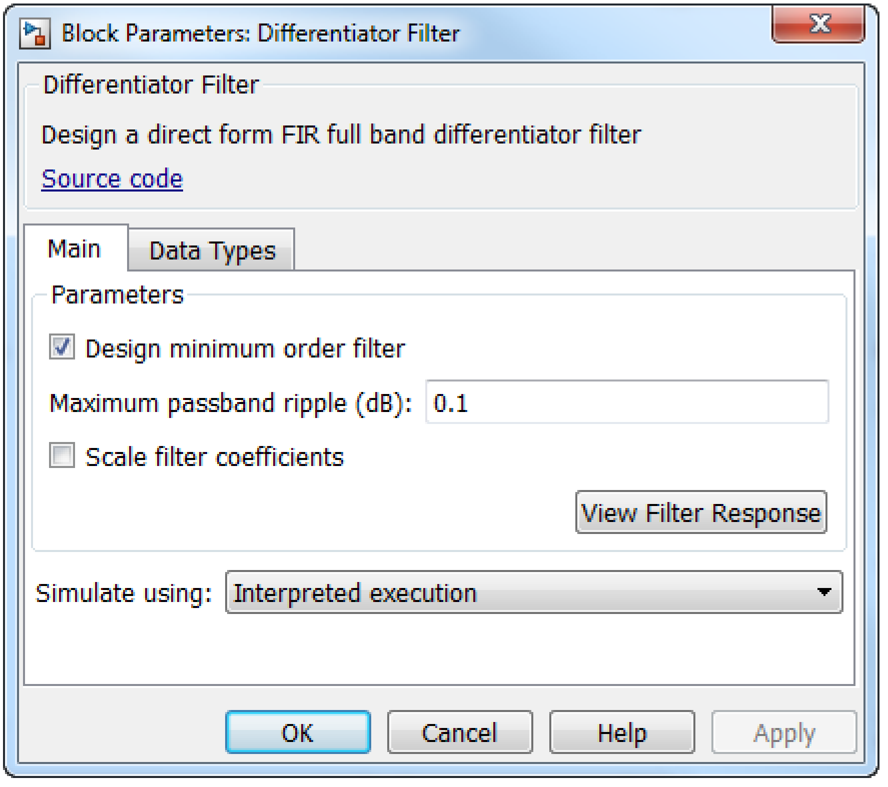
Main Tab



Design minimum order filter

When you select this check box, the block designs a filter with the minimum order, with the passband ripple specified in **Maximum passband ripple (dB)**. When you clear this check box, specify the order of the filter in **Filter order**.

By default, this check box is selected.

Filter order

Filter order of the differentiator filter, specified as an odd positive scalar integer. You can specify the filter order only when **Design minimum order filter** check box is not selected. The default is 31.

Maximum passband ripple (dB)

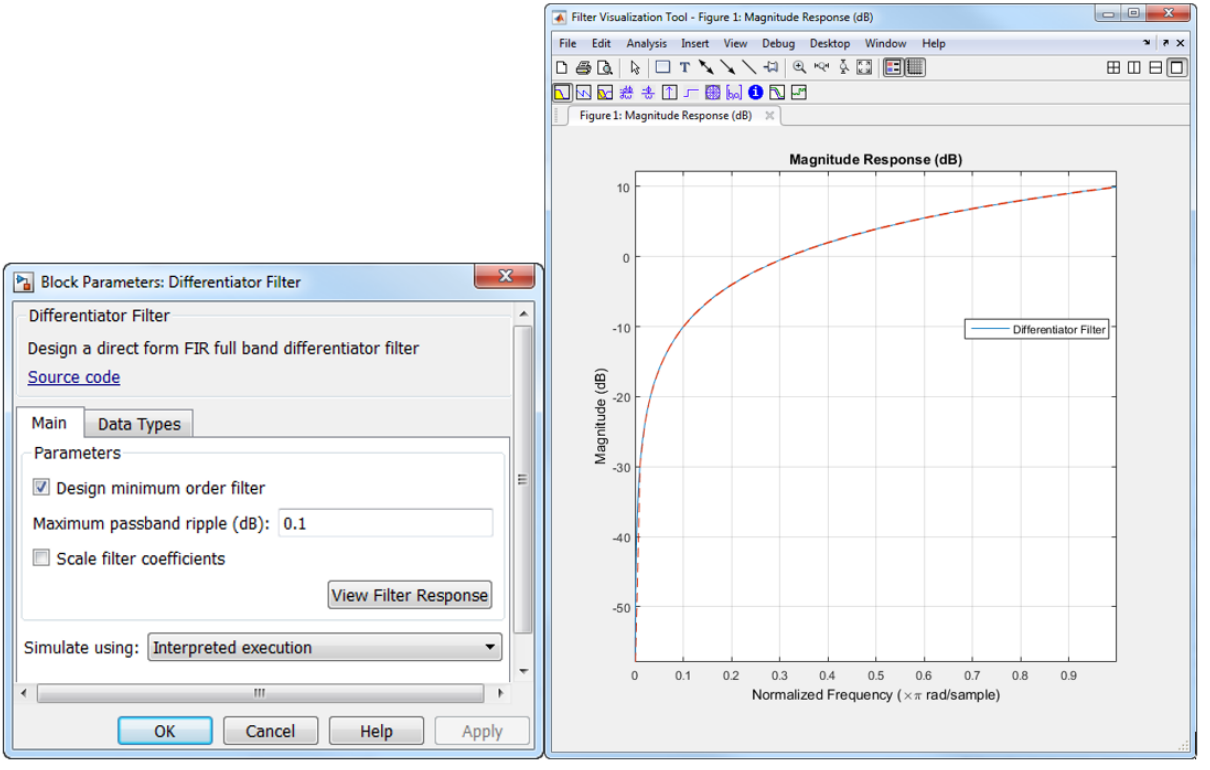
Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB. The default is `0.1`.

Scale filter coefficients

When you select this check box, the filter coefficients are scaled to preserve the input dynamic range. By default, this check box is not selected.

View Filter Response

Opens the Filter Visualization Tool (`fvtool`) and displays the magnitude and phase response of the Differentiator Filter block. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

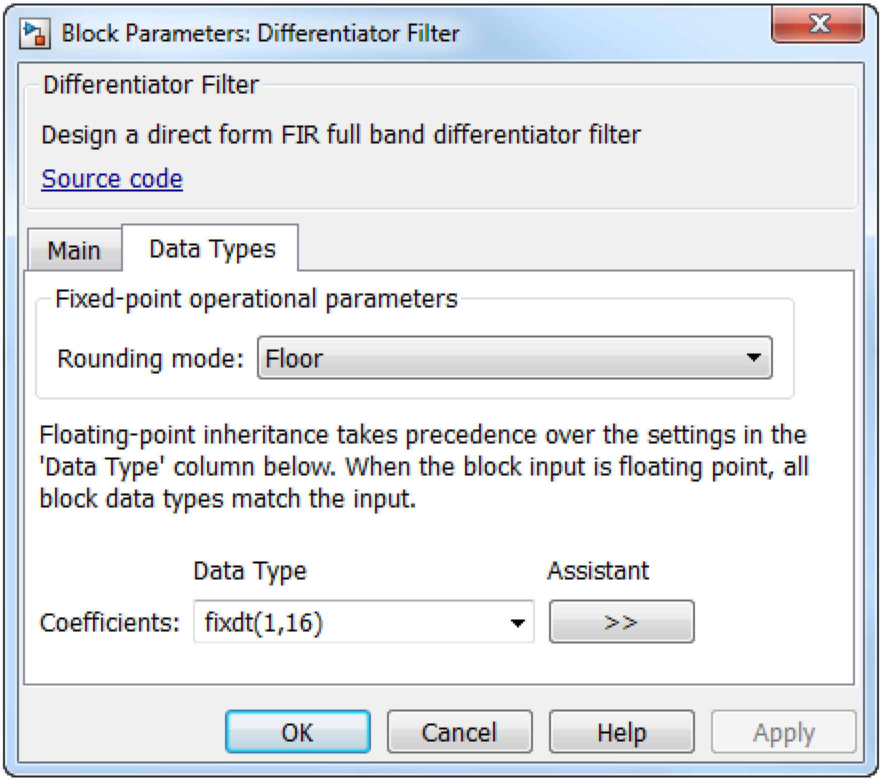
- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed than `Code generation`.

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values such that the coefficients occupy the maximum representable range without overflowing.

- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16` and fraction length `0`. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16, 15)`). Specify the sign mode of this data type as `[ ]` or `true`.
- `Refresh Data Type` — Refresh to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

The word length of the output is same as the word length of the input. The fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the block computes the fraction length, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

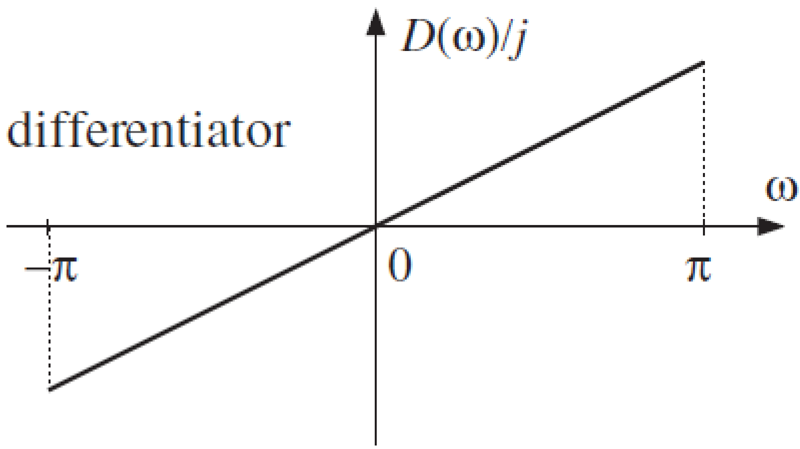
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)

Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \le \omega \le \pi$.



The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M-1-n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If *M* is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0\ 2\pi f_p]$, where f_p is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If *M* is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order mode

Select either `Minimum` or `Specify` (the default). Selecting `Specify` enables the **Order** option so you can enter the filter order.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`. The default order is 31.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are `Unconstrained` and `Passband edge and stopband edge`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands. These parameters are only available for minimum-order designs.

Magnitude constraints

This option is only available when you specify the order of your filter design. The available **Magnitude constraints** depend on the value of the **Frequency constraints** parameter. When you set the **Frequency constraints** parameter to `Unconstrained`, the **Magnitude constraints** parameter must also be `Unconstrained`. When you set the **Frequency constraints** parameter to `Passband edge and stopband edge`, the **Magnitude constraints** parameter can be `Unconstrained`, `Passband ripple`, or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2006b

Digital Down-Converter

Translate digital signal from Intermediate Frequency (IF) band to baseband and decimate it

Library

Signal Operations

`dspsigops`

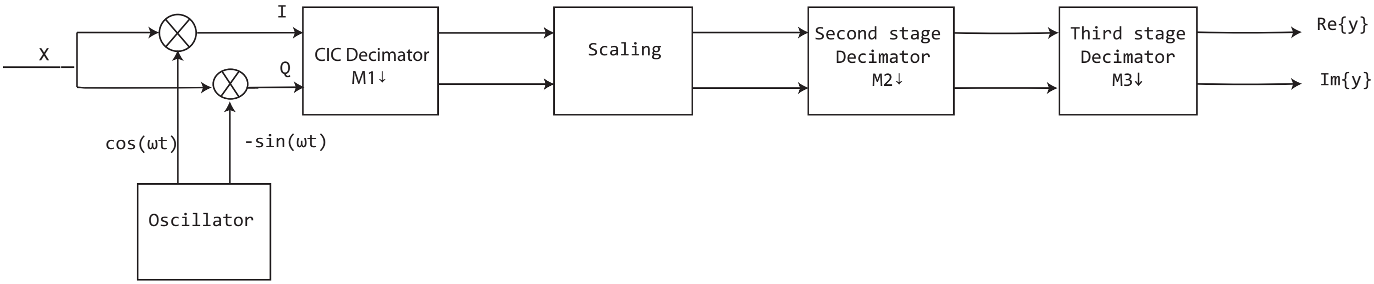
Description

The Digital Down-Converter (DDC) block converts a digitized real signal, centered at an intermediate frequency (IF) to a baseband complex signal centered at zero frequency. The DDC block downsamples the frequency down-converted signal using a cascade of three decimation filters. This block designs the decimation filters according to the filter parameters set in the block dialog box.

Structure

This block brings the capabilities of dsp.DigitalDownConverter System object to the Simulink environment.

The DDC block consists of a CIC decimator, a CIC compensator, and a FIR decimator. You can bypass the FIR Decimator, depending on how you set the DDC block parameters.



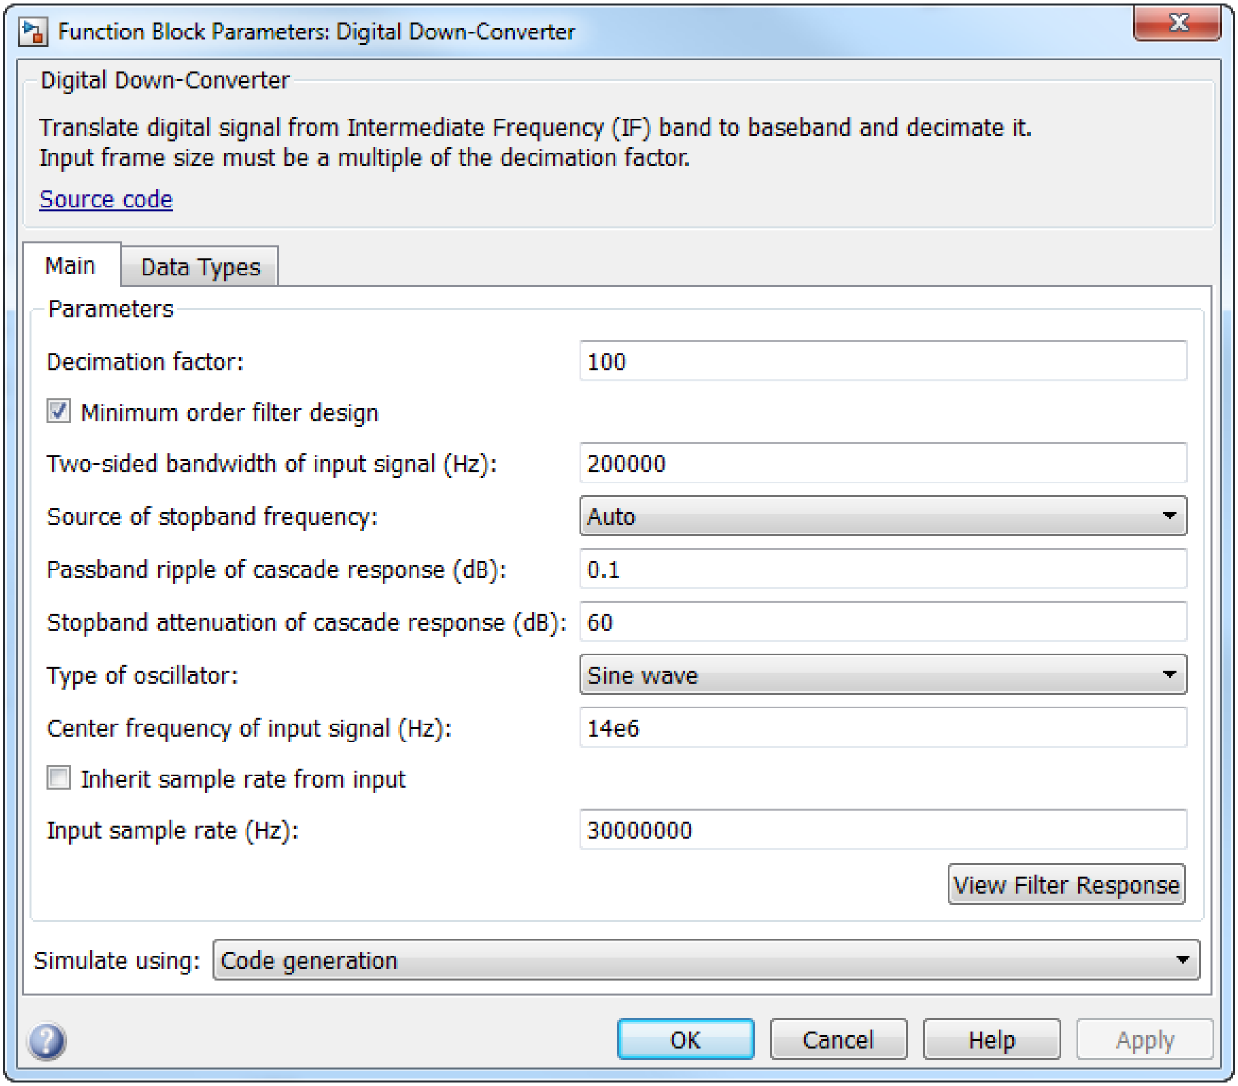
For more information on the structure that the DDC block uses, including the flow of fixed-point input, see the “Construction” on page 4-559 section in `dsp.DigitalDownConverter`.

Examples

- “Digital Up and Down Conversion for Family Radio Service”

Dialog Box

Main Tab



Decimation factor

Decimation factor, specified as a positive integer scalar, or as a 1-by-2 or 1-by-3 vector of positive integers. The default is 100.

When you set this parameter to a scalar, the block chooses the decimation factors for each of the three filtering stages.

When you set this parameter to a 1-by-2 vector, the block bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements, respectively. Both elements of **Decimation factor** must be greater than 1.

When you set this parameter to a 1-by-3 vector, the *i*th element of the vector specifies the decimation factor for the *i*th filtering stage. The first and second elements of **Decimation factor** must be greater than 1, and the third element must be 1 or 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the requirements specified in these parameters:

- **Passband ripple of cascade response (dB)**
- **Stopband attenuation of cascade response (dB)**
- **Two sided bandwidth of input signal (Hz)**
- **Source of stopband frequency**
- **Stopband frequency (Hz)**

When you clear this check box, the block designs filters with orders that you specify in **Number of sections of CIC decimator**, **Order of CIC compensation filter stage**, and **Order of third filter stage**. The filter designs meet the passband and stopband frequency specifications that you set in **Two sided bandwidth of input signal (Hz)**, **Source of stopband frequency**, and **Stopband frequency (Hz)**. By default, this check box is selected.

Number of sections of CIC decimator

Number of sections in the CIC decimator, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is 3.

Order of CIC compensation filter stage

Order of the CIC compensation filter stage, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is 12.

Order of third filter stage

Order of the third filter stage, specified as an even positive integer scalar. When you specify **Decimation factor** as a 1-by-2 vector, the block ignores the value of **Order of third filter stage** because the block bypasses the third filter stage. This parameter applies when you clear the **Minimum order filter design** check box. The default is `10`.

Two sided bandwidth of input signal (Hz)

Two sided bandwidth of the input signal, specified as a positive integer scalar. The block sets the passband frequency of the cascade of filters to half the value that you specify in this parameter. Set the value of this parameter to less than **Input sample rate/Decimation factor**. When you select the **Inherit sample rate from input** check box, then set this value to less than ((1/*Ts*) / **Decimation factor**), where *Ts* is the sample time of the input signal. The default is `200` kHz.

Source of stopband frequency

Source of the stopband frequency, specified as `Auto` or `Property`. The default is `Auto`.

When you set this parameter to `Auto`, the block places the cutoff frequency of the cascade filter response at approximately $F_c = SampleRate / M/2$ Hz, where M is the total decimation factor specified in **Decimation factor**. *SampleRate* is computed as 1/ *Ts*, where *Ts* is the sample time of the input signal. The block computes the stopband frequency as $F_{stop} = F_c + (TW / 2)$. TW is the transition bandwidth of the cascade response, computed as $2\times(F_c - F_p)$, where the passband frequency, F_p, equals *Bandwidth*/2.

When you set this parameter to `Property`, specify the source in **Stopband frequency (Hz)**.

Stopband frequency (Hz)

Stopband frequency, specified as a double-precision positive scalar. This parameter applies when you set the **Source of stopband frequency** to `Property`. The default is `150` kHz.

Passband ripple of cascade response (dB)

Passband ripple of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the passband ripple that you specify in **Passband ripple of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design**. The default is `0.1` dB.

Stopband attenuation of cascade response (dB)

Stopband attenuation of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the stopband attenuation that you specify in **Stopband attenuation of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design**. The default is `60`.

Type of oscillator

Oscillator type, specified as one of the following:

- `Sine wave` (default) — The block performs frequency down conversion on input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function.
- `NCO` — The block performs frequency down conversion on input signal with a complex exponential obtained using a numerically controlled oscillator (NCO).
- `Input port` — The block performs frequency down conversion on input signal using the complex signal that you provide through the input port of the block.
- `None` — The mixer stage in the block is not present and the block acts as three stage cascaded decimator.

Center frequency of input signal (Hz)

Center frequency of the input signal, specified as a double-precision positive scalar that is less than or equal to half the sample rate. The block downconverts the input signal from the passband center frequency, which you specify in **Center frequency of input signal (Hz)**, to `0` Hz. This parameter applies when you set **Type of oscillator** to `Sine wave` or `NCO`. The default is `14e6`.

Number of NCO accumulator bits

Number of NCO accumulator bits, specified as an integer scalar in the range `[1 128]`. This parameter applies when you set **Type of oscillator** to `NCO`. The default is `16`.

Number of NCO quantized accumulator

Number of NCO quantized accumulator bits, specified as an integer scalar in the range `[1 128]`. This value must be less than the value you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to `NCO`. The default is `12`.

Dither control for NCO

When you select this check box, a number of dither bits specified in **Number of NCO dither bits** applies dither to the NCO signal. This parameter applies when you set **Type of oscillator** to `NCO`. By default, this check box is selected.

Number of NCO dither bits

Number of NCO dither bits, specified as an integer scalar smaller than the number of accumulator bits that you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to NCO and select the **Dither control for NCO**. The default is 4.

Inherit sample rate from input

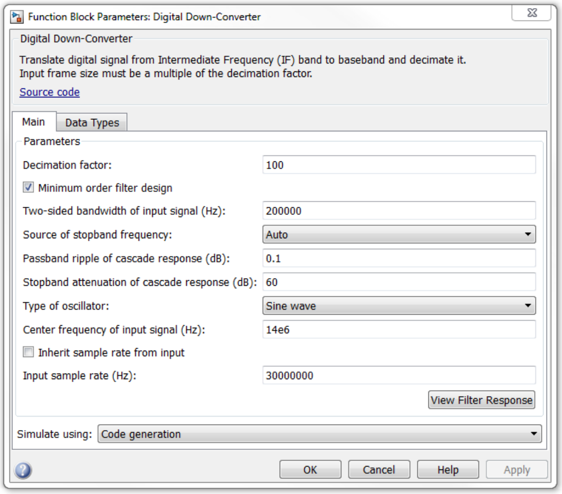
When you select this check box, sample rate is computed as N/ *Ts*, where *N* is the frame size of the input signal, and *Ts* is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

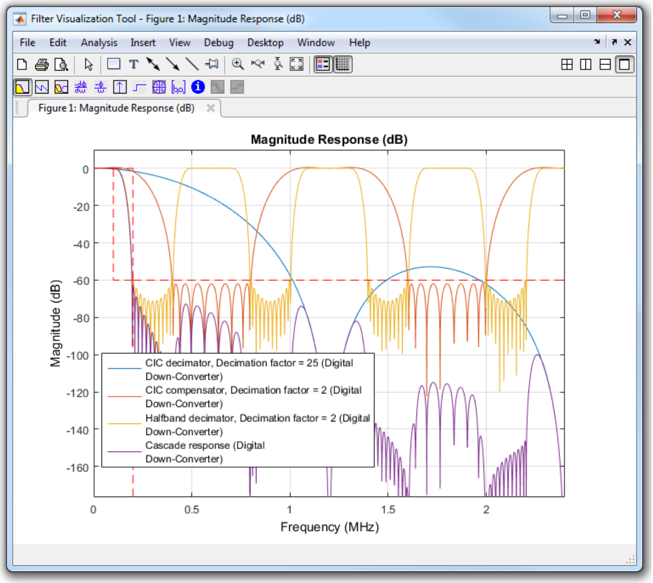
Input sample rate

Input sample rate, specified as a positive scalar value, greater than or equal to twice the value of the **Center frequency of input signal (Hz)**. The default is 30 MHz. This parameter applies when you clear the **Inherit sample rate from input** check box.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of each stage as well as the cascade of stages in the Digital Down-Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

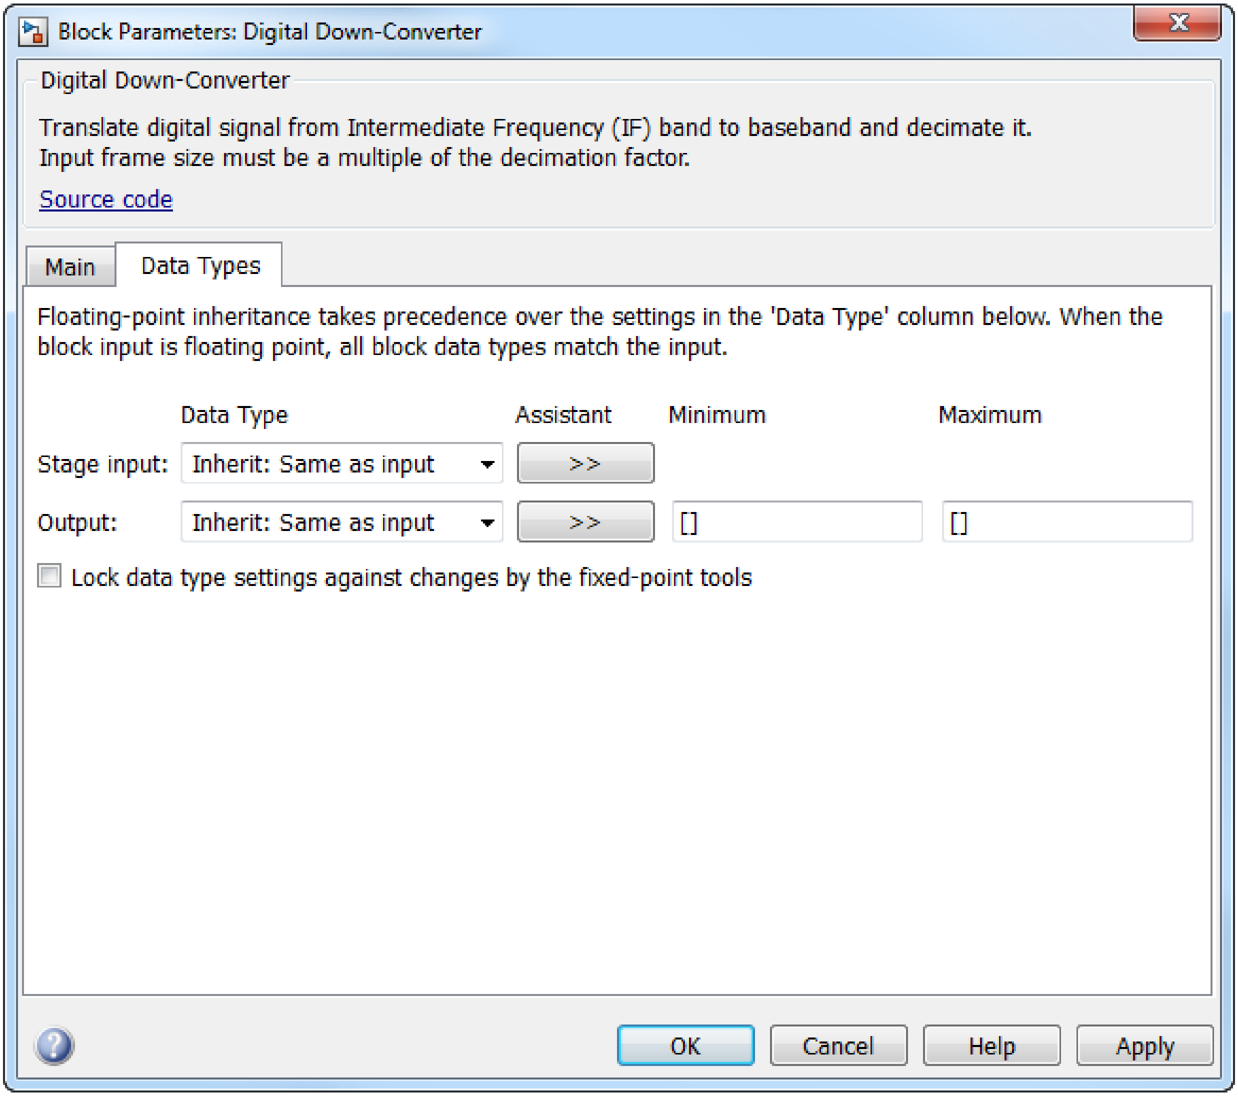
- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types tab



Stage input

Data type of the input of the first, second, and third filter stages. You can set this parameter to:

- `Inherit: Same as input` (default) — The block inherits the **Stage input** from the input signal.
- `fixdt([],16,0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([],16,15)`. Specify the sign mode of this data type as `[]` or `true`.

Click the **Show data type assistant** button 

to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output

Data type of the block output. You can set this parameter to:

- `Inherit: Same as input` (default) — The block Inherits the output datatype from the input.
- `fixdt([],16,0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([],16,15)`. Specify the sign mode of this data type as `[]` or `true`.

Click the **Show data type assistant** button 

to display the data type assistant, which helps you set the **Output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Minimum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Maximum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers

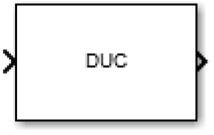
Introduced in R2015a

Digital Up-Converter

Interpolate digital signal and translate it from baseband to Intermediate Frequency (IF) band



Library

Signal Operations

`dspsigops`

Description

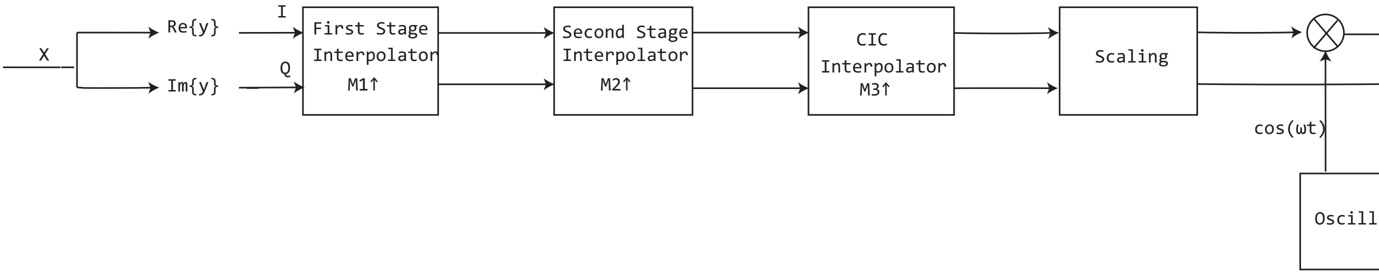
The Digital Up-Converter (DUC) block converts a complex digital baseband signal to a real passband signal.

The DUC block upsamples the input signal using a cascade of three interpolation filters. The block frequency upconverts the upsampled signal by multiplying it by the specified center frequency of the output signal. This block designs the interpolation filters according to the filter parameters that you set in the block dialog.

Structure

This block brings the capabilities of dsp.DigitalUpConverter System object to the Simulink environment.

The DUC block consists of a FIR interpolator, a CIC compensator, and a CIC interpolator. You can bypass the FIR interpolator, depending on how you set the DUC block parameters.



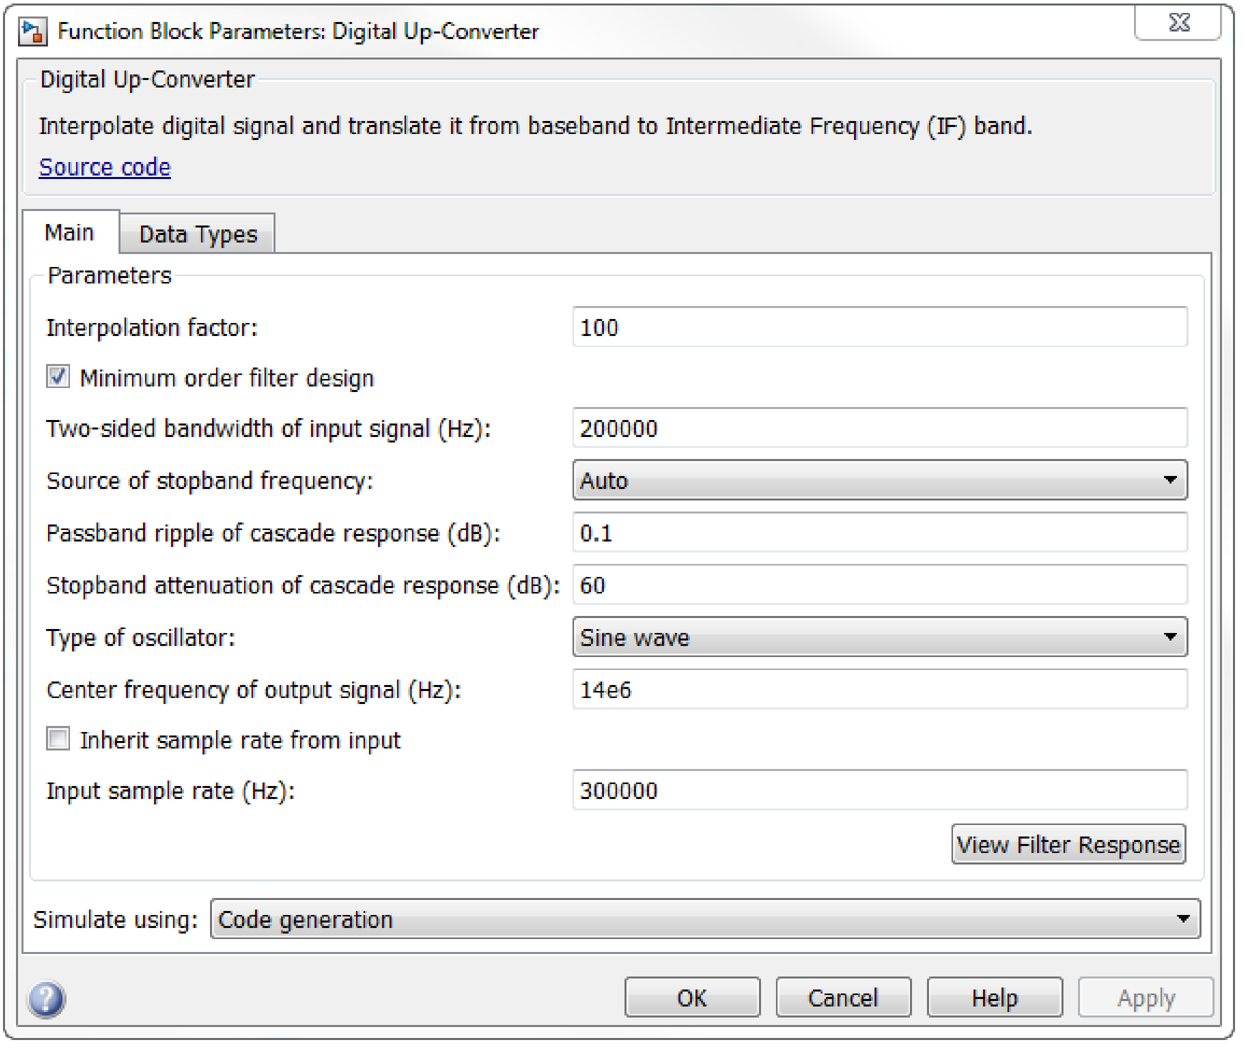
For more information on the structure that the DUC block uses, including the flow of fixed-point input, see the Construction on page 4-597 section in `dsp.DigitalUpConverter`.

Examples

- "Digital Up and Down Conversion for Family Radio Service"

Dialog Box

Main Tab



Interpolation factor

Interpolation factor, specified as a positive integer scalar, or as a 1-by-2 or 1-by-3 vector of positive integers. The default is 100.

When you set this parameter to a scalar, the block chooses the interpolation factors for each of the three filtering stages.

When you set this parameter to a 1-by-2 vector, the block bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. Both elements of the **Interpolation factor** must be greater than 1.

When you set this parameter to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of **Interpolation factor** must be greater than 1, and the first element must be 1 or 2.

Minimum order filter design

When you select this check box, the block designs filters with the minimum order that meets the requirements specified in these parameters:

- **Passband ripple of cascade response (dB)**
- **Stopband attenuation of cascade response (dB)**
- **Two sided bandwidth of input signal (Hz)**
- **Source of stopband frequency**
- **Stopband frequency (Hz)**

When you clear this check box, the block designs filters with orders that you specify in **Order of first filter stage**, **Order of CIC compensation filter stage**, and **Number of sections of CIC interpolator**. The filter designs meet the passband and stopband frequency specifications that you set in **Two sided bandwidth of input signal (Hz)**, **Source of stopband frequency**, and **Stopband frequency (Hz)**. By default, this check box is selected.

Order of first filter stage

Order of the first filter stage, specified as an even positive integer scalar. When you specify **Interpolation factor** as a 1-by-2 vector, the block ignores the value of **Order of first filter stage** because the block bypasses the first filter stage. This parameter applies when you clear the **Minimum order filter design** check box. The default is 10.

Order of CIC compensation filter stage

Order of the CIC compensation filter stage, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is `12`.

Number of sections of CIC interpolator

Number of sections in the CIC interpolator, specified as a positive integer scalar. This parameter applies when you clear the **Minimum order filter design** check box. The default is `3`.

Two sided bandwidth of input signal (Hz)

Two sided bandwidth of the input signal, specified as a positive integer scalar. The block sets the passband frequency of the cascade of filters to half the value that you specify in this parameter. The default is 200 kHz.

Source of stopband frequency

Source of the stopband frequency, specified as `Auto` or `Property`. The default is `Auto`.

When you set this parameter to `Auto`, the block places the cutoff frequency of the cascade filter response at approximately $F_c = SampleRate/2$ Hz, and computes the stopband frequency as $F_{stop} = F_c + TW/2$. *SampleRate* is computed as `1/` *Ts*, where *Ts* is the sample time of the input signal. *TW* is the transition bandwidth of the cascade response, computed as $2\times(F_c - F_p)$, and the passband frequency, F_p, equals *Bandwidth*/2.

When you set this parameter to `Property`, specify the source in **Stopband frequency (Hz)**.

Stopband frequency (Hz)

Stopband frequency, specified as a double-precision positive scalar. This parameter applies when you set the **Source of stopband frequency** to `Property`. The default is `150` kHz.

Passband ripple of cascade response (dB)

Passband ripple of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the passband ripple that you specify in **Passband ripple of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design** check box. The default is `0.1` dB.

Stopband attenuation of cascade response (dB)

Stopband attenuation of the cascade response, specified as a double-precision positive scalar. When you select the **Minimum order filter design** check box, the block designs the filters so that the cascade response meets the stopband attenuation that you specify in **Stopband attenuation of cascade response (dB)**. This parameter applies when you select the **Minimum order filter design** check box. The default is `60` dB.

Type of oscillator

Oscillator type, specified as one of the following:

- `Sine wave` (default) — The block frequency upconverts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function.
- `NCO` — The block performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

Center frequency of output signal (Hz)

Center frequency of the output signal, specified as a double-precision positive scalar. The value of this parameter must be less than or equal to half the product of the *SampleRate* times the total interpolation factor. *SampleRate* is computed as `1/` *Ts*, where *Ts* is the sample time of the input signal. The block up converts the input signal so that the output spectrum centers at the frequency you specify in **Center frequency of output signal (Hz)**. The default is `14` MHz.

Number of NCO accumulator bits

Number of NCO accumulator bits, specified as an integer scalar in the range `[1 128]`. This parameter applies when you set **Type of oscillator** to `NCO`. The default is `16`.

Number of NCO quantized accumulator

Number of NCO quantized accumulator bits, specified as an integer scalar in the range `[1 128]`. This value must be less than the value you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to `NCO`. The default is `12`.

Dither control for NCO

When you select this check box, a number of dither bits specified in **Number of NCO dither bits** applies dither to the NCO signal. This parameter applies when you set **Type of oscillator** to `NCO`. By default, this check box is selected.

Number of NCO dither bits

Number of NCO dither bits, specified as an integer scalar smaller than the number of accumulator bits that you specify in **Number of NCO accumulator bits**. This parameter applies when you set **Type of oscillator** to NCO and select the **Dither control for NCO**. The default is 4.

Inherit sample rate from input

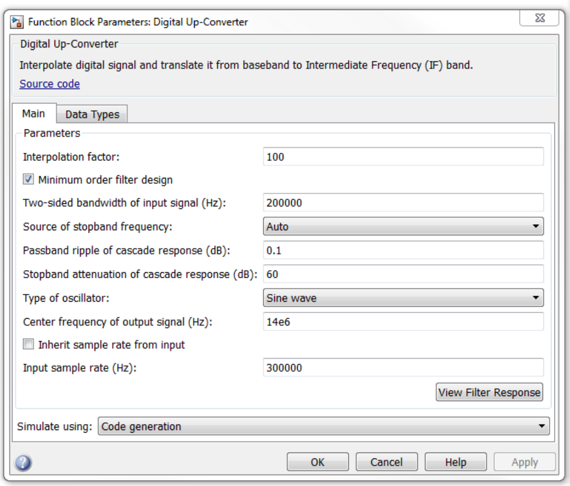
When you select this check box, sample rate is computed as N/ *Ts*, where *N* is the frame size of the input signal, and *Ts* is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

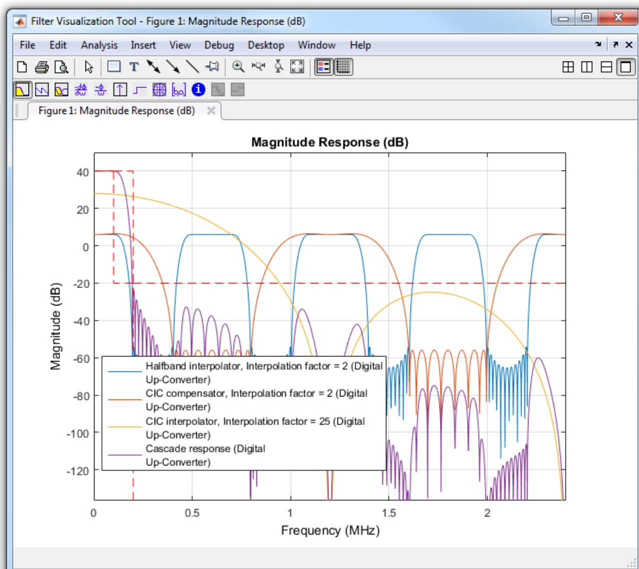
Input sample rate

Input sample rate, specified as a positive scalar. The value of this parameter multiplied by the total interpolation factor must be greater than or equal to twice the value of the **Center frequency of output signal (Hz)**. The default is 30 MHz. This parameter applies when you clear the **Inherit sample rate from input** check box.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of each stage as well as the cascade of stages in the Digital Up-Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

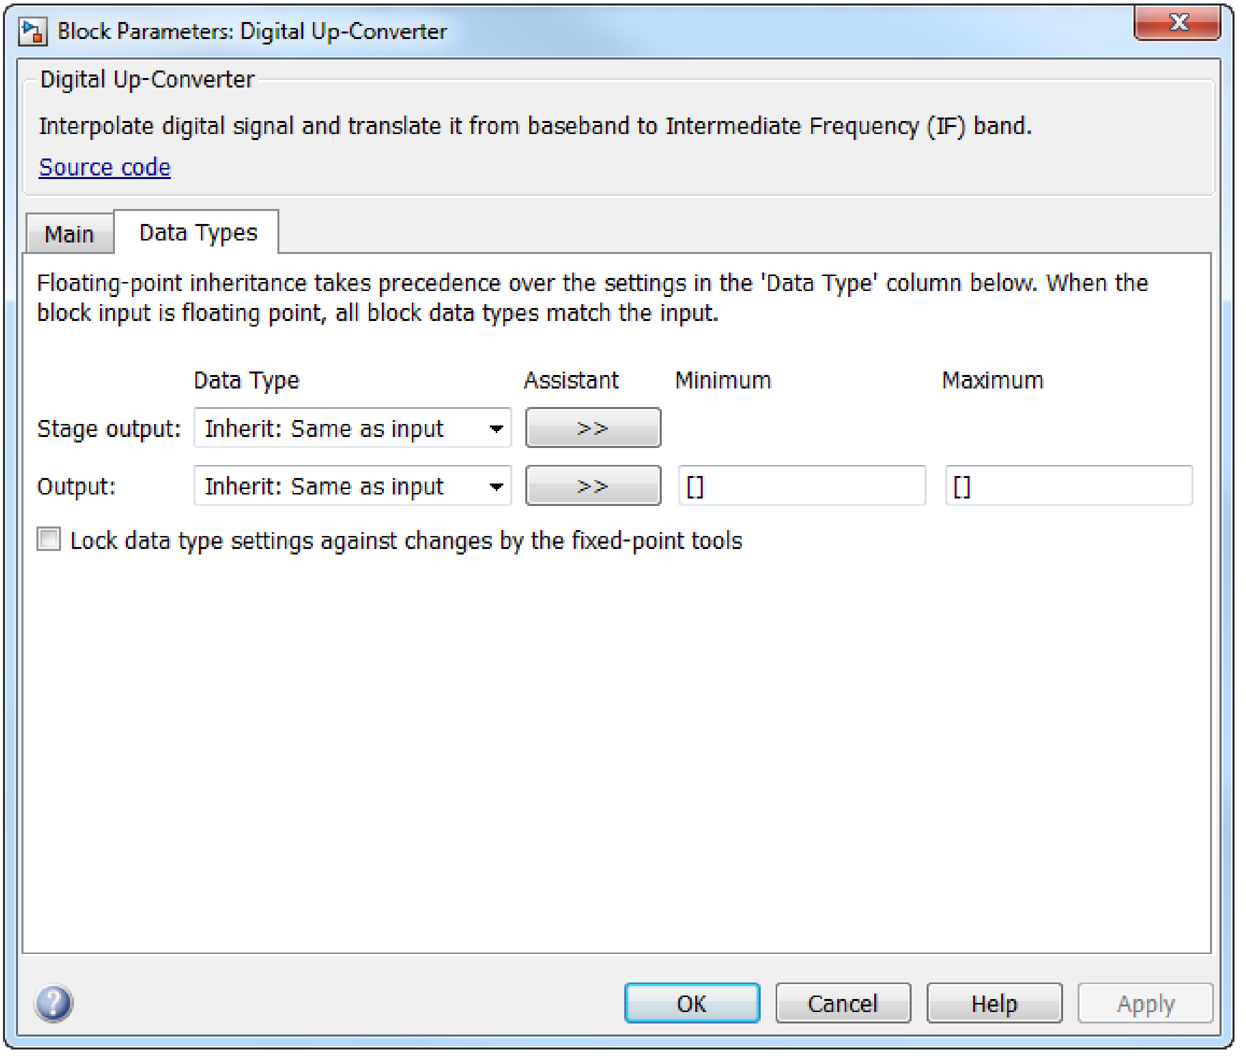
Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types Tab



Stage output

Data type of the output of the first, second, and third filter stages. You can set this parameter to:

- `Inherit: Same as input` (default) — The block inherits the **Stage output** from the input signal.
- `fixdt([],16,0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([],16,15)`. Specify the sign mode of this data type as `[]` or `true`.

The block casts the data at the output of each filter stage according to the value you set in this parameter. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage output parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output

Data type of the block output. You can set this parameter to:

- `Inherit: Same as input` (default) — The block Inherits the output datatype from the input.
- `fixdt([],16,0)` — Fixed-point data type with binary point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([],16,15)`. Specify the sign mode of this data type as `[]` or `true`.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the **Output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Minimum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Maximum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, 32- and 64-bit signed integers

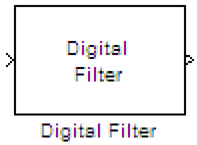
Digital Filter (Obsolete)

Filter each channel of input over time using static or time-varying digital filter implementations



Library

Filtering / Filter Implementations

`dsparch4`

Description

Note: Use of Digital Filter block in future releases is not recommended. Existing instances will continue to operate, but certain functionality will be disabled. See "Functionality being removed or replaced for blocks and System objects". We strongly recommend using one of `Discrete FIR Filter`, Discrete Filter, `Biquad Filter`, or `Allpole Filter` in new designs.

You can use the Digital Filter block to efficiently implement a floating-point or fixed-point filter for which you know the coefficients, or that is already defined in a `dfilt` object. The block independently filters each channel of the input signal with a specified digital IIR or FIR filter. The block can implement *static filters* with fixed coefficients, as well as *time-varying filters* with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. You must set the **Input processing** parameter to specify how the block interprets the input signal. You can select one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as an independent channel.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as an individual channel.

The output dimensions always match those of the input signal. The outputs of this block numerically match the outputs of the `Digital Filter Design` block and of the `dfilt` object.

Note: The Digital Filter block has direct feedthrough, so if you connect the output of this block back to its input you get an algebraic loop. For more information on direct feedthrough and algebraic loops, see "Algebraic Loops" (Simulink).

Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Supported Filter Structures

When you select **Discrete-time filter object (DFILT)**, the following `dfilt` structures are supported:

- `dfilt.df1`
- `dfilt.df1t`
- `dfilt.df2`
- `dfilt.df2t`
- `dfilt.df1sos`
- `dfilt.df1tsos`
- `dfilt.df2sos`
- `dfilt.df2tsos`
- `dfilt.dffir`
- `dfilt.dffirt`
- `dfilt.dfsymfir`
- `dfilt.dfasymfir`
- `dfilt.latticear`
- `dfilt.latticemamin`

When you select **Dialog parameters** or **Input port(s)**, the list of filter structures offered in the **Filter structure** parameter depends on whether you set the **Transfer function type** to `IIR (poles & zeros)`, `IIR (all poles)`, or `FIR (all zeros)`, as summarized in the following table.

Note Each structure listed in the table below supports both fixed-point and floating-point signals.

The table also shows the vector or matrix of filter coefficients you must provide for each filter structure.

Filter Structures and Filter Coefficients

Transfer Function Type	Supported Filter Structures	Filter Coefficient Specification

IIR (poles & zeros)	`Direct form I`
	`Direct form I transposed`
	`Direct form II`
	`Direct form II transposed`
		• Numerator coefficients vector [b0, b1, b2, ..., bn]
		• Denominator coefficients vector [a0, a1, a2, ..., am]
		See Special Consideration for the Leading Denominator Coefficient on page 2-530.

	`Biquadratic direct form I (SOS)`
	`Biquadratic direct form I transposed (SOS)`
	`Biquadratic direct form II (SOS)`
	`Biquadratic direct form II transposed (SOS)`
		• *M*-by-6 second-order section (SOS) matrix.
		• Scale values

IIR (all poles)	`Direct form` `Direct form transposed`	Denominator coefficients vector [a0, a1, a2, ..., am] See Special Consideration for the Leading Denominator Coefficient on page 2-530.
	`Lattice AR`	Reflection coefficients vector [k1, k2, ..., kn]

FIR (all zeros)	`Direct form`
	`Direct form symmetric`
	`Direct form antisymmetric`
	`Direct form transposed`
		Numerator coefficients vector [b0, b1, b2, ..., bn]

	`Lattice MA`	Reflection coefficients vector [k1, k2, ..., kn]

Special Considerations for the Leading Denominator Coefficient

In some cases, the Digital Filter block requires the leading denominator coefficient (a_0) to be 1. This requirement applies under the following conditions:

- The Digital Filter block is operating in a fixed-point mode. The block operates in a fixed-point mode when at least one of the following statements is true:
  - The input to the Digital Filter block has a fixed-point or integer data type.
  - The **Fixed-point instrumentation mode** parameter under **Analysis > Fixed Point Tool** has a setting of `Minimums, maximums and overflows`.
- The **Coefficient source** has a setting of `Dialog` or `Input port(s)`.

Note: If you are working in one of the fixed-point situations described in the previous bullet, and the **Coefficient source** is set to `Input port(s)`, you must select the **First denominator coefficient = 1, remove a0 term in the structure** check box.

- The **Transfer function type** and **Filter structure** parameters are set to one of the combinations described in the following table.

Transfer function type	Filter structure
IIR (poles & zeros)	`Direct form I`
	`Direct form I transposed`
	`Direct form II`
	`Direct form II transposed`
IIR (all poles)	`Direct form`
	`Direct form transposed`

The Digital Filter block produces an error if you use it in one of the these configurations and your leading denominator coefficient (a_0) does not equal 1. To resolve the error, set your leading denominator coefficient to 1 by scaling all numerator and denominator coefficients by a factor of a_0.

Specifying Initial Conditions

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial conditions** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial condition values you must specify, and how to specify them, see the following table on Valid Initial Conditions and Number of Delay Elements (Filter States). The **Initial conditions** parameter can take one of four forms as described in the following table.

Valid Initial Conditions

Initial Condition	Examples	Description
Scalar	`5` Each delay element for each channel is set to `5`.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: [d_1 d_2] The delay elements for all channels are d1 and d2.	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a 3-channel input signal and a filter with two delay elements: [d_1 d_2 D_1 D_2 d_1 d_2] or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ • The delay elements for channel 1 are d_1 and d_2. • The delay elements for channel 2 are D_1 and D_2. • The delay elements for channel 3 are $d_1$and d_2.	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: • The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). • The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.

Initial Condition	Examples	Description
Empty matrix	`[ ]` Each delay element for each channel is set to `0`.	The empty matrix, `[ ]`, is equivalent to setting the **Initial conditions** parameter to the scalar value `0`.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements per Channel

`Direct form`
`Direct form transposed`
`Direct form symmetric`
`Direct form antisymmetric`
	`#_of_filter_coeffs-1`

`Direct form I` `Direct form I transposed`	• `#_of_zeros-1` • `#_of_poles-1`
`Direct form II` `Direct form II transposed`	`max(#_of_zeros, #_of_poles)-1`

`Biquadratic direct form I (SOS)`
`Biquadratic direct form I transposed (SOS)`
`Biquadratic direct form II (SOS)`
`Biquadratic direct form II transposed (SOS)`
	`2 * #_of_filter_sections`

`Lattice AR` `Lattice MA`	`#_of_reflection_coeffs`

State Logging

Simulink enables you to log the states in your model to the MATLAB workspace. The following table indicates which filter structures of the Digital Filter block support the Simulink state logging feature. See "States" (Simulink) for more information.

Transfer Function Type	Filter Structure	State Logging Supported
IIR (poles & zeros)	`Direct form I`	No
	`Direct form I transposed`	Yes
	`Direct form II`	No
	`Direct form II transposed`	Yes
	`Biquadratic direct form I (SOS)`	Yes
	`Biquadratic direct form I transposed (SOS)`	Yes
	`Biquadratic direct form II (SOS)`	Yes
	`Biquadratic direct form II transposed (SOS)`	Yes
IIR (all poles)	`Direct form`	No
	`Direct form transposed`	Yes
	`Lattice AR`	Yes
FIR (all zeros)	`Direct form`	No
	`Direct form symmetric`	No
	`Direct form antisymmetric`	No
	`Direct form transposed`	Yes
	`Lattice MA`	Yes

Fixed-Point Data Types

All structures supported by the Digital Filter block support fixed-point data types. You can specify intermediate fixed-point data types for quantities such as the coefficients, accumulator, and product output for each filter structure. See "Filter Structure

Diagrams" on page 2-549 for diagrams depicting the use of these intermediate fixed-point data types in each filter structure.

Dialog Box

Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

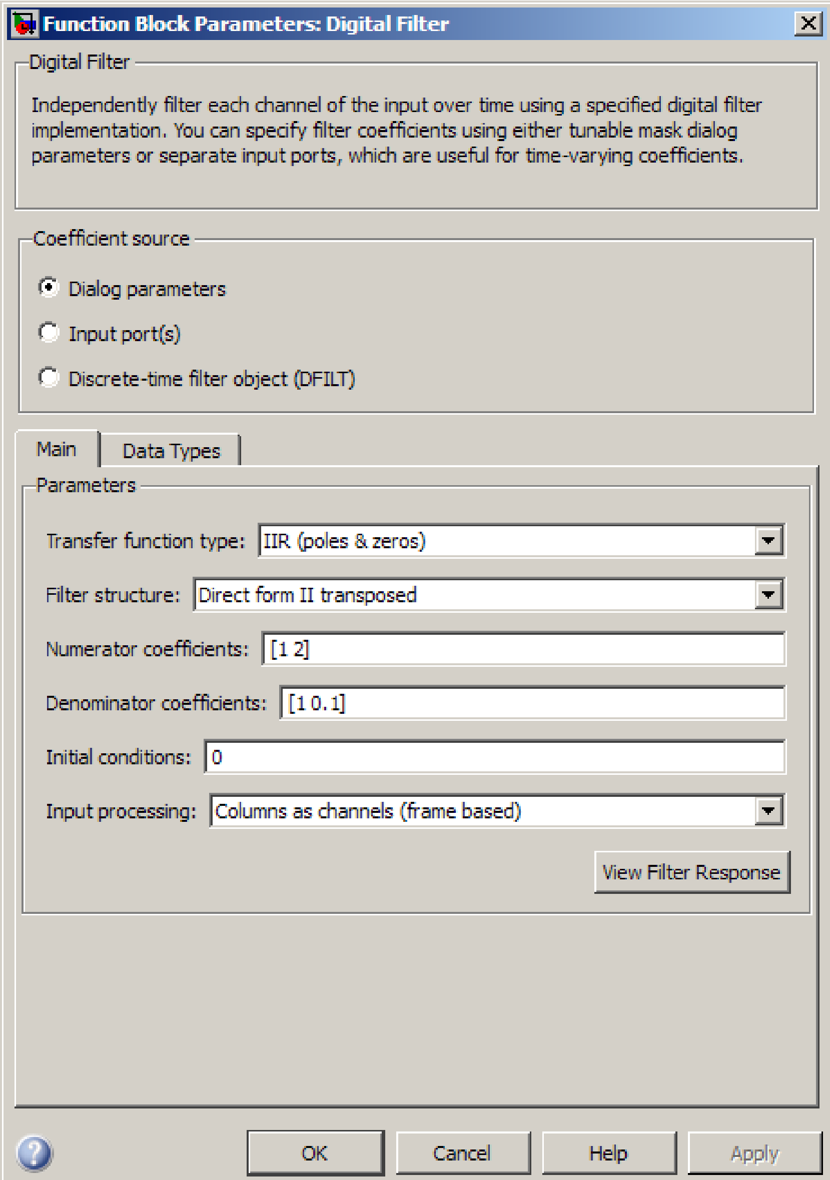
- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Different items appear on the Digital Filter block dialog depending on whether you select **Dialog parameters**, **Input port(s)**, or **Discrete-time filter object (DFILT)** in the **Coefficient source** group box. See the following sections for details:

- "Specify Filter Characteristics in Dialog and/or Through Input Ports" on page 2-535
- "Specify Discrete-Time Filter Object" on page 2-545

Specify Filter Characteristics in Dialog and/or Through Input Ports

The **Main** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, as noted.



Transfer function type

Select the type of transfer function of the filter; `IIR (poles & zeros)`, `IIR (all poles)`, or `FIR (all zeros)`. See "Supported Filter Structures" on page 2-528 for more information.

Filter structure

Select the filter structure. The selection of available structures varies depending the setting of the **Transfer function type** parameter. See "Supported Filter Structures" on page 2-528 for more information.

Numerator coefficients

Specify the vector of numerator coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with numerator coefficients. Tunable (Simulink).

Denominator coefficients

Specify the vector of denominator coefficients of the filter's transfer function.

In some cases, the leading denominator coefficient (a0) must be 1. See Special Consideration for the Leading Denominator Coefficient on page 2-530 for more information.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with denominator coefficients. Tunable (Simulink).

Reflection coefficients

Specify the vector of reflection coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with reflection coefficients. Tunable (Simulink).

SOS matrix (Mx6)

Specify an *M*-by-6 *SOS matrix* containing coefficients of a second-order section (SOS) filter, where *M* is the number of sections. You can use the `ss2sos` and `tf2sos` functions from Signal Processing Toolbox software to check whether your SOS matrix is valid.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. Tunable (Simulink).

Scale values

Specify the scale values to be applied before and after each section of a biquadratic filter.

- If you specify a scalar, that value is applied before the first filter section. The rest of the scale values are set to 1.
- You can also specify a vector with $M + 1$ elements, assigning a different value to each scale. See “Filter Structure Diagrams” on page 2-549 for diagrams depicting the use of scale values in biquadratic filter structures.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. Tunable (Simulink).

First denominator coefficient = 1, remove a0 term in the structure

Select this parameter to reduce the number of computations the block must make to produce the output by omitting the `1 / a`$_0$ term in the filter structure. The block output is invalid if you select this parameter when the first denominator filter coefficient is *not* always 1 for your time-varying filter.

This parameter is only enabled when the **Input port(s)** is selected *and* when the selected filter structure lends itself to this specification.

Coefficient update rate

Specify how often the block updates time-varying filters; once per sample or once per frame.

This parameter appears only when the following conditions are met:

- You specify **Input port(s)** in the Coefficient source group box.
- You set the **Input processing** parameter to `Columns as channels (frame based)`.

Initial conditions

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-530.

Initial conditions on zeros side

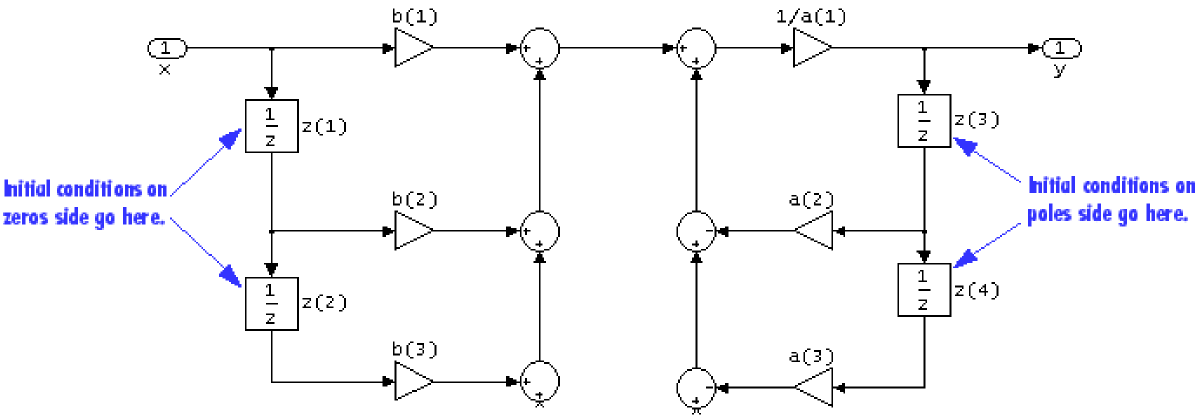
(Not shown in dialog above.) Specify the initial conditions for the filter states on the side of the filter structure with the zeros (b_0, b_1,b_2, ...); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles (a_k) and zeros (b_k). To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 2-530.

Initial conditions on poles side

(Not shown in dialog above). Specify the initial conditions for the filter states on the side of the filter structure with the poles (a_0, a_1,a_2, ...); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles (a_k) and zeros (b_k). To learn how to specify initial conditions, see "Specifying Initial Conditions" on page 2-530.



Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

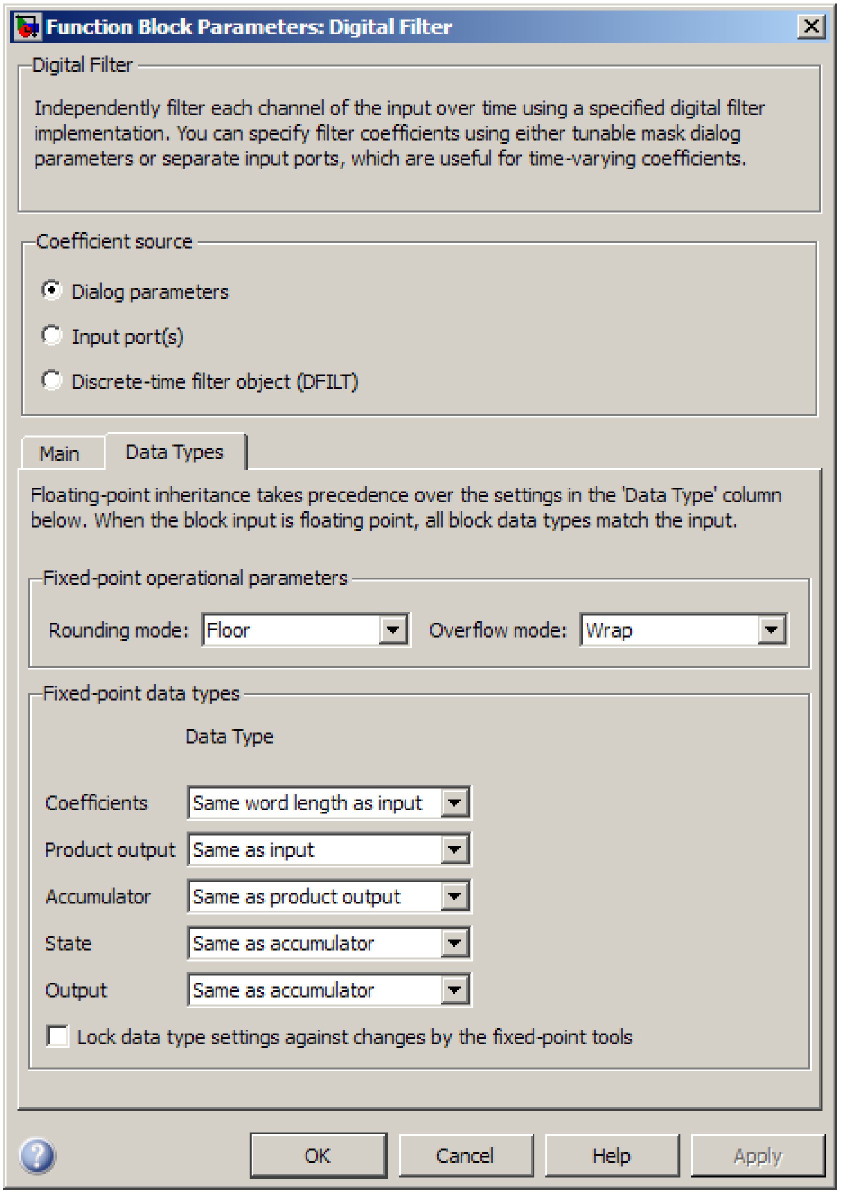
Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined by the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, depending on the filter structure and whether the coefficients are being entered via ports or on the block mask.



Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Overflow mode

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Section I/O

Choose how you specify the word length and the fraction length of the fixed-point data type going into and coming out of each section of a biquadratic filter. See "Filter Structure Diagrams" on page 2-549 for illustrations depicting the use of the section I/O data type in this block.

This parameter is only visible when the selected filter structure is biquadratic:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word and fraction lengths of the section input and output, in bits.
- When you select `Slope and bias scaling`, you can enter the word lengths, in bits, and the slopes of the section input and output. This block requires power-of-two slope and a bias of zero.

Tap sum

Choose how you specify the word length and the fraction length of the tap sum data type of a direct form symmetric or direct form antisymmetric filter. See "Filter Structure Diagrams" on page 2-549 for illustrations depicting the use of the tap sum data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form symmetric` or `Direct form antisymmetric`:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the tap sum accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the tap sum accumulator. This block requires power-of-two slope and a bias of zero.

Multiplicand

Choose how you specify the word length and the fraction length of the multiplicand data type of a direct form I transposed or biquadratic direct form I transposed filter. See “Filter Structure Diagrams” on page 2-549 for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`:

- When you select `Same as output`, these characteristics match those of the output to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the multiplicand data type, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the multiplicand data type. This block requires power-of-two slope and a bias of zero.

Coefficients

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “Filter Structure Diagrams” on page 2-549 for illustrations depicting the use of the coefficient data types in this block:

- When you select `Same word length as input`, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Specify word length`, you can enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the coefficients, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator coefficients.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the coefficients. If applicable, you can enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.

- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; they are always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Filter Structure Diagrams" on page 2-549 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Filter Structure Diagrams" on page 2-549 and "Multiplication Data Types" for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

State

Use this parameter to specify how you would like to designate the state word and fraction lengths. See "Filter Structure Diagrams" on page 2-549 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for direct form and direct form I filter structures.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

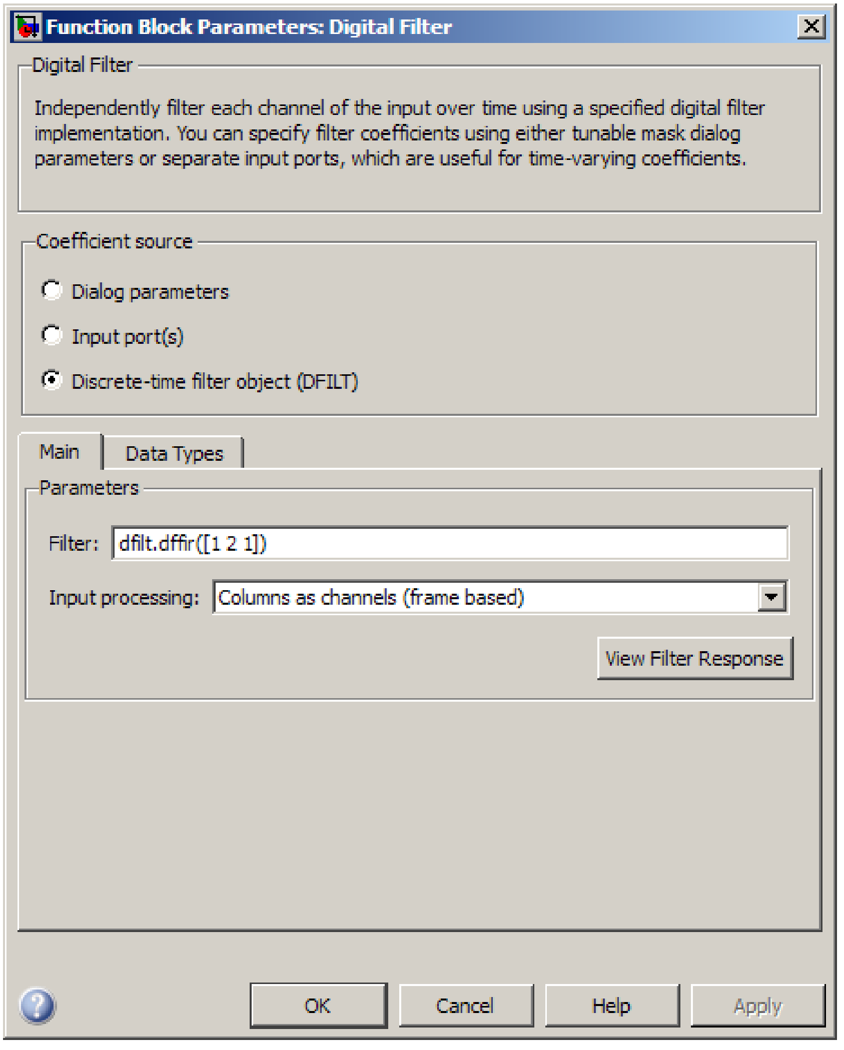
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Discrete-Time Filter Object

The **Main** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.



Filter

Specify the discrete-time filter object (`dfilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `dfilt` object in the block mask, as shown in the default value.

- You can enter the variable name of a `dfilt` object that is defined in any workspace.
- You can enter a variable name for a `dfilt` object that is not yet defined.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

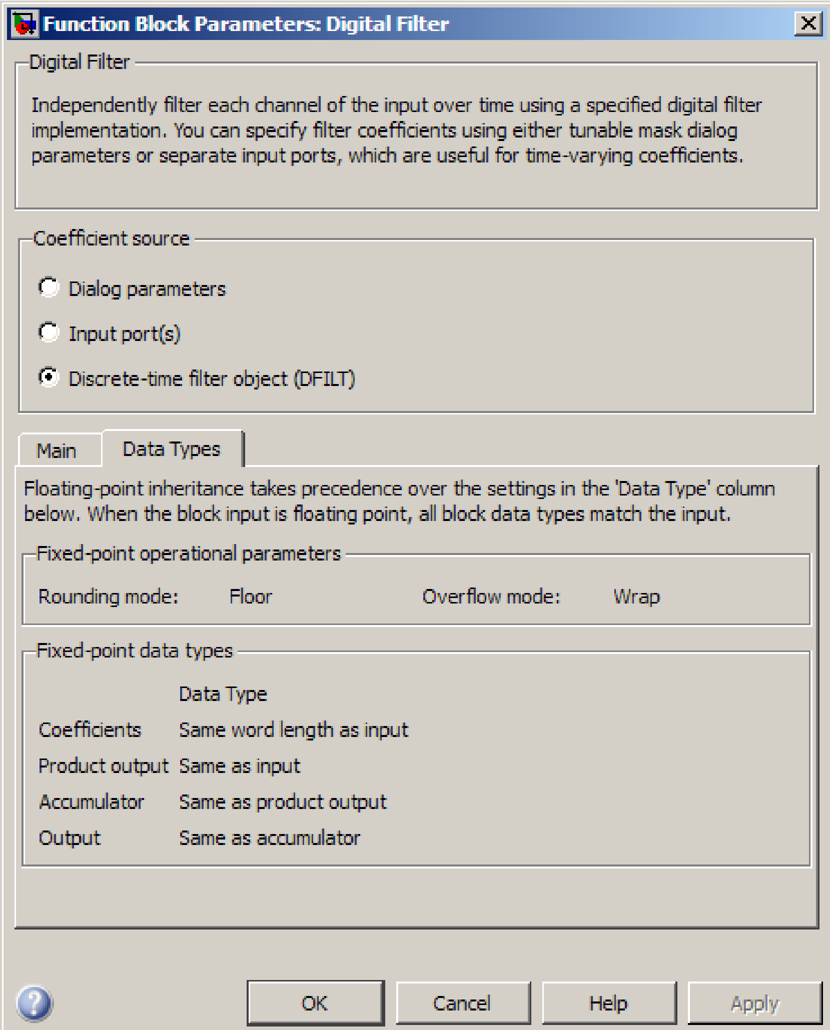
Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the `dfilt` object specified in the **Filter** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.



The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

For more information on discrete-time filter objects, see the `dfilt` reference page.

Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Digital Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the coefficient, output, accumulator, product output, and state data types shown in these diagrams in the block dialog. This is discussed in "Dialog Box" on page 2-535.

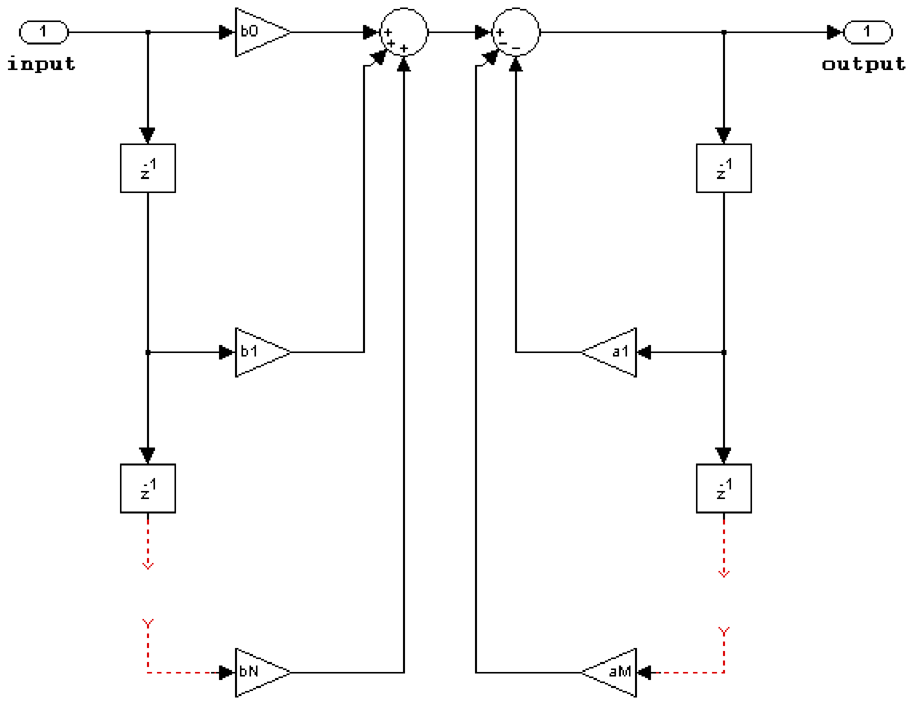
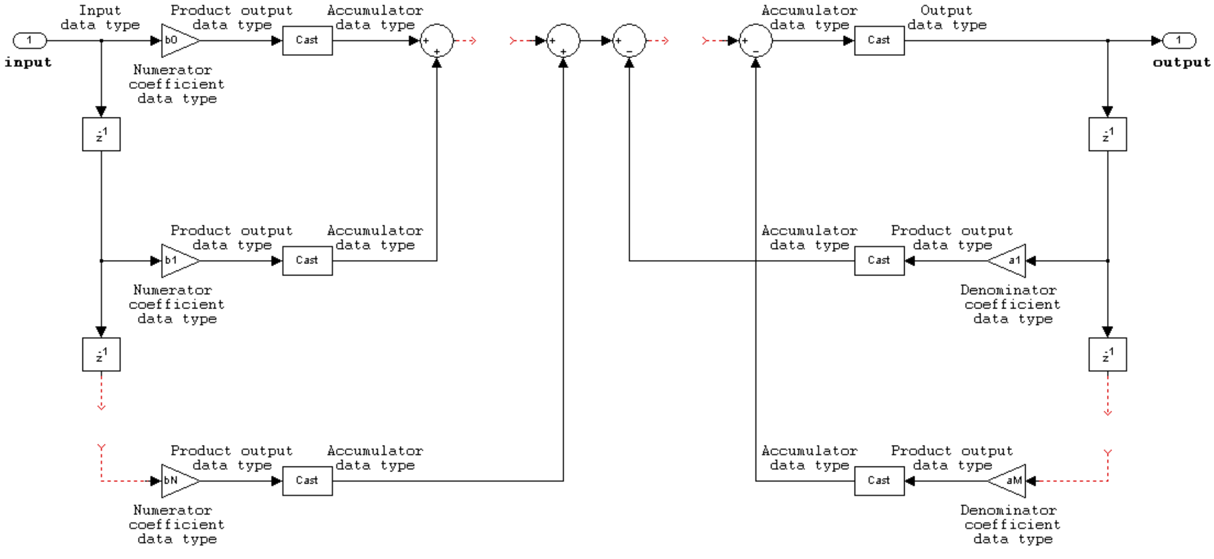
IIR direct form I



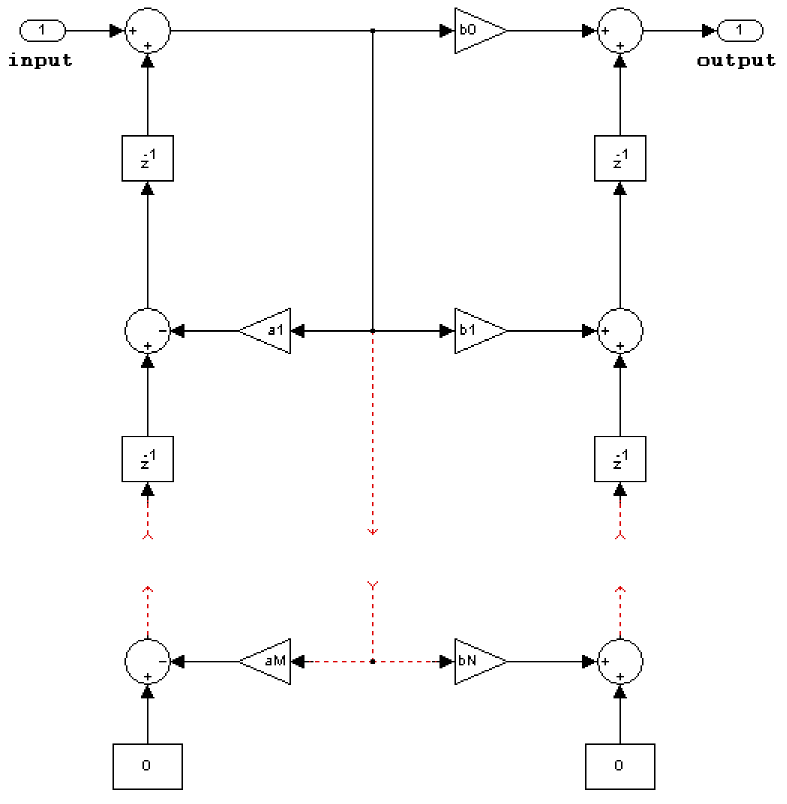
The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.
- The State data type cannot be specified on the block mask for this structure, because the input and output states have the same data types as the input and output buffers.



IIR direct form I transposed

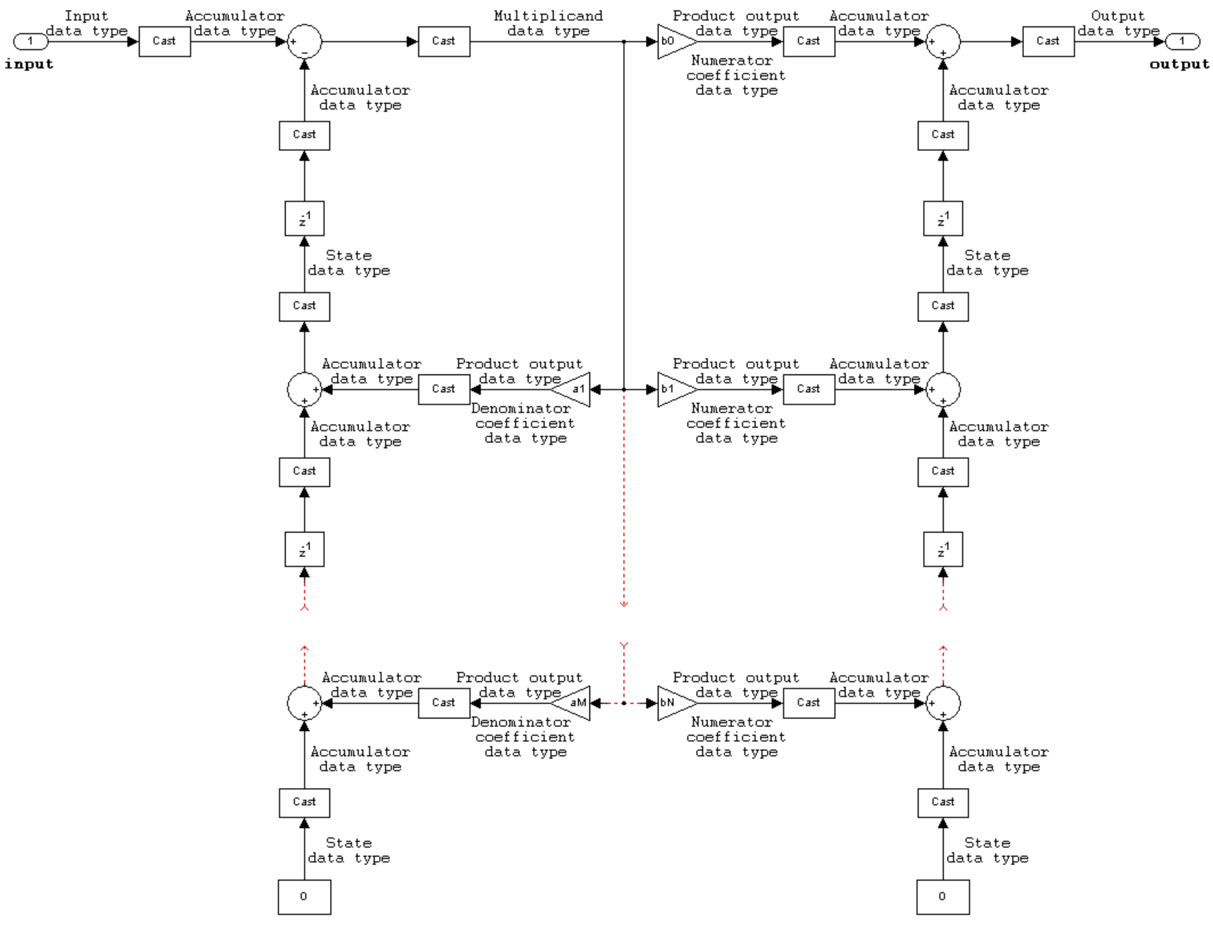


The following constraints are applicable when processing a fixed-point signal with this filter structure:

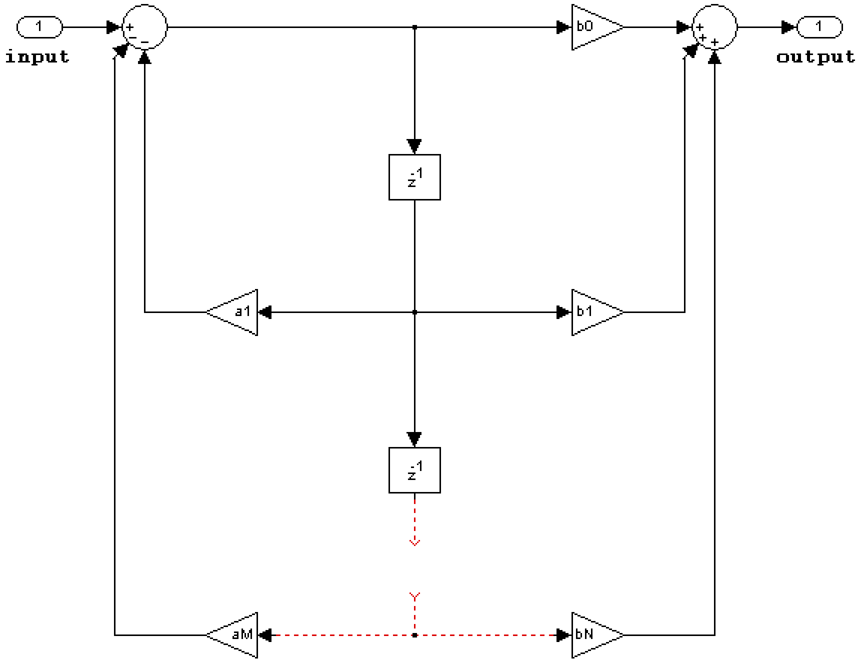
- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but

instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the input or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.



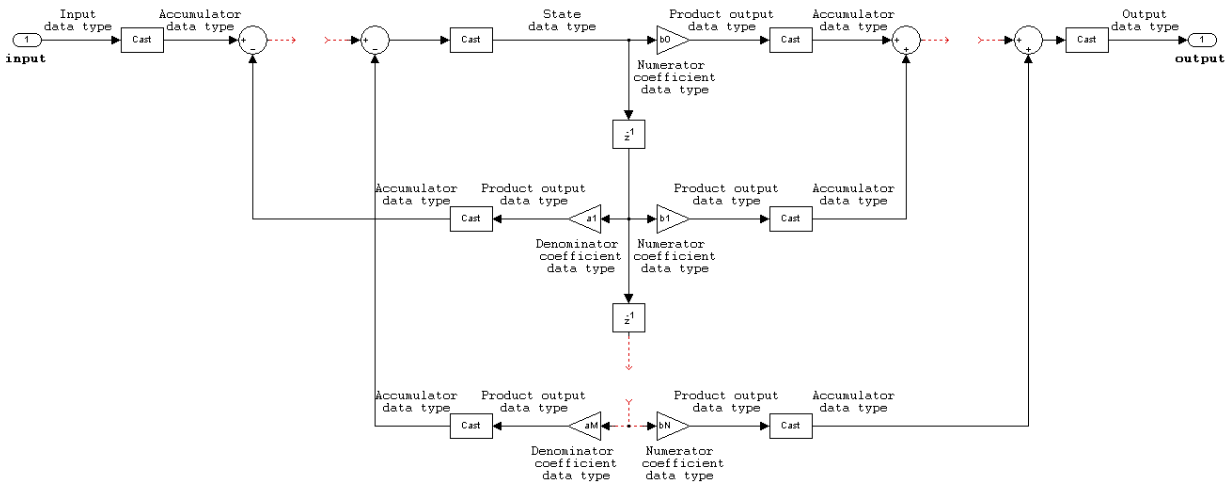
IIR direct form II



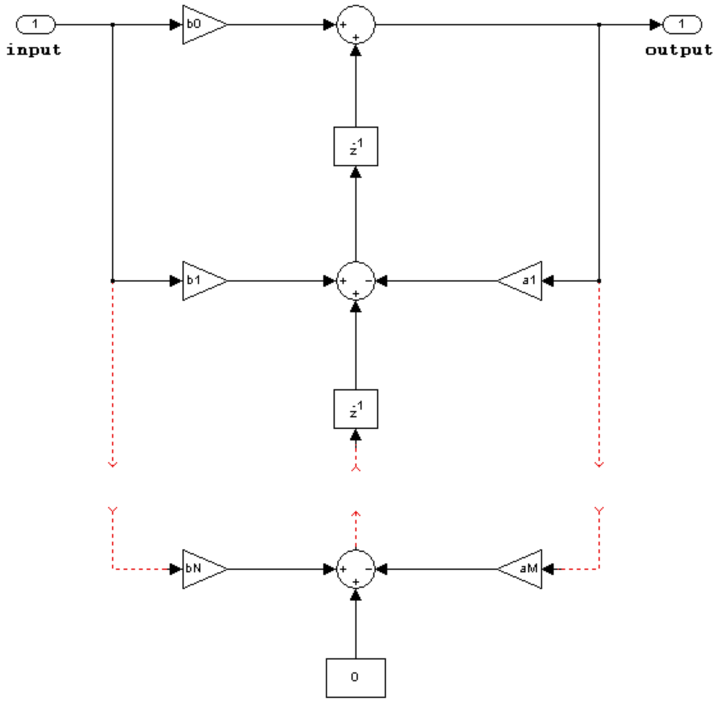
The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.



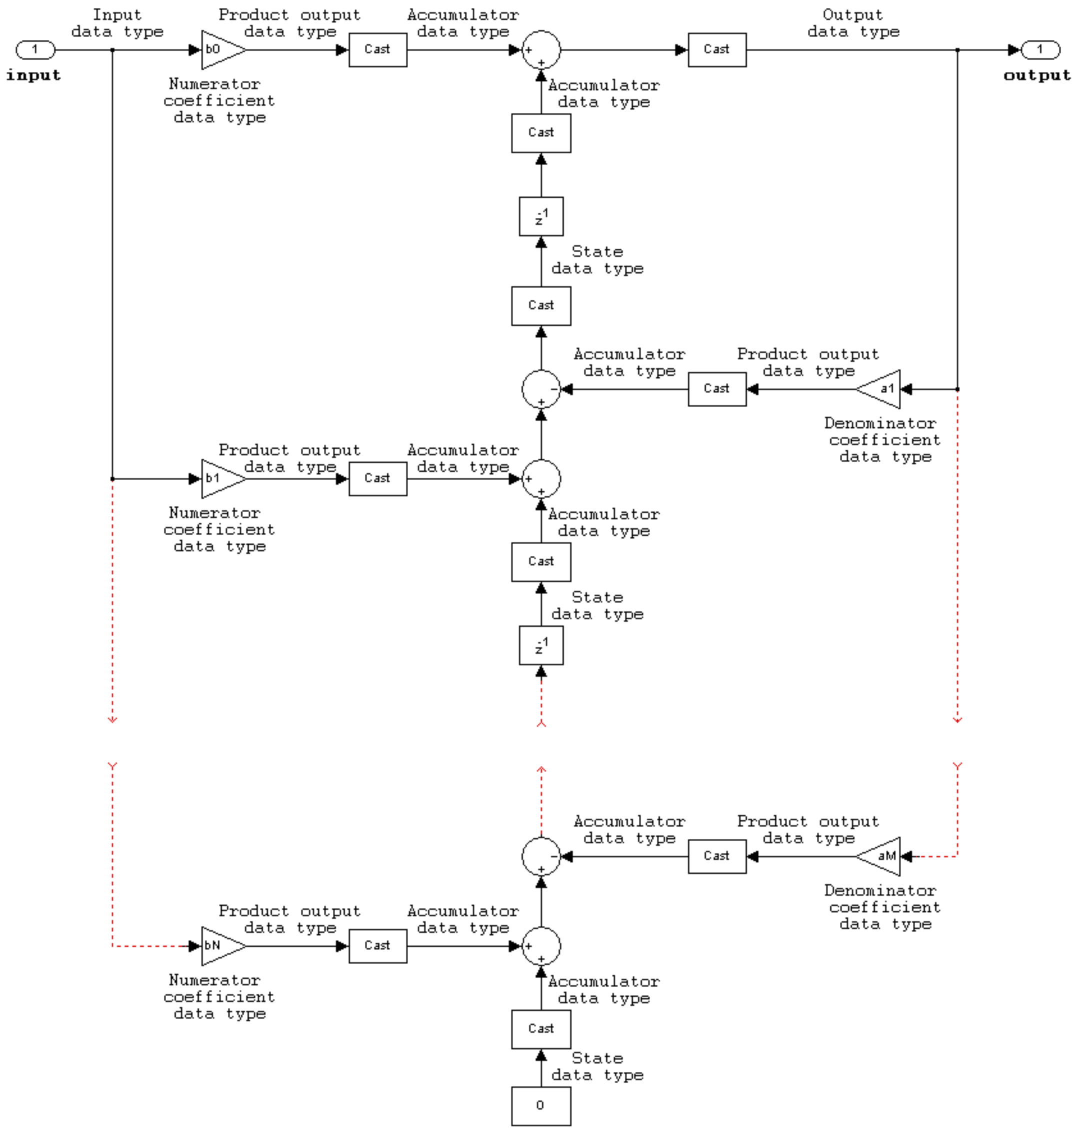
IIR direct form II transposed



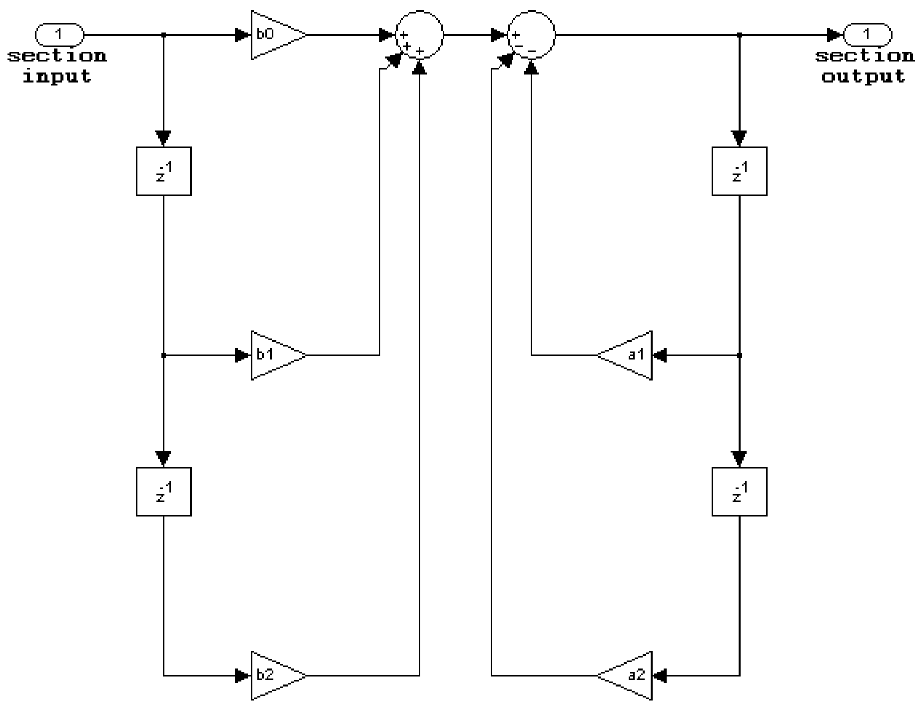
The following constraints are applicable when processing a fixed-point signal with this filter structure:

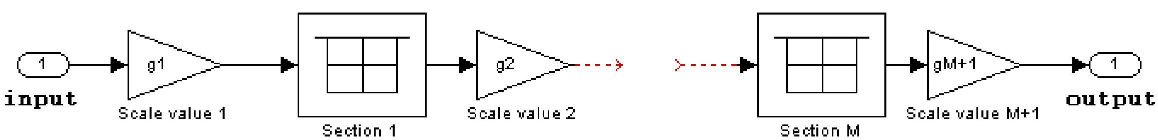
- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
    - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
    - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.



IIR biquadratic direct form I



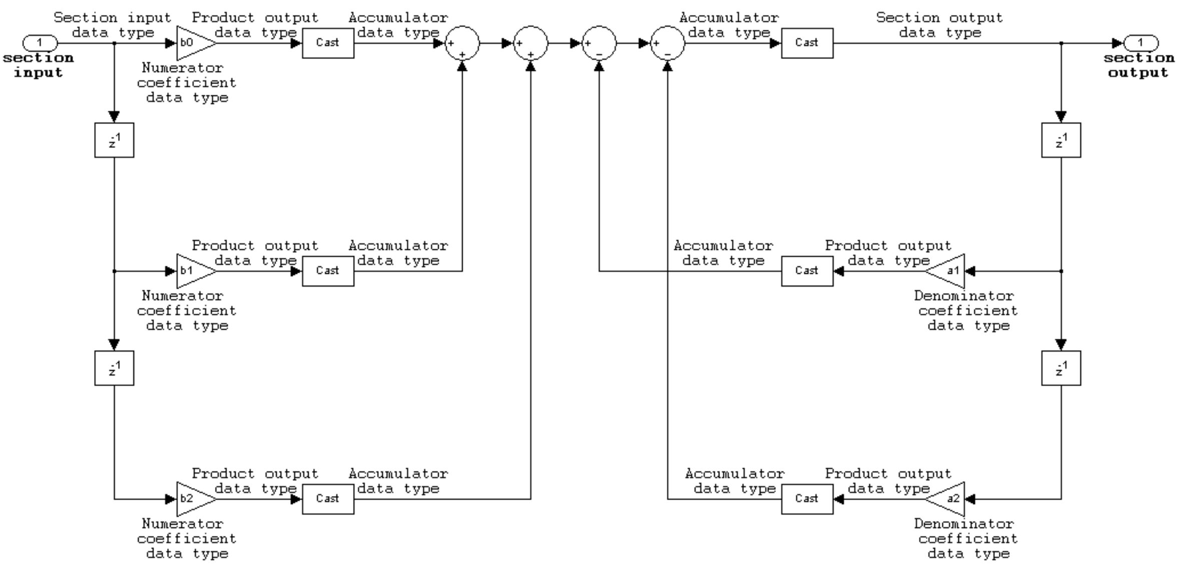


The following constraints are applicable when processing a fixed-point signal with this filter structure:

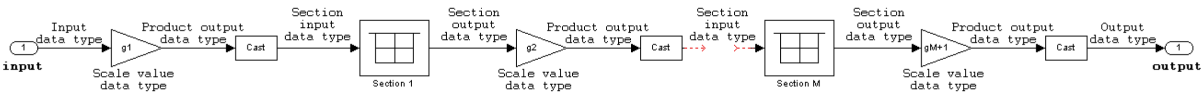
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.

- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length M+1, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and stage output data type must have the same word length but can have different fraction lengths.

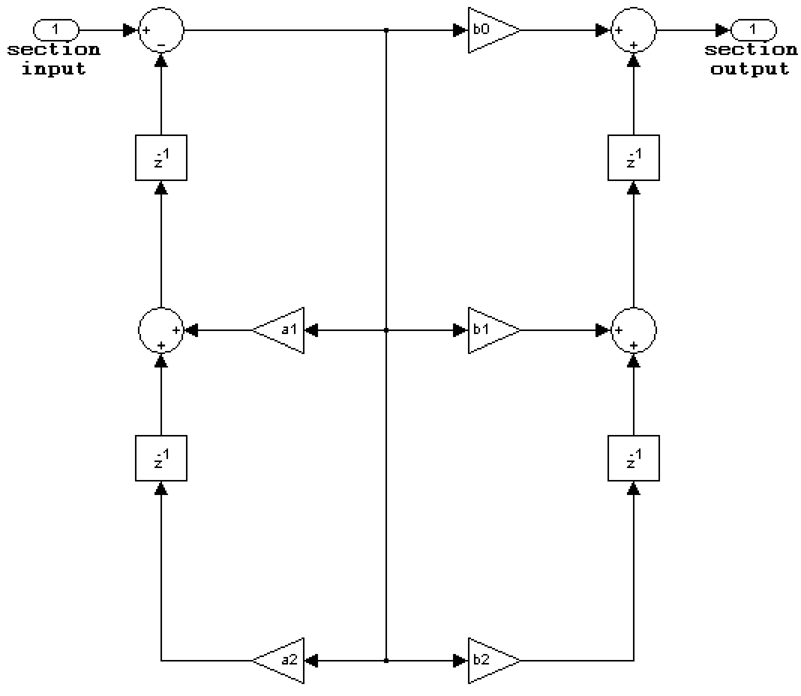
The following diagram shows the data types for one section of the filter.

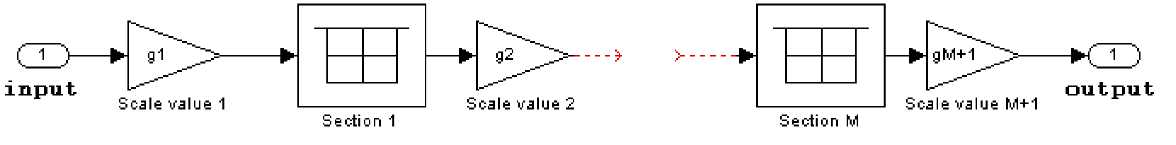


The following diagram shows the data types between filter sections.



IIR biquadratic direct form I transposed



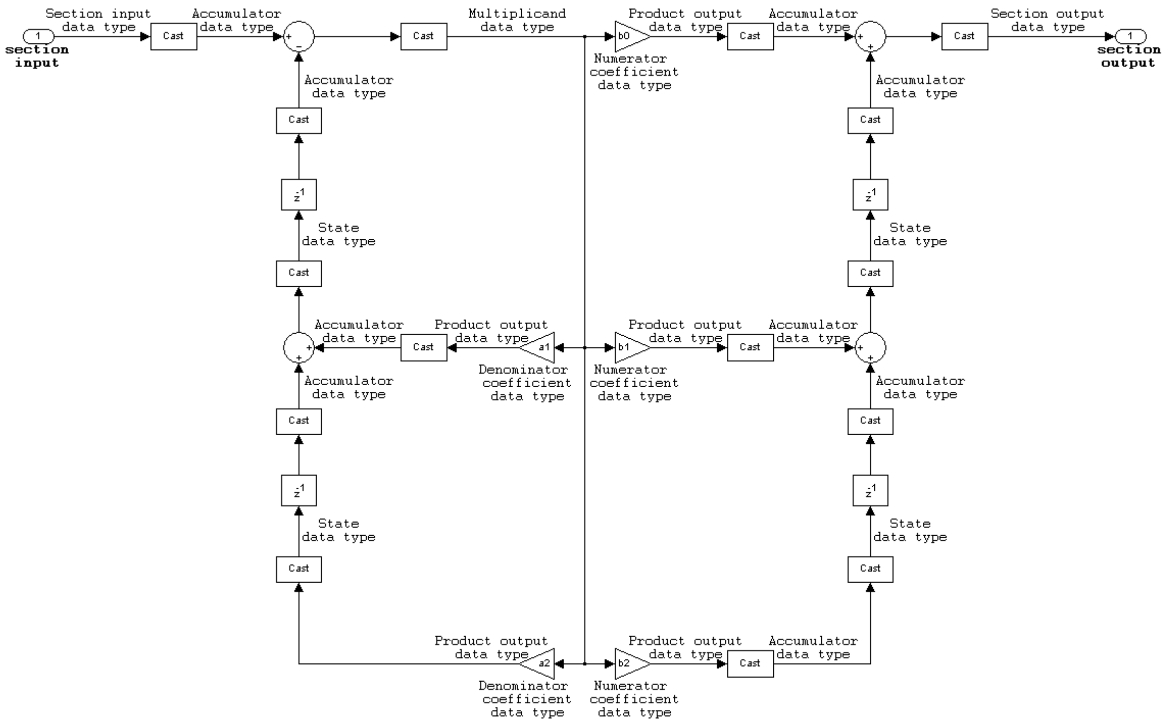


The following constraints are applicable when processing a fixed-point signal with this filter structure:

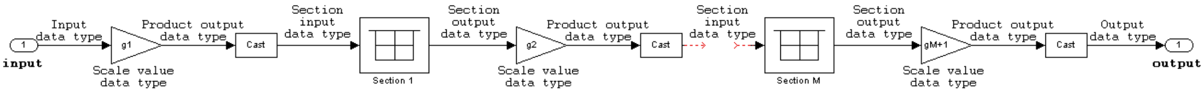
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.

- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length $M+1$, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

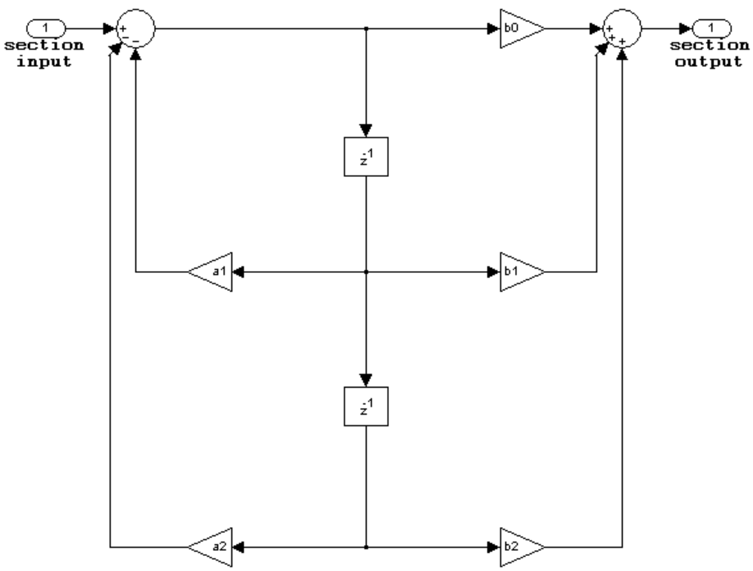
The following diagram shows the data types for one section of the filter.

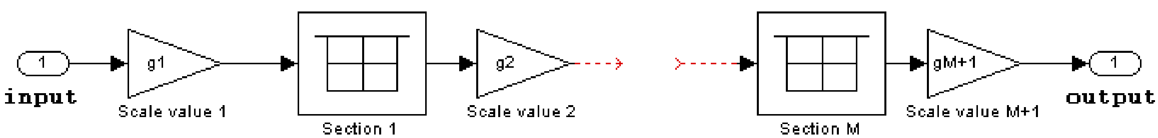


The following diagram shows the data types between filter sections.



IIR biquadratic direct form II



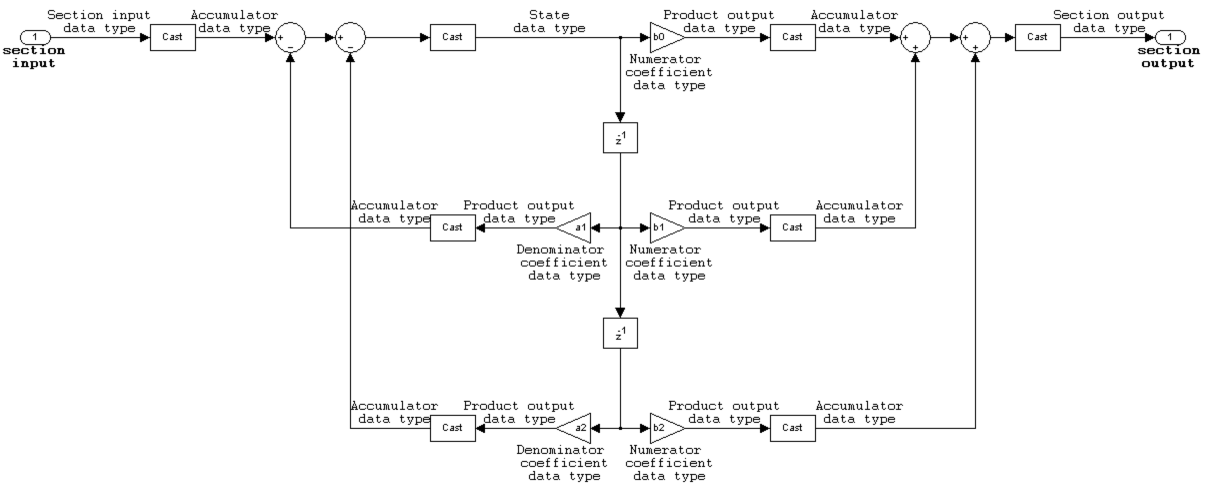


The following constraints are applicable when processing a fixed-point signal with this filter structure:

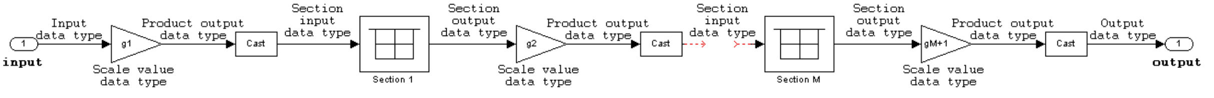
- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.

- Specify the coefficients by a M-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length M+1, where M is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

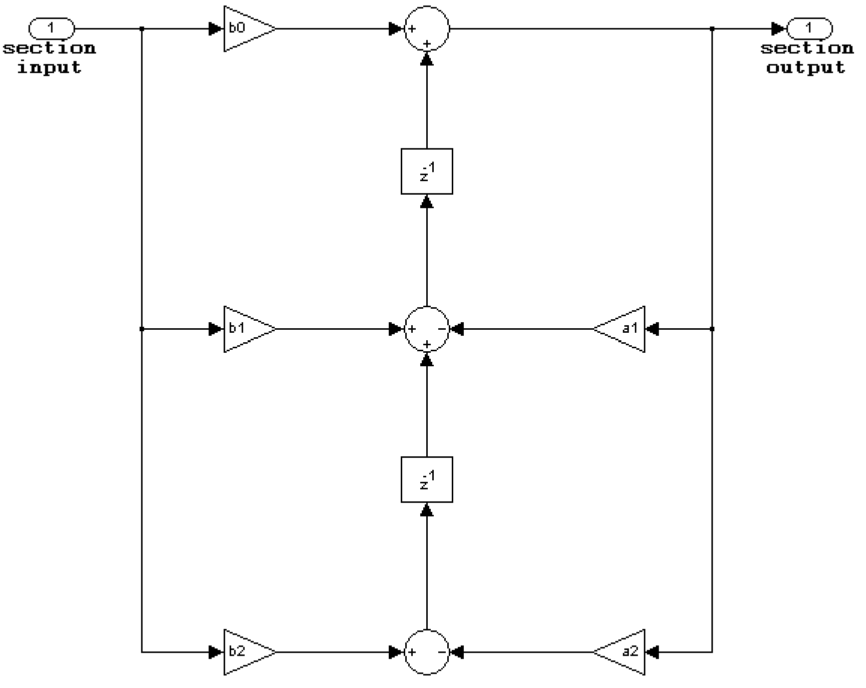
The following diagram shows the data types for one section of the filter.

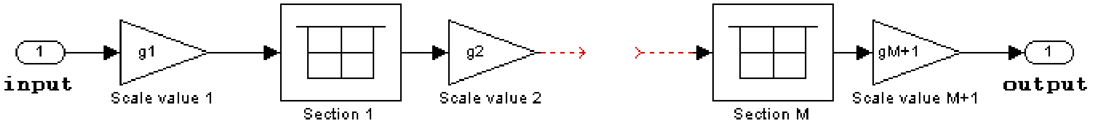


The following diagram shows the data types between filter sections.



IIR biquadratic direct form II transposed

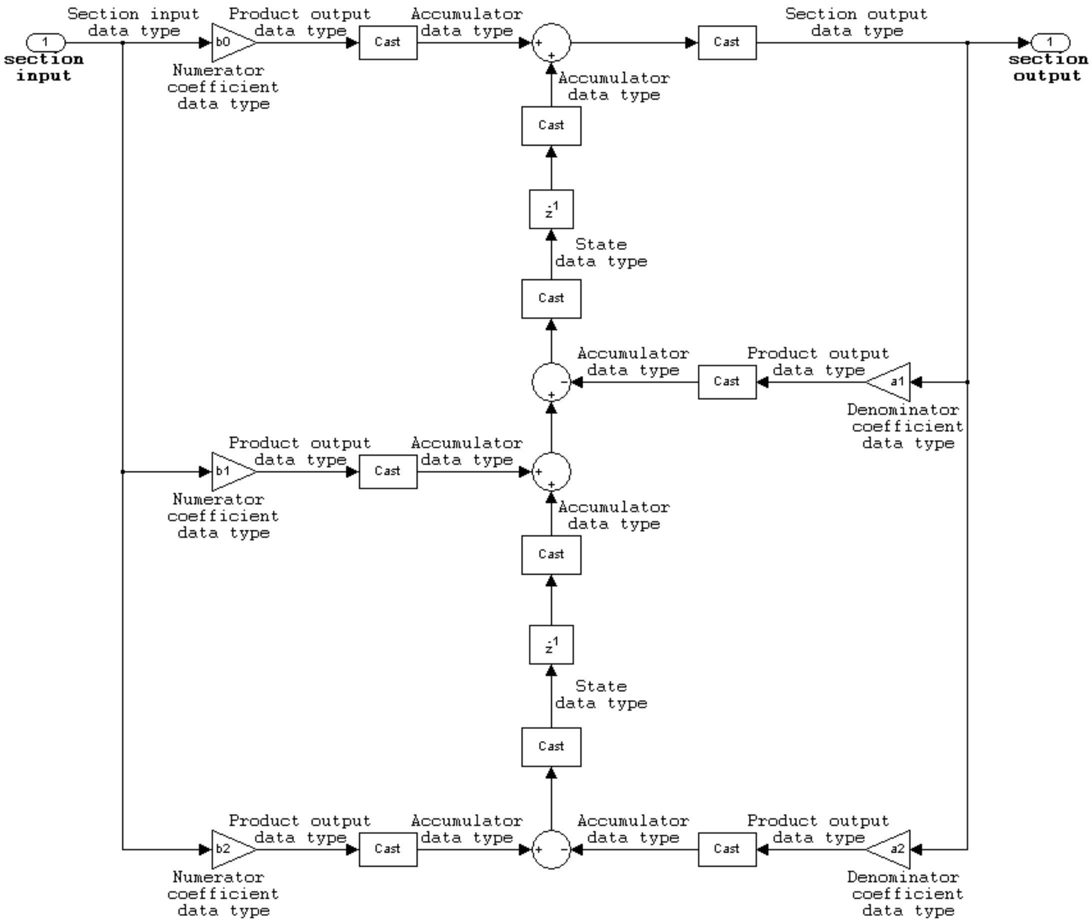




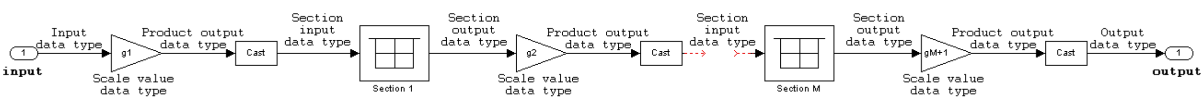
The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a *M*-by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the a0 element of any row is not equal to one, that row is normalized by a0 prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length *M*+1, where *M* is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

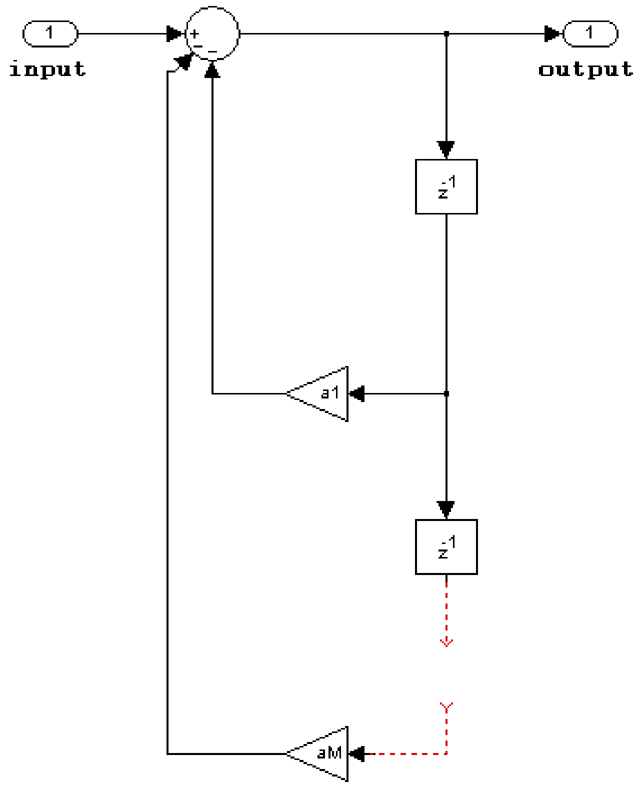
The following diagram shows the data types for one section of the filter.



The following diagram shows the data types between filter sections.



IIR (all poles) direct form



The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Denominator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.

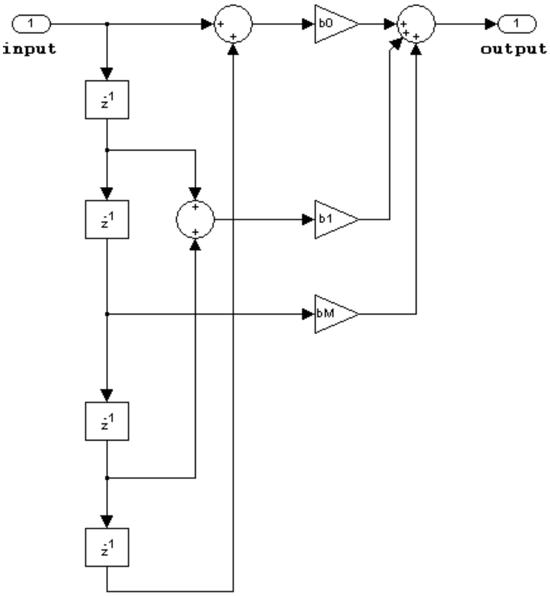
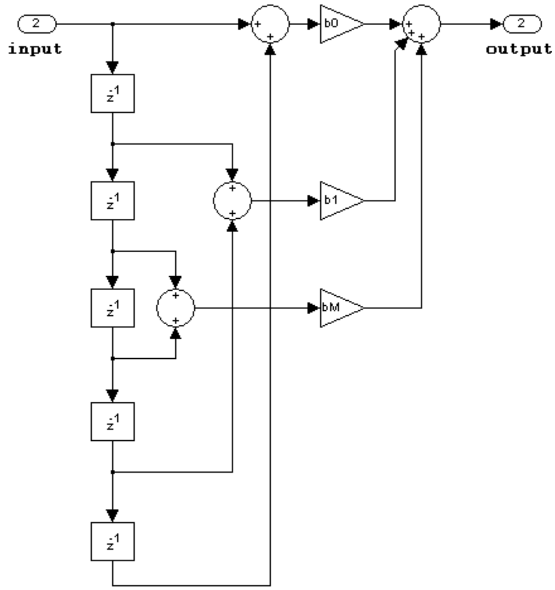
FIR (all zeros) direct form symmetric



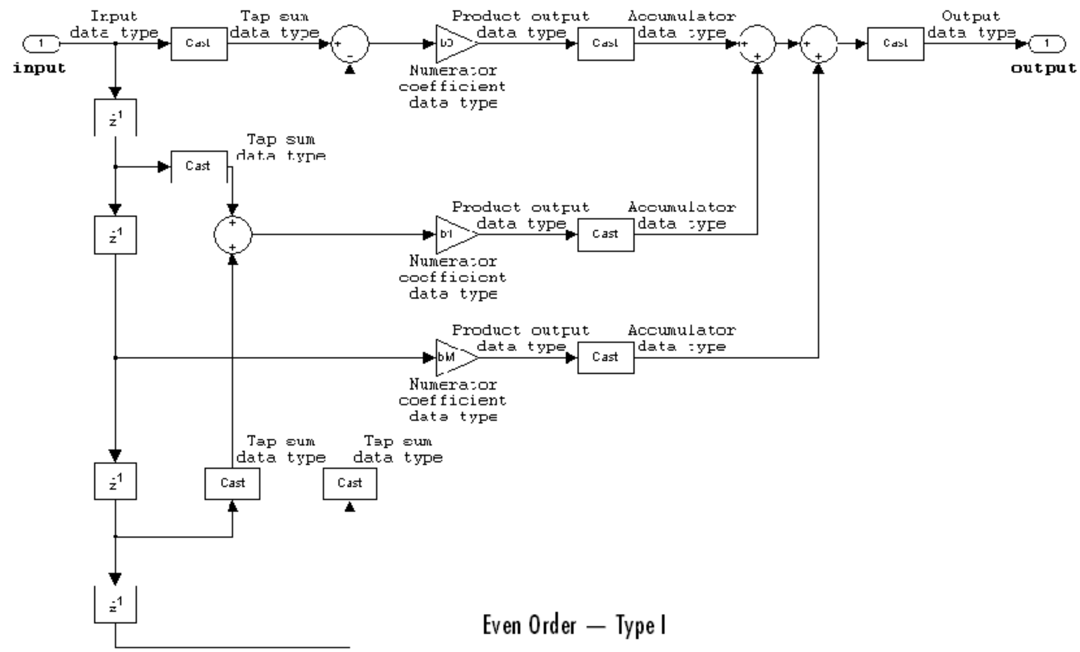
Even Order — Type I



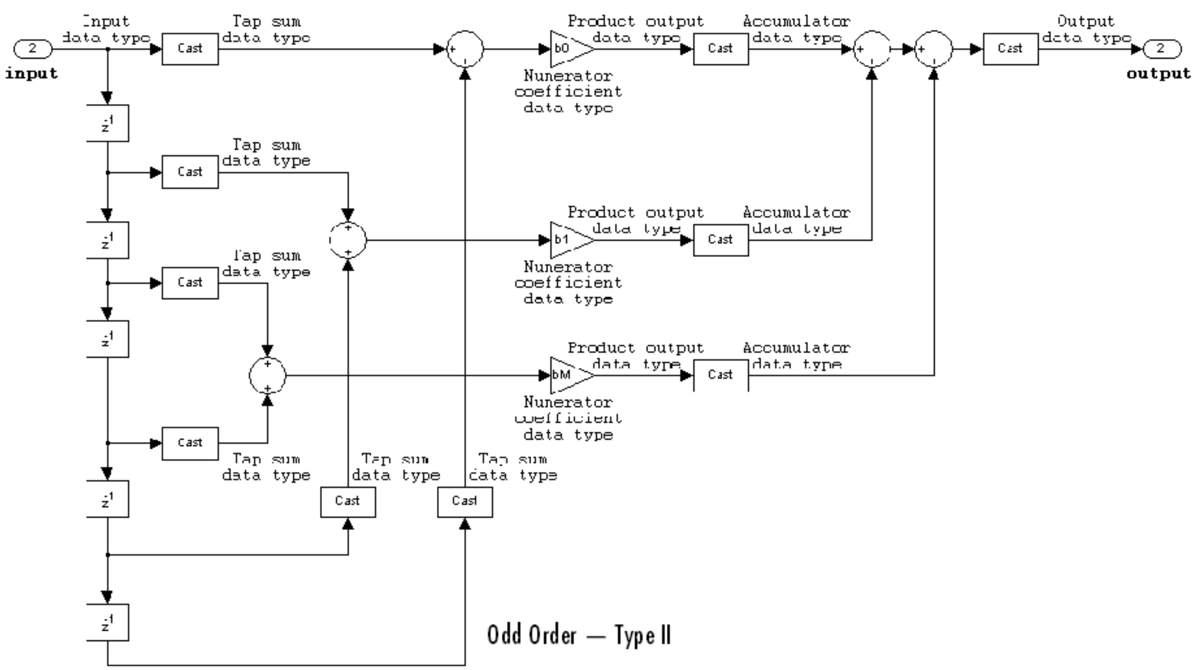
Odd Order — Type II

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are symmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.

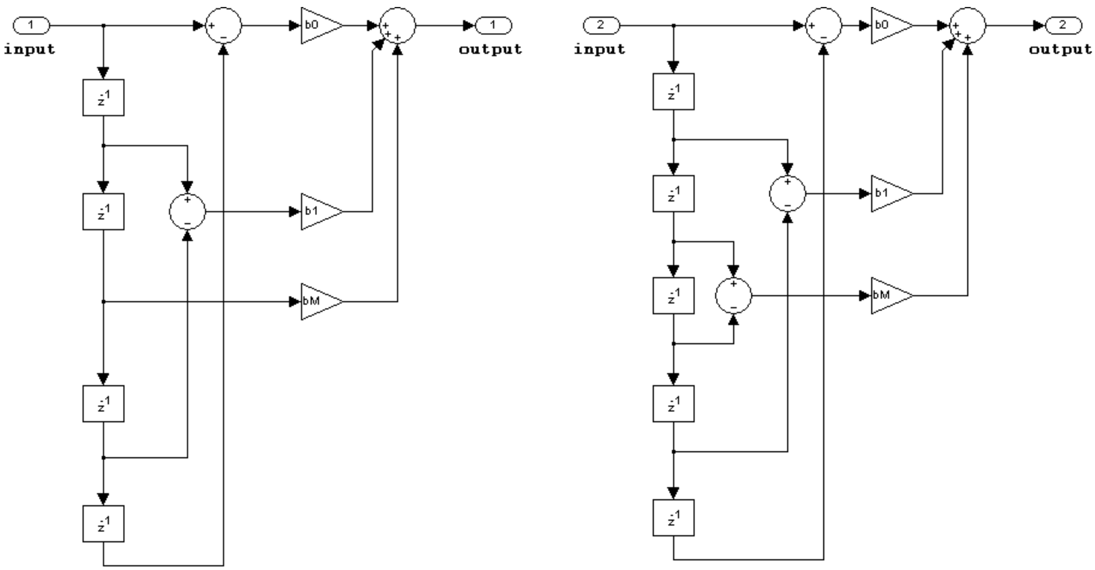


Even Order — Type I



Odd Order — Type II

FIR (all zeros) direct form antisymmetric

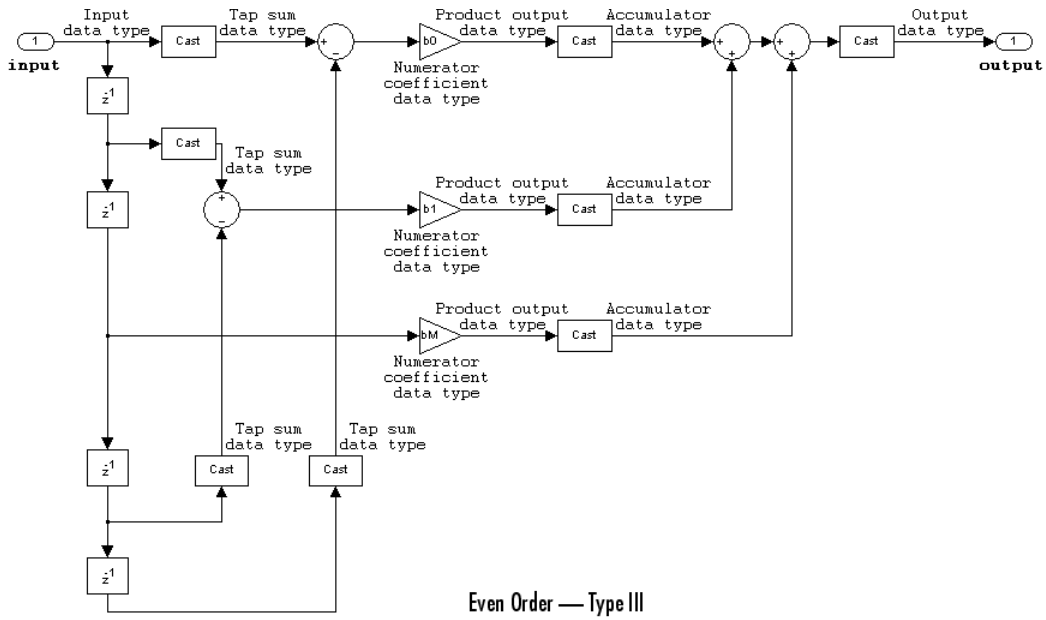


Even Order — Type III

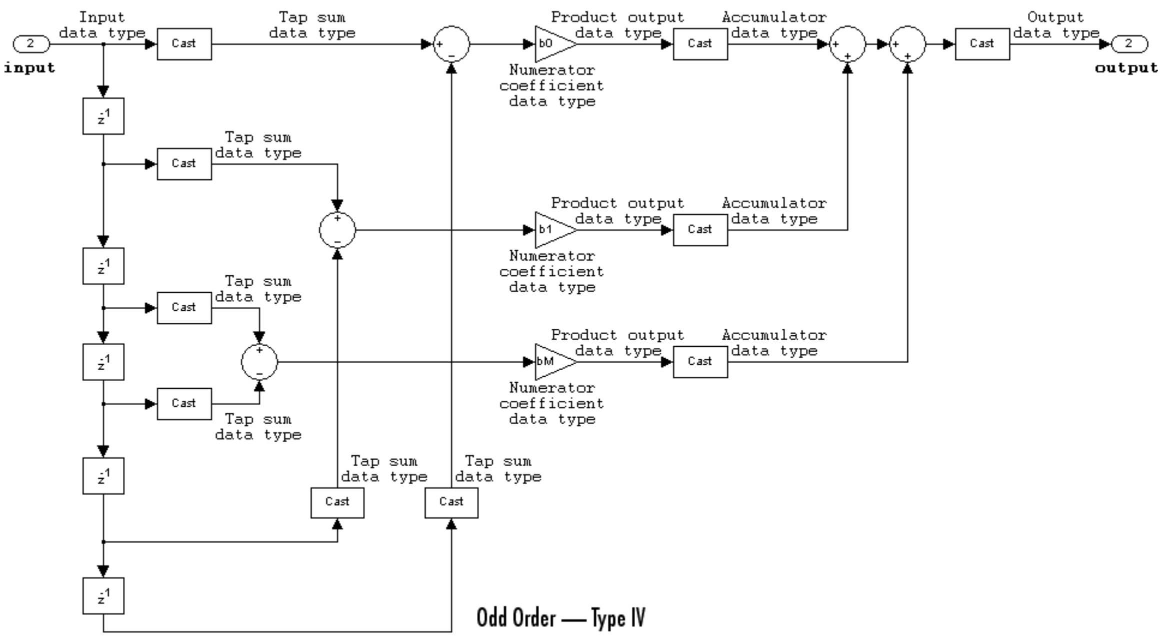
Odd Order — Type IV

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are antisymmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.



Even Order — Type III



Odd Order — Type IV

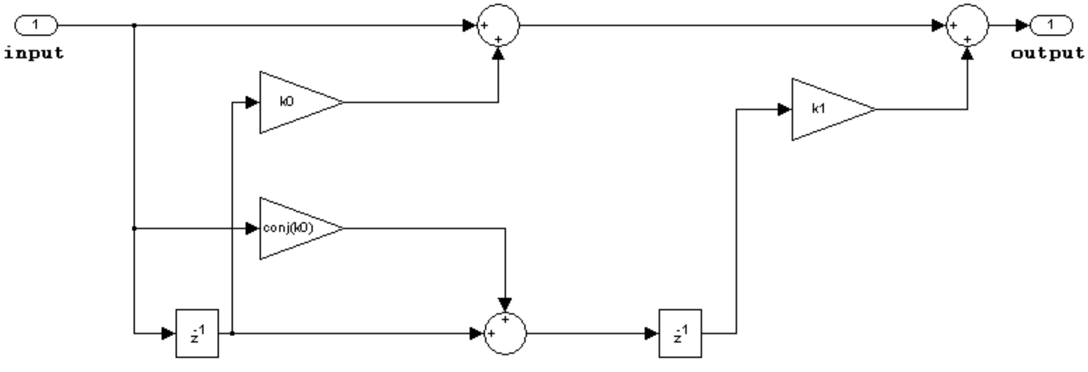
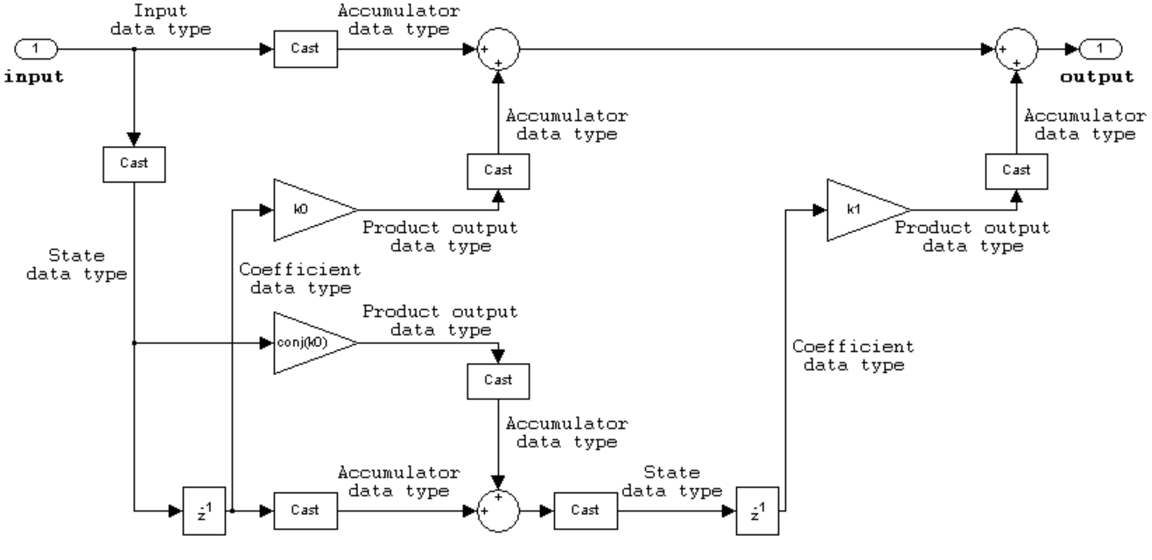
FIR (all zeros) lattice MA



The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Coefficients can be real or complex.



Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

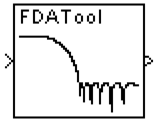
Digital Filter Design

Design and implement digital FIR and IIR filters



Library

Filtering / Filter Implementations

`dsparch4`

Description

Note: Use this block to design, analyze, and efficiently implement floating-point filters. The following blocks also implement digital filters, but serve slightly different purposes:

- `Discrete FIR Filter` and `Biquad Filter`— Use to efficiently implement floating-point or fixed-point filters that you have already designed. These blocks provide the same exact filter implementation as the Digital Filter Design block.
- `Filter Realization Wizard` — Use to implement floating-point or fixed-point filters built from Sum, Gain, and Unit Delay blocks. You can either design the filter within this block, or import the coefficients of a filter that you designed elsewhere.

The Digital Filter Design block implements a digital FIR or IIR filter that you design using the filter designer (`filterDesigner`) app. This block provides the same filter implementation as the Discrete FIR Filter or Biquad Filter blocks.

You must specify whether the block performs frame-based or sample-based processing on the input by setting the **Input processing** parameter. The block applies the specified filter to each channel of a discrete-time input signal, and outputs the result. The outputs of the block numerically match the outputs of the Discrete FIR Filter or Biquad Filter block, the MATLAB `filter` function, and the DSP System Toolbox `filter` function.

The sampling frequency, Fs, that you specify in the filter designer app should be identical to the sampling frequency of the input to the Digital Filter Design block. When the sampling frequencies do not match, the Digital Filter Design block returns a warning message and inherits the sampling frequency of the input block.

Designing the Filter

Double-click the Digital Filter Design block to open filter designer. Use filter designer to design or import a digital FIR or IIR filter. To learn how to design filters with this block and filter designer, see the following topics:

- “Digital Filter Design Block”
- `filterDesigner` reference page

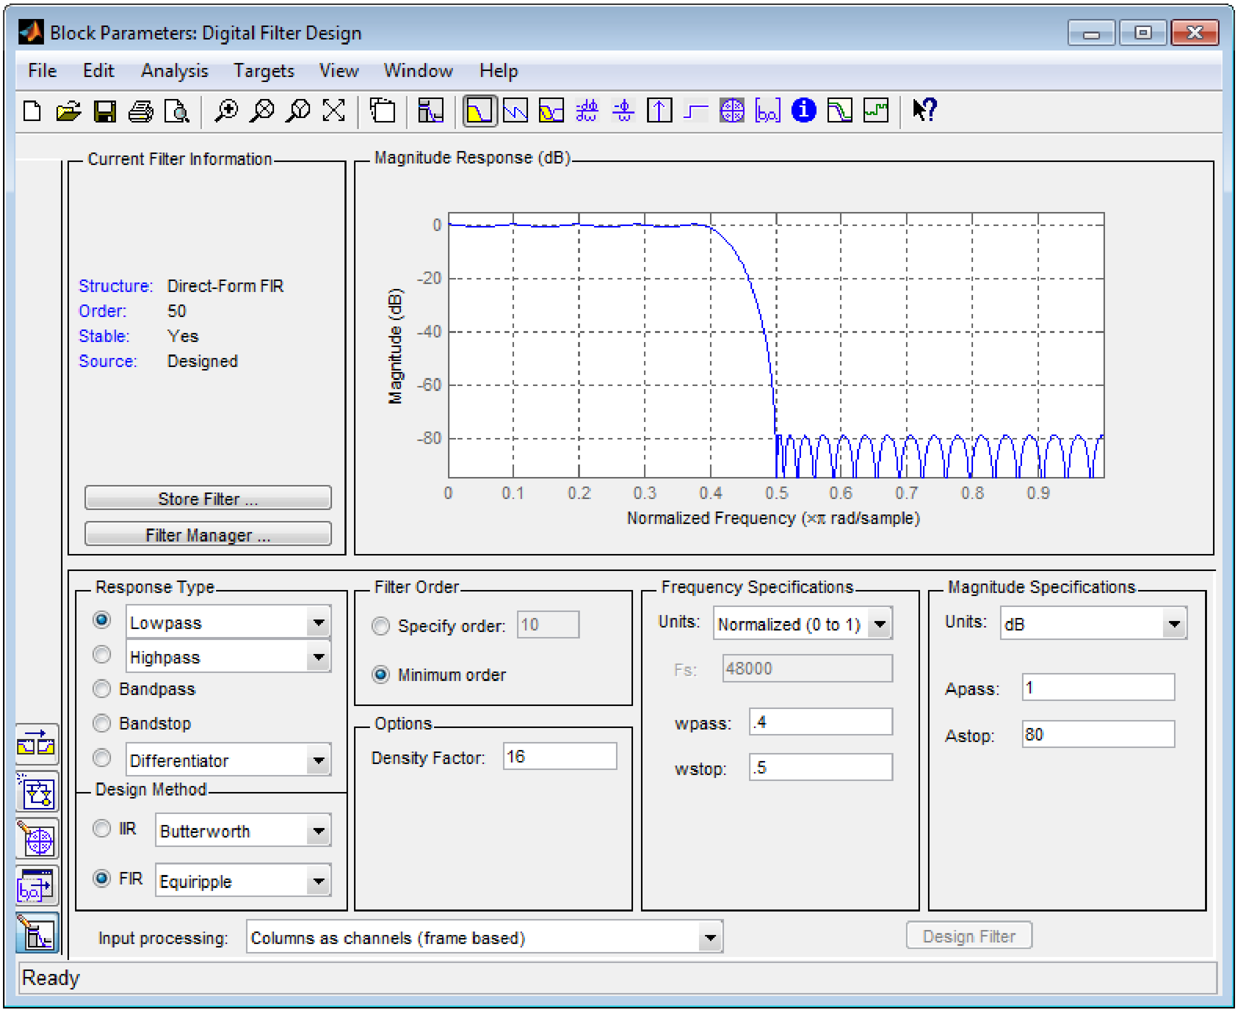
Tuning the Filter During Simulation

You can tune the filter specifications in filter designer during simulations as long as your changes do not modify the filter length or filter order. The filter updates as soon as you apply any filter changes in filter designer.

Examples

See “Digital Filter Design Block”.

Dialog Box



For more information about the parameters on this dialog box, see "Getting Started with Filter Designer" (Signal Processing Toolbox).

Supported Data Types

- Double-precision floating point
- Single-precision floating point

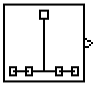
Discrete Impulse

Generate discrete impulse



Library

Sources

`dspsrcs4`

Description

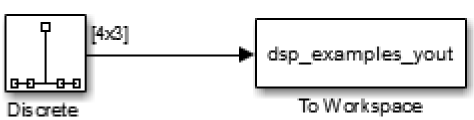
The Discrete Impulse block generates an impulse (the value `1`) at output sample `D+1`, where `D` is specified by the **Delay** parameter (`D` ≥`0`). All output samples preceding and following sample `D+1` are zero.

When `D` is a length-N vector, the block generates an M-by-N matrix output representing N distinct channels, where frame size M is specified by the **Samples per frame** parameter. The impulse for the `i`th channel appears at sample `D(i)+1`.

The **Sample time** parameter value, T_s, specifies the output signal sample period. The resulting frame period is $M*T_s$.

Examples

Construct the model below.



Configure the Discrete Impulse block to generate a three-channel output of type `double`, with impulses at samples 1, 4, and 6 of channels 1, 2, and 3, respectively. Use a sample period of 0.25 and a frame size of 4. The corresponding settings should be as follows:

- **Delay** = `[0 3 5]`
- **Sample time** = `0.25`
- **Samples per frame** = 4
- **Output data type** = `double`

Run the model and look at the output, `dsp_examples_yout`. The first few samples of each channel are shown below.

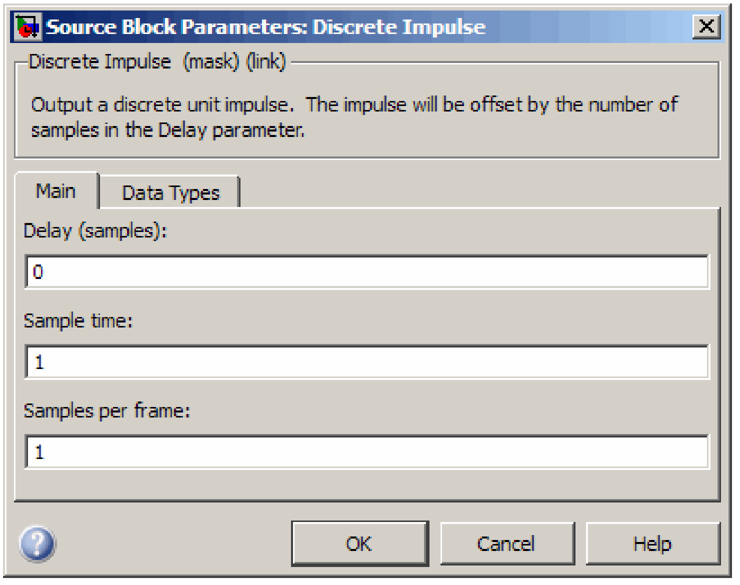
```
dsp_examples_yout(1:10,:)

ans =
     1     0     0
     0     0     0
     0     0     0
     0     1     0
     0     0     0
     0     0     1
     0     0     0
     0     0     0
     0     0     0
     0     0     0
```

The block generates an impulse at sample 1 of channel 1 (first column), at sample 4 of channel 2 (second column), and at sample 6 of channel 3 (third column).

Dialog Box

The **Main** pane of the Discrete Impulse block dialog appears as follows.



Delay

The number of zero-valued output samples, `D`, preceding the impulse. A length-N vector specifies an N-channel output.

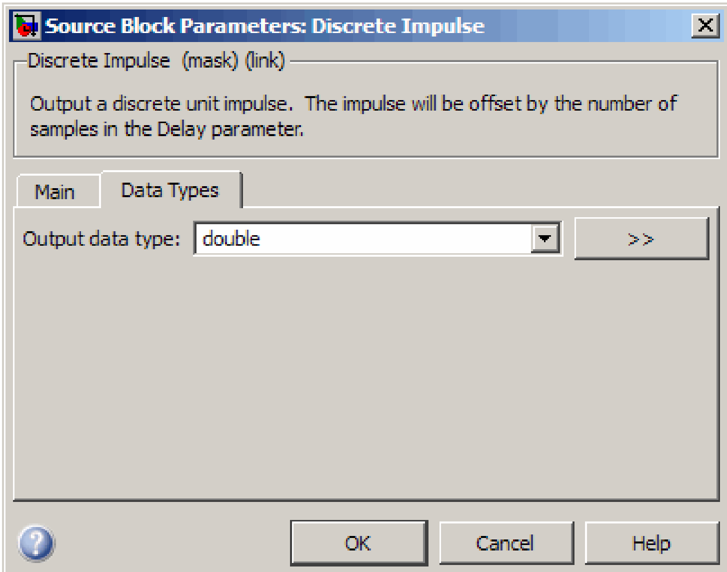
Sample time

The sample period, T_s, of the output signal. The output frame period is $M*T_s$.

Samples per frame

The number of samples, M, in each output frame.

The **Data Types** pane of the Discrete Impulse block dialog appears as follows.



Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

- Double-precision floating point

- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

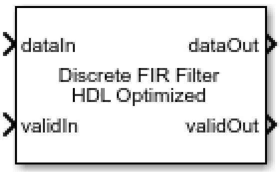
Discrete FIR Filter HDL Optimized

Finite impulse response filter—optimized for HDL code generation

Library: DSP System Toolbox / Filtering / Filter Implementations
DSP System Toolbox HDL Support / Filtering



Description

The Discrete FIR Filter HDL Optimized block models FIR filter architectures optimized for HDL code generation. The block is sample based, accepting one scalar at a time. It provides a hardware-friendly interface with optional input and output flow control signals.

The block implements a direct-form systolic FIR filter architecture based on multiply-accumulate operations with pipeline registers. The choice of architecture makes the block well-suited for high-throughput HDL code generation targeted for FPGAs with dedicated DSP blocks. The generated HDL code runs at a high clock rate and can filter new input data on every cycle.

The block provides flexible and efficient resource sharing options. This property results in tradeoffs between throughput and resource utilization. A sharing factor of *N* indicates that the block reduces overall DSP resource utilization by a factor of *N*. In this case, the block can process only input samples that are at least *N* cycles apart. To determine when the block is ready for new input data, use the optional **ready** output port.

To provide a cycle-accurate simulation of the generated HDL code, the block models pipeline registers and resource sharing. These operations cause a delay between valid input data and the corresponding valid output data. The actual latency depends on the number of coefficients and the sharing factor.

Ports

Input

`dataIn` — Input data

real or complex scalar

Input data, specified as a real or complex scalar. When the input data type is integer or fixed point, the block uses fixed-point arithmetic for internal calculations. `double` and `single` are accepted for simulation but not for HDL code generation.

Data Types: `fixed_point` | `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`
Complex Number Support: Yes

`validIn` — Indicates valid input data (optional)

logical scalar

When **validIn** is `true`, the block captures the input data on **dataIn**. The port is enabled by default and is required when you select DSP resource sharing.

Dependencies

To enable this port, on the **Main** tab, select **Share DSP resources**. Alternatively, if you clear **Share DSP resources**, you can enable this port by selecting **Enable valid input port** on the **Control Ports** tab.

Data Types: `Boolean`

Output

`dataOut` — Filtered output data

real or complex scalar

Filtered output data, returned as a real or complex scalar. When the input data type is floating point, the output data inherits the data type of the input data. When the input data is integer or fixed point, the **Output** parameter on the **Data Types** tab controls the output data type.

Data Types: `fixed_point` | `single` | `double`

Complex Number Support: Yes

validOut — Indicates valid output data
logical scalar

The block sets **validOut** to `true` with each valid output data returned by **dataOut**.

Data Types: `Boolean`

ready — Indicates that the block is ready for new input data (optional)
logical scalar

The block sets **ready** to `true` to indicate that it is ready for new input data on the next cycle.

Dependencies

To enable this port, on the **Control Port** tab, select **Enable ready output port**.

Data Types: `Boolean`

Parameters

Main

Coefficients — Discrete FIR filter coefficients
`[ 0.5, 0.5 ]` (default) | vector of numeric values

Discrete FIR filter coefficients, specified as a vector of numeric values. You can also specify the vector as a workspace variable, or as a call to a filter design function. Complex coefficients are not supported. When the input data type is floating point, the block casts the coefficients to the same data type as the input. When the input data type is integer or fixed point, you can modify coefficient type casting details by setting the **Coefficients** on the **Data Types** tab.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Share DSP resources — Enable resource sharing
off (default) | on

Enable resource sharing to reduce overall DSP resource utilization on the FPGA. When this parameter is selected, specify the **Sharing factor** by which you want to reduce the number of DSPs.

`Sharing factor` — Factor by which the number of DSPs is reduced

`2` (default) | positive integer

Factor by which the number of DSPs is reduced, specified as a positive integer. A sharing factor of *N* indicates that the block reduces DSP resource utilization by a factor of *N*. In this case, the block can process only input samples that are at least *N* cycles apart.

Dependencies

To enable this parameter, on the **Main** tab, select **Share DSP resources**.

Data Types

`Rounding mode` — Rounding mode for type casting the output

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Zero`

Rounding mode for type casting the output to the data type specified by **Output**. When the input data type is floating point, the value of **Rounding mode** has no effect. See "Rounding Modes" for more details.

`Overflow mode` — Overflow handling for type casting the output

`Wrap` (default) | `Saturate`

Overflow handling for type casting the output to the data type specified by **Output**. When the input data type is floating point, the value of **Overflow mode** has no effect. See "Overflow Handling" for more details.

`Coefficients` — Data type of discrete FIR filter coefficients

`Inherit: Same word length as input` (default) | `<data type expression>`

The block casts the filter coefficients of the discrete FIR filter to this data type. The quantization uses nearest rounding and saturate overflow modes. When the input data type is floating point, the value of **Coefficients** has no effect.

`Output` — Data type of discrete FIR filter output

`Inherit: Same word length as input` (default) | `Inherit: Inherit via internal rule` | `<data type expression>`

The block casts the output of the discrete FIR filter to this data type. The quantization uses the settings of **Rounding mode** and **Overflow mode**. When the input data type is floating point, the value of the **Output** data type has no effect.

Control Ports

`Enable valid input port` — Enable valid input control signal
on (default) | off

Select this parameter to enable the **validIn** port.

Dependencies

To enable this parameter, on the **Main** tab, clear **Share DSP resources**. When DSP resources are shared, the **validIn** port always shows.

`Enable ready output port` — Enable optional ready control signal
off (default) | on

Select this parameter to enable the **ready** port.

Model Examples

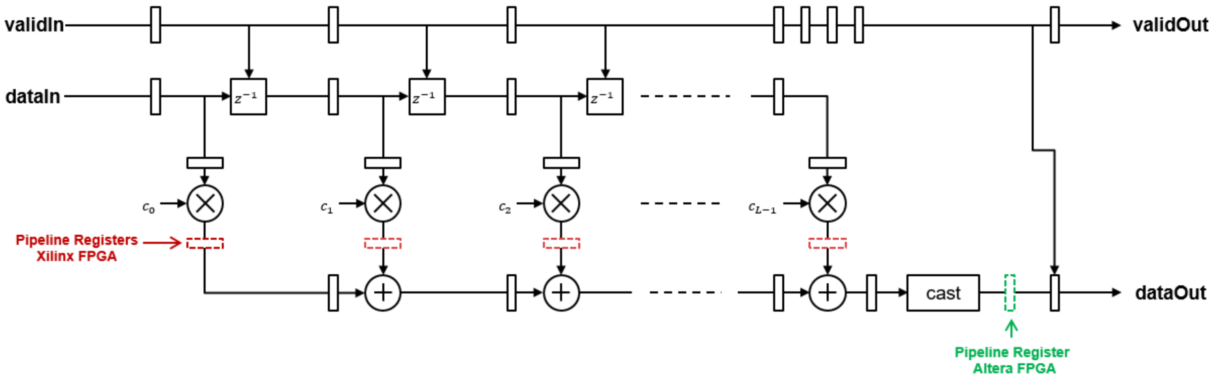
Algorithm

The block implements a direct-form systolic FIR filter architecture based on multiply-accumulate operations with pipeline registers. The simulation models the latency incurred by the pipeline registers of the generated HDL code, so that the latency of the block matches the hardware.

The transfer function has L coefficients. The sharing factor, N, and the target device determine the specifics of the architecture used for simulation and HDL code generation. The implementation takes into account vendor-specific hardware details of the DSP blocks when adding pipeline registers to the architecture. The following diagrams depict the differences between the architecture choices made for FPGA targets from two different hardware vendors.

Fully Parallel FIR Systolic Architecture ($N = 1$)

With no DSP resource sharing, or when resource sharing is of factor 1, the block implements a fully parallel systolic architecture. In this case, the implementation utilizes L DSP (multiply-add) blocks and is heavily pipelined, resulting in high throughput. The filter can accept a new input sample on every cycle. The latency of the block is $L + 4$.



Resource Utilization and Performance

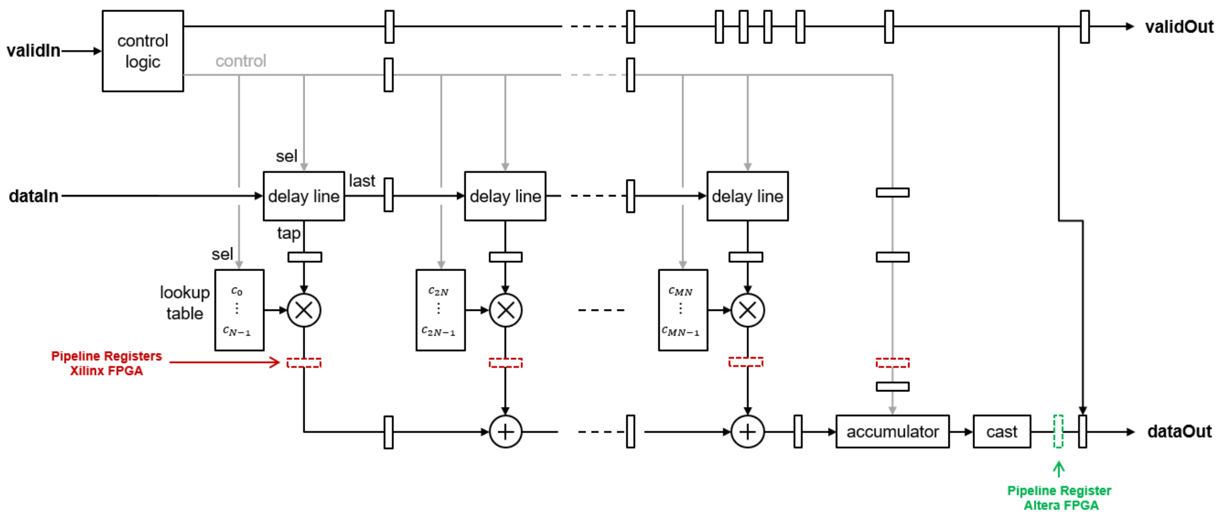
The following table shows post synthesis resource utilization for the HDL code generated from the “Fully Parallel Systolic FIR Filter Implementation” example. The implementation is for a 25-tap FIR filter with 16 bit input and 16 bit coefficients. The synthesis targets a Xilinx Virtex-6 (XC6VLX240T-1FF1156) FPGA. The reset type is synchronous and minimize clock enables is switched on.

Resource	Uses
FFS	830
Xilinx LogiCORE DSP48	25

After place and route, the maximum clock frequency of the design is 421 MHz.

Partly Serial FIR Systolic Architecture ($1 < N < L$)

When DSP resource sharing is of factor N, where $1 < N < L$, the block implements a partly serial systolic architecture. In this case, the implementation uses `M = ceil(L/N)` systolic cells. Each cell consists of a delay line, a coefficient lookup table, and a DSP (multiply-add) block. The coefficients are spread across the M lookup tables. The computation performed by each DSP block is serialized. Input samples to the block must be at least N cycles apart. The latency of the block is M + `ceil(`L`/`M`)` + 5.



Resource Utilization and Performance

The following table shows post synthesis resource utilization for the HDL code generated from the "Partly Serial Systolic FIR Filter Implementation" example. The implementation is for a 32-tap FIR filter with 16 bit input, 16 bit coefficients and a sharing factor of 8. The synthesis targets a Xilinx Virtex-6 (XC6VLX240T-1FF1156) FPGA. The reset type is synchronous and minimize clock enables is switched on.

Resource	Uses
LUT	192
FFS	606
Xilinx LogiCORE DSP48	5

After place and route, the maximum clock frequency of the design is 376 MHz.

Fully Serial FIR Systolic Architecture ($N \geq L$)

When DSP resource sharing is of factor N, where $N \geq L$, the block implements a fully serial systolic architecture. In this case, the implementation utilizes a single DSP (multiply-add) block with a delay line and a lookup table for all L coefficients. Input samples must be at least N cycles apart. The latency of the block is $L + 5$.

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Discrete Transfer Function Estimator block estimates the frequency-domain transfer function of a system using the Welch's method of averaged modified periodograms.

The block takes two inputs, x and y. x is the system input signal and y is the system output signal. x and y must have the same dimensions. For 2D inputs, the block treats each column as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats 1D inputs as one channel. The sample rate of the block is equal to $1/T$. T is the sample time of the inputs to the block.

The block buffers the input data into overlapping segments. You can set the length of the data segment and the amount of data overlap through the parameters set in the block dialog box.

The block first applies a window function to the two inputs, x and y, and then scales them by the window power. It takes the FFT of each signal, calling them X and Y. The block calculates P_{xx} which is the square magnitude of the FFT, X. The block then calculates P_{yx} which is X multiplied by the conjugate of Y. The output transfer function estimate, H, is calculated by dividing P_{yx} by P_{xx}.

Parameters

Window length source

Source of the window length value. You can set this parameter to:

- `Same as input frame length` (default) — Window length is set to the frame size of the input.
- `Specify on dialog` — Window length is the value specified in **Window length**.

This parameter is nontunable.

Window length

Length of the window, in samples, used to compute the spectrum estimate, specified as a positive integer scalar greater than `2`. This parameter applies when you set **Window length source** to `Specify on dialog`. The default is `1024`. This parameter is nontunable.

Window Overlap (%)

Percentage of overlap between successive data windows, specified as a scalar in the range [`0,100`). The default is `0`. This parameter is nontunable.

Number of spectral averages

Specify the number of spectral averages. The Transfer Function Estimator block computes the current estimate by averaging the last *N* estimates. *N* is the number of spectral averages. It can be any positive integer scalar, and the default is `1`.

FFT length source

Specify the source of the FFT length value. It can be one of `Auto` (default) or `Property`. When the source of the FFT length is set to `Auto`, the Transfer Function Estimator block sets the FFT length to the input frame size. When the source of the FFT length is set to `Property`, you specify the FFT length in the **FFT length** parameter.

FFT length

Specify the length of the FFT that the Transfer Function Estimator block uses to compute spectral estimates. It can be any positive integer scalar, and the default is 128.

Window function

Specify a window function for the Transfer Function Estimator block. Possible values are:

- `Hann` (default)
- `Rectangular`
- `Chebyshev`
- `Flat Top`
- `Hamming`
- `Kaiser`

Sidelobe attenuation of window (dB)

Specify the sidelobe attenuation of the window. It can be any real positive scalar value in decibels (dB). The default is `60`.

Note: This parameter is visible only when **Window function** is set to `Kaiser` or `Chebyshev`.

Frequency range

Specify the frequency range of the transfer function estimate.

- `centered` (default)

  When you set the frequency range to `centered`, the Transfer Function Estimator block computes the centered two-sided transfer function of the real or complex input signals, x and y.
- `onesided`

  When you set the frequency range to `onesided`, the Transfer Function Estimator block computes the one-sided transfer function of real input signals, x and y.
- `twosided`

  When you set the frequency range to `twosided`, the Transfer Function Estimator block computes the two-sided transfer function of the real or complex input signals, x and y.

Output magnitude squared coherence estimate

Select this check box to compute and output the magnitude squared coherence estimate using Welch's averaged, modified periodogram method. The magnitude squared coherence estimate indicates how well two inputs correspond to each other at each frequency.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

The Discrete Transfer Function Estimator block supports real and complex inputs.

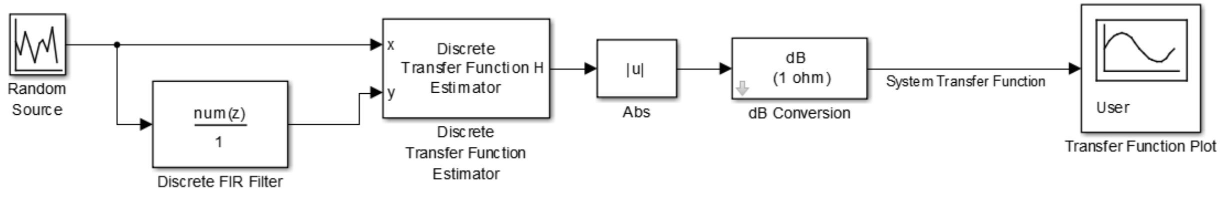
Port	Supported Data Type
x	• Double-precision floating point • Single-precision floating point
y	• Double-precision floating point • Single-precision floating point
Output, *H*	• Double-precision floating point • Single-precision floating point

Examples

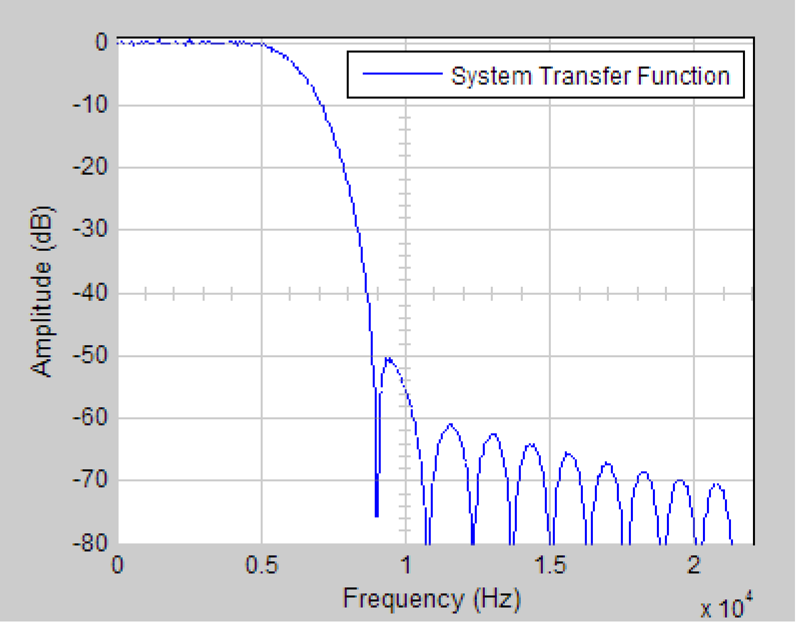
This example shows how to use the Discrete Transfer Function Estimator block to estimate the frequency-domain transfer function of a system.

The Random Source block represents the system input signal. The sample rate of the system input is 44.1 KHz. The Random Source input passes through a low-pass filter with a normalized cutoff frequency of 0.3. The filtered signal represents the system output signal. Because the Discrete Transfer Function Estimator block outputs complex values, take the magnitude of the output to see a plot of the transfer function estimate.

To view this example, execute `ex_discrete_transfer_function_estimator` in MATLAB Command prompt.



The transfer function plot displays the system transfer function, a low-pass filter that matches the frequency response of the Discrete FIR Filter block.



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

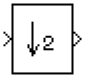
Introduced in R2008a

Downsample

Resample input at lower rate by deleting samples



Library

Signal Operations

`dspsigops`

Description

The Downsample block decreases the sampling rate of the input by deleting samples. When the block performs frame-based processing, it resamples the data in each column of the M_i-by-N input matrix independently. When the block performs sample-based processing, it treats each element of the input as a separate channel and resamples each channel of the input array across time. The resample rate is K times lower than the input sample rate, where K is the integer you specify for the **Downsample factor** parameter. The Downsample block resamples the input by discarding K–1 consecutive samples following each sample that is passed through to the output.

The **Sample offset** parameter delays the output samples by an integer number of sample periods, D, where $0 \leq D \leq (K–1)$, so that any of the K possible output phases can be selected. For example, when you downsample the sequence 1, 2, 3, ... by a factor of 4, you can select from the following four phases.

Input Sequence	Sample Offset, D	Output Sequence (K=4)
`1,2,3,...`	0	`1,5,9,13,17,21,25,29,...`
`1,2,3,...`	1	`0,2,6,10,14,18,22,26,...`
`1,2,3,...`	2	`0,3,7,11,15,19,23,27,...`
`1,2,3,...`	3	`0,4,8,12,16,20,24,28,...`

The initial zero in each of the latter three output sequences in the table is a result of the default zero **Initial conditions** parameter setting for this example. See "Latency" on page 2-611 for more information on the **Initial conditions** parameter.

This block supports triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the input can be an N-D array. The Downsample block treats each element of the input as a separate channel, and resamples each channel of the input over time. The block downsamples the input array by discarding K–1 samples following each sample that it passes through to the output. The input and output sizes of the Downsample block are identical.

The **Rate options** parameter specifies how the block adjusts the rate at the output to accommodate the reduced number of samples. There are two available options:

- `Allow multirate processing`

  When you select `Allow multirate processing`, the sample period of the output is K times longer than the input sample period ($T_{so} = KT_{si}$).

- `Enforce single-rate processing`

  When you select `Enforce single-rate processing`, the block forces the output sample rate to match the input sample rate ($T_{so} = T_{si}$) by repeating every Kth input sample K times at the output. In this mode, the behavior of the block is similar to the operation of a Sample and Hold block with a repeating trigger event of period KT_{si}.

Frame-Based Processing

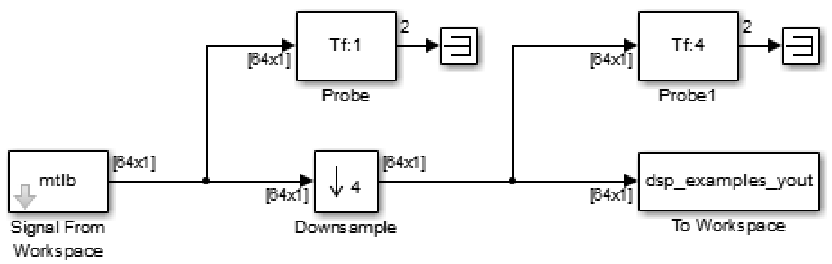
When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each of the N input columns as an individual channel containing M_i sequential time samples. The block downsamples each channel independently by discarding K–1 rows of the input matrix following each row that it passes through to the output.

The **Rate options** parameter specifies how the block adjusts the rate at the output to accommodate the reduced number of samples. There are two available options:

- `Allow multirate processing`

  The block generates the output at the slower (downsampled) rate by using a proportionally longer frame *period* at the output port than at the input port. For downsampling by a factor of K, the output frame period is K times longer than the input frame period ($T_{fo} = KT_{fi}$), but the input and output frame sizes are equal.

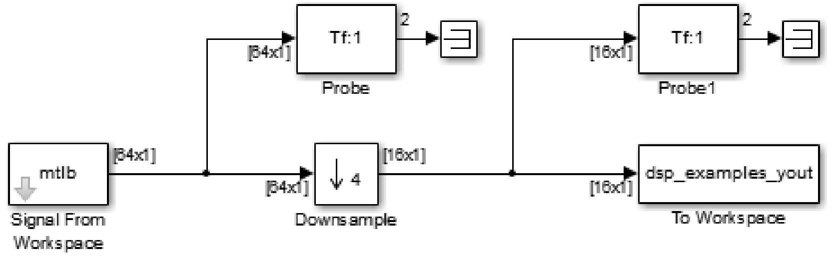
  The ex_downsample_ref1 model shows a single-channel input with a frame period of 1 second being downsampled by a factor of 4 to a frame period of 4 seconds. The input and output frame sizes are identical.



- `Enforce single rate processing`

  The block generates the output at the slower (downsampled) rate using a proportionally smaller frame *size* than the input. For downsampling by a factor of K, the output frame size is K times smaller than the input frame size ($M_o = M_i/K$), but the input and output frame rates are equal.

  The ex_downsample_ref2 model shows a single-channel input with a frame size of 64 being downsampled by a factor of 4 to a frame size of 16. The input and output frame rates are identical.



Latency

The Downsample block has *zero-tasking latency* in the following cases:

- The **Downsample factor** parameter, K, is `1`.
- The **Input processing** parameter is set to `Columns as channels (frame based)` and the **Rate options** parameter is set to `Enforce single-rate processing`.
- The **Input processing** parameter is set to `Columns as channels (frame based)` and the input frame size is equal to one.
- The **Input processing** parameter is set to `Elements as channels (sample based)`, and **Sample offset** parameter, D, is `0`.

Zero-tasking latency means that the block propagates input sample D+1 (received at t=0) as the first output sample, followed by input sample D+1+K, input sample D+1+2K, and so on. When there is zero-tasking latency, the block ignores the value of the **Initial conditions** parameter.

In all other cases, the latency is nonzero:

- When the **Input processing** parameter is set to `Elements as channels (sample based)`, the latency is one sample.
- When the **Input processing** parameter is set to `Columns as channels (frame based)` and the input frame size is greater than one, the latency is one frame.

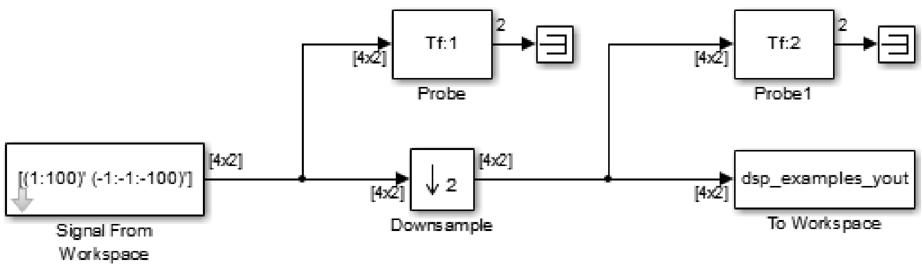
In all cases of *one-sample latency*, the initial condition for each channel appears as the first output sample. Input sample D+1 appears as the second output sample for each channel, followed by input sample D+1+K, input sample D+1+2K, and so on. The **Initial conditions** parameter can be an array of the same size as the input, or a scalar to be applied to all signal channels.

In all cases of *one-frame latency*, the M_i rows of the initial condition matrix appear in sequence as the first M_i output rows. Input sample D+1 (i.e, row D+1 of the input matrix) appears in the output as sample M_i+1, followed by input sample D+1+K, input sample D+1+2K, and so on. The **Initial conditions** value can be an M_i-by-N matrix containing one value for each channel, or a scalar to be repeated across all elements of the M_i-by-N matrix. See the following example for an illustration of this case.

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Examples

Open the ex_downsample_ref3 model.



Run the model and look at the output, `yout`. The first few samples of each channel are as follows:

```
yout =
    11    -11
    12    -12
    13    -13
    14    -14
     2     -2
     4     -4
     6     -6
     8     -8
    10    -10
    12    -12
    14    -14
```

You can see from the two Probe blocks that there are at least two distinct frame rates in this model. Because you ran this model in multirate, multitasking mode, the first row of the initial condition matrix appears as the first output sample, followed by the other three initial condition rows. The second row of the first input matrix (row D+1, where D is the **Sample offset**) appears in the output as sample 5 (sample M_i+1, where M_i is the input frame size).

Parameters

Downsample factor

The integer factor, K, by which to decrease the input sample rate.

Sample offset

The sample offset, D, which must be an integer in the range [0, K–1].

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. See “Frame-Based Processing” on page 2-609 for more information
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. See “Sample-Based Processing” on page 2-609 for more information.

Rate options

Specify the method by which the block should downsample the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate.
- `Allow multirate processing` — When you select this option, the block downsamples the signal such that the output sample rate is K times slower than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency. You can specify a scalar, or an array of the same size as the input. This parameter appears only when you set the **Rate options** parameter to `Allow multirate processing`.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see Downsample.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

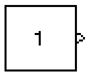
DSP Constant (Obsolete)

Generate discrete- or continuous-time constant signal



Library

Sources

`dspobslib`

Description

Note The DSP Constant block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Constant block.

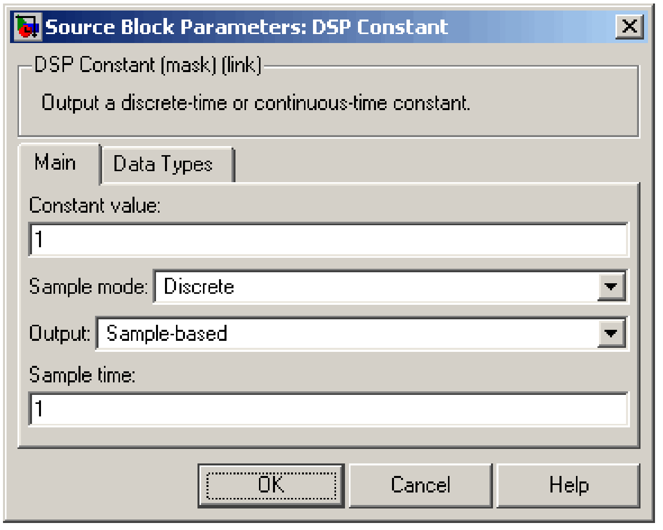
The DSP Constant block generates a signal whose value remains constant throughout the simulation. The **Constant value** parameter specifies the constant to output, and can be any valid MATLAB expression that evaluates to a scalar, vector, or matrix.

When **Sample mode** is set to `Continuous`, the output is a continuous-time signal. When **Sample mode** is set to `Discrete`, the **Sample time** parameter is visible, and the signal has the discrete output period specified by the **Sample time** parameter.

You can set the output signal to `Frame-based`, `Sample-based`, or `Sample-based (interpret vectors as 1-D)` with the **Output** parameter.

Dialog Box

The **Main** pane of the DSP Constant block dialog box appears as follows.



Constant value

Specify the constant to generate. This parameter is Tunable (Simulink); values entered here can be tuned, but their dimensions must remain fixed.

When you specify any data type information in this field, it is overridden by the value of the **Output data type** parameter in the **Data Types** pane, unless you select `Inherit from 'Constant value'`.

Sample mode

Specify the sample mode of the output, `Discrete` for a discrete-time signal or `Continuous` for a continuous-time signal.

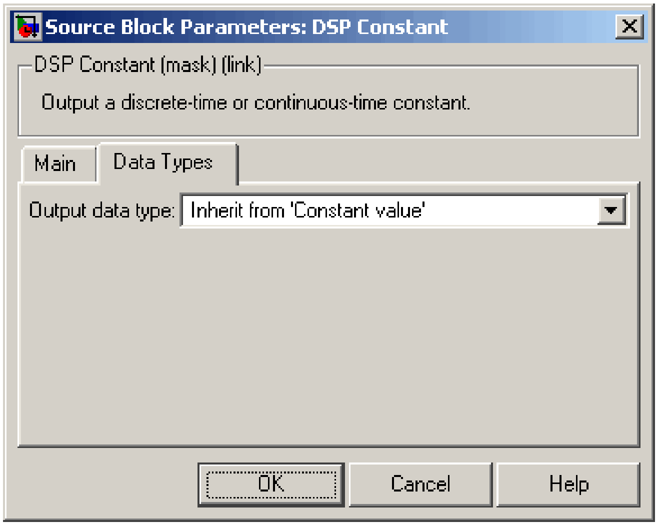
Output

Specify whether the output is `Sample-based (interpret vectors as 1-D)`, `Sample-based`, or `Frame-based`. When you select `Sample-based` and the output is a vector, its dimension is constrained to match the **Constant value** dimension (row or column). When you select `Sample-based (interpret vectors as 1-D)`, however, the output has no specified dimensionality.

Sample time

Specify the discrete sample period for sample-based outputs. When you select `Frame-based` for the **Output** parameter, this parameter is named **Frame period**, and is the discrete frame period for the frame-based output. This parameter is only visible when you select `Discrete` for the **Sample mode** parameter.

The **Data Types** pane of the DSP Constant block dialog box appears as follows.



Output data type

Specify the output data type in one of the following ways:

- Choose one of the built-in data types from the list.
- Choose `Fixed-point` to specify the output data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `User-defined` to specify the output data type and scaling in the **User-defined data type**, **Set fraction length in output to** , and **Fraction length** parameters.
- Choose `Inherit from 'Constant value'` to set the output data type and scaling to match the values of the **Constant value** parameter in the **Main** pane.
- Choose `Inherit via back propagation` to set the output data type and scaling to match the following block.

The value of this parameter overrides any data type information specified in the **Constant value** parameter in the **Main** pane, except when you select `Inherit from 'Constant value'`.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

Word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the following Fixed-Point Designer functions: `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Output data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose `Best precision` to have the output scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the output scaling in the **Fraction length** parameter.

This parameter is only visible when you select `Fixed-point` for the **Output data type** parameter, or when you select `User-defined` and the specified output data type is a fixed-point data type.

Fraction length

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Output data type** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers

- 8-, 16-, and 32-bit unsigned integers

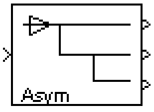
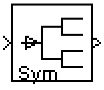
DWT

Discrete wavelet transform (DWT) of input or decompose signals into subbands with smaller bandwidths and slower sample rates





Library

Transforms

`dspxfrm3`

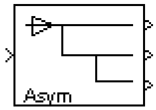
Description

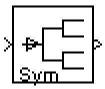
The DWT block is the same as the Dyadic Analysis Filter Bank block in the Multirate Filters library, but with different default settings. See the `Dyadic Analysis Filter Bank` block reference page for more information.

Introduced before R2006a

Dyadic Analysis Filter Bank

Decompose signals into subbands with smaller bandwidths and slower sample rates or compute discrete wavelet transform (DWT)





Library

Filtering / Multirate Filters

`dspmlti4`

Description

Note: This block always interprets input signals as frames. The frame size of the input signal must be a multiple of 2^n, where `n` is the value of the **Number of levels** parameter. The block decomposes the input signal into either n+1 or 2^n subbands. To decompose signals with a frame size that is not a multiple of 2^n, use the `Two-Channel Analysis Subband Filter` block. (You can connect multiple copies of the Two-Channel Analysis Subband Filter block to create a multilevel dyadic analysis filter bank.)

You can configure this block to compute the Discrete Wavelet Transform (DWT) or decompose a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The block uses a series of highpass and lowpass FIR filters to repeatedly divide the input frequency range, as illustrated in “Wavelet Filter Banks” on page 2-625 (the Asymmetric one).

You can specify the filter bank's highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask, or, if you have a Wavelet

Toolbox™ license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

For the same input, the DWT configuration of this block does not produce the same results as the Wavelet Toolbox `dwt` function. Because DSP System Toolbox is designed for real-time implementation and Wavelet Toolbox is designed for analysis, the products handle boundary conditions and filter states differently. To make the output of the `dwt` function match the DWT output of this block, complete the following steps:

1. Set the boundary condition of the `dwt` function to zero-padding. To do so, type `dwtmode('zpd')` at the MATLAB command line.
2. To match the latency of the block (implemented using FIR filters), add zeros to the input of the `dwt` function. The number of zeros you add must be equal to the half-length of the filter.

Input Requirements

- Input must be a vector or matrix.
- The input frame size must be a multiple of 2^n, where n is the number of filter bank levels. For example, a frame size of 16 would be appropriate for a three-level tree (16 is a multiple of 2^3).
- The block always treats input signals as frames and operates along the columns.

For an illustration of why the above input requirements exist, see the figure Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank.

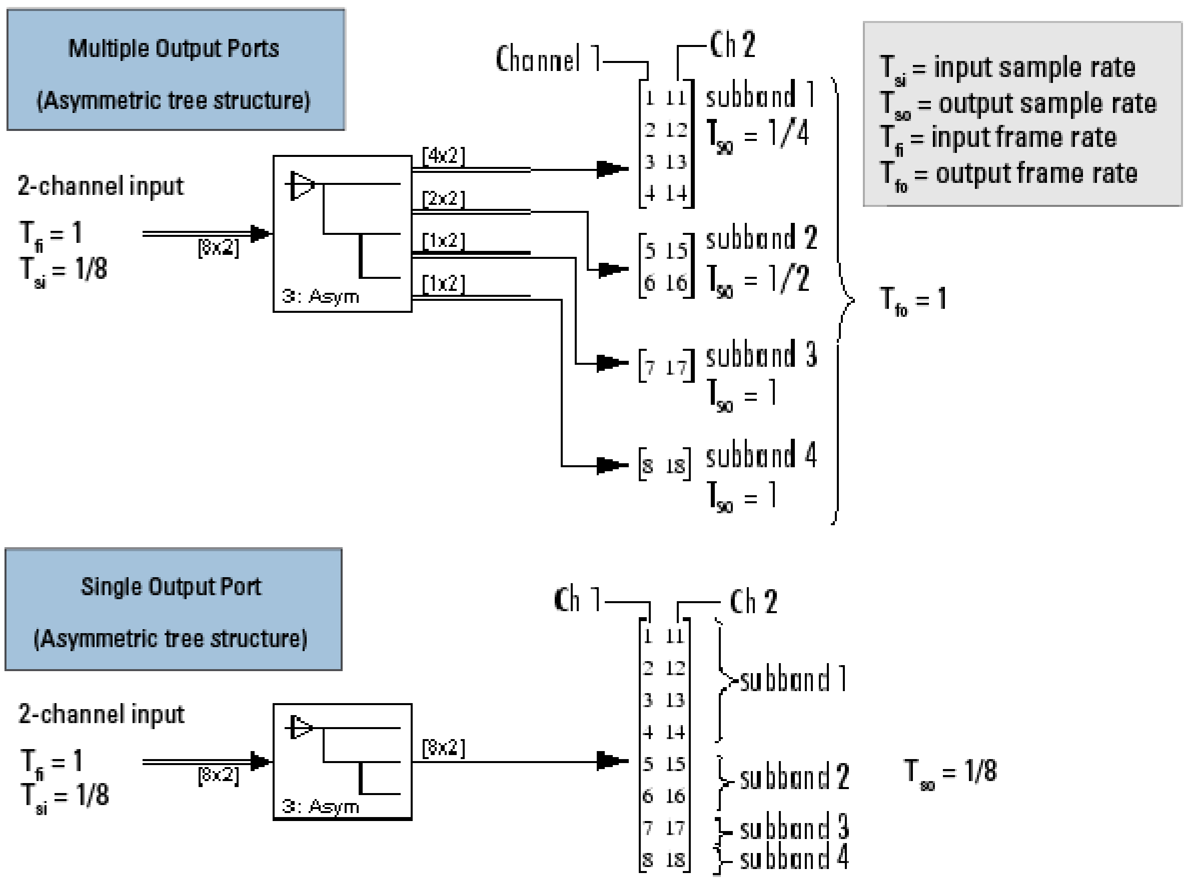
Output Characteristics

The output characteristics vary depending on the block's parameter settings, as summarized in the following list and figure:

- **Number of levels** parameter set to n
- **Tree structure** parameter setting:
  - `Asymmetric` — Block produces n+1 output subbands
  - `Symmetric` — Block produces 2^n output subbands
- **Output** parameter setting can be `Multiple ports` or `Single port`. When you set the **Output** parameter to `Single port`, the block outputs one vector or matrix of

concatenated subbands. The following figure illustrates the difference between the two settings for a 3-level asymmetric dyadic analysis filter bank. For an explanation of the illustrated output characteristics, see the table Output Characteristics for an n-Level Dyadic Analysis Filter Bank.

For more information about the filter bank levels and structures, see “Dyadic Analysis Filter Banks”.



Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank

The following table summarizes the different output characteristics of the block when it is set to output from single or multiple ports.

Output Characteristics for an n-Level Dyadic Analysis Filter Bank

	Single Output Port	Multiple Output Ports
Output Description	Block concatenates all the subbands into one vector or matrix, and outputs the concatenated subbands from a single output port. Each output column contains subbands of the corresponding input channel.	Block outputs each subband from a separate output port. The topmost port outputs the subband with the highest frequencies. Each output column contains a subband for the corresponding input channel.
Output Frame Rate	*Not applicable*	Same as input frame rate (However, the output frame sizes can vary, so the output sample rates can vary.)
Output Dimensions (Frame Size)	Same number of rows and columns as the input.	The output has the same number of columns as the input. The number of output rows is the output frame size. For an input with frame size M_i output y_k has frame size $M_{o,k}$: • `Symmetric` — All outputs have the frame size, $M_i / 2^n$. • `Asymmetric` — The frame size of each output (except the last) is half that of the output from the previous level. The outputs from the last two output ports have the same frame size since they originate from the same level in the filter bank. $$M_{o,k} = \begin{cases} M_i / 2^k & (1 \le k \le n) \\ M_i / 2^n & (k = n+1) \end{cases}$$
Output Sample Rate	Same as input sample rate.	Though the outputs have the same frame rate as the input, they have different frame sizes than

	Single Output Port	Multiple Output Ports
		the input. Thus, the output sample rates, F_{so}, k, are different from the input sample rate, F_{si}: • `Symmetric` — All outputs have the sample rate F_{si} / 2^n. • `Asymmetric` — $F_{so,k} = \begin{cases} F_{si}/2^k & (1 \le k \le n) \\ F_{si}/2^n & (k = n+1) \end{cases}$

Wavelet Filter Banks

- "Filter Banks"

Filter Bank Filters

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- `User defined` — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops.
- Wavelet such as `Biorthogonal` or `Daubechies` — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox `wfilters` function. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) You must have a Wavelet Toolbox license to use wavelets.

Specifying Filters with the Filter Parameter and Related Parameters

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
User-defined	Filters based on Daubechies wavelets with wavelet order `3`:	None

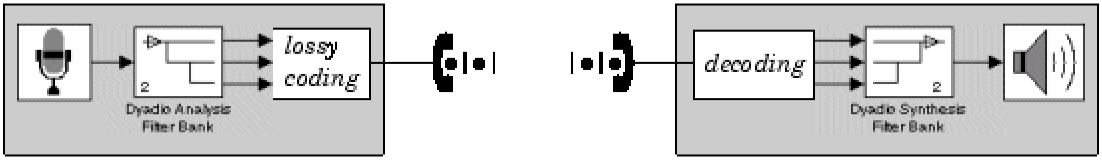
Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
	• **Lowpass FIR filter coefficients** = `[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` • **Highpass FIR filter coefficients** = `[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]`	
Haar	None	`wfilters('haar')`
Daubechies	**Wavelet order** = 4	`wfilters('db4')`
Symlets	**Wavelet order** = 3	`wfilters('sym3')`
Coiflets	**Wavelet order** = 1	`wfilters('coif1')`
Biorthogonal	**Filter order [synthesis / analysis]** = [3/1]	`wfilters('bior3.1')`
Reverse Biorthogonal	**Filter order [synthesis / analysis]** = [3/1]	`wfilters('rbio3.1')`
Discrete Meyer	None	`wfilters('dmey')`

Examples

Wavelets

The primary application for dyadic analysis filter banks and dyadic synthesis filter banks is coding for data compression using wavelets.

At the transmitting end, the output of the dyadic analysis filter bank is fed to a lossy compression scheme, which typically assigns the number of bits for each filter bank output in proportion to the relative energy in that frequency band. This represents the more powerful signal components by a greater number of bits than the less powerful signal components.



At the receiving end, the transmission is decoded and fed to a dyadic synthesis filter bank to reconstruct the original signal. The filter coefficients of the complementary analysis and synthesis stages are designed to cancel aliasing introduced by the filtering and resampling.

See “Calculate Channel Latencies Required for Wavelet Reconstruction” for an example using the Dyadic Analysis and Dyadic Synthesis Filter Bank blocks.

Examples

See the floating-point frame-based version of the DSP System Toolbox Wavelet Reconstruction and Noise Reduction example, which uses the Dyadic Analysis Filter Bank and Dyadic Synthesis Filter Bank blocks.

Parameters

The parameters displayed in the block dialog vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.

Filter

The type of filter used to determine the high- and low-pass FIR filters in the filter bank:

Select `User defined` to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

Select a wavelet such as `Biorthogonal` or `Daubechies` to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order [synthesis / analysis]** might become enabled. For a list of the supported wavelets, see Specifying Filters with the Filter Parameter and Related Parameters.

Lowpass FIR filter coefficients

A vector of filter coefficients (descending powers of z) that specifies coefficients used by all the lowpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order `3`.

Highpass FIR filter coefficients

A vector of filter coefficients (descending powers of z) that specifies coefficients used by all the highpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order `3`.

Wavelet order

The order of the wavelet selected in the **Filter** parameter. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in the Specifying Filters with the Filter Parameter and Related Parameters table.

Filter order [synthesis / analysis]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to `Biorthogonal` and set the **Filter order [synthesis / analysis]** parameter to `[2 / 6]`, the block calls the `wfilters` function with input argument `'bior2.6'`. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in Specifying Filters with the Filter Parameter and Related Parameters.

Number of levels

The number of filter bank levels. An n-level asymmetric structure has n+1 outputs, and an n-level symmetric structure has 2^n outputs, as shown in “Wavelet Filter Banks” on page 2-625. The block's icon changes depending on the value of this parameter.

The default setting of this parameter is `2`.

Tree structure

The structure of the filter bank: `Asymmetric`, or `Symmetric`. See “Wavelet Filter Banks” on page 2-625.

The default setting of this parameter is `Asymmetric` for the Dyadic Analysis Filter Bank block, and `Symmetric` for the DWT block.

Output

Set to `Multiple ports` to output each output subband on a separate port (the topmost port outputs the subband with the highest frequency band). Set to `Single port` to concatenate the subbands into one vector or matrix and output the concatenated subbands on a single port. For more information, see "Output Characteristics" on page 2-622.

The default setting of this parameter is `Multiple ports` for the Dyadic Analysis Filter Bank block, and `Single port` for the DWT block.

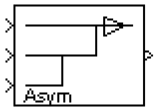
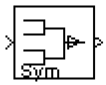
Dyadic Synthesis Filter Bank

Reconstruct signals from subbands with smaller bandwidths and slower sample rates or compute inverse discrete wavelet transform (IDWT)





Library

Filtering / Multirate Filters

`dspmlti4`

Description

Note This block always does frame-based processing, and its inputs must be of certain sizes. To use input subbands that do not fit the criteria of this block, use the `Two-Channel Synthesis Subband Filter` block. (You can connect multiple copies of the Two-Channel Synthesis Subband Filter block to create a multilevel dyadic synthesis filter bank.)

You can configure this block to compute the inverse discrete wavelet transform (IDWT) or reconstruct a signal from subbands with smaller bandwidths and slower sample rates. When the block computes the inverse discrete wavelet transform (IDWT) of the input, the output has the same dimensions as the input. Each column of the output is the IDWT of the corresponding input column. When reconstructing a signal, the block uses a series of highpass and lowpass FIR filters to reconstruct the signal from the input subbands, as illustrated in “Wavelet Filter Banks” on page 2-635 (the Asymmetric one). The reconstructed signal has a wider bandwidth and faster sample rate than the input subbands.

You can specify the filter bank's highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask, or, if you have a Wavelet Toolbox license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

When you set the **Input** parameter to `Multiple ports`, you must provide each subband to the block through a different input port as a vector or matrix. You should input the highest frequency band through the topmost port. When you set the **Input** parameter to `Single port`, the block input must be a vector or matrix of concatenated subbands.

Note To use a dyadic synthesis filter bank to perfectly reconstruct the output of a dyadic analysis filter bank, the number of levels and tree structures of both filter banks *must* be the same. In addition, the filters in the synthesis filter bank *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect.

This block automatically computes wavelet-based perfect reconstruction filters when the wavelet selection in the **Filter** parameter of this block is the *same* as the **Filter** parameter setting of the corresponding `Dyadic Analysis Filter Bank` block. The use of wavelets requires a Wavelet Toolbox license. To learn how to design your own perfect reconstruction filters, see “References” on page 2-639.

Input Requirements

The inputs to this block are usually the outputs of a `Dyadic Analysis Filter Bank` block. Since the Dyadic Analysis Filter Bank block can output from either a single port or multiple ports, the Dyadic Synthesis Filter Bank block accepts inputs to either a single port or multiple ports.

The **Input** parameter sets whether the block accepts inputs from a single port or multiple ports, and thus determines the input requirements, as summarized in the following lists and figure.

Note: Any output of a Dyadic Analysis Filter Bank block whose parameter settings match the corresponding settings of this block is a valid input to this block. For example, the setting of the Dyadic Analysis Filter Bank block parameter, **Output**, must be the same as this block's **Input** parameter (`Single port` or `Multiple ports`).

Valid Inputs for Input Set to Single Port

- Inputs must be vectors or matrices of concatenated subbands.
- Each input column contains the subbands for an independent signal.
- Upper input rows contain the high-frequency subbands, and the lower rows contain the low-frequency subbands.

Valid Inputs for Input Set to Multiple Ports

- Each subband must be provided as a vector or matrix to separate block input ports.
- The columns of each input contains a subband for an independent signal.
- The input to the topmost input port is the subband containing the highest frequencies, and the input to the bottommost port is the subband containing the lowest frequencies.

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Output Characteristics

The following table summarizes the output characteristics for both types of inputs. For an illustration of why the output characteristics exist, see the figure Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank.

	Input = Multiple ports	Input = Single port (Concatenated Subband Inputs)
Output Frame Rate	Same as the input frame rate.	Same as the input rate (the rate of the concatenated subband inputs).

Output Frame Dimensions	• The output has the same number of columns as the inputs.
	• The number of output rows depends on the tree structure of the filter bank:
	  • **Asymmetric** — The number of output rows is twice the number of rows in the input to the topmost input port.
	  • **Symmetric** — The number of output rows is the product of the number of input ports and the number of rows in an input to any input port.
		The output has the same number of rows and columns as the input.

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Wavelet Filter Banks

- “Filter Banks”

Filter Bank Filters

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- `User defined` — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops. To use this block to perfectly reconstruct a signal decomposed by a `Dyadic Analysis Filter Bank` block, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. To learn how to design your own perfect reconstruction filters, see "References" on page 2-639.
- Wavelet such as `Biorthogonal` or `Daubechies` — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox function `wfilters`. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) To use this block to reconstruct a signal decomposed by a `Dyadic Analysis Filter Bank` block, you must set both blocks to use the same wavelets with the same order. You must have a Wavelet Toolbox license to use wavelets.

Specifying Filters with the Filter Parameter and Related Parameters

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
User-defined	Filters based on Daubechies wavelets with wavelet order `3`: • **Lowpass FIR filter coefficients** = `[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` • **Highpass FIR filter coefficients** = `[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]`	None
Haar	None	`wfilters('haar')`
Daubechies	**Wavelet order** = `4`	`wfilters('db4')`
Symlets	**Wavelet order** = `3`	`wfilters('sym3')`
Coiflets	**Wavelet order** = `1`	`wfilters('coif1')`

Filter	Sample Setting for Related Filter Specification Parameters	Corresponding Wavelet Function Syntax
Biorthogonal	**Filter order [synthesis / analysis]** = `[3/1]`	`wfilters('bior3.1')`
Reverse Biorthogonal	**Filter order [synthesis / analysis]** = `[3/1]`	`wfilters('rbio3.1')`
Discrete Meyer	None	`wfilters('dmey')`

Examples

See "Examples" on page 2-626 on the `Dyadic Analysis Filter Bank` block reference page.

Parameters

The parameters displayed in the block dialog vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.

Note To use this block to reconstruct a signal decomposed by a `Dyadic Analysis Filter Bank` block, all the parameters in this block must be the same as the corresponding parameters in the Dyadic Analysis Filter Bank block (except the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients**; see the descriptions of these parameters).

Filter

The type of filter used to determine the high- and low-pass FIR filters in the filter bank:

- Select `User defined` to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.
- Select a wavelet such as `Biorthogonal` or `Daubechies` to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order**

[synthesis / analysis] might become enabled. For a list of the supported wavelets, see the table Specifying Filters with the Filter Parameter and Related Parameters.

Lowpass FIR filter coefficients

A vector of filter coefficients (descending powers of *z*) that specifies coefficients used by all the lowpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the `Dyadic Analysis Filter Bank`, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order `3`).

Highpass FIR filter coefficients

A vector of filter coefficients (descending powers of *z*) that specifies coefficients used by all the highpass filters in the filter bank. This parameter is enabled when you set **Filter** to `User defined`. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the `Dyadic Analysis Filter Bank`, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order `3`).

Wavelet order

The order of the wavelet selected in the **Filter** parameter. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in the table Specifying Filters with the Filter Parameter and Related Parameters.

Filter order [synthesis / analysis]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to **Biorthogonal** and set the **Filter order [synthesis / analysis]** parameter to `[2 / 6]`, the block calls the `wfilters` function with input argument `'bior2.6'`. This parameter is enabled only when you set **Filter** to certain types of wavelets, as shown in Specifying Filters with the Filter Parameter and Related Parameters.

Number of levels

The number of filter bank levels. An n-level asymmetric structure has n+1 inputs, and an n-level symmetric structure has 2^n inputs, as shown in "Wavelet Filter Banks" on page 2-635.

The default setting of this parameter is `2`.

Tree structure

The structure of the filter bank: `Asymmetric`, or `Symmetric`. See "Wavelet Filter Banks" on page 2-635.

The default setting of this parameter is `Asymmetric` for the Dyadic Synthesis Filter Bank block, and `Symmetric` for the IDWT block.

Input

Set to `Multiple ports` to accept each input subband at a separate port (the topmost port accepts the subband with the highest frequency band). Set to `Single port` to accept one vector or matrix of concatenated subbands at a single port. For more information, see "Input Requirements" on page 2-632.

The default setting of this parameter is `Multiple ports` for the Dyadic Synthesis Filter Bank block, and `Single port` for the IDWT block.

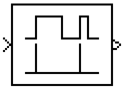
Introduced before R2006a

Edge Detector

Detect transition from zero to nonzero value



Library

Signal Management / Switches and Counters

`dspswit3`

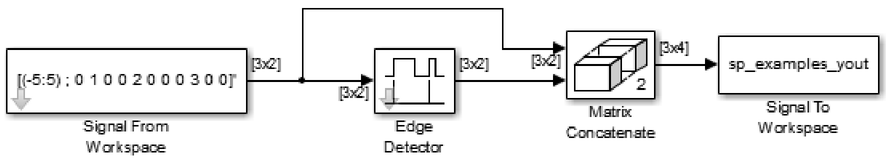
Description

The Edge Detector block generates an impulse (the value 1) in a given output channel when the corresponding channel of the input transitions from zero to a nonzero value. When the input does not transition from zero to a nonzero value, the block generates a zero in the corresponding output channel.

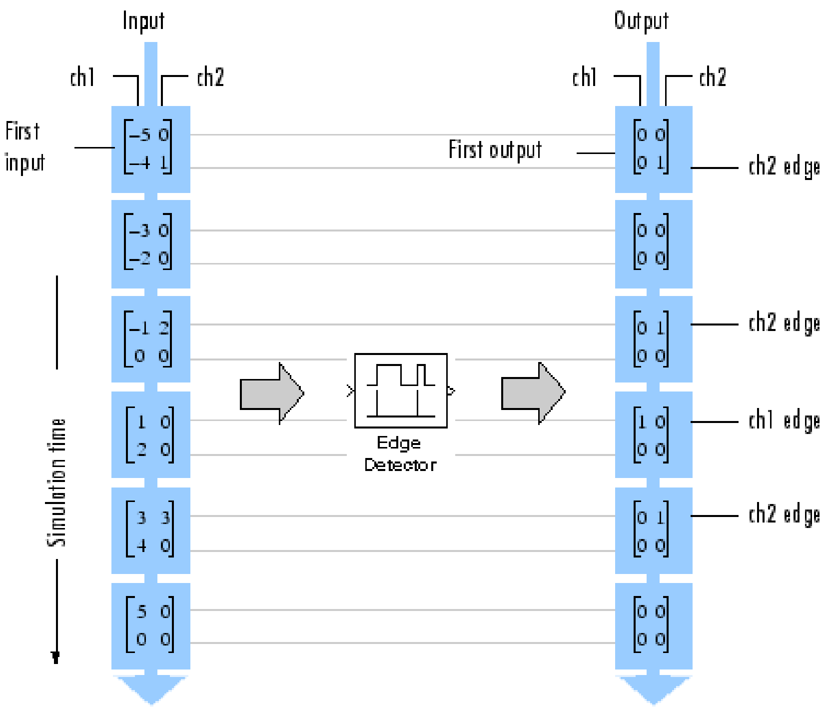
The output has the same dimension and sample rate as the input. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block counts an edge that is split across two consecutive frames in the frame that contains the nonzero value. For example, if there is a zero at the bottom of the first frame and a nonzero value at the top of the second frame, the block counts the edge in the second frame.

Examples

In the ex_edgedetector_ref model, the **Input processing** parameter of the Edge Detector block is set to `Columns as channels (frame based)`. Thus, the block interprets the 3-by-2 input as a multichannel signal with a frame size of 3. The Matrix Concatenate block concatenates the two input channels of the original signal with the two output channels of the Edge Detector block to create the four-channel workspace variable `sp_examples_yout`.



As shown in the following figure, the block finds edges at sample 7 in channel 1, and at samples 2, 5, and 9 in channel 2.



Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block might output Boolean values depending on the input data type, and whether Boolean support is enabled or disabled.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

See Also

Counter	DSP System Toolbox
Event-Count Comparator	DSP System Toolbox

Introduced before R2006a

Event-Count Comparator

Detect threshold crossing of accumulated nonzero inputs

Library

Signal Management / Switches and Counters

`dspswit3`

Description

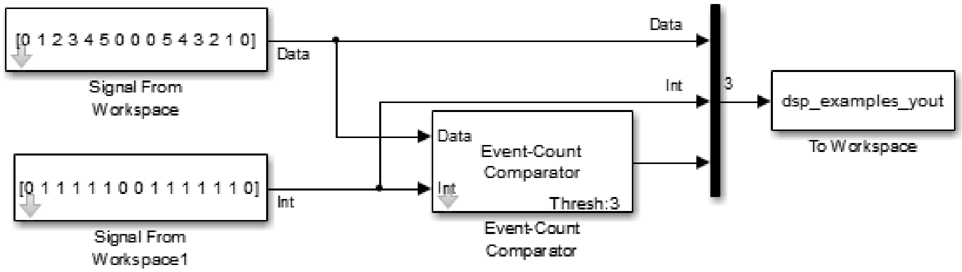
The Event-Count Comparator block records the number of nonzero inputs to the Data port during the period that the block is enabled by a high signal (the value 1) at the Int port. Both inputs must be scalars.

When the number of accumulated nonzero inputs first equals the **Event threshold** setting, the block waits one additional sample interval, and then sets the output high (1). The block holds the output high until recording is restarted by a low-to-high (0-to-1) transition at the Int port.

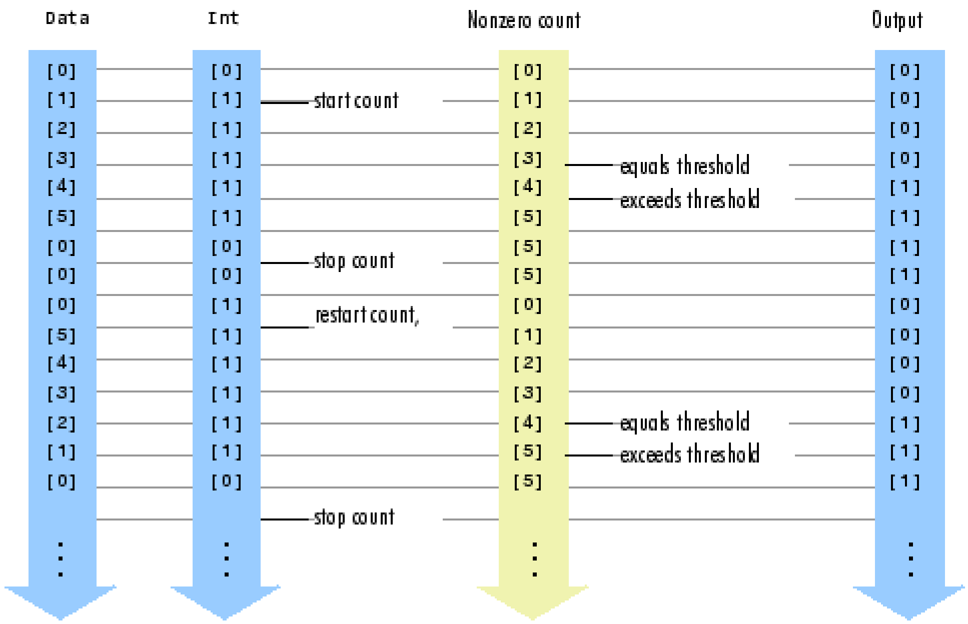
The Event-Count Comparator block accepts real and complex floating-point and fixed-point inputs. However, because the block has discrete state, it does not support constant or continuous sample times. Therefore, at least one input or output port of the Event-Count Comparator block must be connected to a block whose **Sample time** parameter is discrete. The Event-Count Comparator block inherits this non-infinite discrete sample time.

Examples

In the ex_eventcountcomp_ref model, the Event-Count Comparator block (**Event threshold** = 3) detects two threshold crossings in the input to the Data port, one at sample 4 and one at sample 12.



All inputs and outputs are multiplexed into the workspace variable `yout`, whose contents are shown in the figure below. The two left columns in the illustration show the inputs to the Data and Int ports, the center column shows the state of the block's internal counter, and the right column shows the block's output.



Parameters

Event threshold

Specify the value against which to compare the number of nonzero inputs. Tunable (Simulink).

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

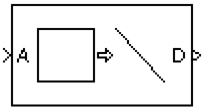
Extract Diagonal

Extract main diagonal of input matrix



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Extract Diagonal block populates the unoriented output vector with the elements on the main diagonal of the M-by-N input matrix `A`.

```
D = diag(A)     Equivalent MATLAB code
```

The output vector has length `min(M,N)`.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — Block outputs are always Boolean.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

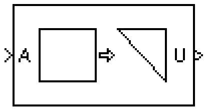
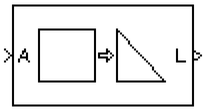
Introduced before R2006a

Extract Triangular Matrix

Extract lower or upper triangle from input matrices





Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

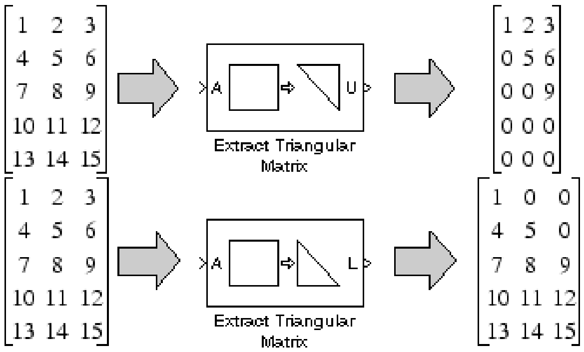
The Extract Triangular Matrix block creates a triangular matrix output from the upper or lower triangular elements of an M-by-N input matrix. The block treats length-M unoriented vector inputs as an M-by-1 matrix.

The **Extract** parameter selects between the two components of the input:

- `Upper` — Copies the elements on and above the main diagonal of the input matrix to an output matrix of the same size. The first *row* of the output matrix is therefore identical to the first *row* of the input matrix. The elements below the main diagonal of the output matrix are zero.
- `Lower` — Copies the elements on and below the main diagonal of the input matrix to an output matrix of the same size. The first *column* of the output matrix is therefore identical to the first *column* of the input matrix. The elements above the main diagonal of the output matrix are zero.

Examples

The ex_extracttriang_ref model below shows the extraction of upper and lower triangles from a 5-by-3 input matrix.



Parameters

Extract

The component of the matrix to copy to the output: upper triangle or lower triangle.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
U	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned)

Port	Supported Data Types
	• Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
L	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

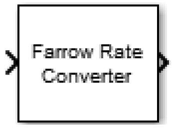
Farrow Rate Converter

Polynomial sample-rate converter with arbitrary conversion factor



Library

Signal Operations

`dspsigops`

Description

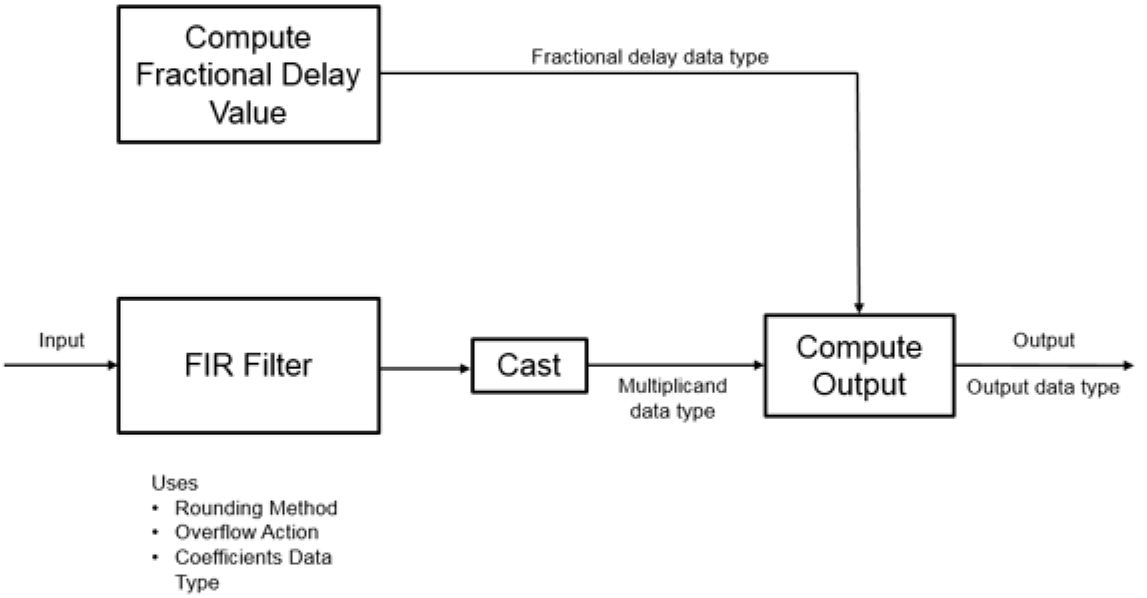
The Farrow Rate Converter block converts the sample rate of an input signal using polynomial fit sample-rate conversion. Polynomial-based filters are efficient at implementing fractional sample rate conversion. Farrow structures are implementations of polynomial-based filters. This block uses a Farrow structure to implement arbitrary rate-change factors efficiently. The rate-change factors can be irrational.

The input frame size must be a multiple of the decimation factor of the rate converter. The decimation factor depends on the parameter settings of the block. To determine the decimation factor, in the block dialog box click **View Info** .

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel. The inputs to the block can be single, double, or fixed-point data type.

Fixed-Point Data Types

The signal flow diagram shows the data types used within the farrow rate converter for fixed-point signals and floating-point signals. You can specify these data types in the Farrow rate converter. If the input is floating point, all the data types with in the signal flow diagram have the same data type as the input, which can be single or double.



If the input is fixed point, the FIR filter uses the rounding mode, overflow mode, and the coefficients data type data you provide to the Farrow rate converter. The accumulator data type and the product data type in the signal flow are full precision.

Dialog Box

Main tab:

Sample rate of input signal (Hz)

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest. The default is `48e3`.

Sample rate of output signal (Hz)

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate must be higher or lower than the input sample rate. The default is `98e3`.

Tolerance for output sample rate

Maximum allowed tolerance for the output sample rate, specified as a positive scalar in the range [`0` to`0.5`]. The default is `0`.

The actual output sample rate varies but is within the specified range. For example, suppose that you set the **Tolerance for output sample rate** to 0.01. Then the actual output sample rate is in the range given by sample rate of output signal ± 1%. This flexibility allows for a simpler filter design.

Specification method

Method used to specify the polynomial interpolator coefficients, specified as one of the following:

- `Polynomial order` — Specify the order of the Lagrange interpolation filter polynomial through the **Polynomial order** parameter.
- `Coefficients` — Specify the polynomial coefficients directly through the **Coefficients** parameter.

Polynomial order

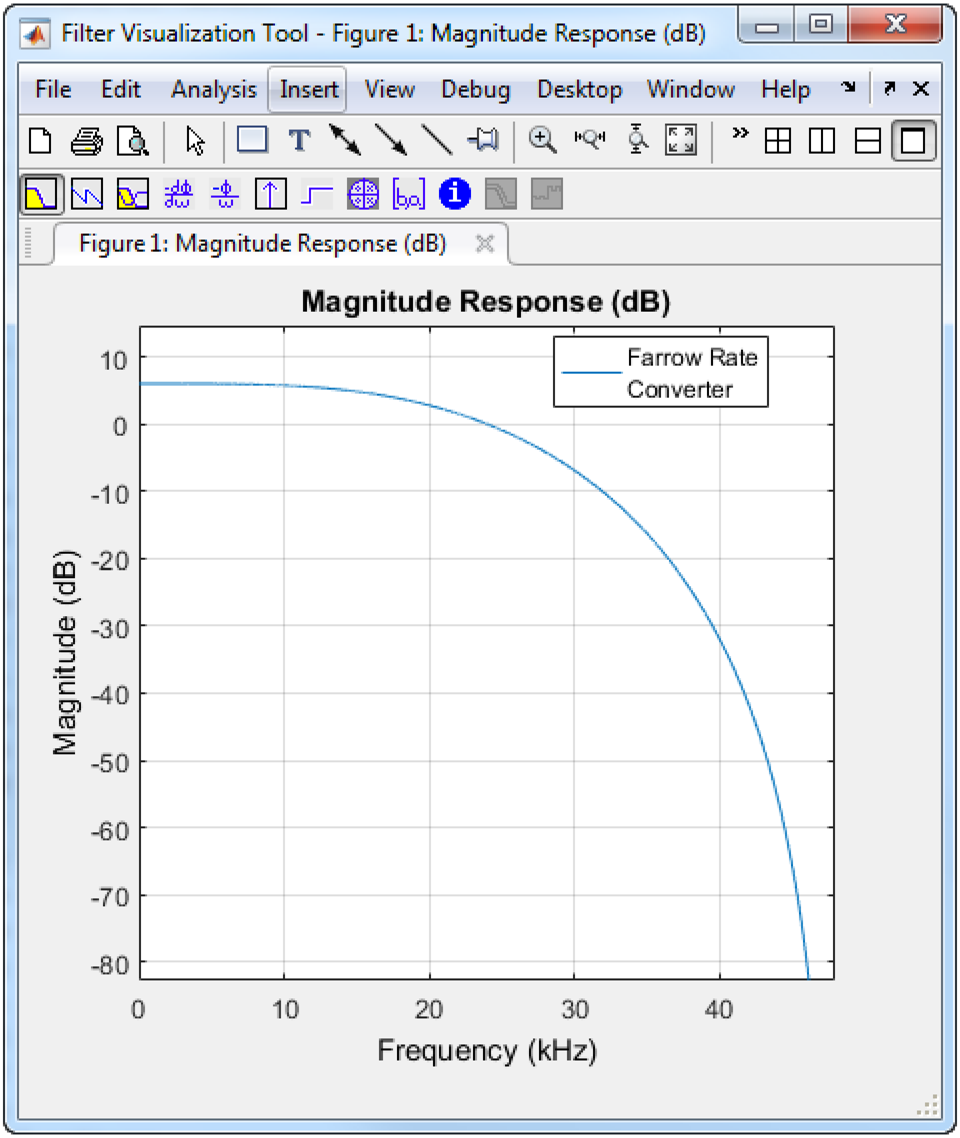
Order of filter polynomial, specified as a `1`, `2`, `3`, or `4`. The default is `3`. This parameter applies only when you set **Specification method** to `Polynomial order`.

Coefficients

Filter polynomial coefficients, specified as a real-valued square matrix. The default is `[-1 1; 1 0]`. This property applies only when you set **Specification method** to `Coefficients`.

View Filter Response

Opens the fvtool and displays the magnitude/phase response of the Farrow Rate Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

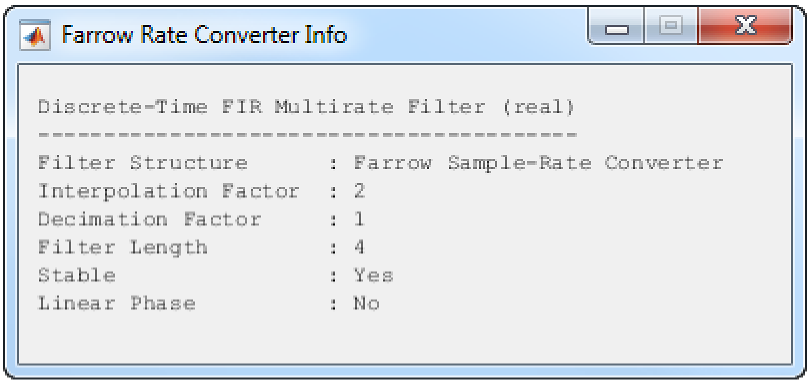


To update the magnitude response while fvtool is running, modify the dialog box parameters and click **Apply**.

View Info

Display the following information about the Farrow filter system:

- `Filter Structure`
- `Interpolation Factor`
- `Decimation Factor`
- `Filter Length`
- `Stable`
- `Linear Phase`



This button brings the functionality of the `dsp.FarrowRateConverter.info` method into the Simulink environment.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types tab:

Rounding mode

Rounding mode for fixed-point operations, specified as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Zero`. The default is `Floor`. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

Overflow mode

Overflow action for fixed-point operations, specified as `Wrap` | `Saturate` . The default is `Wrap`. For more details on the overflow action to select, see the 'Overflow Handling' section of “Precision and Range”.

This property is not tunable.

Coefficients

Data type of the filter coefficients, specified as a signed fixed-point object. The default, `fixdt(1,16)`, corresponds to a signed fixed-point type object with 16-bit coefficients. To give the best possible precision, fraction length is determined based on the coefficient values.

This property is not tunable.

Fractional Delay

Data type of the fractional delay, specified as an unsigned fixed-point object. The default, `fixdt(0,8)`, corresponds to an unsigned fixed-point data type object with 8-bit word length. To give the best possible precision, fractional length computed based on the fractional delay values.

This property is not tunable.

Multiplicand

Data type of the multiplicand, specified as a signed fixed-point object. The default, `fixdt(1,16,13)`, corresponds to a signed fixed-point multiplicand data type with 16-bit word length and 13-bit fraction length.

This property is not tunable.

Output

Word length and fraction length of the output data type, specified as one of the following:

- `Inherit: Same word length as input` (default) — Output word length and fraction lengths are the same as the input.
- `Inherit: Same as accumulator` — Output word length and fraction lengths are the same as the accumulator.
- `fixdt(1,16)` — Signed fixed-point data type with 16-bit word length. To give the best possible precision, fraction length is computed based on the input range. The dynamic range of the input is preserved.
- `fixdt(1,16,0)` — Signed fixed-point data type with 16-bit word length and zero fraction length.

This property is not tunable.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform automatic scaling of fixed-point data types.

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform automatic scaling of fixed-point data types.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Signed fixed point • 8-, 16-, and 32-bit signed integers

`dspadpt3`

Description

The Fast Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of the filter weights occurs once for every block of data samples. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS Filter equations. For more information, see Block LMS Filter. The Fast Block LMS Filter block implements the convolution operation involved in the calculations of the filtered output, y, and the weight update function in the frequency domain using the FFT algorithm used in the Overlap-Save FFT Filter block. See Overlap-Save FFT Filter for more information.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The input frame length must be a multiple of the **Block size** parameter.

The **Step-size (mu)** parameter corresponds to μ in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor, $0 < 1 - \mu\alpha \le 1$, in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k-1) - f(\mathbf{u}(n), e(n), \mu)$$

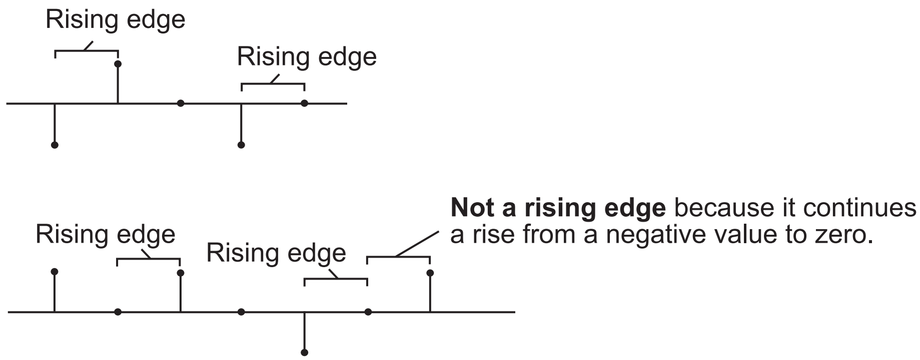
Enter the initial filter weights, $\mathbf{w}(0)$, as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

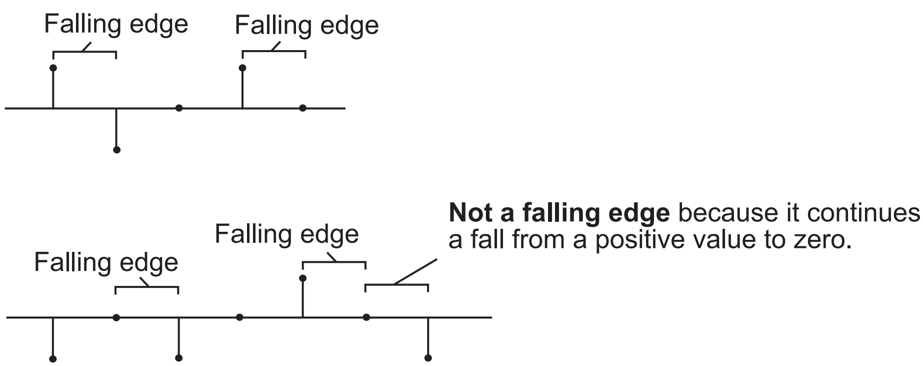
When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Parameters

Filter length

Enter the length of the FIR filter weights vector. The sum of the **Block size** and the **Filter length** must be a power of 2.

Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**. The sum of the **Block size** and the **Filter length** must be a power of 2.

Specify step-size via

Select `Dialog` to enter a value for mu, or select `Input port` to specify mu using the Step-size input port.

Step-size (mu)

Enter the step-size. Tunable (Simulink).

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

Reset input

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Desired	• Must be the same as Input
Step-size	• Must be the same as Input
Adapt	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Reset	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Same as Input
Error	• Same as Input
Wts	• Same as Input

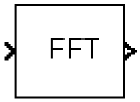
FFT

Fast Fourier transform (FFT) of input



Library

Transforms

`dspxfrm3`

Description

The FFT block computes the fast Fourier transform (FFT) across the first dimension of an *N*-D input array, *u*. For user-specified FFT lengths, not equal to *P*, zero padding or truncating, or modulo-length data wrapping occurs before the FFT operation.

```
y = fft(u,M)  % P ≤ M
```

Wrapping:

```
y(:,l) = fft(datawrap(u(:,l),M))  % P > M; l = 1,...,N
```

Truncating:

```
y (:,l) = fft(u,M)     % P > M; l = 1,...,N
```

When the input length, *P*, is greater than the FFT length, *M*, you may see magnitude increases in your FFT output. These magnitude increases occur because the FFT block uses modulo-*M* data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample, *P*, to the FFT length, *M*. To do so, place a `Pad` block before the FFT block in your model.

The *k*th entry of the *l*th output channel, $y(k, l)$, equals the *k*th point of the *M*-point discrete Fourier transform (DFT) of the *l*th input channel:

$$y(k,l) = \sum_{p=1}^{P} u(p,l) e^{-j2\pi(p-1)(k-1)/M} \qquad k = 1, \ldots, M$$

The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library or an implementation based on a collection of Radix-2 algorithms. You can select `Auto` to allow the block to choose the implementation.

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation will be restricted to those computers which are capable of running MATLAB. The input data type must be floating-point.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension M of the M-by-N input matrix, must be a power of two. To work with other input sizes, use the `Pad` block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real and Complex Signals

Complexity of Input	Output Ordering	Algorithms Used for FFT Computation
Complex	Linear	Bit-reversed operation and radix-2 DIT
Complex	Bit-reversed	Radix-2 DIF
Real	Linear	Bit-reversed operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
Real	Bit-reversed	Radix-2 DIF in conjunction with the half-length and double-signal algorithms

The efficiency of the FFT algorithm can be enhanced for real input signals by forming complex-valued sequences from the real-valued sequences prior to the computation of the DFT. When there are $2N+1$ real input channels, the FFT block forms these complex-valued sequences by applying the double-signal algorithm to the first $2N$ input channels, and the half-length algorithm to the last odd-numbered channel.

For real input signals with fixed-point data types, it is possible to see different numerical results in the output of the last odd numbered channel, even when all input channels are identical. This numerical difference results from differences in the double-signal algorithm and the half-length algorithm.

You can eliminate this numerical difference in two ways:

- Using full precision arithmetic for fixed-point input signals
- Changing the input data type to floating point

For more information on the double-signal and half-length algorithms, see [2]. "Efficient Computation of the DFT of Two Real Sequences" on page 475 describes the double signal algorithm. "Efficient Computation of the DFT of a 2N-Point Real Sequence" on page 476 describes the half-length algorithm.

Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block's Radix–2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

where K is the greater value of either M or N and $k = 0, \cdots, K-1$. The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

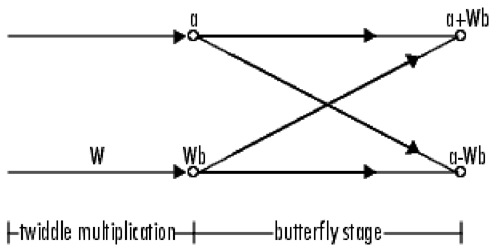
Number of Table Entries for N-Point FFT	
floating-point	3 N/4
fixed-point	N

Fixed-Point Data Types

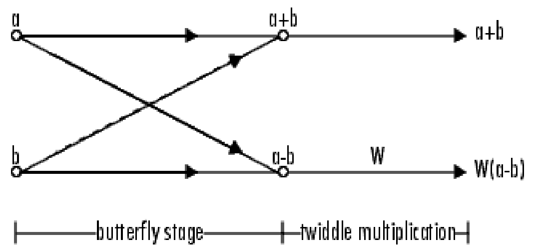
The following diagrams show the data types used in the FFT block for fixed-point signals. You can set the Sine table, Accumulator, Product output, and Output data types displayed in the diagrams in the FFT dialog box as discussed in "Dialog Box" on page 2-671.

Inputs to the FFT block are first cast to the output data type and stored in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time FFT and after each butterfly stage in a decimation-in-frequency FFT.

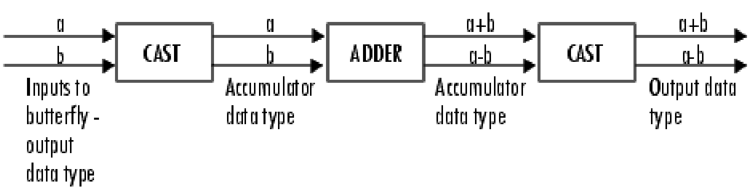
Decimation-in-time IFFT



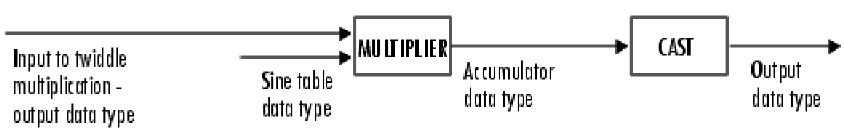
Decimation-in-frequency IFFT



Butterfly stage data types



Twiddle multiplication data types

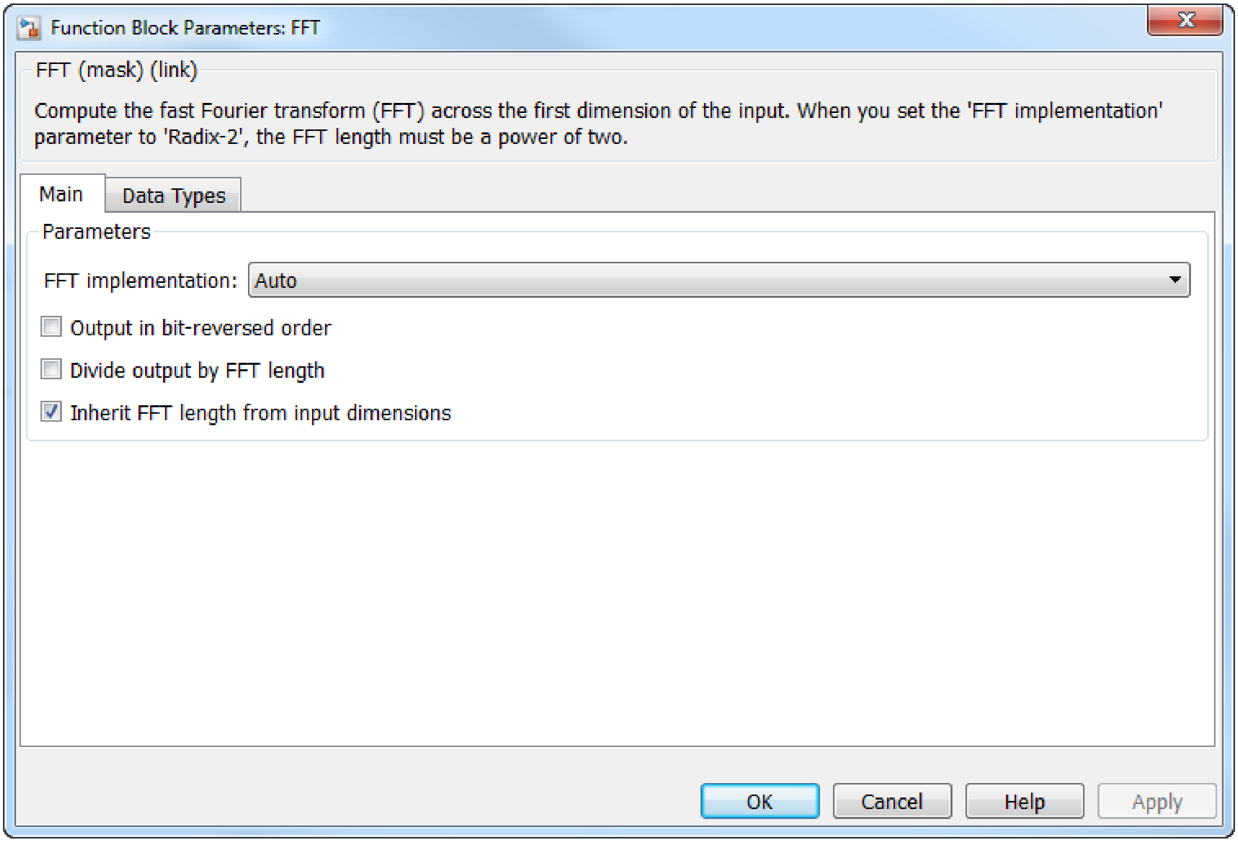


The output of the multiplier appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

The **Main** pane of the FFT block dialog appears as follows.



FFT implementation

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to host computers capable of running MATLAB.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The dimension M of the M-by-N input matrix, must be a power of two. To work with other input sizes, use the `Pad` block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation. See "Radix-2 Implementation" on page 2-667.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Output in bit-reversed order

Designate the order of the output channel elements relative to the ordering of the input elements. When you select this check box, the output channel elements appear in bit-reversed order relative to the input ordering. If you clear this check box, the output channel elements appear in linear order relative to the input ordering.

Linearly ordering the output requires extra data sorting manipulation, so in some situations it might be better to output in bit-reversed order.

Note: The FFT block calculates its output in bit-reversed order. Linearly ordering the FFT block output requires an extra bit-reversal operation. Thus, in many situations, you can increase the speed of the FFT block by selecting the **Output in bit-reversed order** check box.

For more information ordering of the output, see "Linear and Bit-Reversed Output Order".

Divide output by FFT length

When you select this parameter, the block divides the output of the FFT by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

Inherit FFT length from input dimensions

Select to inherit the FFT length from the input dimensions. When you select this check box, the input length must be a power of two. When you do not select this check box, the **FFT length** parameter becomes available to specify the length.

FFT length

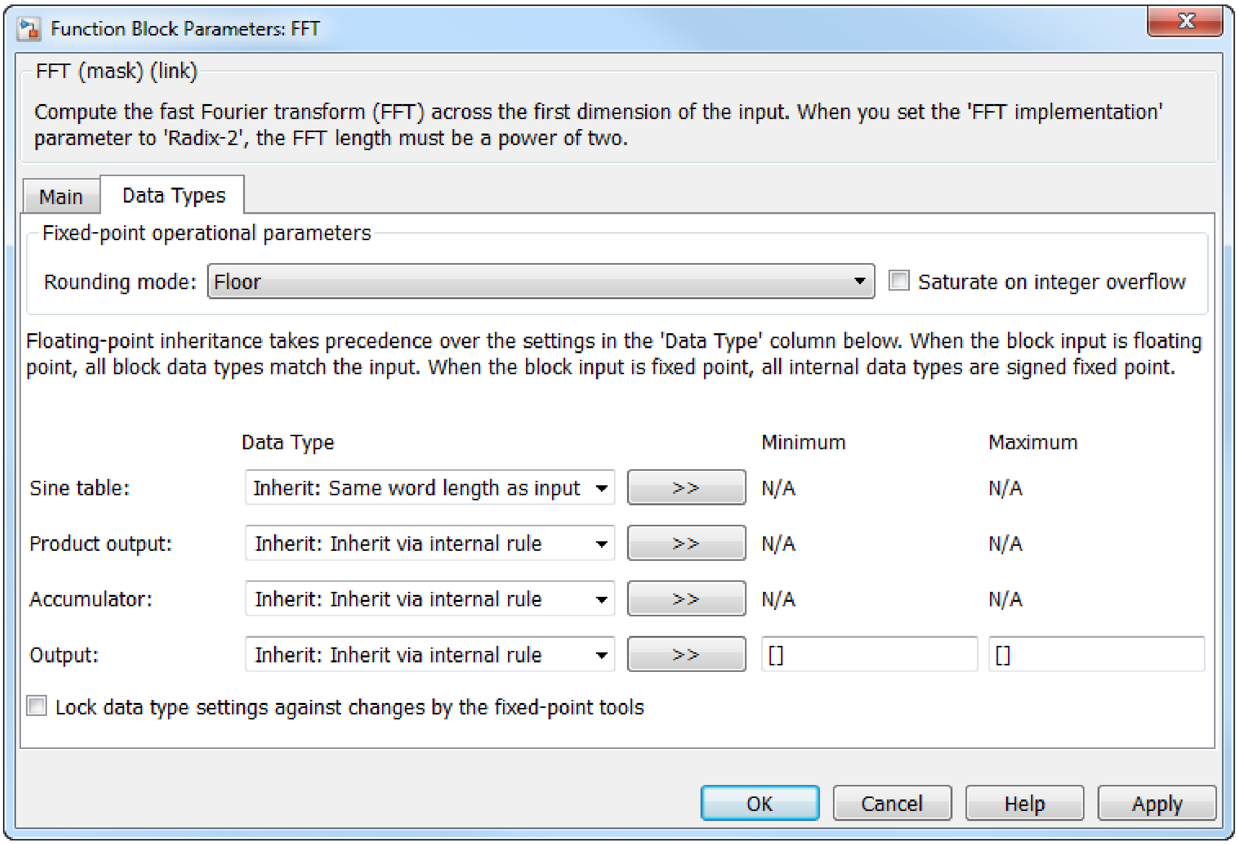
Specify FFT length. This parameter becomes available only when you do not select the **Inherit FFT length from input dimensions** parameter.

When you set the **FFT implementation** parameter to `Radix-2`, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the FFT length. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

The **Data Types** pane of the FFT block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; instead, they always round to `Nearest`.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to `Nearest`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Sine table data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Product output data type

Specify the product output data type. See and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

  - When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
  - When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(FFT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see "Inherit via Internal Rule".

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See "Control Signal Data Types" (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges" (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges" (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Examples

See the section on "Transform Time-Domain Data into Frequency Domain" in the *DSP System Toolbox User's Guide.*

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - **FFT implementation** is set to `FFTW`.
  - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

  Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

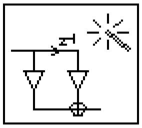
Filter Realization Wizard

Construct filter realizations using digital filter blocks or Sum, Gain, and Delay blocks



Library

Filtering / Filter Implementations

`dsparch4`

Description

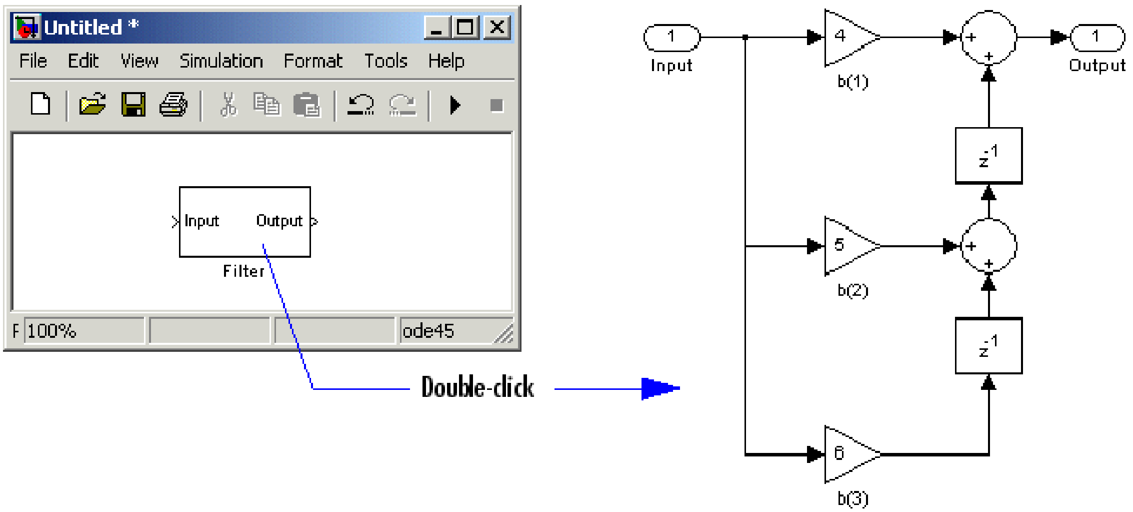
Note: Use this block to implement fixed-point or floating-point digital filters using Sum, Gain, and Delay blocks or digital filter blocks from the DSP System Toolbox library. You can either design a filter by using the block parameters, or import the coefficients of a filter you have designed elsewhere.

The following blocks also implement digital filters, but serve slightly different purposes:

- `Discrete FIR Filter` and `Biquad Filter`— Use to implement floating-point or fixed-point filters that you have already designed
- `Digital Filter Design` — Use to design, analyze, and then implement floating-point filters.

The Filter Realization Wizard is a tool for automatically implementing a digital filter. You must specify a filter, its structure, and the data types for the inputs, outputs, and computations. The filter can support double-precision, single-precision, or fixed-point data types.

The Filter Realization Wizard can implement a digital filter in one of two ways. It can use digital filter blocks from the DSP System Toolbox library, or it can create a subsystem block that implements the specified filter using Sum, Gain, and `Delay` blocks. If the Filter Realization Wizard creates a block, double-click the block to open the dialog box. If it creates a subsystem, double-click the subsystem block to see the filter implementation as shown in the figure below.



For more information about filter implementation, see “Specify the Filter Implementation” on page 2-682.

The parameters of the Filter Realization Wizard are a part of a larger app, the filter designer (`filterDesigner`). You can use filter designer to design and analyze your filter, and then use the Filter Realization Wizard parameters to implement the filter in your models.

Specify the Filter and Data Types

To specify a purely double-precision filter, you can either design a filter using the **Design Filter** panel, or import a filter using the **Import Filter** panel. In the **Import Filter** panel, you can specify the coefficients directly or specify the workspace variables which store the coefficients.

You can also specify a fixed-point filter or a single-precision filter by using the **Set Quantization Parameters** panel.

Note: *Running* a model containing implementations of fixed-point filters requires the Fixed-Point Designer product, but you can still edit models containing such filter implementations without it. See the Fixed-Point Designer documentation for more information.

See the following topics to learn how to use the panels to specify your filter:

- For more information on the **Design Filter** panel, see "Filter Designer" (Signal Processing Toolbox).
- For more information on the **Import Filter** panel, see "Importing a Filter Design".
- For more information on the **Set Quantization Parameters** panel, see "Access the Quantization Features of Filter Designer".

To open a panel, click the appropriate button in the lower-left corner of filter designer.

Supported Filter Structures

The Filter Realization Wizard supports the following structures:

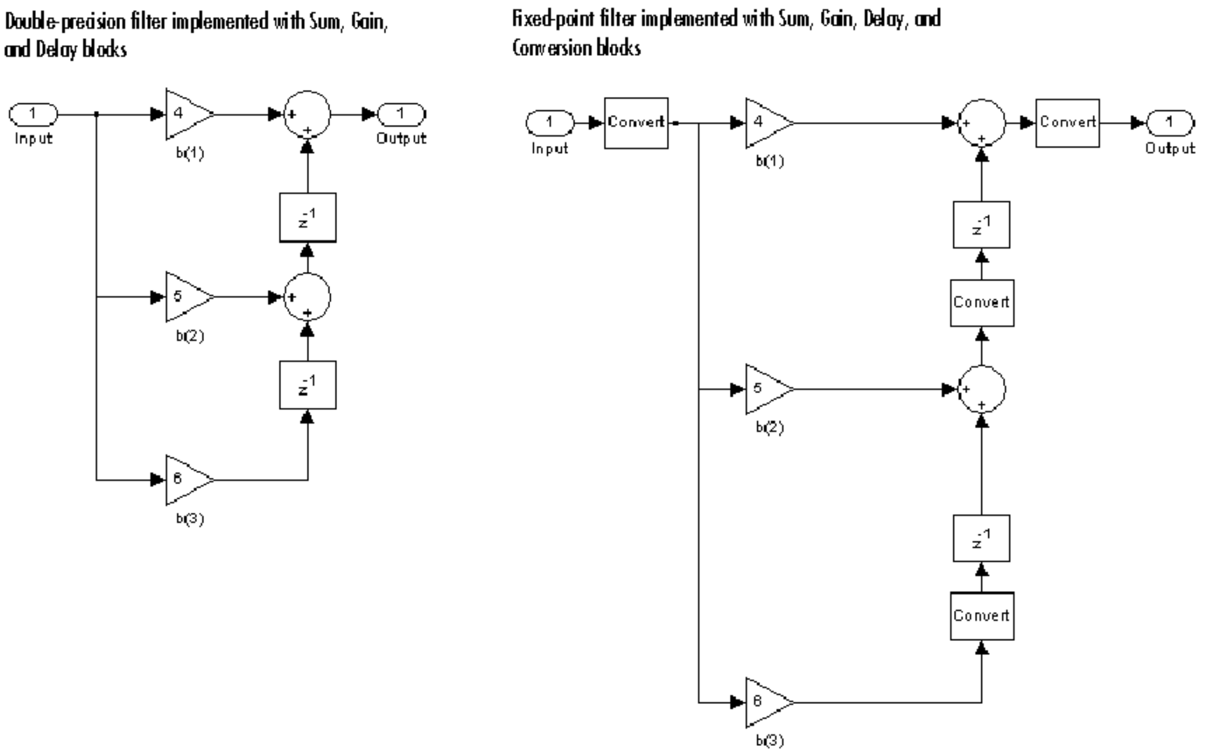
- Direct form I
- Direct form I, second-order sections
- Direct form I transposed
- Direct form I transposed, second-order sections
- Direct form II
- Direct form II, second-order sections
- Direct form II transposed
- Direct form II transposed, second-order sections
- Direct form FIR
- Direct form FIR transposed
- Direct form symmetric FIR
- Direct form antisymmetric FIR
- Lattice all-pass
- Lattice AR

- Lattice ARMA
- Lattice MA for maximum phase
- Lattice MA for minimum phase
- Cascade
- Parallel

Specify the Filter Implementation

You can determine how the Filter Realization Wizard models the specified filter. In the **Realize Model** panel, select the **Build model using basic elements** check box. When you select this check box and click on the **Realize Model** button, the Filter Realization Wizard creates a subsystem block that implements your filter using Sum, Gain, and `Delay` blocks. When you clear this check box, the Filter Realization Wizard uses a digital filter block to implement your filter. The **Build model using basic elements** check box is available only when your filter can be implemented using a digital filter block available in the DSP System Toolbox library.

The Filter Realization Wizard can generate a subsystem that represents either a double-precision or fixed-point filter. You must install the Fixed-Point Designer product to simulate a fixed-point filter. You can still edit the blocks used to implement the filter without installing the Fixed-Point Designer product.



Implementations of Double-Precision and Fixed-Point Filters

Command Line Alternative to Realize Model Button

You can enter `realizemdl(`*`sysobj`*`)` in the MATLAB command prompt to generate an architectural model of the filter System object, *`sysobj`*, in a Simulink subsystem block using individual sum, gain, and delay blocks, according to user-defined specifications. For more information, see `realizemdl`.

Parameters

Note: The following parameters for the Filter Realization Wizard are in the **Realize Model** pane of the filter designer app. To open different panels of filter designer, click the different buttons at the lower-left corner. For more information about relevant panels, see “Specify the Filter and Data Types” on page 2-680.

Block Name

Enter the name of the new filter block.

Destination

Specify where the new filter block should be created. This can be in a new model or in the current (most recently selected) model.

User Defined

Specify the name of the target subsystem in which the Filter Realization Wizard should create the new filter block.

Overwrite generated block “Filter” block

When selected, the block overwrites any filter block in the current model with the name specified in the **Block Name** parameter. This parameter is enabled when the **Destination** parameter is set to `Current`.

Build model using basic elements

Select this check box to implement your filter using Sum, Gain, and Delay blocks. Clear this check box to implement your filter using digital filter blocks from the DSP System Toolbox library. This parameter is available only when your filter can be modeled using an available digital filter block.

Optimize for zero gains

Select this check box to remove zero-gain paths from the filter structure. For an example, see “Optimize the Filter Structure”.

Optimize for unity gains

Select this check box to substitute gains equal to 1 with a wire (short circuit). For an example, see “Optimize the Filter Structure”.

Optimize for negative gains

Select this check box to substitute gains equal to -1 with a wire (short circuit), and change the corresponding sums to subtractions. For an example, see “Optimize the Filter Structure”.

Optimize delay chains

Select this check box to substitute any delay chains made up of n unit delays with a single delay by n. For an example, see “Optimize the Filter Structure”.

Optimize for unity scale values

Select this check box to remove all scale value multiplications by 1 from the filter structure.

Input processing

Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

Rate options

For multirate filters, specify how the block should process the input. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

Realize Model

Click to create a filter block according to the settings you’ve specified. When the **Build model using basic elements** check box is selected, the filter is implemented as a subsystem block consisting of Sum, Gain, and Delay blocks. To see the filter implementation, double-click the subsystem block in your model.

Note: For more information about relevant parameters in other panels of filter designer, see “Specify the Filter and Data Types” on page 2-680.

Supported Data Types

- Double-precision floating point

- Single-precision floating point — Supported only when you install Fixed-Point Designer.
- Fixed point (signed and unsigned) — Supported only when you install Fixed-Point Designer and Fixed-Point Designer.

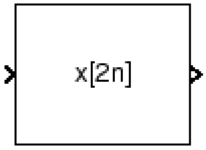
FIR Decimation

Filter and downsample input signals



Library

Filtering / Multirate Filters

`dspmlti4`

Description

The FIR Decimation block resamples the discrete-time input at a rate *K* times slower than the input sample rate, where *K* is the integer value you specify for the **Decimation factor** parameter. To do so, the block implements a polyphase filter structure and performs the following operations:

1. Filters the data in each channel of the input using a direct-form FIR filter.
2. Downsamples each channel of filtered data by discarding *K*–1 consecutive samples following each sample that is retained.

The block uses a polyphase filter implementation because it is more efficient than straightforward filter-then-decimate algorithms. See Fliege [1] for more information.

You can use the FIR Decimation block inside triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

This block supports variable-size input. This means that while the block is simulating, the frame size (number of rows) can change. The output dimensions always equal those of the input signal.

Specifying the Filter Coefficients

To specify the filter coefficients, select the mode you want the FIR Decimation block to operate in. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as structure and coefficients, in the block dialog box.
- **Input port** — Specify the filter coefficients as an input to the block. Coefficient values are tunable (can change during simulation), while their properties must remain constant.
- **Filter object** — Specify the filter using a dsp.FIRDecimator System object.
- **Auto** (default) — Choose the filter coefficients of an FIR Nyquist filter, predesigned for the decimation factor specified in the block dialog box.

When you select **Dialog parameters**, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function $H(z)$.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

You can generate the FIR filter coefficient vector, `[b(1) b(2) ... b(m)]`, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

The filter you specify must be a lowpass filter with a normalized cutoff frequency no greater than $1/K$. The block internally initializes all filter states to zero.

When you select **Auto**, the block designs an FIR decimator with the decimation factor specified in **Decimation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block. For more information on the filter design, see Orfanidis [2].

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. To decimate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output (M_o) is $1/K$ times that of the input ($M_o = M_i/K$),

  In this mode, the input frame size, M_i, must be a multiple of the **Decimation factor**, K.

  For an example of single-rate FIR Decimation, see “Example 1 — Single-Rate Processing” on page 2-691.
- When you set the **Rate options** parameter to `Allow multirate processing`, the input and output of the FIR Decimation block are the same size, but the sample rate of the output is K times slower than that of the input. In this mode, the block treats an M_i-by-N matrix input as N independent channels. The block decimates each column of the input over time by keeping the frame size constant (M_i=M_o), and making the output frame period (T_{fo}) K times longer than the input frame period ($T_{fo} = K*T_{fi}$).

  See “Example 2— Multirate Frame-Based Processing” on page 2-691 for an example that uses the FIR Decimation block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M*N$ independent channels, and decimates each channel over time. The output sample period (T_{so}) is K times longer than the input sample period ($T_{so} = K*T_{si}$), and the input and output sizes are identical.

Latency

When you use the FIR Decimation block in sample-based processing mode, the block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first filtered input sample (received at time t= 0) as the first output sample. That first output sample is then followed by filtered input samples K+1, 2K+1, and so on.

When you use the FIR Decimation block in frame-based processing mode with a frame size greater than one, the block may exhibit *one-frame latency*. Cases of one-frame latency can occur when the input frame size is greater than one, and you set the **Input processing** and **Rate options** parameters of the FIR Decimation block as follows:

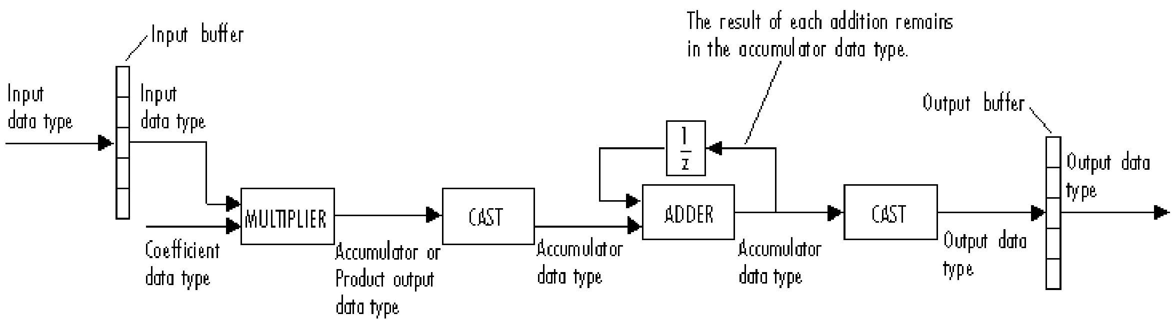
- **Input processing** = `Columns as channels (frame based)`
- **Rate options** = `Allow multirate processing`

In cases of one-frame latency, you can define the value of the first M_i output rows by setting the **Output buffer initial conditions** parameter. The default value of the **Output buffer initial conditions** parameter is `0`. However, you can enter a matrix containing one value for each channel of the input, or a scalar value to be applied to all channels. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample M_i+ 1. That sample is then followed by filtered input samples K+ 1, $2K$+ 1, and so on.

Note: For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Fixed-Point Data Types

The following diagram shows the data types used within the FIR Decimation block for fixed-point signals.



You can set the coefficient, product output, accumulator, and output data types in the block dialog box as discussed in the “Dialog Box” on page 2-692 section. This diagram shows that data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

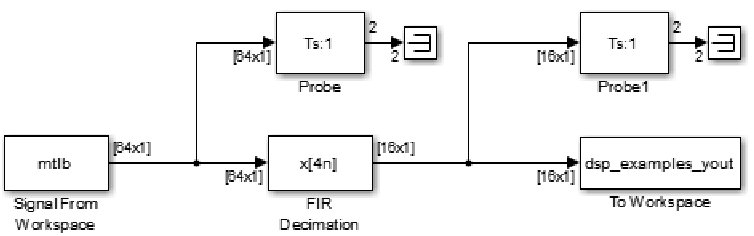
When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see "Multiplication Data Types".

Note: When the block input is fixed point, all internal data types are signed fixed-point values.

Examples

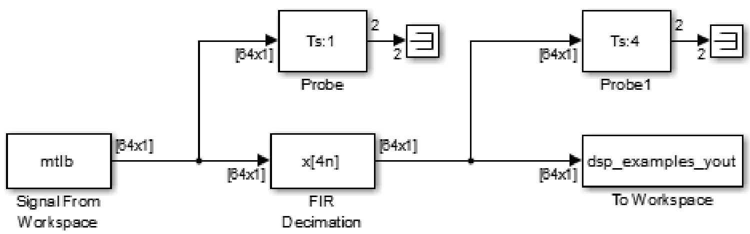
Example 1 — Single-Rate Processing

In the ex_firdecimation_ref2 model, the FIR Decimation block decimates a single-channel input with a frame size of 64. Because the block is doing single-rate processing and the **Decimation factor** parameter is set to 4, the output of the FIR Decimation block has a frame size of 16. As shown in the following figure, the input, and output of the FIR Decimation block have the same sample rate.



Example 2— Multirate Frame-Based Processing

In the ex_firdecimation_ref1 model, the FIR Decimation block decimates a single-channel input with a frame period of one second. Because the block is doing multirate frame-based processing and the **Decimation factor** parameter is set to 4, the frame period of the output is 4 seconds. As shown in the following figure, the input, and output of the FIR Decimation block have the same frame size, but the sample rate of the output is four times that of the input.



Example 3

The ex_polyphasedec model illustrates the underlying polyphase implementations of the FIR Decimation block. Run the model, and view the results on the scope. The output of the FIR Decimation block matches the output of the Polyphase Decimation Filter block.

Example 4

The ex_mrf_nlp model illustrates the use of the FIR Decimation block in several multistage multirate filters.

Dialog Box

Coefficient Source

The FIR Decimation block can operate in four different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as structure and coefficients, in the block mask.
- **Input port** — Specify the filter coefficients with a **Num** input port. The **Num** input port appears when you select the **Input port** option. Coefficient values obtained

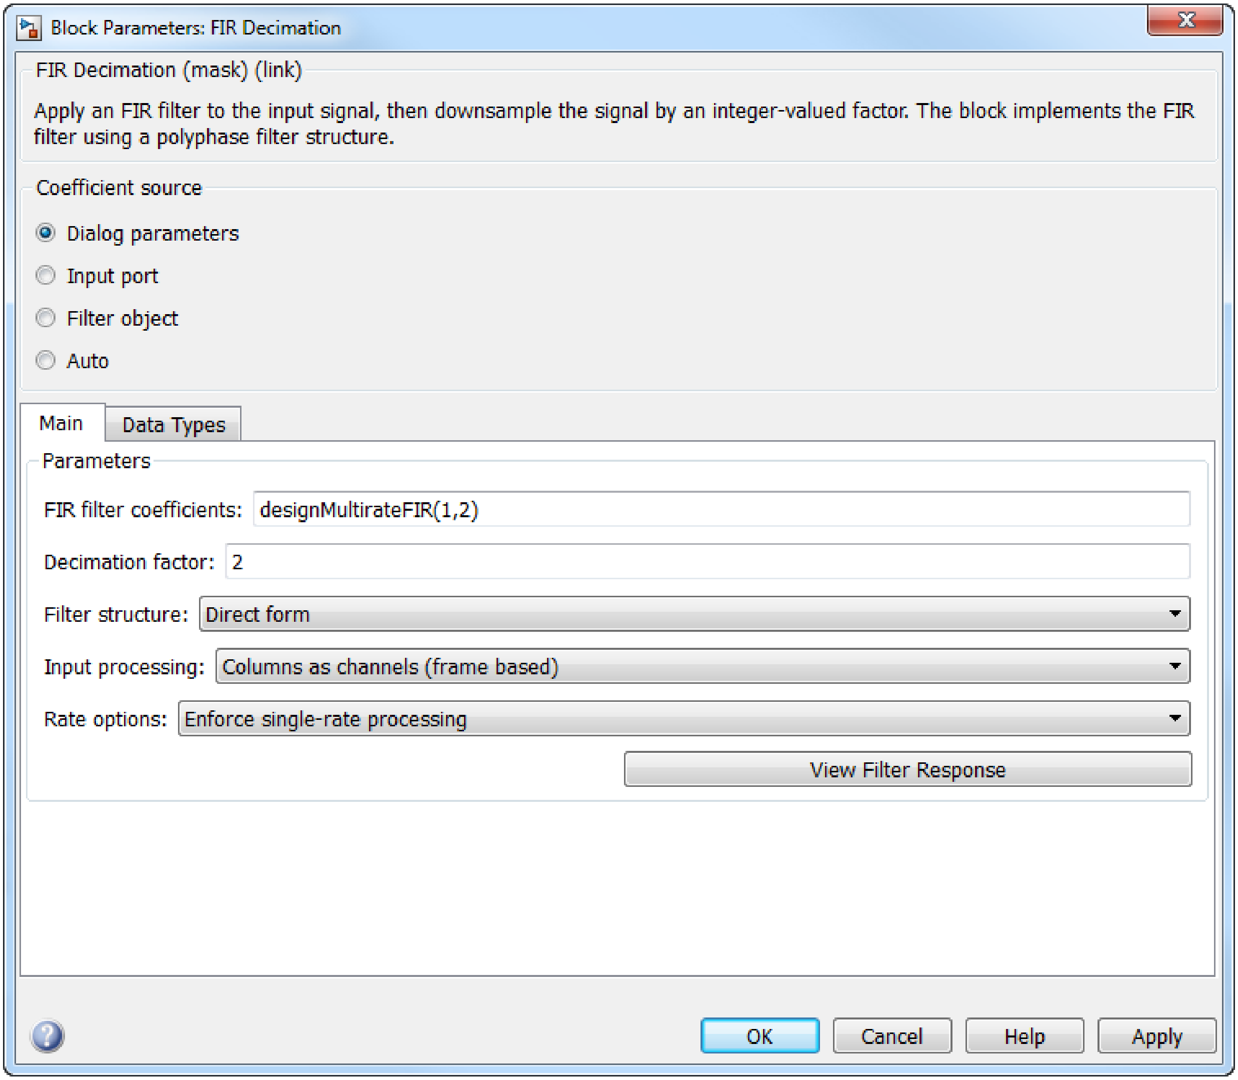
through **Num** are tunable (can change during simulation), while their properties must remain constant.

- **Filter object** — Specify the filter using a dsp.FIRDecimator System object.
- **Auto** (default) — Choose the coefficients of an FIR Nyquist filter, predesigned for the decimation factor specified in the block dialog box.

Different items appear on the FIR Decimation block dialog box depending on whether you select **Dialog parameters**, **Input port**, **Filter object**, or **Auto** in the **Coefficient source** group box.

Specify Filter Characteristics in Dialog Box

The **Main** pane of the FIR Decimation block dialog box appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



FIR filter coefficients

Specify the lowpass FIR filter coefficients, in descending powers of z. By default, `designMultirateFIR(1,2)` computes the filter coefficients.

Decimation factor

Specify the integer factor, *K*, by which to decrease the sample rate of the input sequence. The default is `2`.

Filter Structure

Choose whether to implement a `Direct form` (default) or `Direct form transposed` filter.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should decimate the input. You can select one of the following options:

- `Enforce single-rate processing` (default) — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of *K*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block decimates the signal such that the output sample rate is *K* times slower than the input sample rate.

Output buffer initial conditions

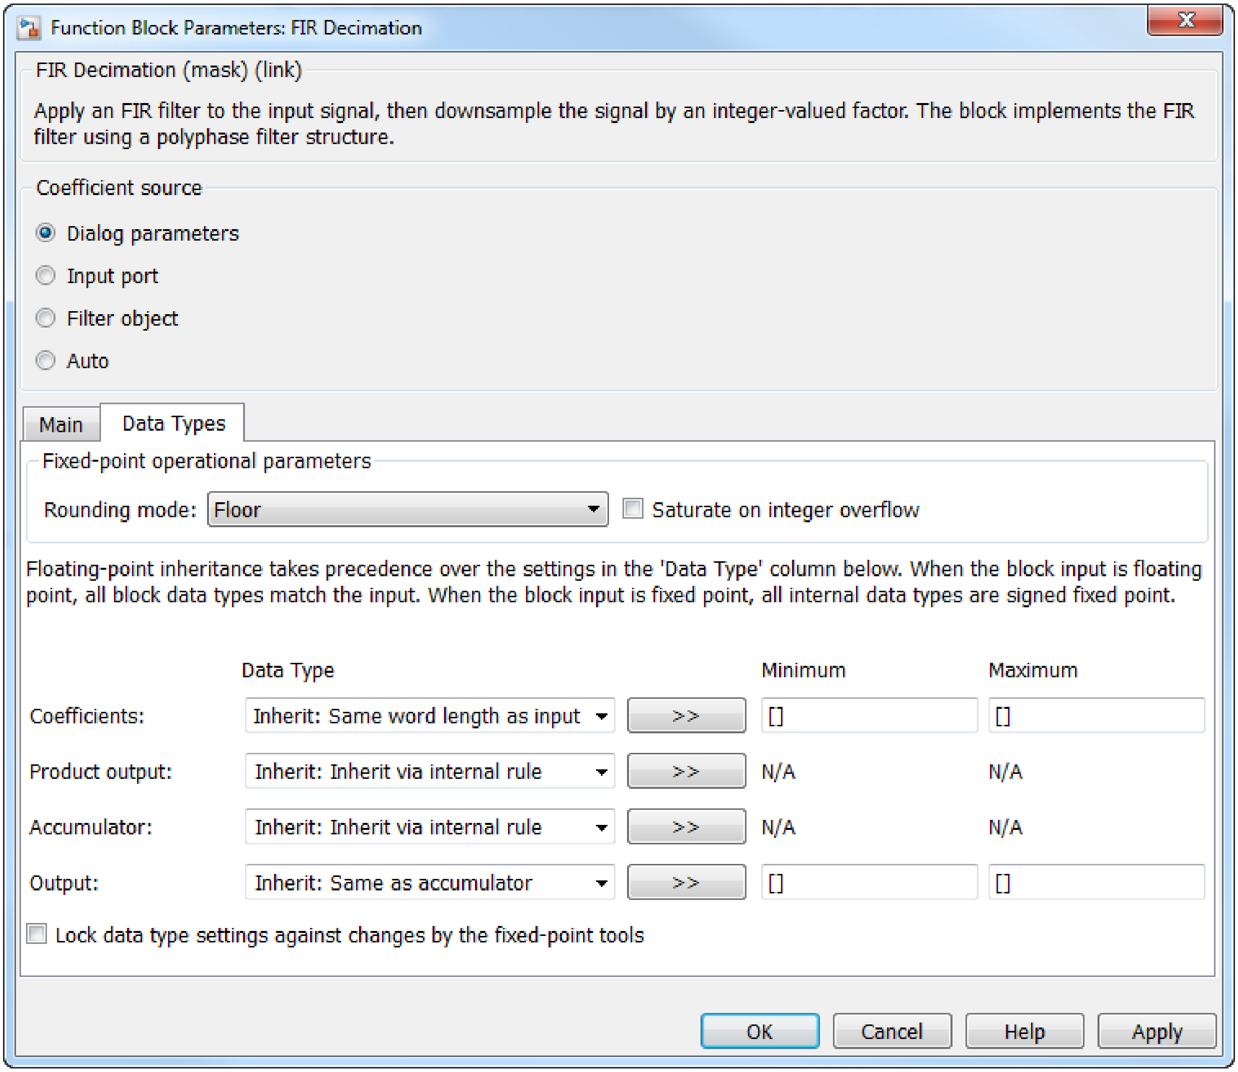
In the case of *one-frame latency*, this parameter specifies the output of the block until the first filtered input sample is available. The default value of this parameter is `0`, but you can enter a matrix containing one value for each channel, or a scalar value to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

See “Latency” on page 2-689 for more information about latency in the FIR Decimation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the FIR Decimation block dialog box appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The default is `Floor`. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-690 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-690 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-690 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-690 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

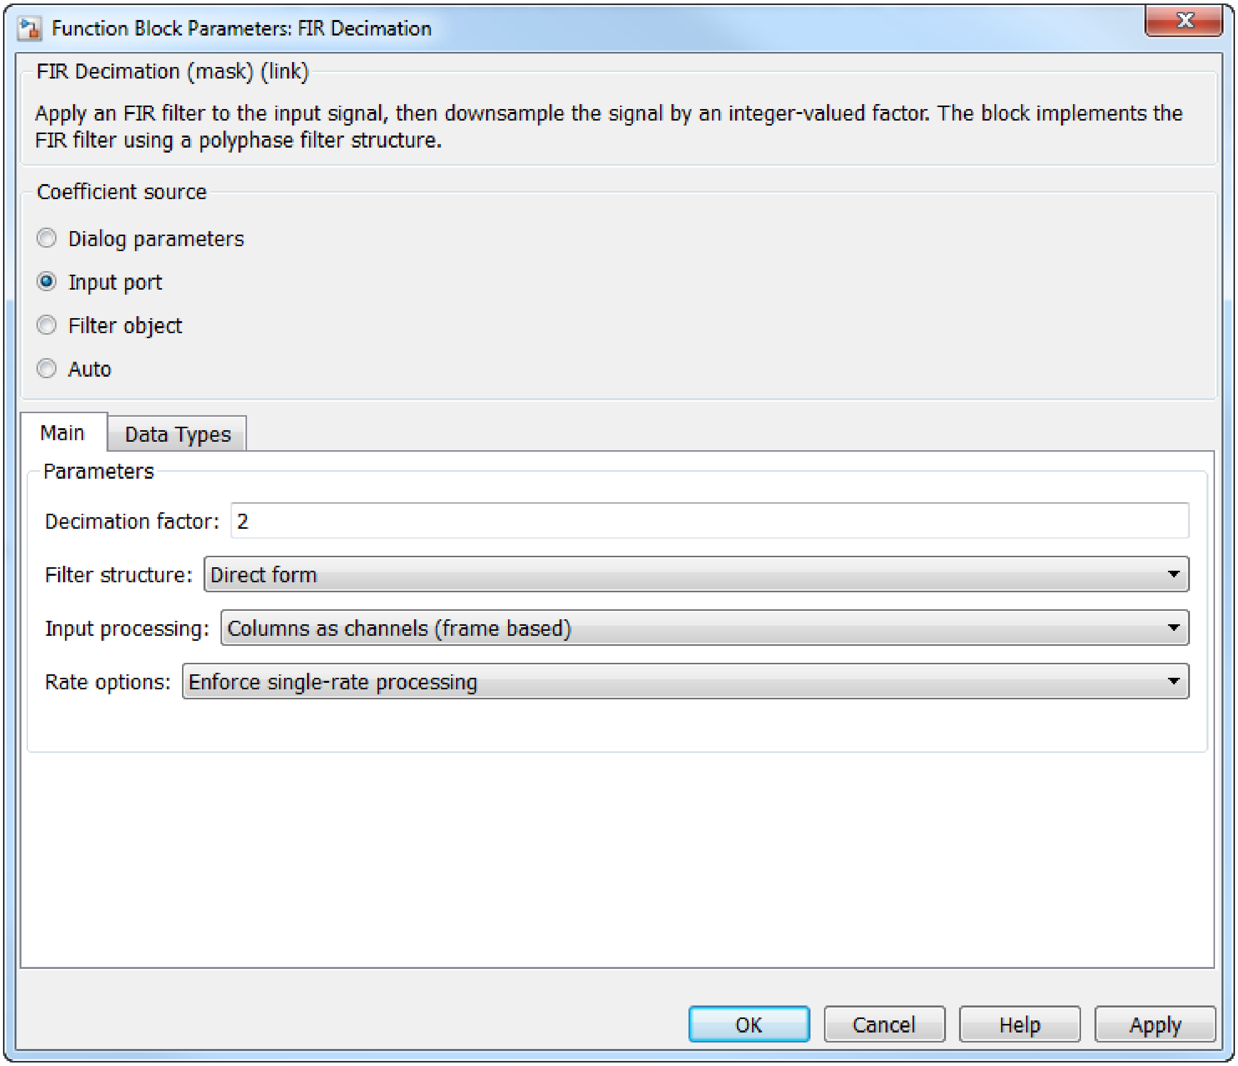
- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Provide Filter Coefficients Through Input Port

The **Main** pane of the FIR Decimation block dialog box appears as follows when you select **Input port** in the **Coefficient source** group box.



Decimation factor

Specify the integer factor, *K*, by which to decrease the sample rate of the input sequence. The default is 2.

Filter Structure

Choose whether to implement a `Direct form` (default) or `Direct form transposed` filter.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should decimate the input. You can select one of the following options:

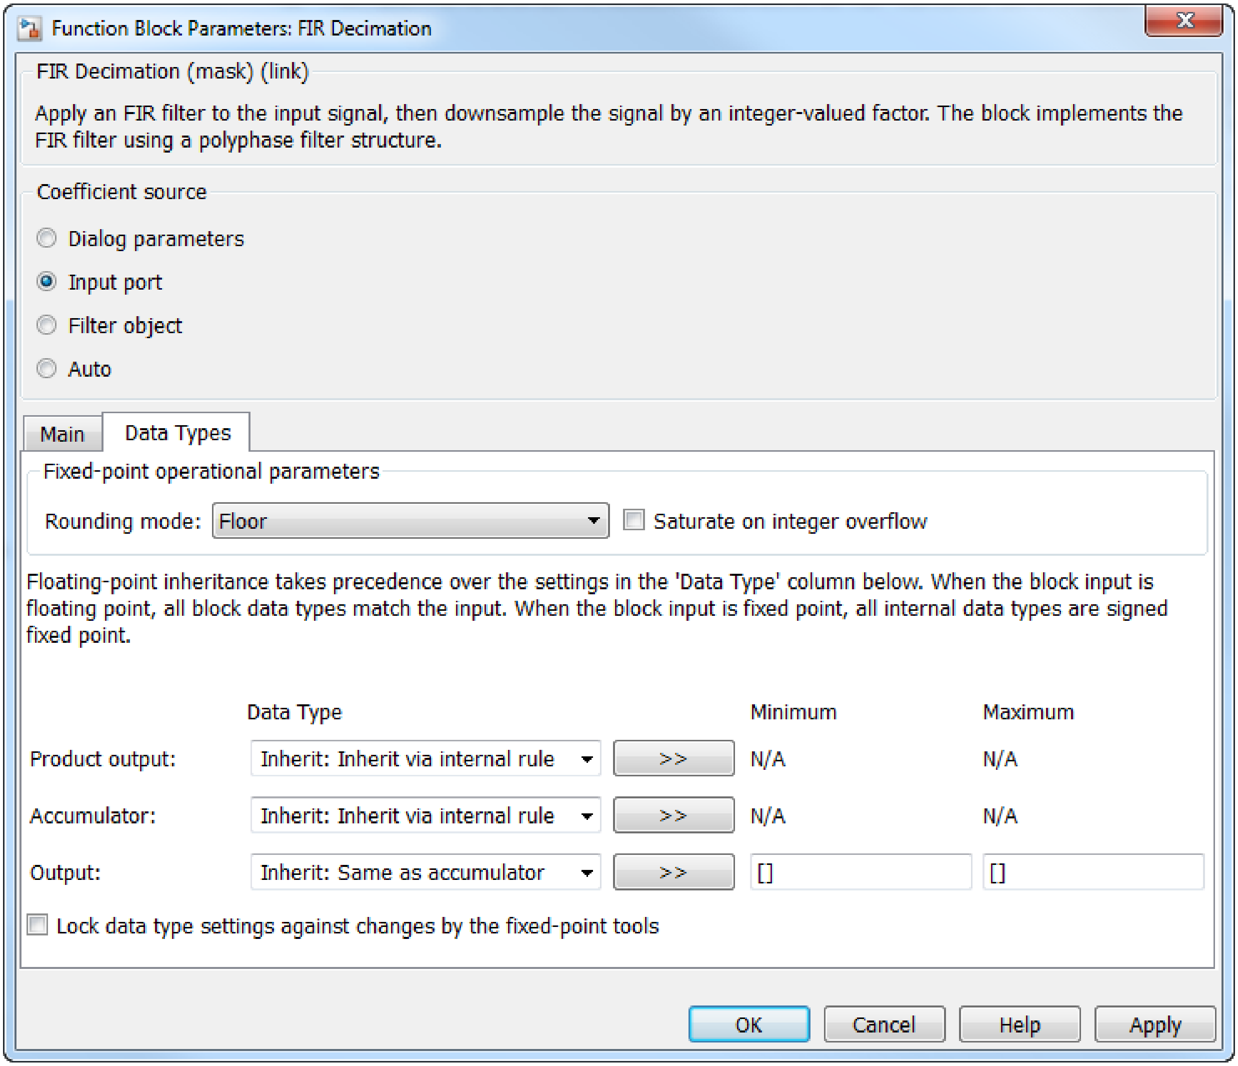
- `Enforce single-rate processing` (default) — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of K. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block decimates the signal such that the output sample rate is K times slower than the input sample rate.

Output buffer initial conditions

In the case of *one-frame latency*, this parameter specifies the output of the block until the first filtered input sample is available. The default value of this parameter is `0`, but you can enter a matrix containing one value for each channel, or a scalar value to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

See "Latency" on page 2-689 for more information about latency in the FIR Decimation block.

The **Data Types** pane of the FIR Decimation block dialog box appears as follows when you select **Input port** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The default is `Floor`. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-690 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button `>>` to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-690 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-690 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

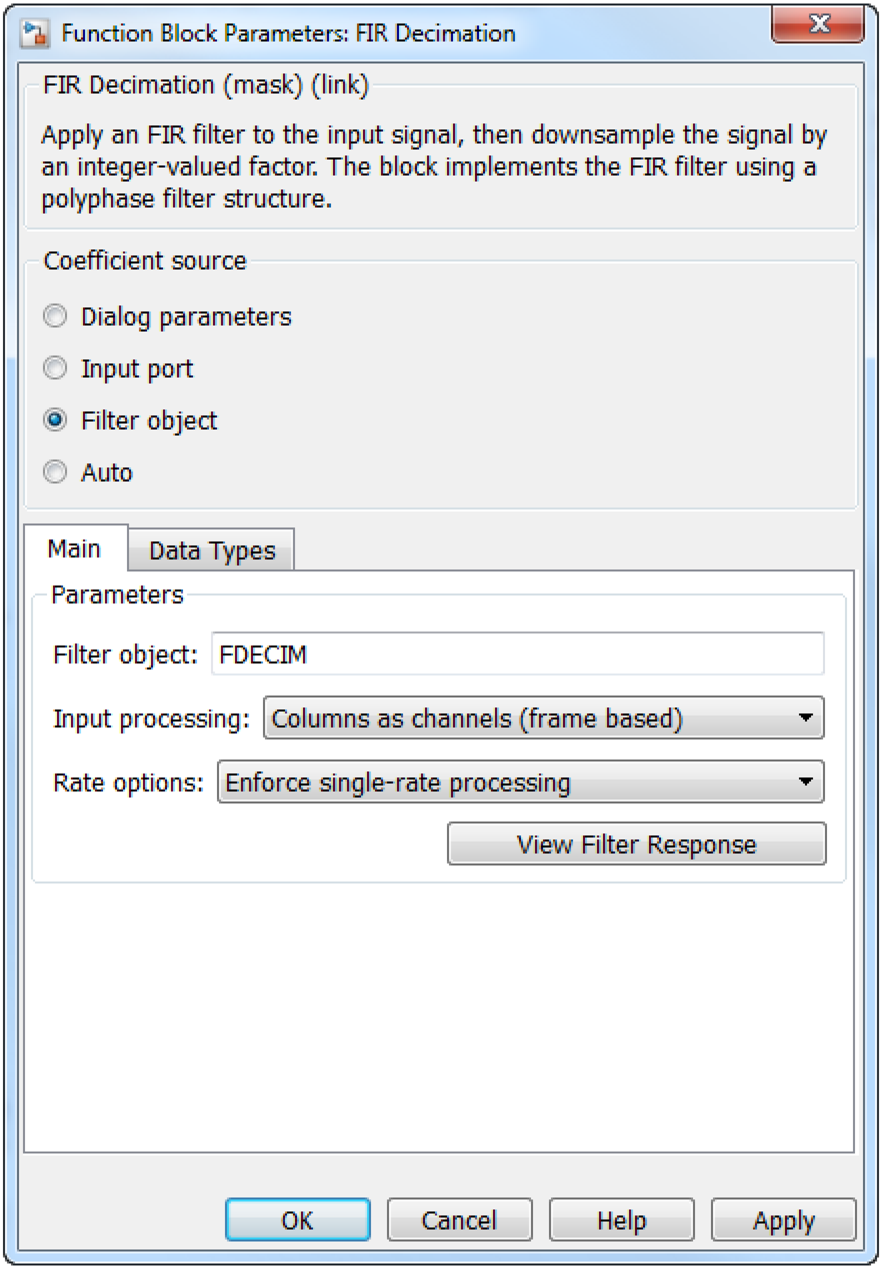
- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Multirate Filter Object

The **Main** pane of the FIR Decimation block dialog box appears as follows when you select **Filter object** in the **Coefficient source** group box.



Function Block Parameters: FIR Decimation
FIR Decimation (mask) (link)
Apply an FIR filter to the input signal, then downsample the signal by an integer-valued factor. The block implements the FIR filter using a polyphase filter structure.

Filter object

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.FIRDecimator System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects” (MATLAB).

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should decimate the input. You can select one of the following options:

- `Enforce single-rate processing` (default) — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of *K*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block decimates the signal such that the output sample rate is *K* times slower than the input sample rate.

Output buffer initial conditions

In the case of *one-frame latency*, this parameter specifies the output of the block until the first filtered input sample is available. The default value of this parameter is `0`, but you can enter a matrix containing one value for each channel, or a scalar value to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

See “Latency” on page 2-689 for more information about latency in the FIR Decimation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the System object specified in the **Filter object** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Decimation block dialog box appears as follows when you select **Filter object** in the **Coefficient source** group box.

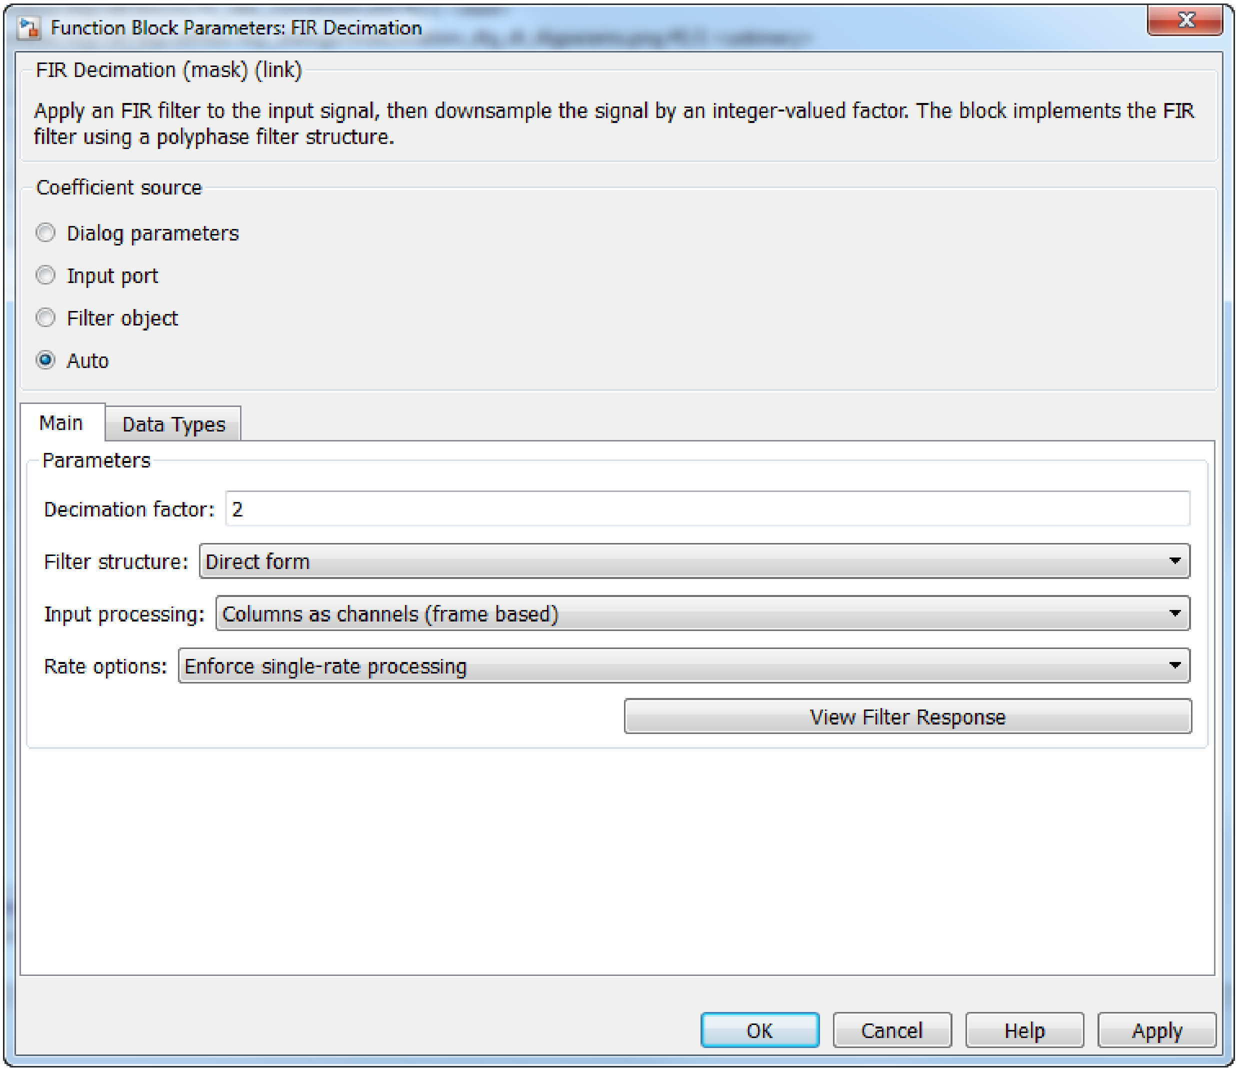
The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings, edit the filter object directly.

For more information on System objects, see “What Are System Objects?” (MATLAB).

Choose Filter Coefficients Automatically

When you select **Auto** in the **Coefficient source** group box, the block chooses the filter coefficients automatically. For more information on the filter design algorithm the block uses, see “Specifying the Filter Coefficients” on page 2-688.

The **Main** pane of the FIR Decimation block dialog box appears as follows when you select **Auto** in the **Coefficient source** group box.



Decimation factor

Specify the integer factor, K, by which to decrease the sample rate of the input sequence. The default is 2.

Filter Structure

Choose whether to implement a `Direct form` (default) or `Direct form transposed` filter.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should decimate the input. You can select one of the following options:

- `Enforce single-rate processing` (default) — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of K. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block decimates the signal such that the output sample rate is K times slower than the input sample rate.

Output buffer initial conditions

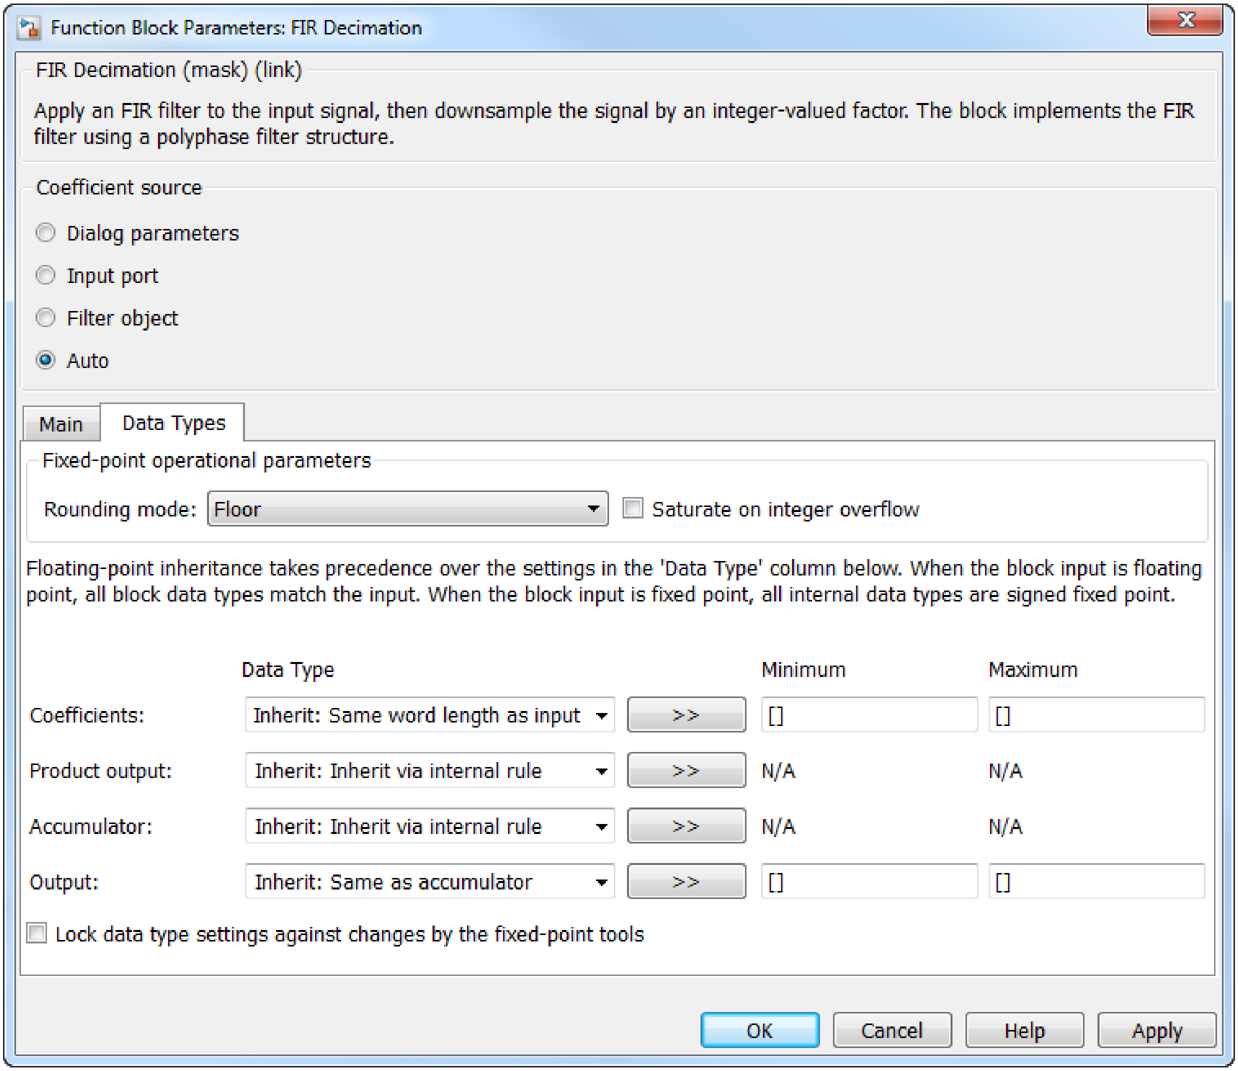
In the case of *one-frame latency*, this parameter specifies the output of the block until the first filtered input sample is available. The default value of this parameter is `0`, but you can enter a matrix containing one value for each channel, or a scalar value to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

See "Latency" on page 2-689 for more information about latency in the FIR Decimation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the FIR Decimation block dialog box appears as follows when you select **Auto** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The default is `Floor`. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-690 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-690 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-690 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-690 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see FIR Decimation.

Filtering / Filter Implementations

`dsparch4`

Description

This block is the same as the Simulink Discrete FIR Filter block. For more information, see the Discrete FIR Filter reference page in the Simulink documentation.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Discrete FIR Filter.

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The FIR Interpolation block resamples the discrete-time input at a rate L times faster than the input sample rate, where L is the integer value you specify for the **Interpolation factor** parameter. To do so, the block implements a polyphase filter structure and performs the following operations:

- Upsamples each channel of the input to a higher rate by inserting L–1 zeros between samples.
- Filters each channel of the upsampled data using a direct-form FIR filter.

The block uses a polyphase filter implementation because it is more efficient than straightforward upsample-then-filter algorithms. See Fliege [1] for more information.

You can use the FIR Interpolation block inside triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Specifying the Filter Coefficients

To specify the filter coefficients, select the mode you want the FIR Interpolation block to operate in. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as coefficients in the block dialog box.

- **Input port** — Specify the filter coefficients as an input to the block. Coefficient values are tunable (can change during simulation), while their properties must remain constant.
- **Filter object** — Specify the filter using a dsp.FIRInterpolator System object.
- **Auto** (default) — Choose the filter coefficients of an FIR Nyquist filter, predesigned for the interpolation factor specified in the block dialog box.

When you select **Dialog parameters**, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function $H(z)$.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

You can generate the FIR filter coefficient vector, `[b(1) b(2) ... b(m)]`, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

The filter you specify must be a lowpass filter with a length greater than the interpolation factor (m>L) and a normalized cutoff frequency no greater than **1**/L. The block internally initializes all filter states to zero.

When you select **Auto**, the block designs an FIR interpolator with the interpolation factor specified in **Interpolation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block. For more information on the filter design, see Orfanidis [2].

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. To interpolate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output (M_o) is L times larger than that of the input ($M_o = M_i * L$).

  For an example of single-rate FIR Interpolation, see “Example 1 — Single-Rate Processing” on page 2-724.

- When you set the **Rate options** parameter to `Allow multirate processing`, the input and output of the FIR Interpolation block are the same size. However, the sample rate of the output is L times faster than that of the input. In this mode, the block treats an M_i-by-N matrix input as N independent channels. The block interpolates each column of the input over time by keeping the frame size constant (M_i=M_o), while making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fo} = T_{fi}/L$).

  See "Example 2 — Multirate Frame-Based Processing" on page 2-725 for an example that uses the FIR Interpolation block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M*N$ independent channels, and interpolates each channel over time. The output sample period (T_{so}) is L times shorter than the input sample period ($T_{so} = T_{si}/L$), while the input and output sizes remain identical.

Latency

When you run your models in Simulink `SingleTasking` mode or set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the FIR Interpolation block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first filtered input sample (received at time t=0) as the first output sample. That first output sample is then followed by L–1 interpolated values, the second filtered input sample, and so on.

The only time the FIR Interpolation block exhibits latency is when you set the **Rate options** parameter set to `Allow multirate processing` and run your models in Simulink `MultiTasking` mode. The amount of latency for multirate, multitasking operation depends on the setting of the **Input processing** parameter, as shown in the following table.

Input processing	Latency
`Elements as channels (sample based)`	L samples

Input processing	Latency
`Columns as channels (frame based)`	L frames (M_i samples per frame)

When the block exhibits latency, the default initial condition is zero. Alternatively, you can use the **Output buffer initial conditions** parameter to specify a matrix of initial conditions containing one value for each channel or a scalar initial condition to be applied to all channels. The block scales the **Output buffer initial conditions** by the **Interpolation factor** and outputs the scaled initial conditions until the first filtered input sample becomes available.

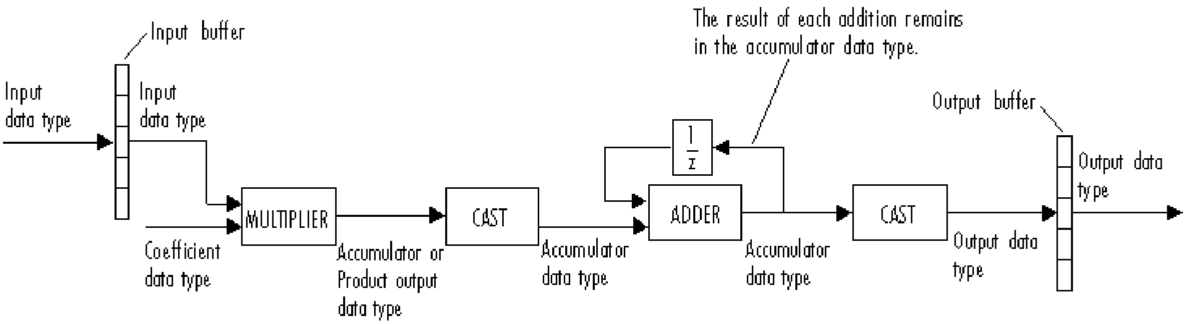
When the block is in sample-based processing mode, the block outputs the scaled initial conditions at the start of each channel, followed immediately by the first filtered input sample, then L–1 interpolated values, and so on.

When the block is in frame-based processing mode and using the default initial condition of zero, the first M_i*L output rows contain zeros, where M_i is the input frame size. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample M_i*L+1. That value is then followed by L–1 interpolated values, the second filtered input sample, and so on.

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Fixed-Point Data Types

The following diagram shows the data types used within the FIR Interpolation block for fixed-point signals.



You can set the coefficient, product output, accumulator, and output data types in the block dialog box as discussed in "Dialog Box" on page 2-726 section. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

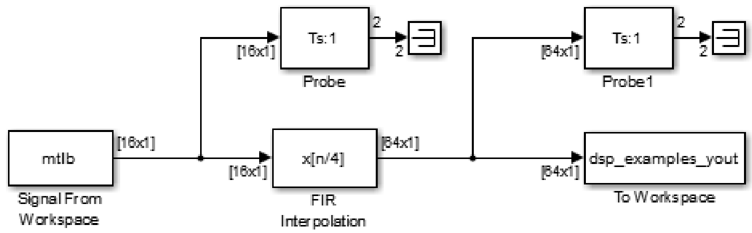
When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see "Multiplication Data Types".

Note: When the block input is fixed point, all internal data types are signed fixed point.

Examples

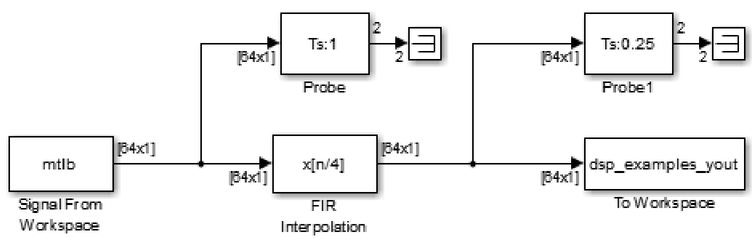
Example 1 — Single-Rate Processing

In the ex_firinterpolation_ref2, the FIR Interpolation block interpolates a single-channel input with a frame size of 16. Because the block is doing single-rate processing and the **Interpolation factor** parameter is set to 4, the output of the FIR Interpolation block has a frame size of 64. As shown in the following figure, the input, and output of the FIR Interpolation block have the same sample rate.



Example 2 — Multirate Frame-Based Processing

In the ex_firinterpolation_ref1, the FIR Interpolation block interpolates a single-channel input with a frame period of 1 second (**Sample time** = 1/64 and **Samples per frame** = 64). Because the block is doing multirate frame-based processing and the **Interpolation factor** parameter is set to 4, the output of the FIR Interpolation block has a frame period of 0.25 seconds. As shown in the following figure, the input and output of the FIR Interpolation block have the same frame size, but the sample rate of the output is 1/4 times that of the input.



Example 3

The ex_polyphaseinterp model illustrates the underlying polyphase implementations of the FIR Interpolation block. Run the model, and view the results on the scope. The output of the FIR Interpolation block matches the output of the Polyphase Interpolation Filter block.

Example 4

The ex_mrf_nlp model illustrates the use of the FIR Interpolation block in a number of multistage multirate filters.

Dialog Box

Coefficient Source

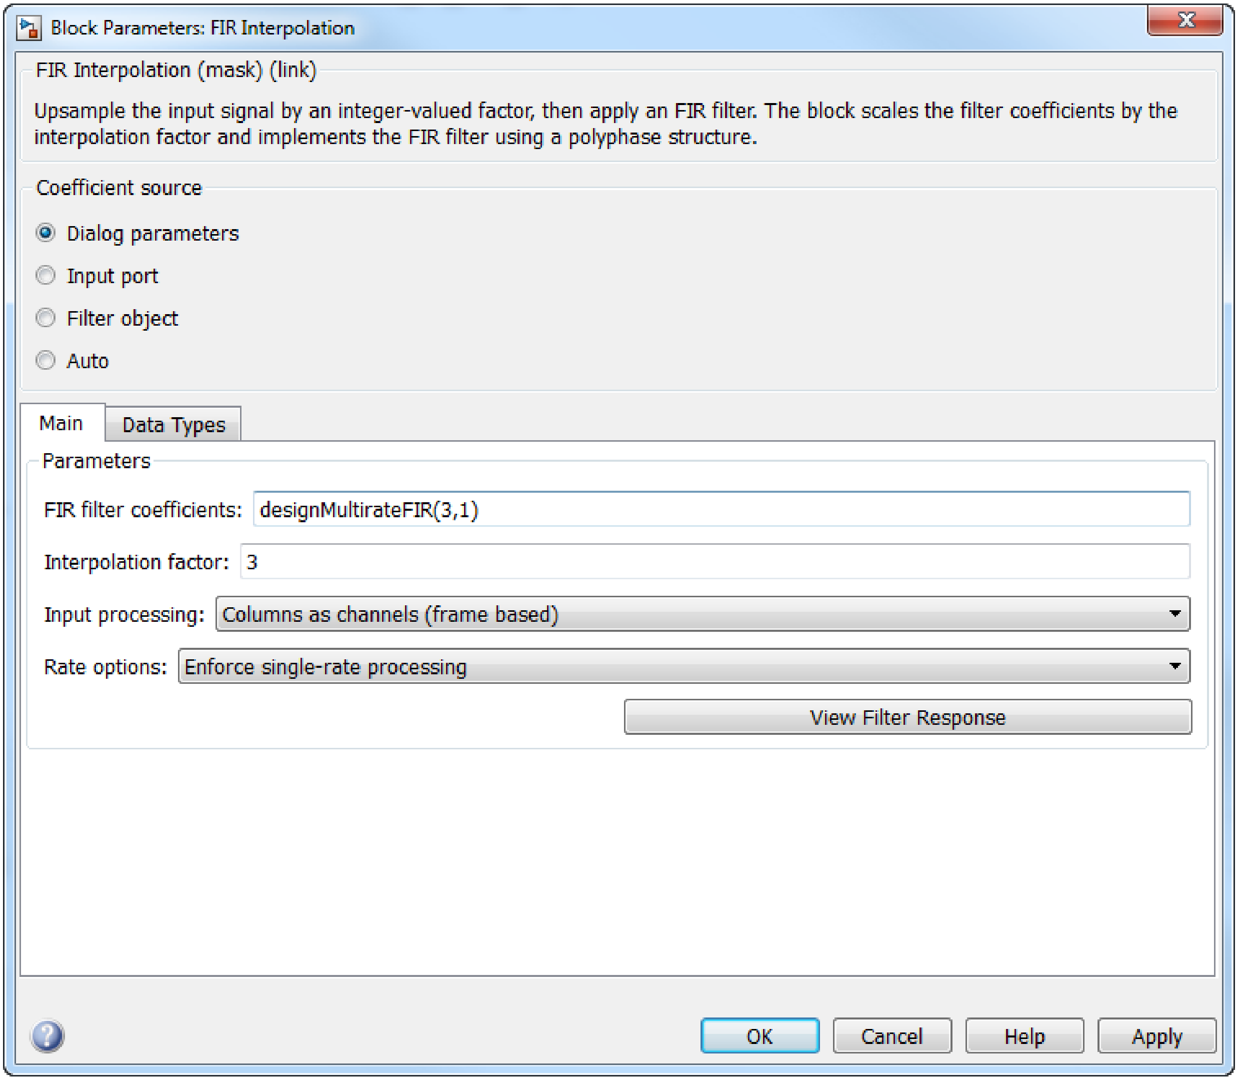
The FIR Interpolation block can operate in four different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as coefficients, in the block mask.
- **Input port** — Specify the filter coefficients with a **Num** input port. The **Num** input port appears when you select the **Input port** option. Coefficient values obtained through **Num** are tunable (can change during simulation), while their properties must remain constant.
- **Filter object** — Specify the filter using a dsp.FIRInterpolator System object.
- **Auto** (default) — Choose the coefficients of an FIR Nyquist filter, predesigned for the Interpolation factor specified in the block dialog box.

Different items appear on the FIR Interpolation block dialog box depending on whether you select **Dialog parameters**, **Input port**, **Filter object**, or **Auto** in the **Coefficient source** group box.

Specify Filter Characteristics in dialog box

The **Main** pane of the FIR Interpolation block dialog box appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



FIR filter coefficients

Specify the FIR filter coefficients, in descending powers of z. By default, `designMultirateFIR(3,1)` computes the filter coefficients.

Interpolation factor

Specify the integer factor, *L*, by which to increase the sample rate of the input sequence. The default is `3`.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is *L* times faster than the input sample rate.

Output buffer initial conditions

In cases of nonzero latency, the block divides this parameter by the **Interpolation factor** and outputs the results at the output port until the first filtered input sample is available. The default initial condition value is `0`, but you can enter a matrix containing one value for each channel, or a scalar to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

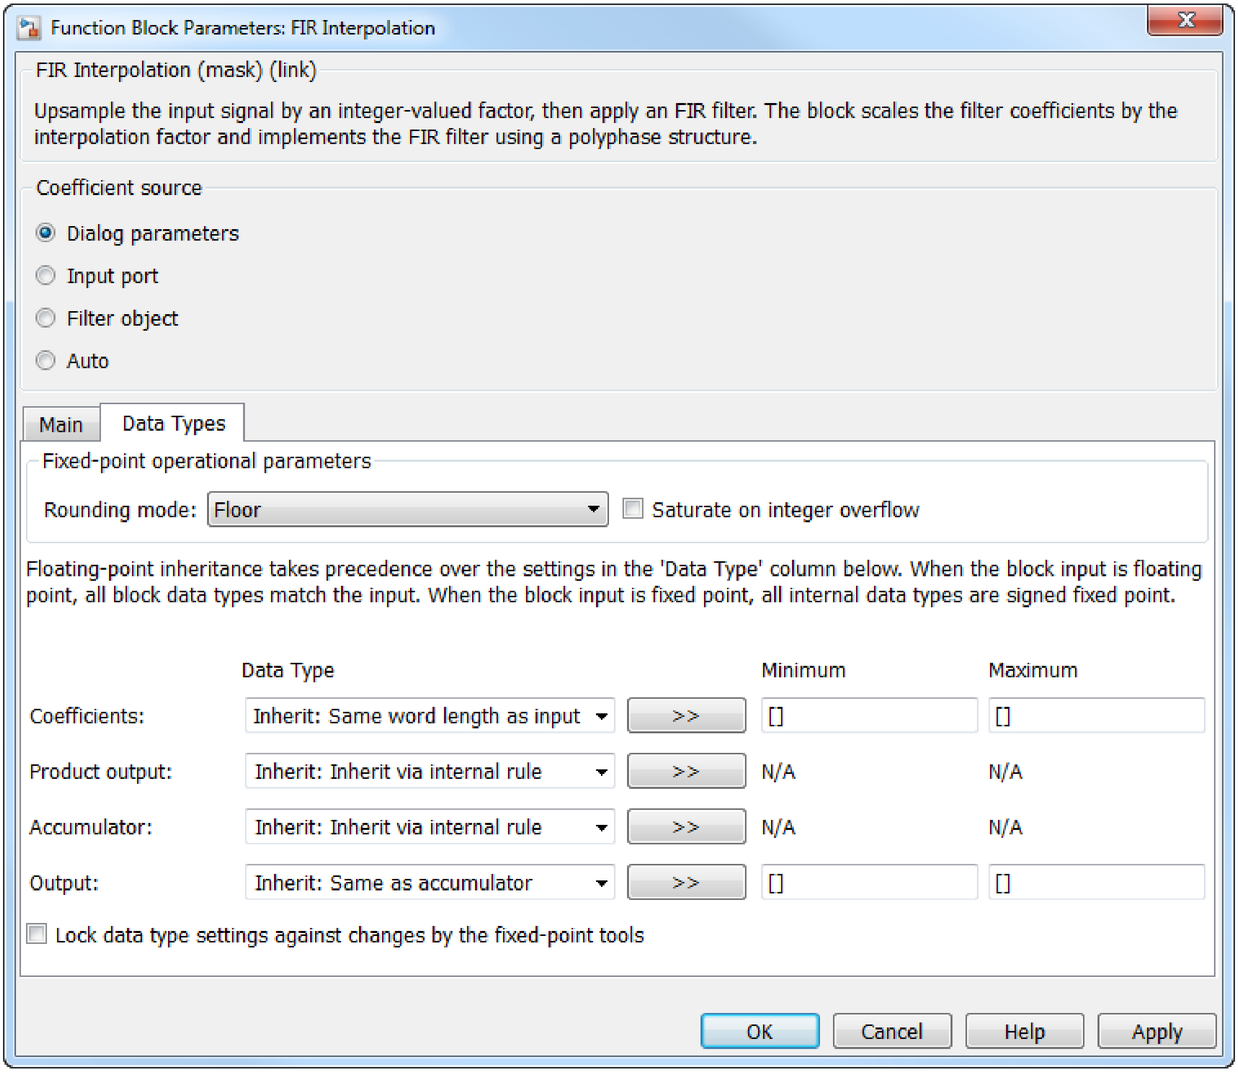
Output buffer initial conditions are stored in the output data type and scaling.

See “Latency” on page 2-722 for more information about latency in the FIR Interpolation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the FIR Interpolation block dialog box appears as follows when you select **Dialog parameters** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The default is `Floor`. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-723 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-723 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-723 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-723 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

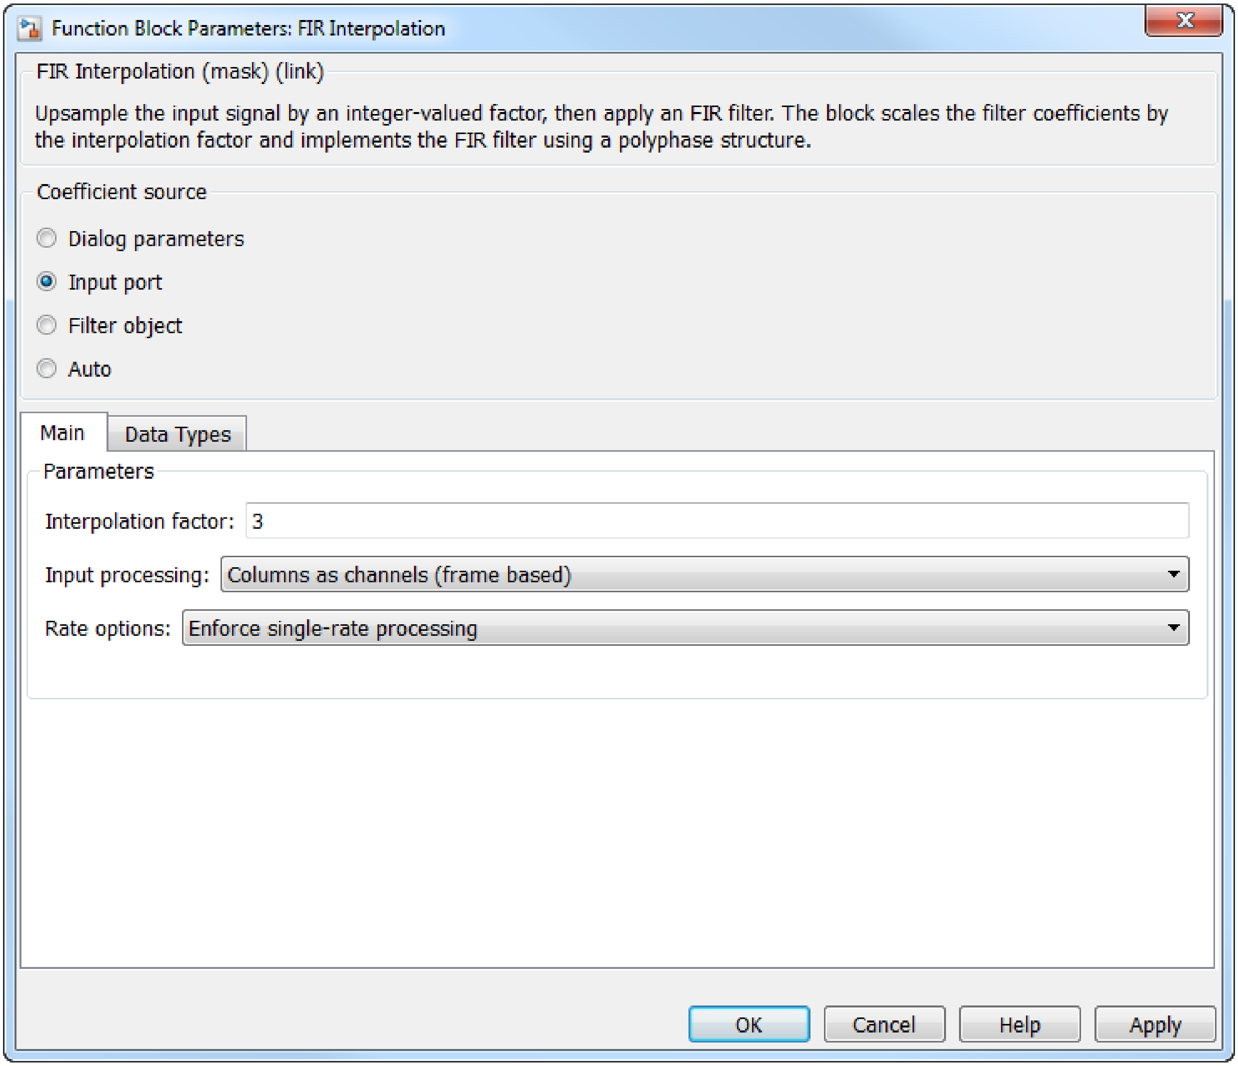
- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Provide Filter Coefficients Through Input Port

The **Main** pane of the FIR Interpolation block dialog box appears as follows when you select **Input port** in the **Coefficient source** group box.



Interpolation factor

Specify the integer factor, L, by which to increase the sample rate of the input sequence. The default is 3.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is *L* times faster than the input sample rate.

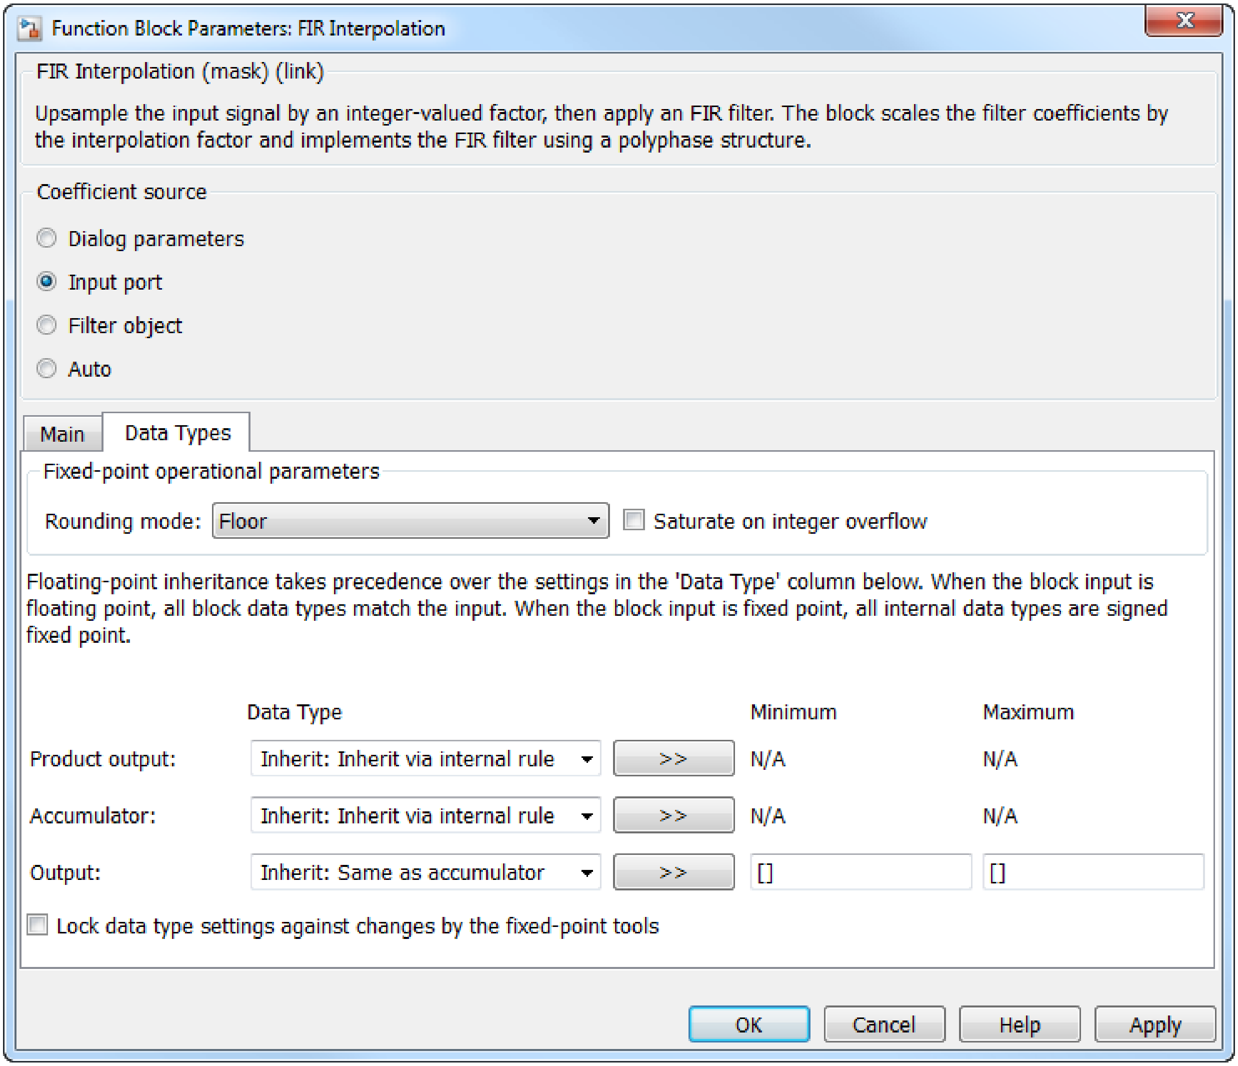
Output buffer initial conditions

In cases of nonzero latency, the block divides this parameter by the **Interpolation factor** and outputs the results at the output port until the first filtered input sample is available. The default initial condition value is `0`, but you can enter a matrix containing one value for each channel, or a scalar to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

Output buffer initial conditions are stored in the output data type and scaling.

See "Latency" on page 2-722 for more information about latency in the FIR Interpolation block.

The **Data Types** pane of the FIR Interpolation block dialog box appears as follows when you select **Input port** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The default is `Floor`. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Product output data type

Specify the product output data type. See "Fixed-Point Data Types" on page 2-723 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see "Inherit via Internal Rule".
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See "Fixed-Point Data Types" on page 2-723 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see "Inherit via Internal Rule".

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-723 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

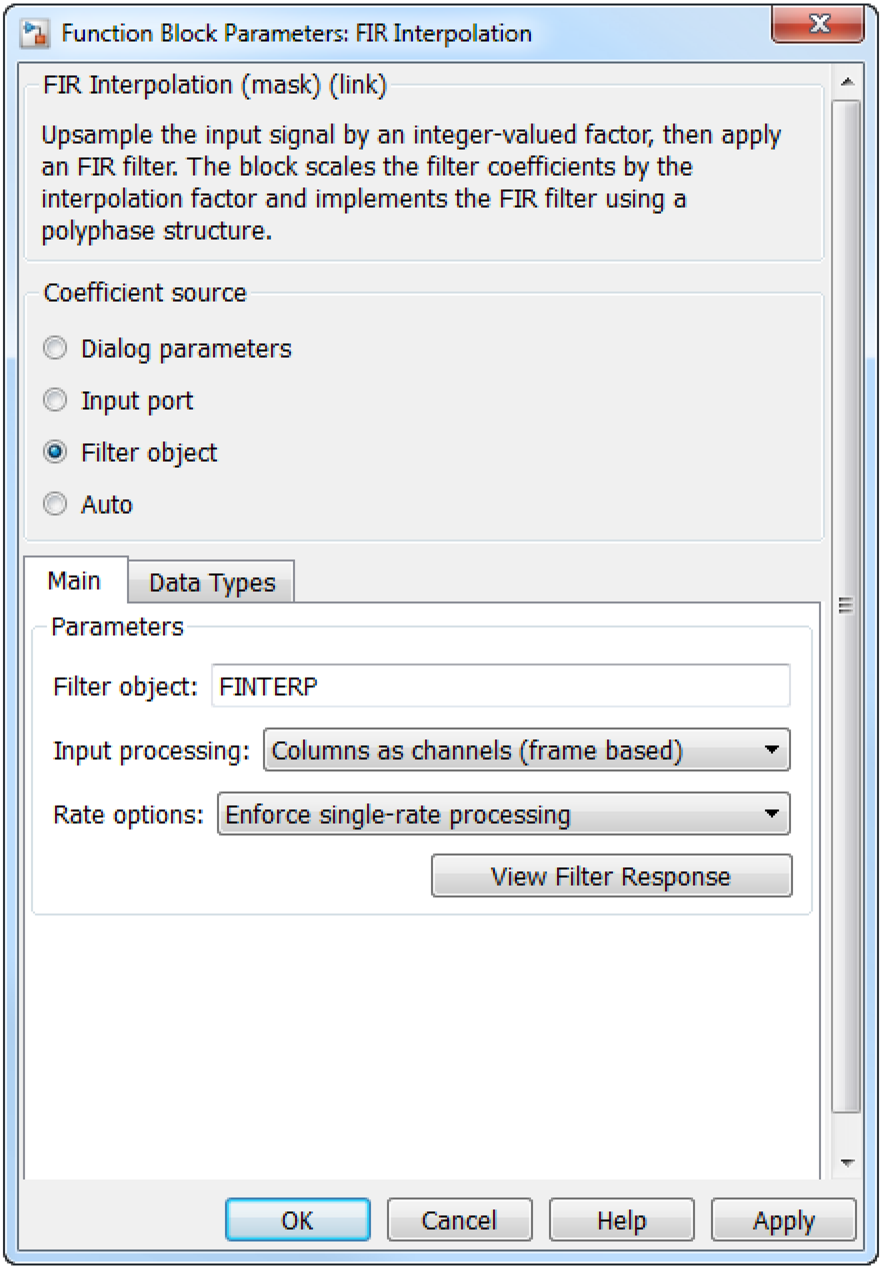
- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Multirate Filter Object

The **Main** pane of the FIR Interpolation block dialog box appears as follows when you select **Filter object** in the **Coefficient source** group box.



Function Block Parameters: FIR Interpolation

Filter object

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.FIRInterpolator System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see "Define Basic System Objects" (MATLAB).

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is *L* times faster than the input sample rate.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the System object specified in the **Filter object** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Interpolation block dialog box appears as follows when you select **Filter object** in the **Coefficient source** group box.

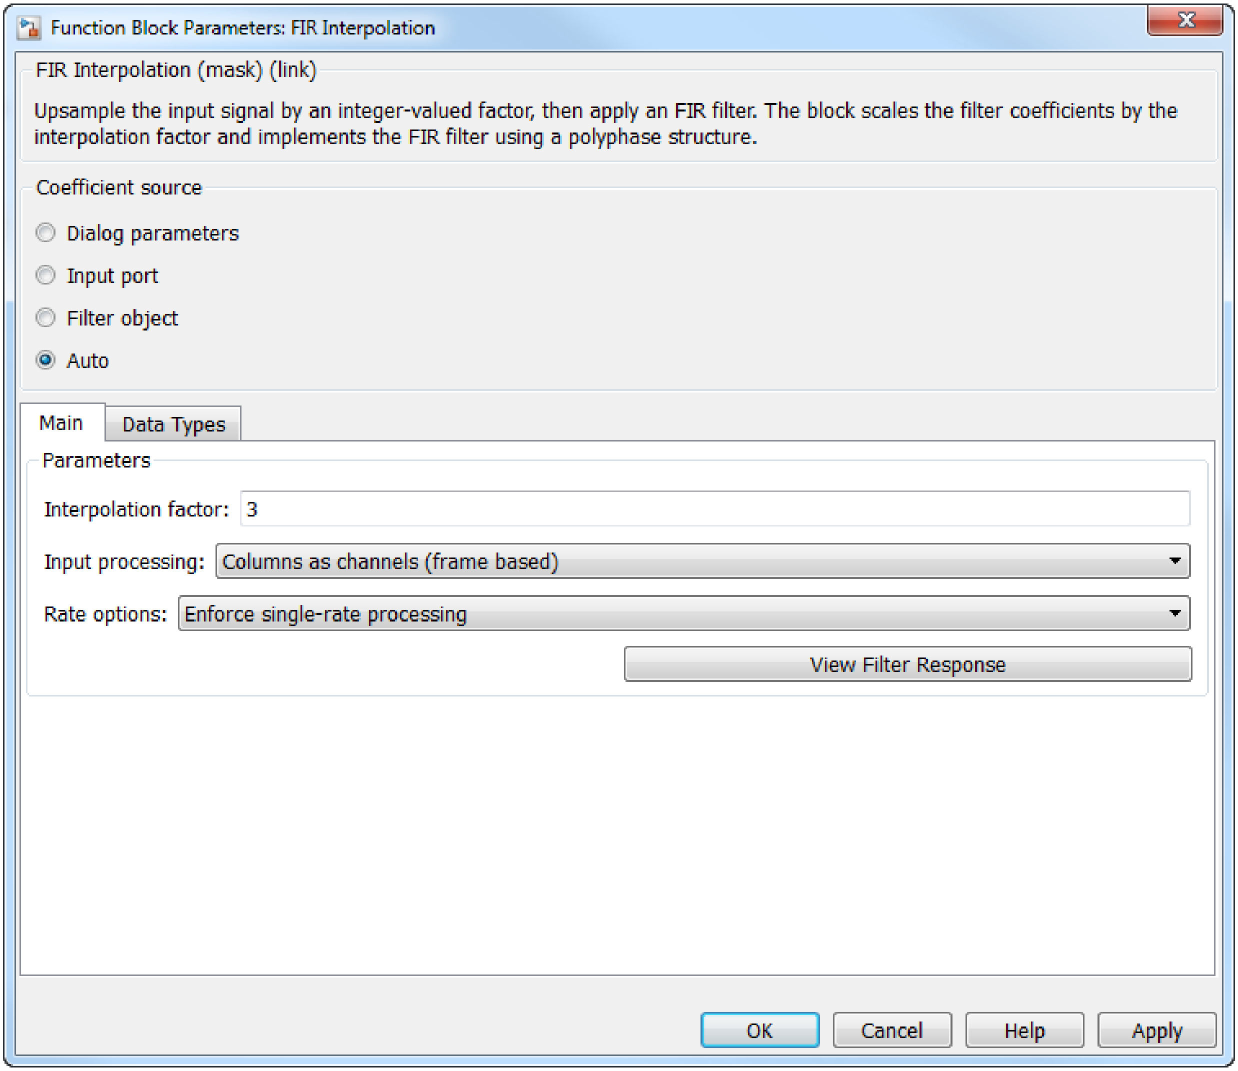
The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings, edit the filter object directly.

For more information on System objects, see “Define Basic System Objects” (MATLAB).

Choose Filter Coefficients Automatically

When you select **Auto** in the **Coefficient source** group box, the block chooses the filter coefficients automatically. For more information on the filter design algorithm the block uses, see “Specifying the Filter Coefficients” on page 2-720.

The **Main** pane of the FIR Interpolation block dialog box appears as follows when you select **Auto** in the **Coefficient source** group box.



Interpolation factor

Specify the integer factor, L, by which to increase the sample rate of the input sequence. The default is 3.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of L. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is L times faster than the input sample rate.

Output buffer initial conditions

In cases of nonzero latency, the block divides this parameter by the **Interpolation factor** and outputs the results at the output port until the first filtered input sample is available. The default initial condition value is `0`, but you can enter a matrix containing one value for each channel, or a scalar to be applied to all signal channels. This parameter appears only when you configure the block to perform multirate processing.

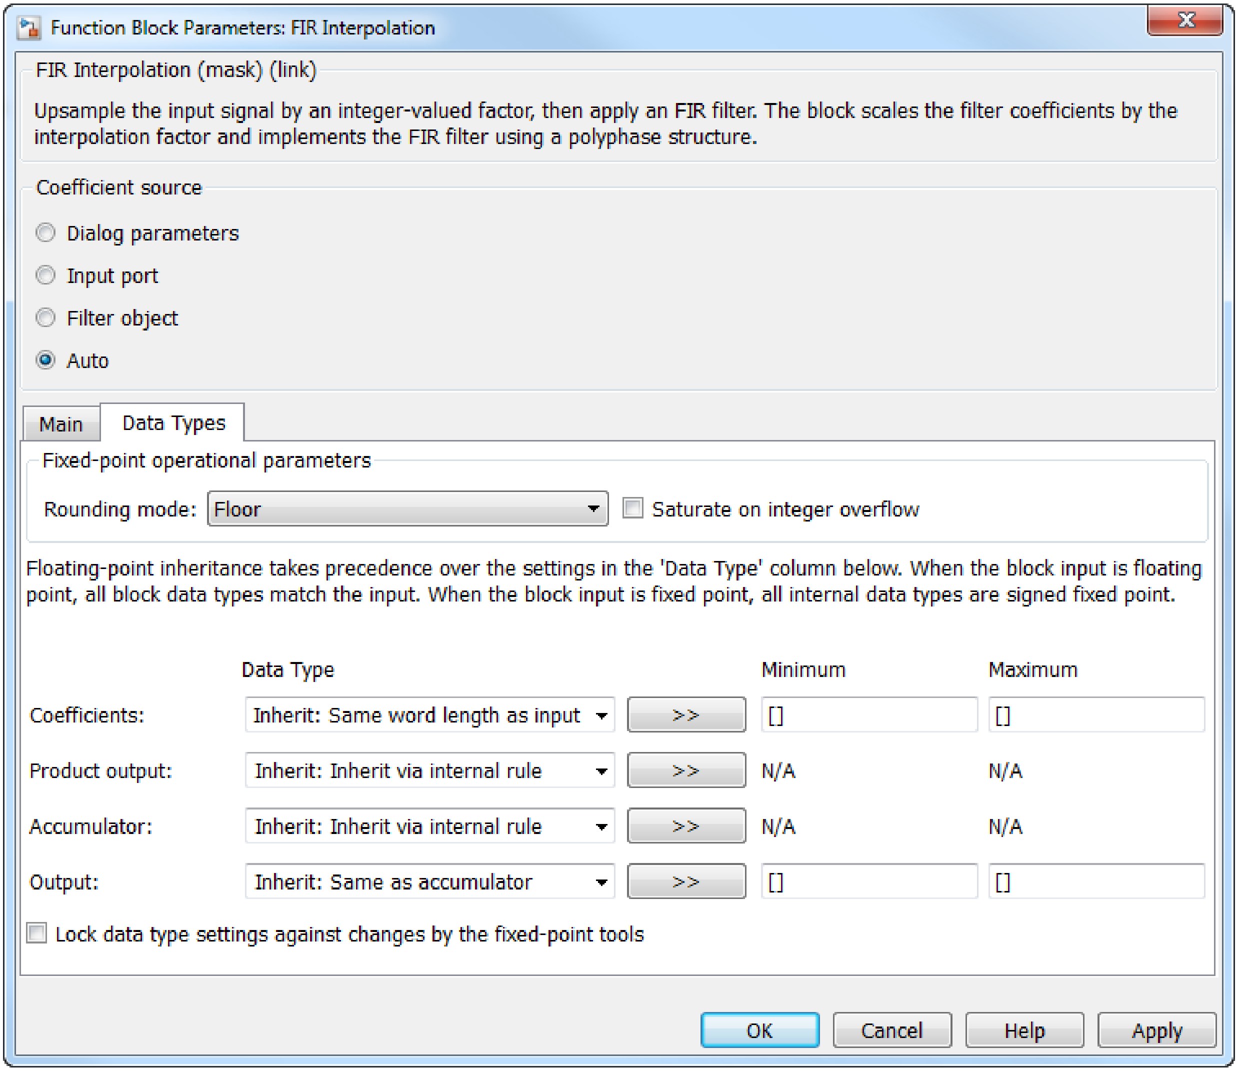
Output buffer initial conditions are stored in the output data type and scaling.

See “Latency” on page 2-722 for more information about latency in the FIR Interpolation block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the FIR Interpolation block dialog box appears as follows when you select **Auto** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The default is `Floor`. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See "Fixed-Point Data Types" on page 2-723 and "Multiplication Data Types" for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See "Fixed-Point Data Types" on page 2-723 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see "Inherit via Internal Rule".
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See "Fixed-Point Data Types" on page 2-723 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see "Inherit via Internal Rule".
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See "Fixed-Point Data Types" on page 2-723 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see FIR Interpolation.

FIR Halfband Decimator

Decimate signal using polyphase FIR halfband filter

Library

Filtering/Filter Designs

`dspfdesign`

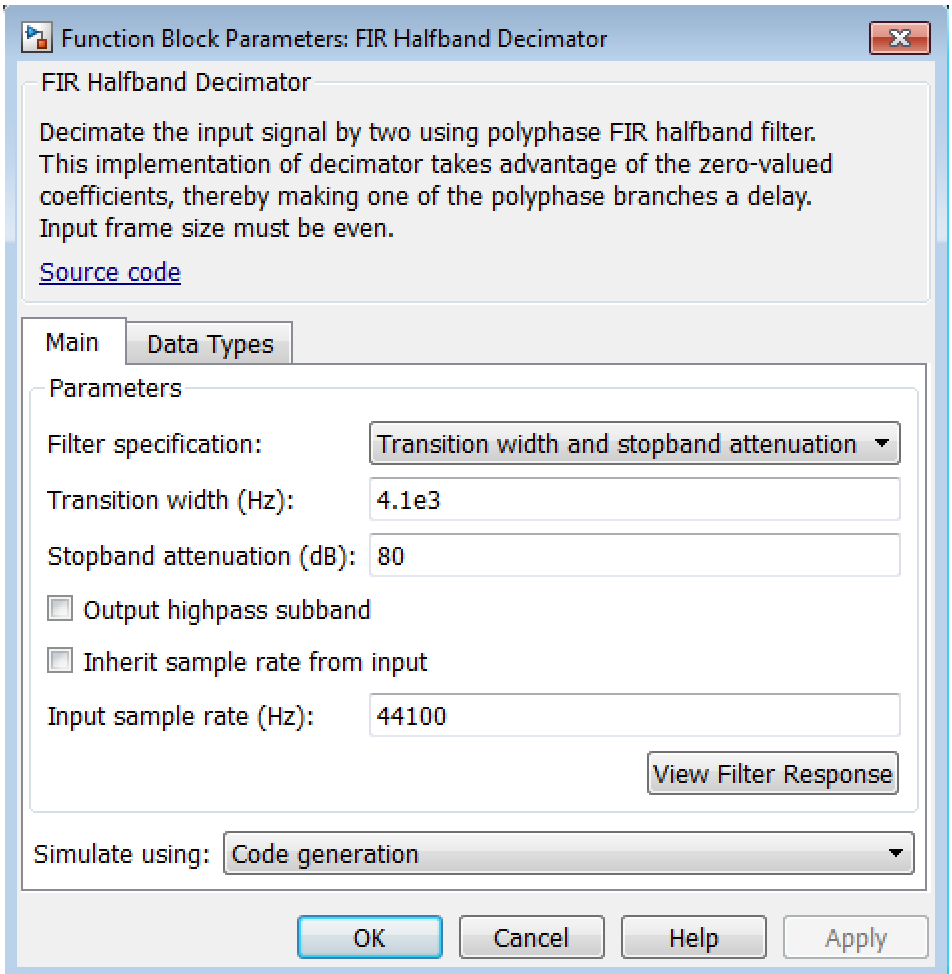
Description

The FIR Halfband Decimator block performs polyphase decimation of the input signal by a factor of two. The block uses an FIR equiripple design to construct the halfband filters. The implementation takes advantage of the zero-valued coefficients of the FIR halfband filter, making one of the polyphase branches a delay. You can also use the block to implement the analysis portion of a two-band filter bank to separate a signal into lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2. The block supports fixed-point operations and ARM® Cortex® code generation. For more information on ARM Cortex code generation, refer “ARM Cortex-M and ARM Cortex-A Optimization”.

Dialog Box

Main Tab



Filter specification

Parameters used to design the FIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of three parameters:

- `Transition width and stopband attenuation` (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- `Filter order and transition width` — Design the filter using **Filter order** and **Transition width (Hz)**.
- `Filter order and stopband attenuation` — Design the filter using **Filter order** and **Stopband attenuation (dB)**.

Transition width (Hz)

Transition width, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. You can specify the transition width when **Filter specification** is set to `Filter order and transition width` or `Transition width and stopband attenuation`. The default is `4.1e3`.

Filter order

Filter order, specified as an even positive integer. You can specify the filter order when **Filter specification** is set to `Filter order and transition width` or `Filter order and stopband attenuation`. The default is `52`.

Stopband attenuation (dB)

Stopband attenuation, specified as a real positive scalar in dB. You can specify the stopband attenuation when **Filter specification** is set to `Filter order and stopband attenuation` or `Transition width and stopband attenuation`. The default is `80`.

Output highpass subband

When you select this check box, the block acts as a synthesis filter bank and synthesizes a signal from the highpass and lowpass subbands. When you clear this check box, the block acts as an FIR halfband decimator and accepts a single vector– or matrix–valued input.

Inherit sample rate from input

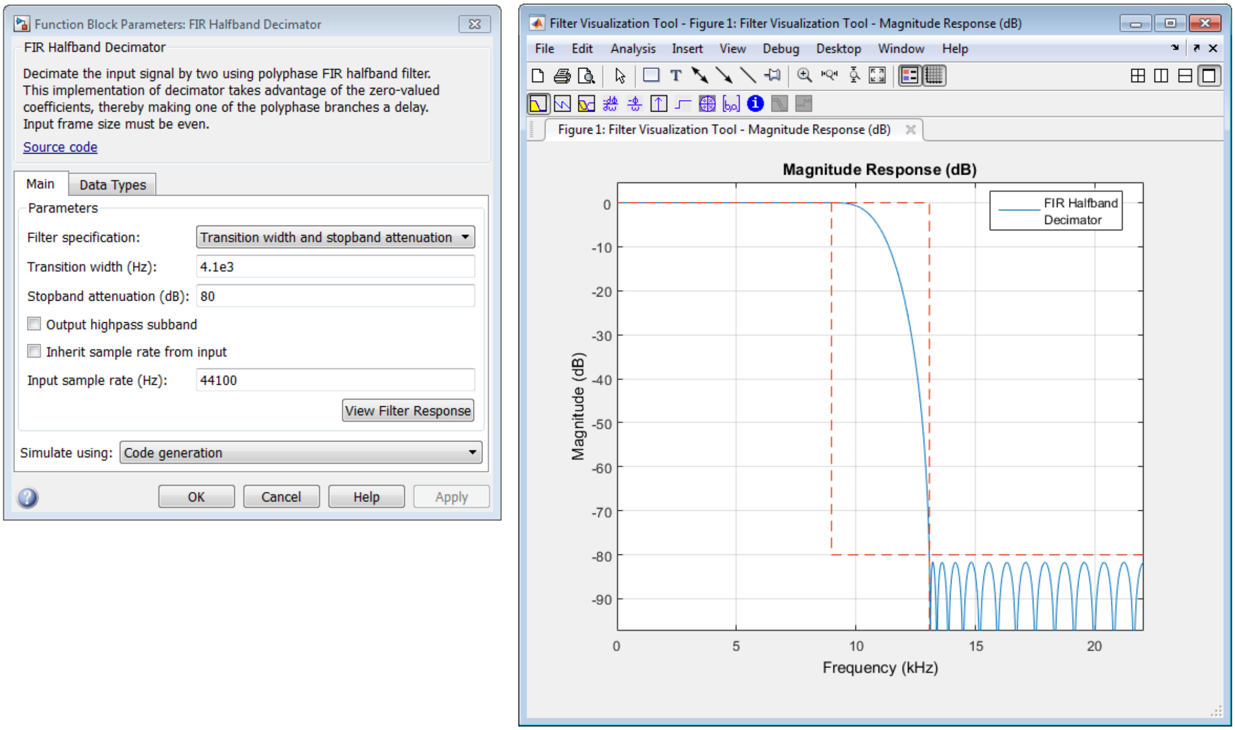
When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is `44100`.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the FIR Halfband Decimator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

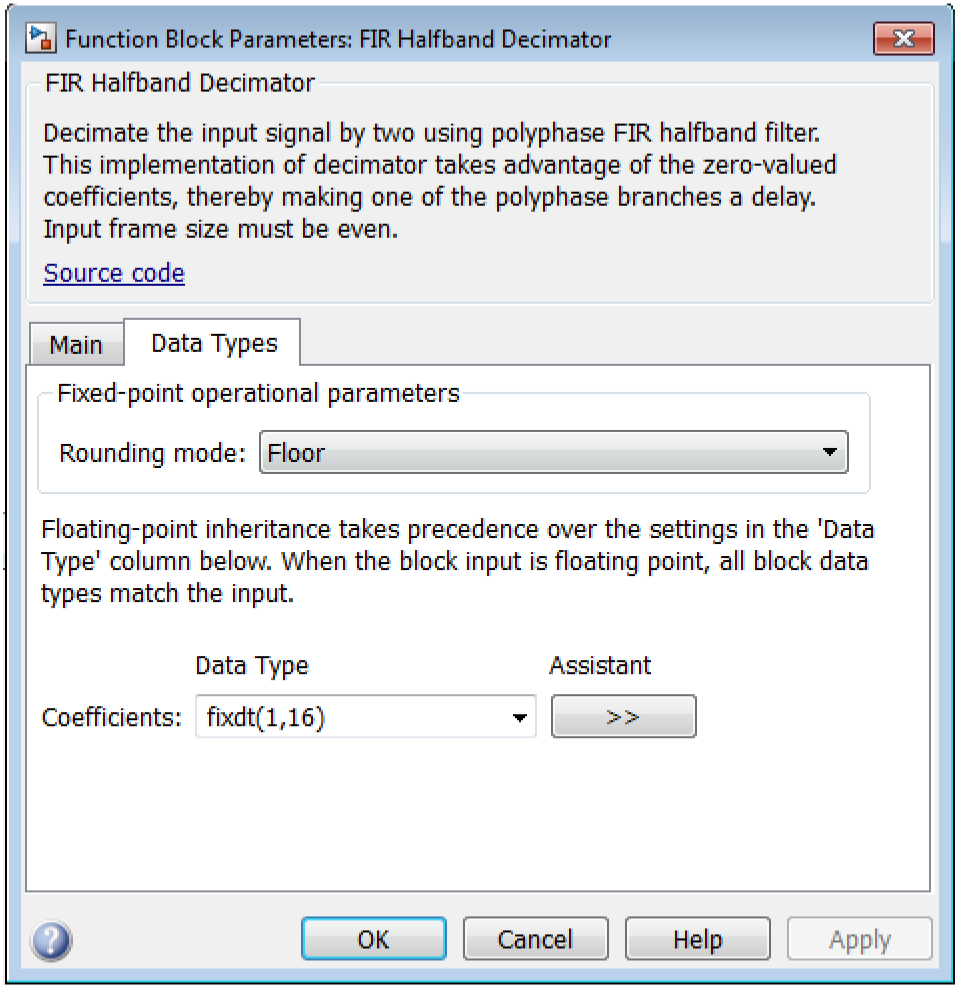
- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients data type

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16` and fraction length, `0`. You can change the fraction length to any other integer value.
- <data type expression> — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt`,`[ ]`,`16`, `15`). Specify the sign mode of this data type as `[ ]` or `true`.
- `Refresh Data Type` — Refreshes to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned) • 8-, 16-, 32-, and 64-bit signed integers • real and complex data
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

Port	Supported Data Types
	• 8-, 16-, 32-, and 64-bit signed integers • real and complex data

FIR Halfband Interpolator

Interpolate signal using polyphase FIR half band filter

Library

Filtering / Filter Designs

`dspfdesign`

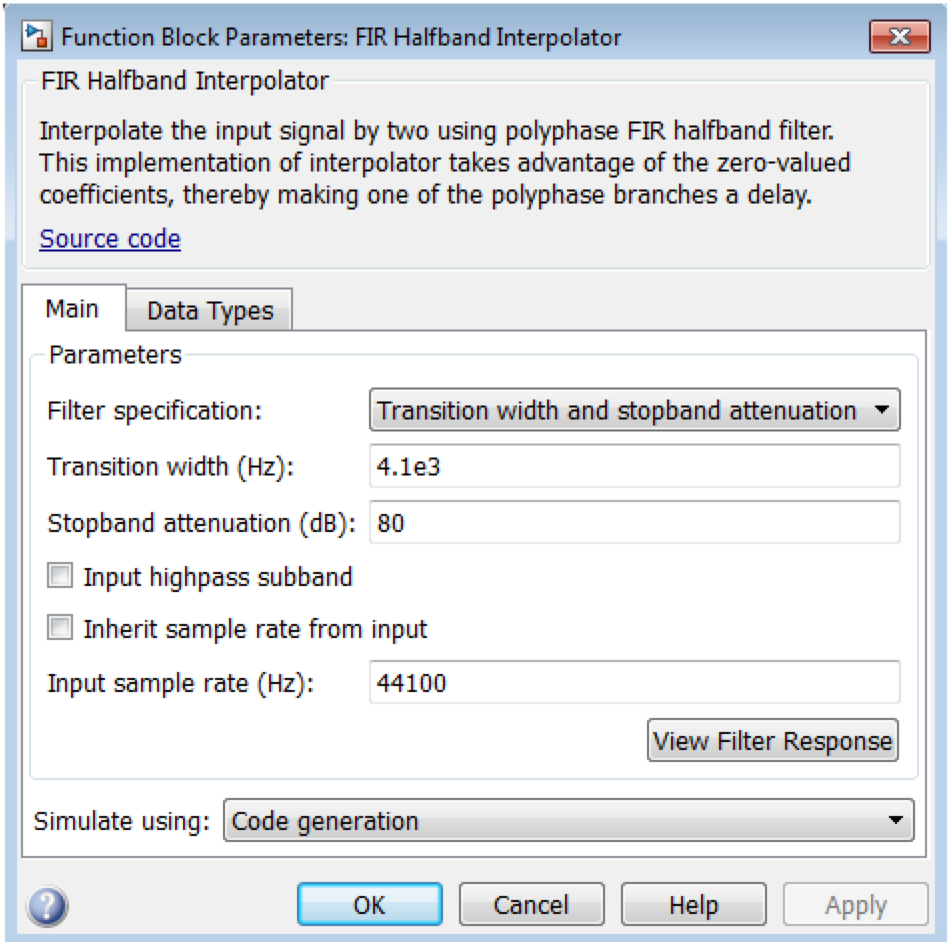
Description

The FIR Halfband Interpolator block performs interpolation of the input signal by a factor of two. The block uses an FIR equiripple design to construct the halfband filters. To filter the input, the block uses an efficient polyphase implementation. The implementation takes advantage of the zero-valued coefficients of the FIR halfband filter, making one of the polyphase branches a delay. You can also use the block to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The block supports fixed-point operations and ARM Cortex code generation. For more information on ARM Cortex code generation, refer “ARM Cortex-M and ARM Cortex-A Optimization”.

Dialog Box

Main Tab



Filter specification

Parameters used to design FIR halfband filter. The filter design has only two degrees of freedom, so you can specify only two of the three parameters:

- `Transition width and stopband attenuation` (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- `Filter order and transition width` — Design the filter using **Filter order** and **Transition width (Hz)**.
- `Filter order and stopband attenuation` — Design the filter using **Filter order** and **Stopband attenuation (dB)**.

Transition width (Hz)

Transition width, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. You can specify the transition width only when **Filter specification** is set to `Filter order and transition width` or `Transition width and stopband attenuation`. The default is `4.1e3`.

Filter order

Filter order, specified as an even positive integer. You can specify only when **Filter specification** is set to `Filter order and transition width` or `Filter order and stopband attenuation`. The default is `52`.

Stopband attenuation (dB)

Stopband attenuation, specified as a real positive scalar in dB. You can specify the stopband attenuation only when **Filter specification** is set to `Filter order and stopband attenuation` or `Transition width and stopband attenuation`. The default is `80`.

Input highpass subband

When you select this check box, the block acts as a synthesis filter bank and synthesizes a signal from the highpass and lowpass subbands. When you clear this check box, the block acts as an FIR half band interpolator and accepts a single vector– or matrix–valued input.

Inherit sample rate from input

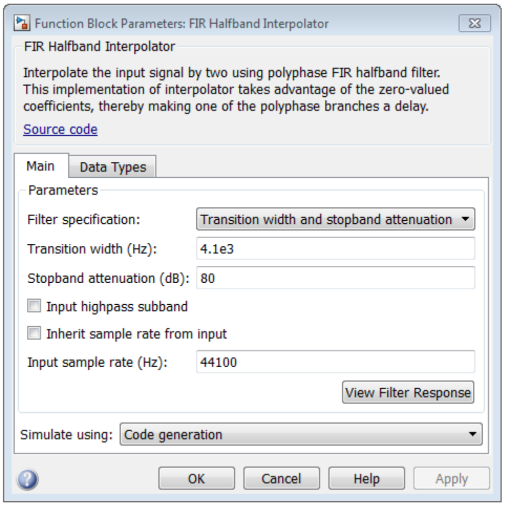
When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input Sample Rate (Hz)**.

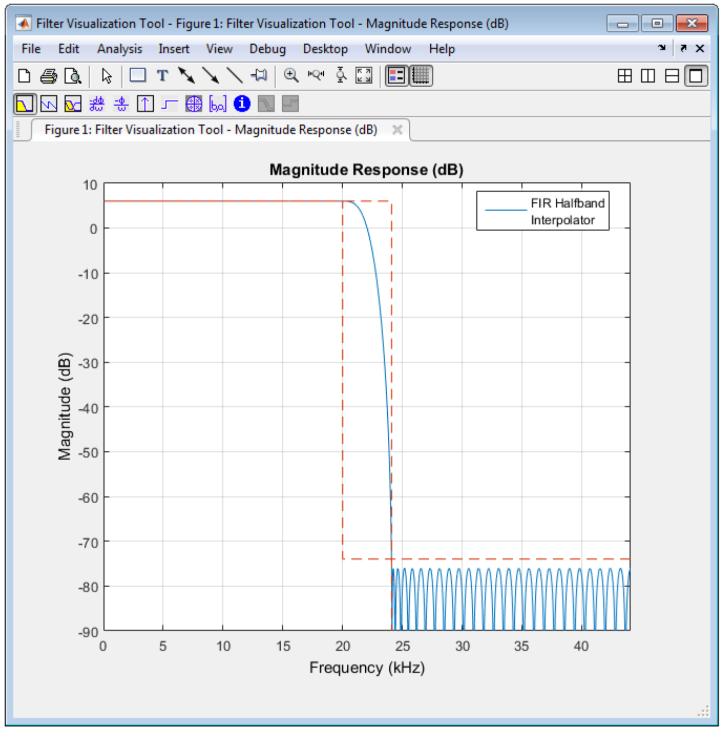
Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default value is `44100`.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the FIR Halfband Interpolator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

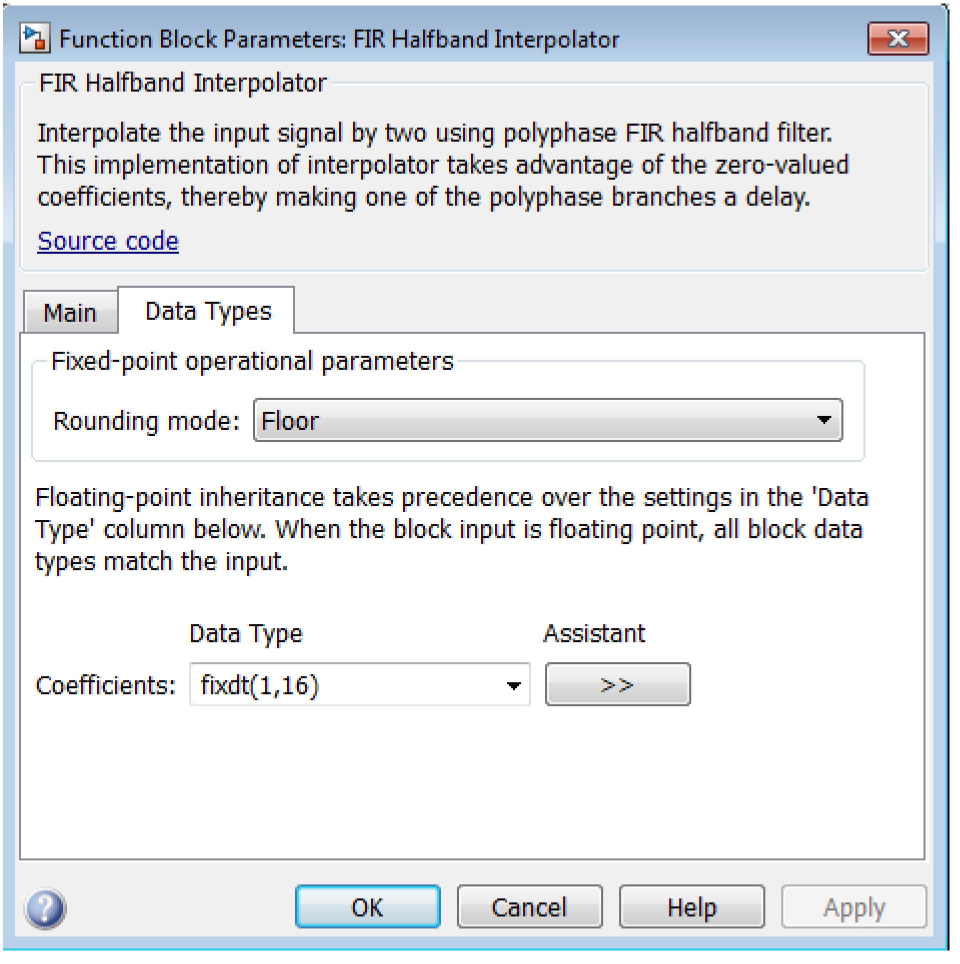
- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients data type

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16` and fraction length, `0`. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`[ ]`,`16`, `15`). Specify the sign mode of this data type as `[ ]` or `true`.
- `Refresh Data Type` — Refreshes to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned) • 8-, 16-, 32-, and 64-bit signed integers • real and complex data
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

Port	Supported Data Types
	• 8-, 16-, 32-, and 64-bit signed integers • real and complex data

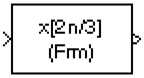
FIR Rate Conversion

Upsample, filter, and downsample input signals



Library

Filtering / Multirate Filters

`dspmlti4`

Description

The FIR Rate Conversion block resamples the discrete-time input such that its sample period is K/L times the input sample period (T_{si}). K is the integer value you specify for the **Decimation factor** parameter, and L is the integer value you specify for the **Interpolation factor** parameter.

The block treats each column of the input as a separate channel, and resamples the data in each channel independently over time. To do so, the block implements a polyphase filter structure and performs the following operations:

1. Upsamples the input to a higher rate by inserting L-1 zeros between input samples.
2. Passes the upsampled data through a direct-form II transpose FIR filter.
3. Downsamples the filtered data to a lower rate by discarding K-1 consecutive samples following each sample that the block retains.

The polyphase filter implementation is more efficient than a straightforward upsample-filter-decimate algorithm. See Orfanidis [1] for more information.

Specifying the Resampling Rate

You specify the resampling rate of the FIR Rate Conversion block using the **Decimation factor** and **Interpolation factor** parameters. For an M_i-by-N matrix input, the **Decimation factor**, K, and the **Interpolation factor**, L, must satisfy the following requirements:

- K and L must be relatively prime integers; that is, the ratio K/L cannot be reduced to a ratio of smaller integers.
- $\frac{K}{L} = \frac{M_i}{M_o}$, where M_i and M_o are the integer frame sizes of the input and output, respectively.

You can satisfy the second requirement by setting the **Decimation factor**, K, equal to the input frame size, M_i. When you do so, the output frame size, M_o, equals the **Interpolation factor**, L.

By changing the frame size in this way, the block is able to hold the frame period constant ($T_{fi} = T_{fo}$) and achieve the desired conversion of the sample period, such that

$$T_{so} = \frac{K}{L} \times T_{si}$$

where T_{so} is the output sample period.

Specifying the FIR Filter Coefficients

To specify the filter coefficients, select the mode you want the FIR Rate Conversion block to operate in. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as coefficients, in the block dialog box.
- **Filter object** — Specify the filter using a dsp.FIRRateConverter System object.
- **Auto** (default) — Choose the filter coefficients automatically.

When you select the **Dialog parameters** option, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function $H(z)$.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

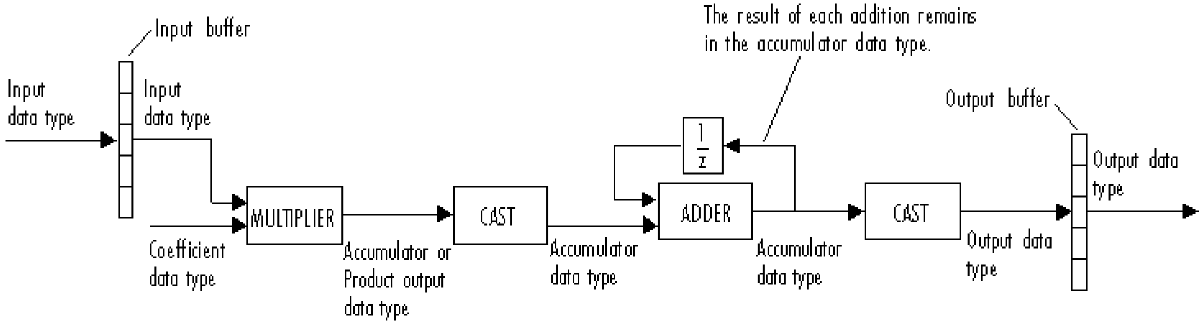
You can generate the FIR filter coefficient vector, `[b(1) b(2) ... b(m)]`, using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

The coefficient vector you specify must have a length greater than the interpolation factor ($m>L$). The FIR filter must be a lowpass filter with a normalized cutoff frequency, no greater than `min`(1/L,1/K). The block internally initializes all filter states to zero.

When you select **Auto**, the block designs an FIR multirate filter with the decimation factor specified in **Decimation factor** and interpolation factor specified in **Interpolation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block. For more information on the filter design, see Orfanidis [1].

Fixed-Point Data Types

The following diagram shows the data types used within the FIR Rate Conversion block for fixed-point signals.



You can set the coefficient, product output, accumulator, and output data types in the block dialog box as discussed in “Dialog Box” on page 2-769. The diagram shows that input data is stored in the input buffer in the same data type and scaling as the input. Filtered data resides in the output buffer in the output data type and scaling that you set in the block dialog. The block stores any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

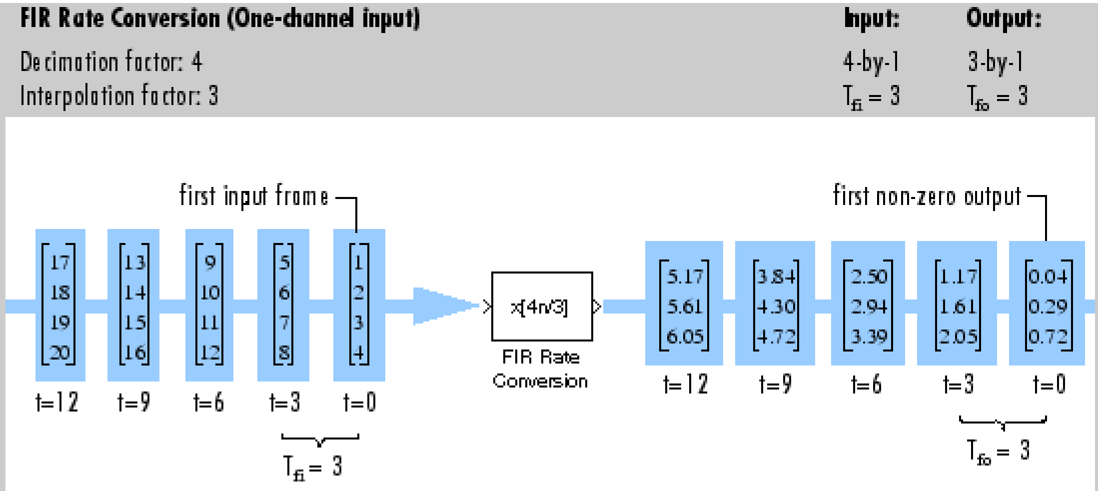
The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Examples

Example 1

The following figure shows how the FIR Rate Conversion block converts a 4-by-1 input with a sample period of 3/4, to a 3-by-1 output with a sample period of 1. The frame period (T_f) of 3 remains constant.



Example 2

The ex_audio_src model provides a simple illustration of one way to convert a speech signal from one sample rate to another. In this model, the data is first sampled at 22,050 Hz and then resampled at 8000 Hz. If you listen to the output, you can hear that the high frequency content has been removed from the signal, although the speech sounds basically the same.

Dialog Box

Coefficient Source

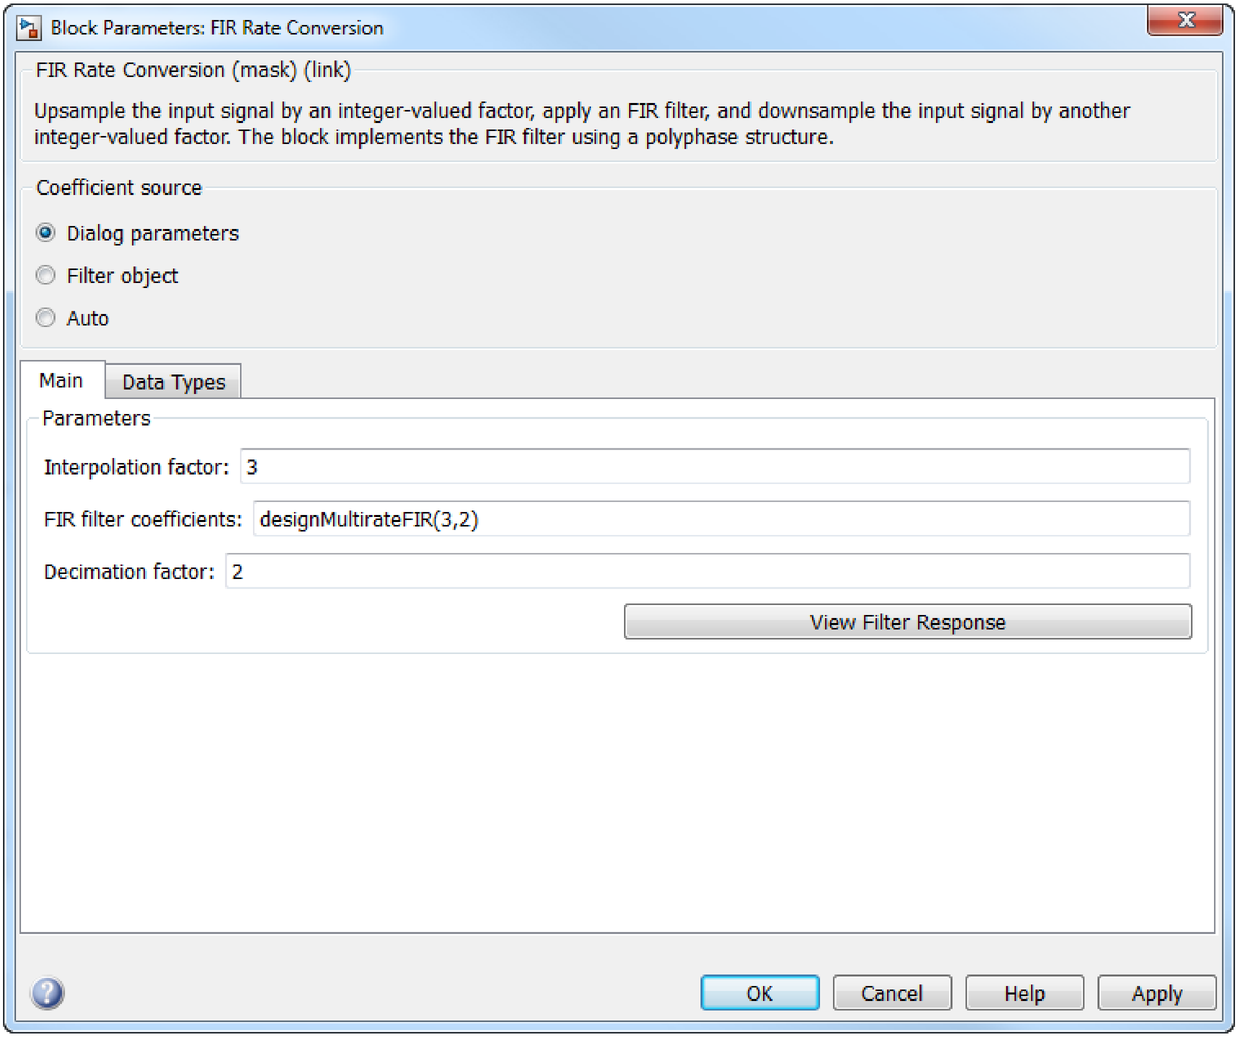
The FIR Rate Conversion block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as coefficients, in the block mask.
- **Filter object** — Specify the filter using a dsp.FIRRateConverter System object.
- **Auto** (default) — Choose the filter coefficients automatically.

Different items appear on the FIR Rate Conversion block dialog box depending on whether you select **Dialog parameters**, **Filter object**, or **Auto** in the **Coefficient source** group box.

Specify Filter Characteristics in Dialog

The **Main** pane of the FIR Rate Conversion block dialog appears as follows when **Dialog parameters** is selected in the **Coefficient source** group box.



Interpolation factor

Specify the integer factor, *L*, by which to upsample the signal before filtering. The default is 3.

FIR filter coefficients

Specify the FIR filter coefficients in descending powers of *z*. By default, `designMultirateFIR(3,2)` computes the filter coefficients.

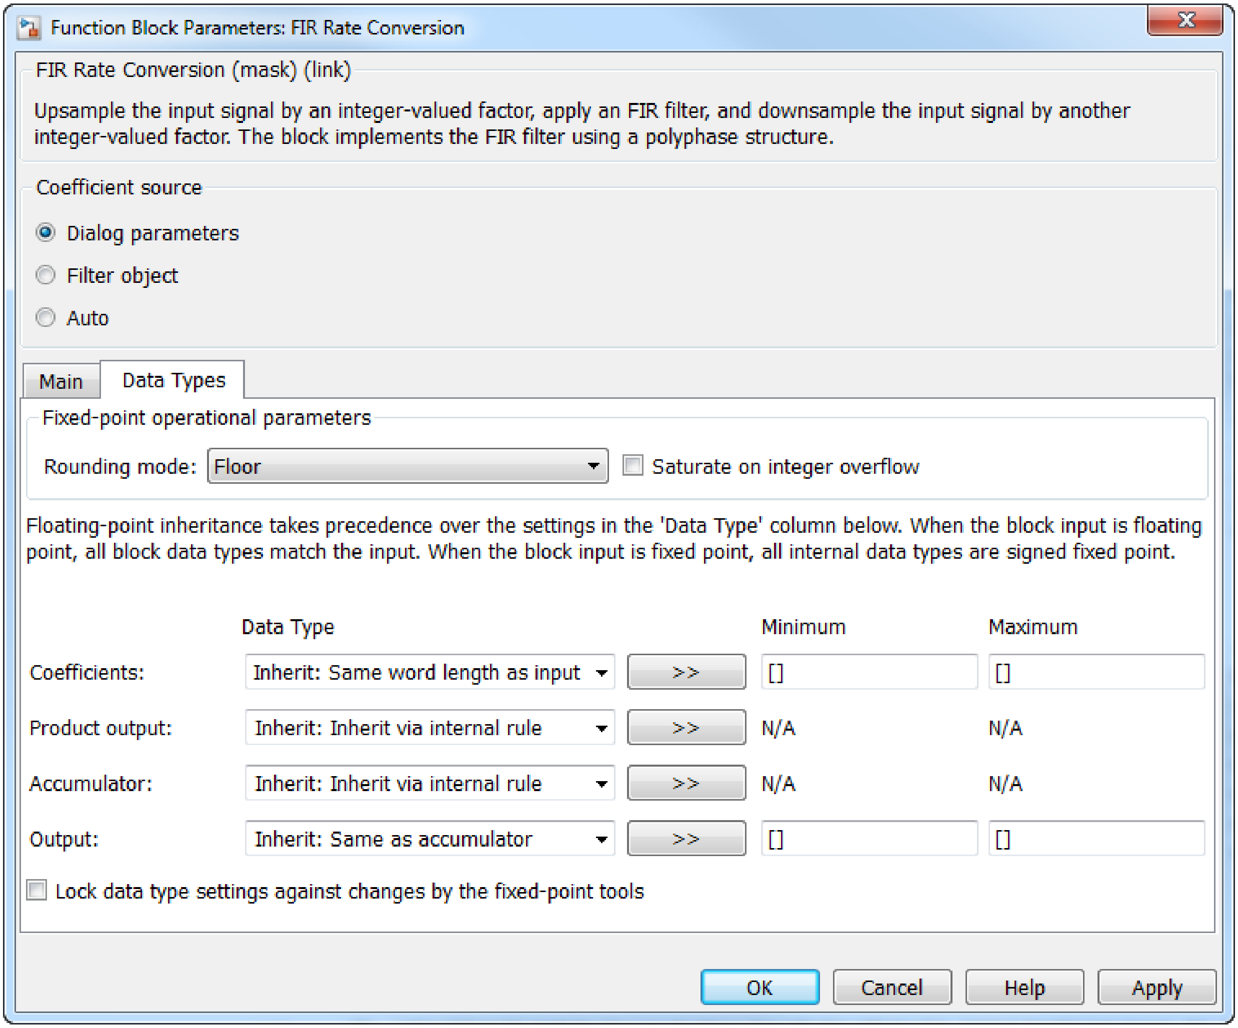
Decimation factor

Specify the integer factor, *K*, by which to downsample the signal after filtering. The default is `2`.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the FIR Rate Conversion block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-768 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-768 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-768 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-768 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

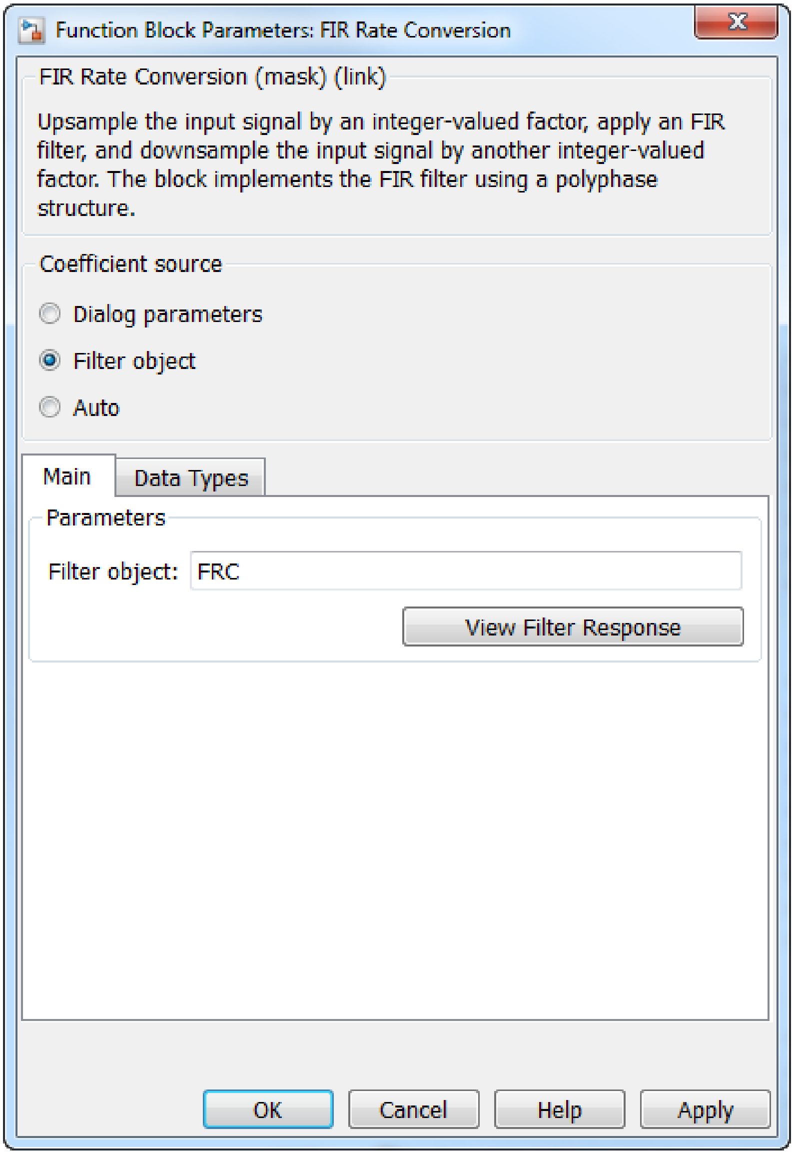
- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Specify Multirate Filter Object

The **Main** pane of the FIR Rate Conversion block dialog appears as follows when **Filter object** is specified in the **Coefficient source** group box.



Filter object

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.FIRRateConverter System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

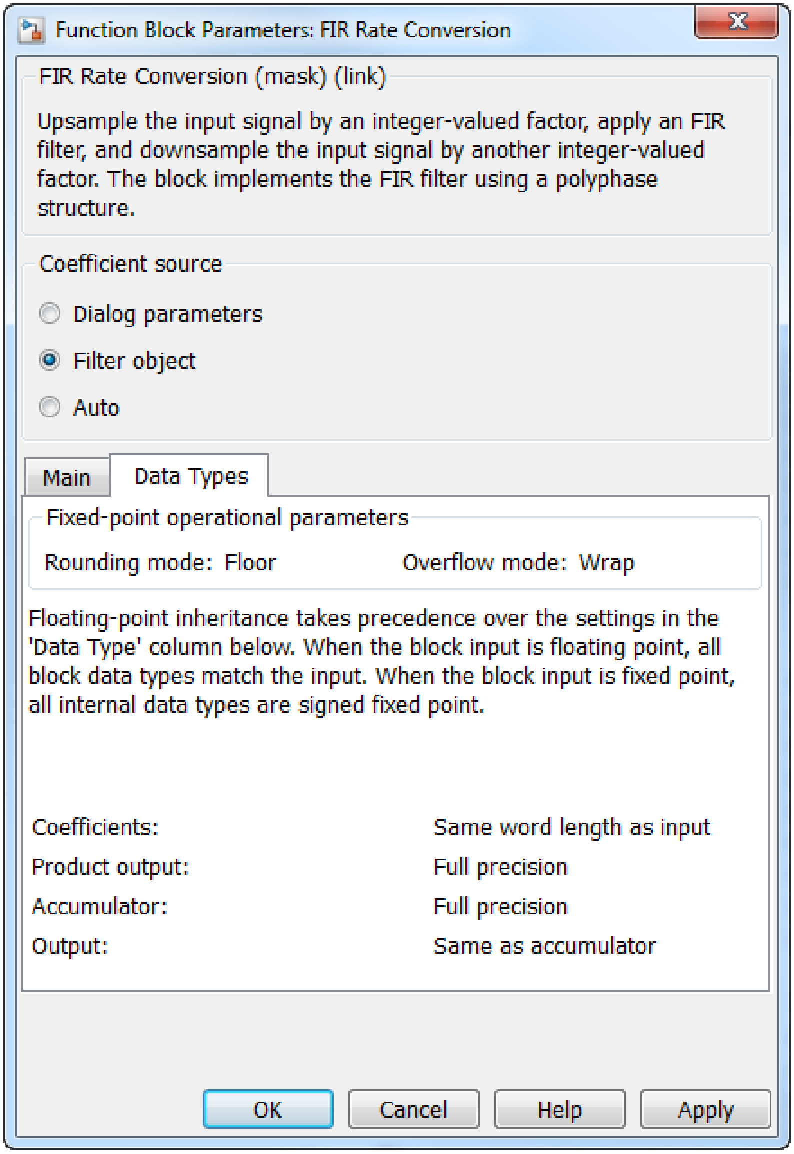
For information on creating System objects, see “Define Basic System Objects” (MATLAB).

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the System object specified in the **Filter object** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

Note: If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View filter response** button.

The **Data Types** pane of the FIR Rate Conversion block dialog appears as follows when you select **Filter object** in the **Coefficient source** group box.



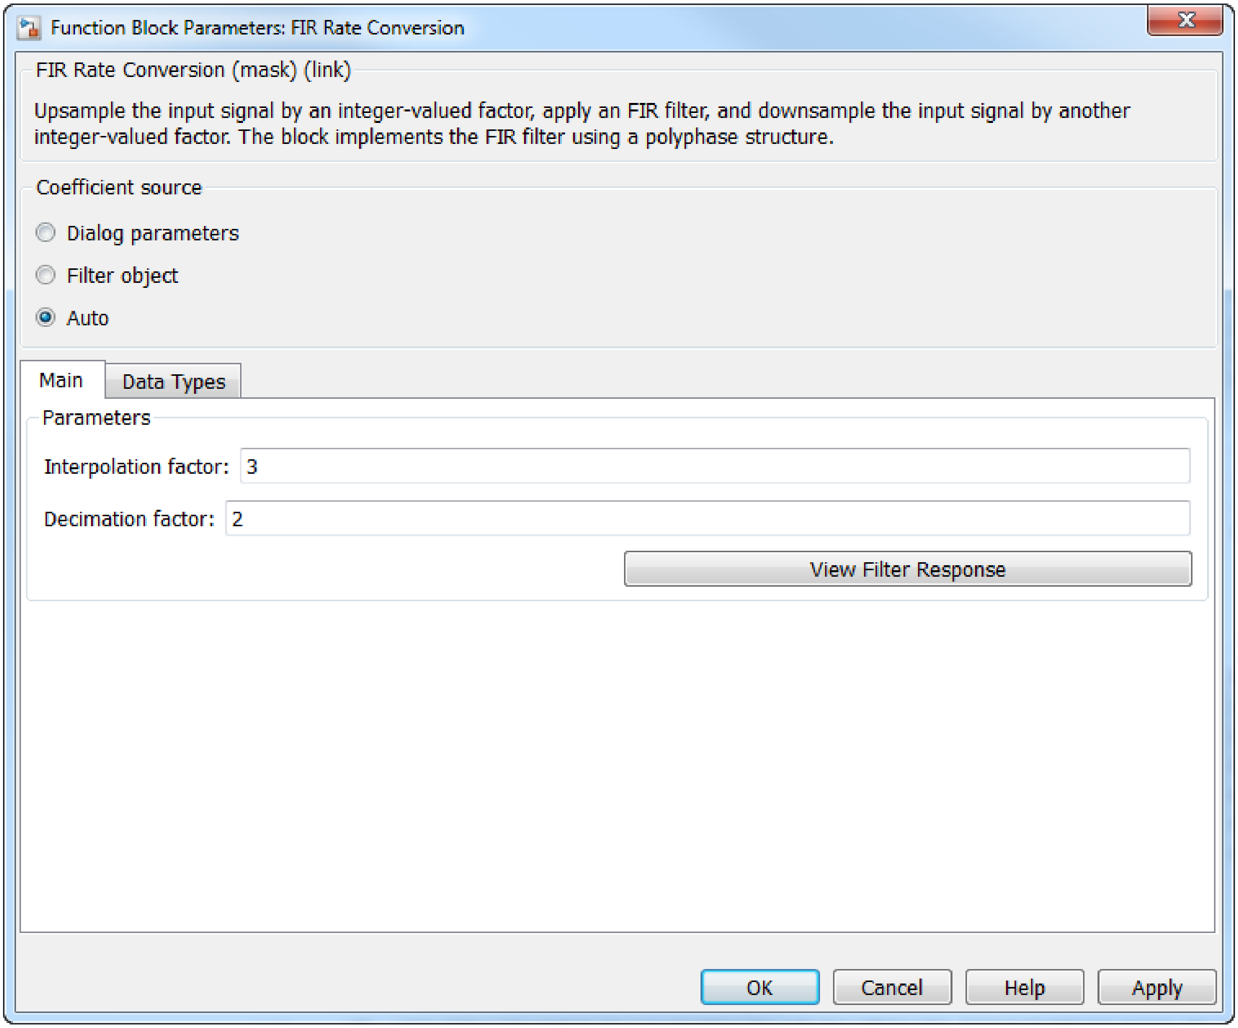
The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

For more information on System objects, see the “What Are System Objects?” (MATLAB).

Choose Filter Coefficients Automatically

When you select **Auto** in the **Coefficient source** group box, the block chooses the filter coefficients automatically. For more information on the filter design algorithm the block uses, see “Specifying the FIR Filter Coefficients” on page 2-767.

The **Main** pane of the FIR Rate Conversion block dialog box appears as follows when you select **Auto** in the **Coefficient source** group box.



Interpolation factor

Specify the integer factor, L, by which to upsample the signal before filtering. The default is 3.

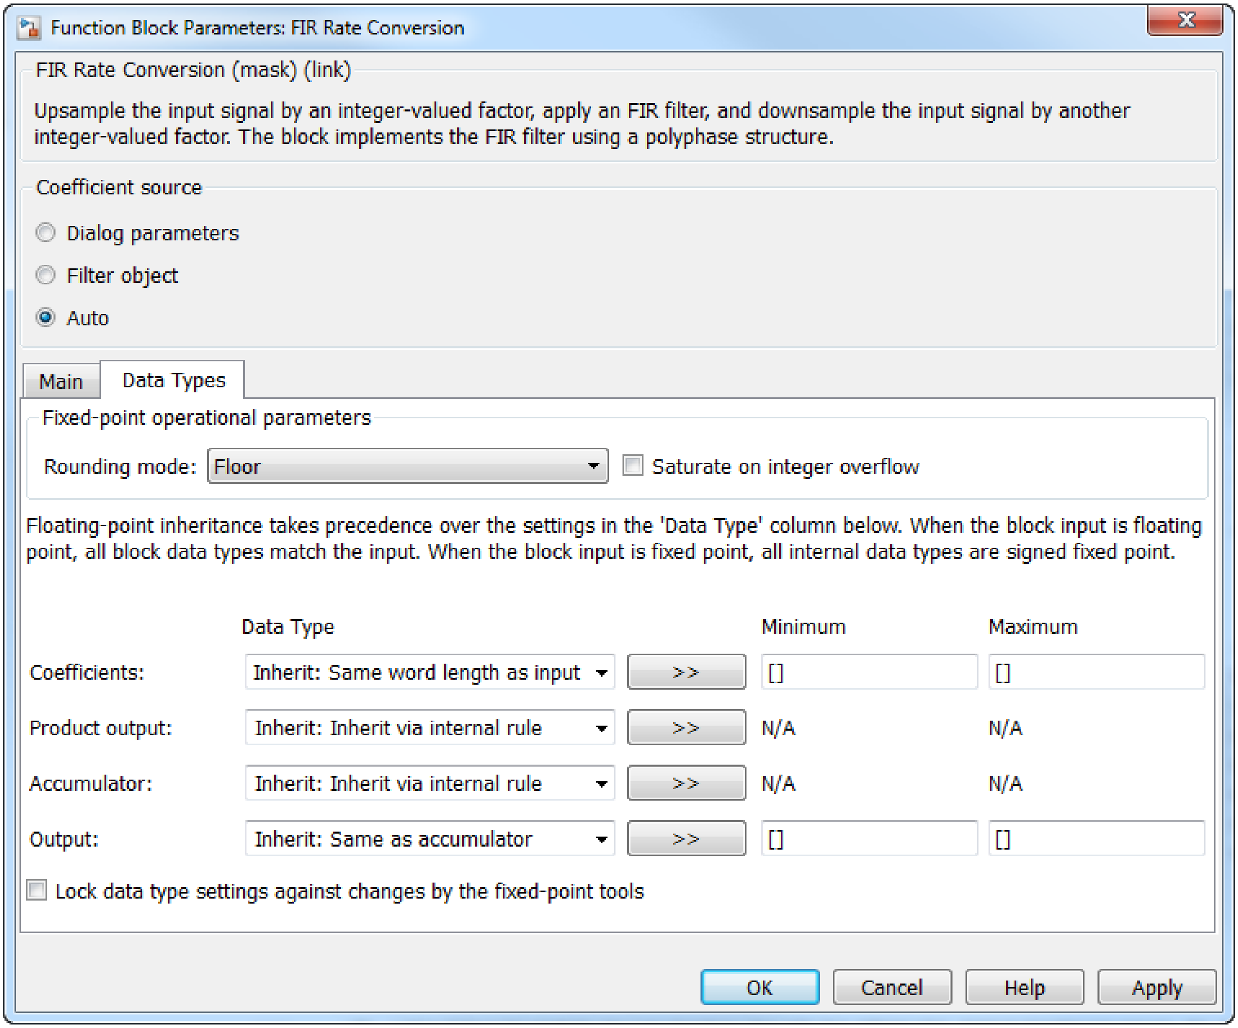
Decimation factor

Specify the integer factor, K, by which to downsample the signal after filtering. The default is 2.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

The **Data Types** pane of the FIR Rate Conversion block dialog box appears as follows when you select **Auto** in the **Coefficient source** group box.



Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See "Fixed-Point Data Types" on page 2-768 and "Multiplication Data Types" for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-768 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-768 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-768 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

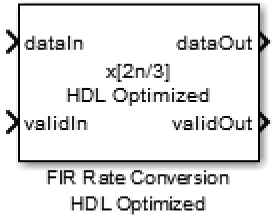
FIR Rate Conversion HDL Optimized

Upsample, filter, and downsample input signals—optimized for HDL code generation



Library

Filtering/Multirate Filters

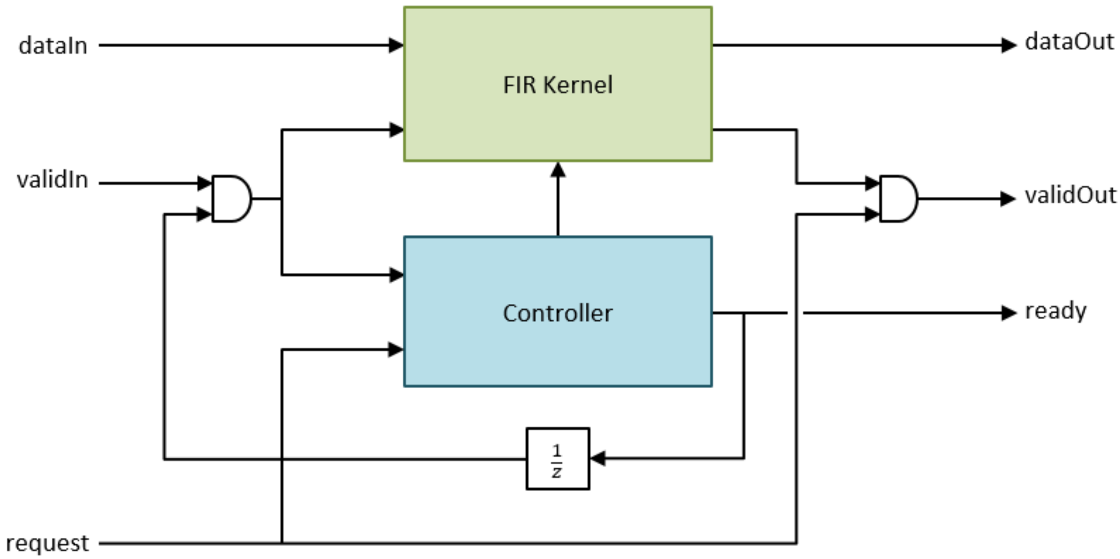
`dspmlti4`

Description

The FIR Rate Conversion HDL Optimized block upsamples, filters, and downsamples input signals. It is optimized for HDL code generation and operates on one sample of each channel at a time. The block implements an efficient polyphase architecture to avoid unnecessary arithmetic operations and high intermediate sample rates.

The block upsamples by an integer factor of L, applies an FIR filter, and downsamples by an integer factor of M.

The block has input and output control ports for pacing the flow of samples. In the default configuration, the block uses `validIn` and `validOut` control signals. For additional flow control, you can enable a `ready` output signal and a `request` input signal.



The `ready` output port indicates that the block can accept a new input data sample on the next time step. When $L \geq M$, you can use the `ready` signal to achieve continuous output data samples. If you apply a new input sample after each time the block returns `ready` = `true`, the block returns a data output sample with `validOut` = `true` on every time step.

When you do not enable the `ready` port, you can apply a valid data sample only every `ceil(L/M)` time steps. For example:

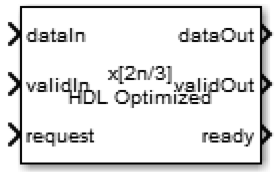
- L/M = 4/5 — You can apply a new input sample on every time step.
- L/M = 3/2 — You can apply a new input sample on every other time step.

When you enable the `request` input port, the block returns the next output sample when `request` is `true` and a valid output sample is available. When you do not use `request` , the block returns output samples when they are available. When no new data is available, the block returns `validOut` = `false`.

You can connect the `request` input port to the `ready` output port of a downstream block.

Signal Attributes

This icon shows all the optional ports of the FIR Rate Conversion HDL Optimized block.



FIR Rate Conversion
HDL Optimized

Port	Direction	Description	Data Type
`dataIn`	Input	Data sample, specified as a scalar, or as a row vector in which each element represents an independent channel. The block accepts real or complex data.	• `fixdt()` • `uint8/16/32`, `int8/16/32` • `double` and `single` are allowed for simulation but not for HDL code generation.
`validIn`	Input	Capture the value of `dataIn`, when `validIn` is `true`. You can apply a valid data sample every `ceil(L/M)` time steps.	`boolean`
`request`	Input (Optional)	Request for a new output sample.	`boolean`
`dataOut`	Output	Resampled and filtered data sample, returned as a scalar, or as a vector in which each element represents an independent channel.	Same as `dataIn`
`validOut`	Output	Qualification of the `dataOut` value. When `validOut` is `true`, `dataOut` is valid.	`boolean`
`ready`	Output (Optional)	Indicates that the block is ready for a new input sample, when `ready` is `true`.	`boolean`

Parameters

Main

Interpolation factor

Upsampling factor, *L*, specified as a scalar integer. The default is 3.

Decimation factor

Downsampling factor, *M*, specified as a scalar integer. The default is 2.

FIR filter coefficients

Filter coefficients, specified as a vector in descending powers of z^{-1}.

You can generate filter coefficients using the Signal Processing Toolbox filter design functions (such as `fir1`). Design a lowpass filter with normalized cutoff frequency no greater than `min(1/L,1/M)`. The block initializes internal filter states to zero. The default coefficients are `firpm(70,[0 .28 .32 1],[1 1 0 0])`.

Enable ready output port

Select this check box to enable a port that indicates when the block is able, on the next time step, to accept a new input data sample.

Enable request input port

Select this check box to enable a port that requests the block return an output sample. When the `request` port is `true`, and there is an output sample available, the block returns a new output sample and sets `validOut` to `true`. When `request` is `false`, or there is no new sample available, the block sets `validOut` to `false`.

Data Types

Rounding mode

The default rounding method for internal fixed point calculations is `Floor`. `Simplest` rounding mode is not supported.

Overflow mode

The default overflow action for internal fixed point calculations is `Wrap`.

Coefficients Data Type

Data type of the FIR filter coefficients, specified as a `fixdt(s,wl,fl)` object with `signedness`, `word length`, and `fractional length` properties. The default is `fixdt(1,16,16)`.

Output Data Type

Data type of the output data samples. You can choose `Inherit: Inherit via internal rule`, `Inherit: Full precision`, or specify a `fixdt(s,wl,fl)` object. The default is `Inherit: Same word length as input`.

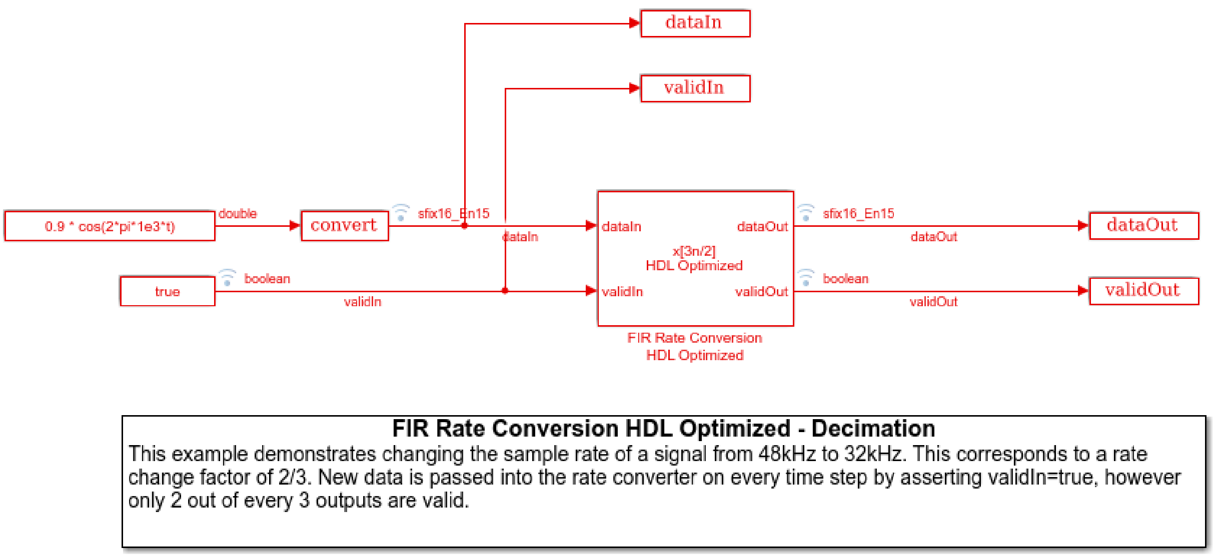
Examples

Downsample a Signal

Convert a signal from 48 kHz to 32 kHz using the FIR Rate Conversion HDL Optimized block.

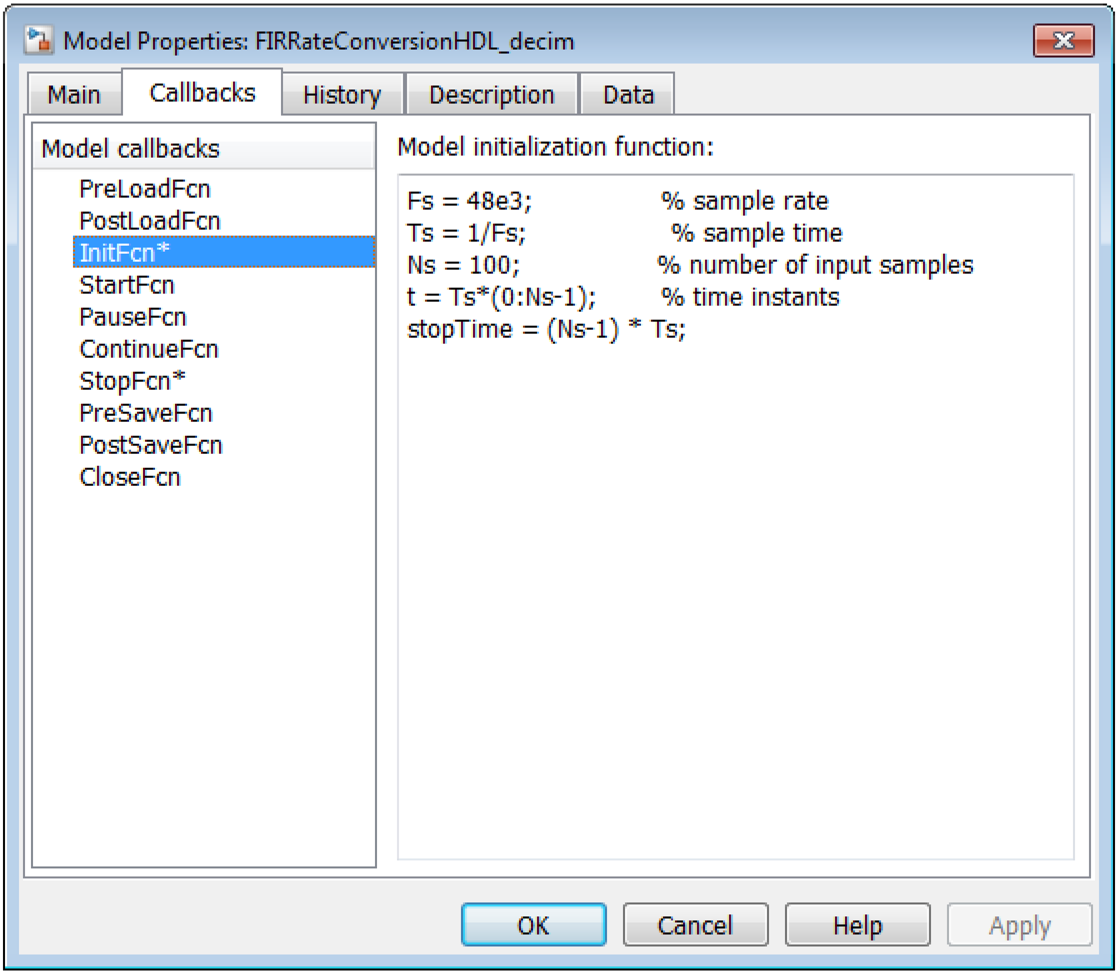
The source is a cosine input signal, sampled at 48kHz. The model passes a new data sample into the block on every time step by holding `validIn` = `true`. After resampling, the `validOut` signal is `true` on only 2/3 of the time steps.

Open the Model



Configure the Model

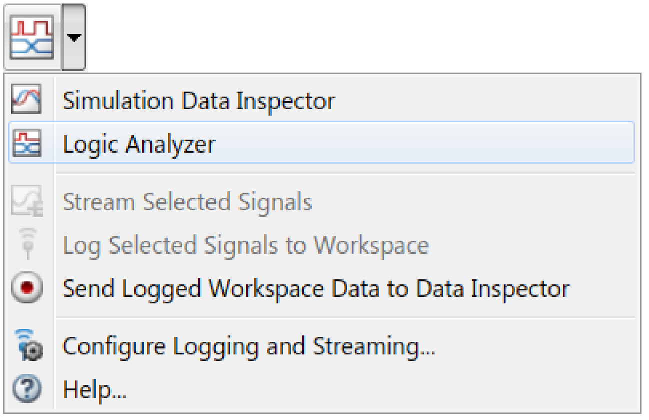
Define the data rate parameters in the `InitFcn` callback.



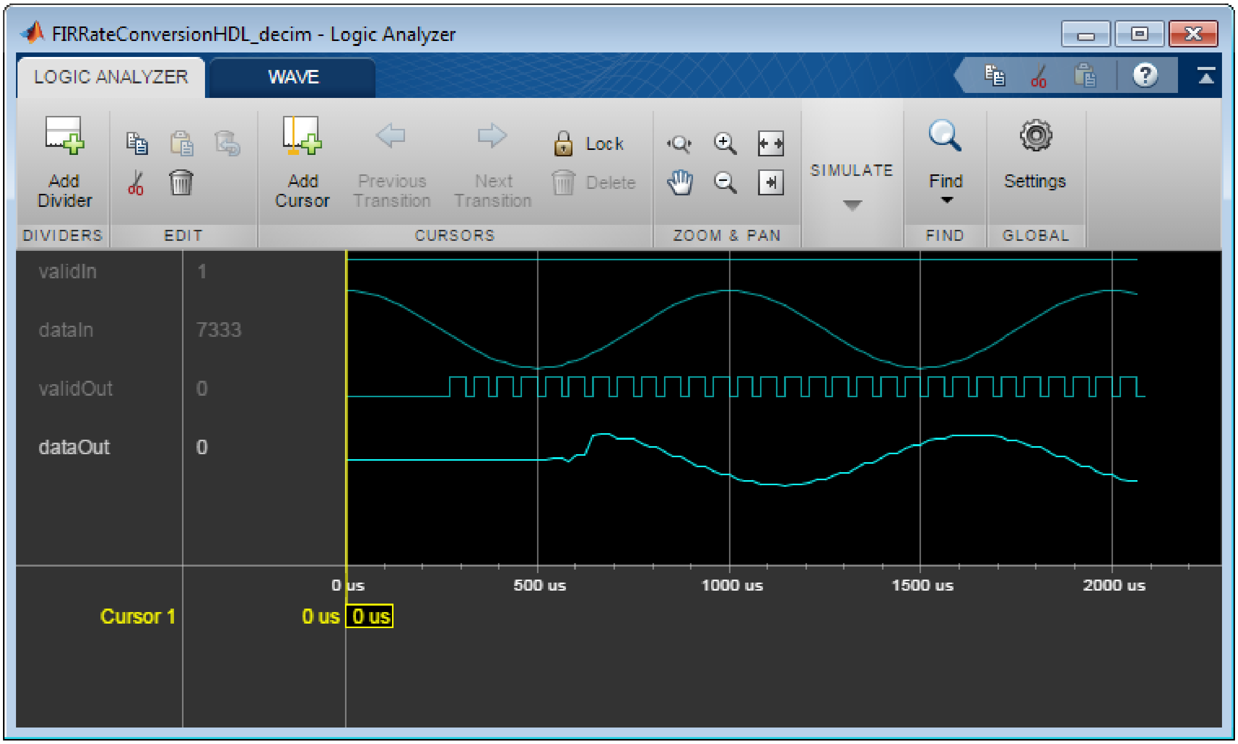
Configure the FIR Rate Conversion HDL Optimized block. Use the default interpolation factor of 2 and decimation factor of 3. Use the `firmpm` function to design an equiripple FIR filter. In the **Data Types** group, set the **Coefficients** data type to `fixdt(1,16,15)` to accommodate the filter you designed.

Run the Model and Display Results

Run the model. Use the **Logic Analyzer** to view the input and output signals of the block. The blue icon in the model indicates streamed signals. Launch the Logic Analyzer from the model's toolbar.



In the Logic Analyzer, note the pattern of `validIn` and the resulting `validOut` signal.



Generate HDL Code

To generate HDL code from the FIR Rate Converter HDL Optimized block, right-click the block and select **Create Subsystem from Selection**. Then right-click the subsystem and select **HDL Code** > **Generate HDL Code for Subsystem**.

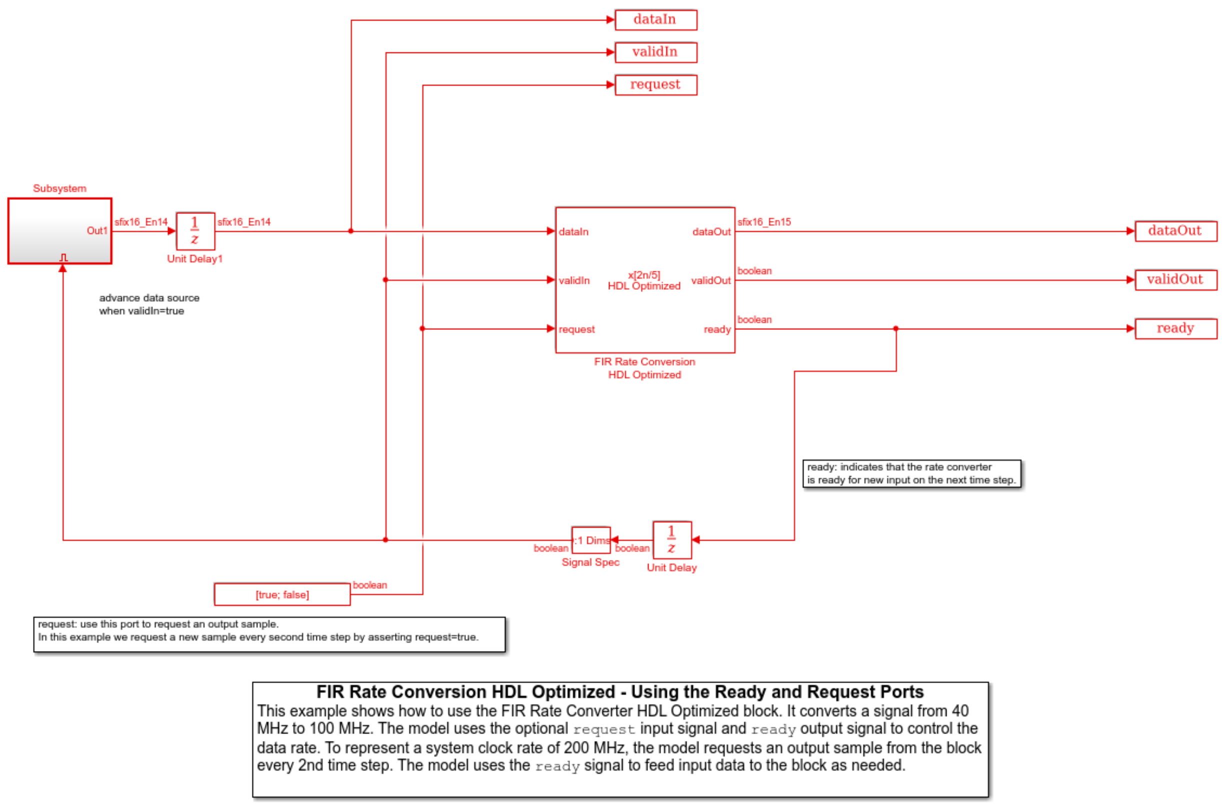
Control Data Rate Using the Ready and Request Ports

Convert a signal from 40 MHz to 100 MHz using the FIR Rate Converter HDL Optimized block. Uses the optional `request` input signal and `ready` output signal to control the data rate.

- To represent a system clock rate of 200MHz, the model connects a repeating true-false signal to the `request` port. This configuration generates output samples at 100 MHz, i.e. every second time step. Alternatively, you can connect this port to the `ready` port of a downstream block.

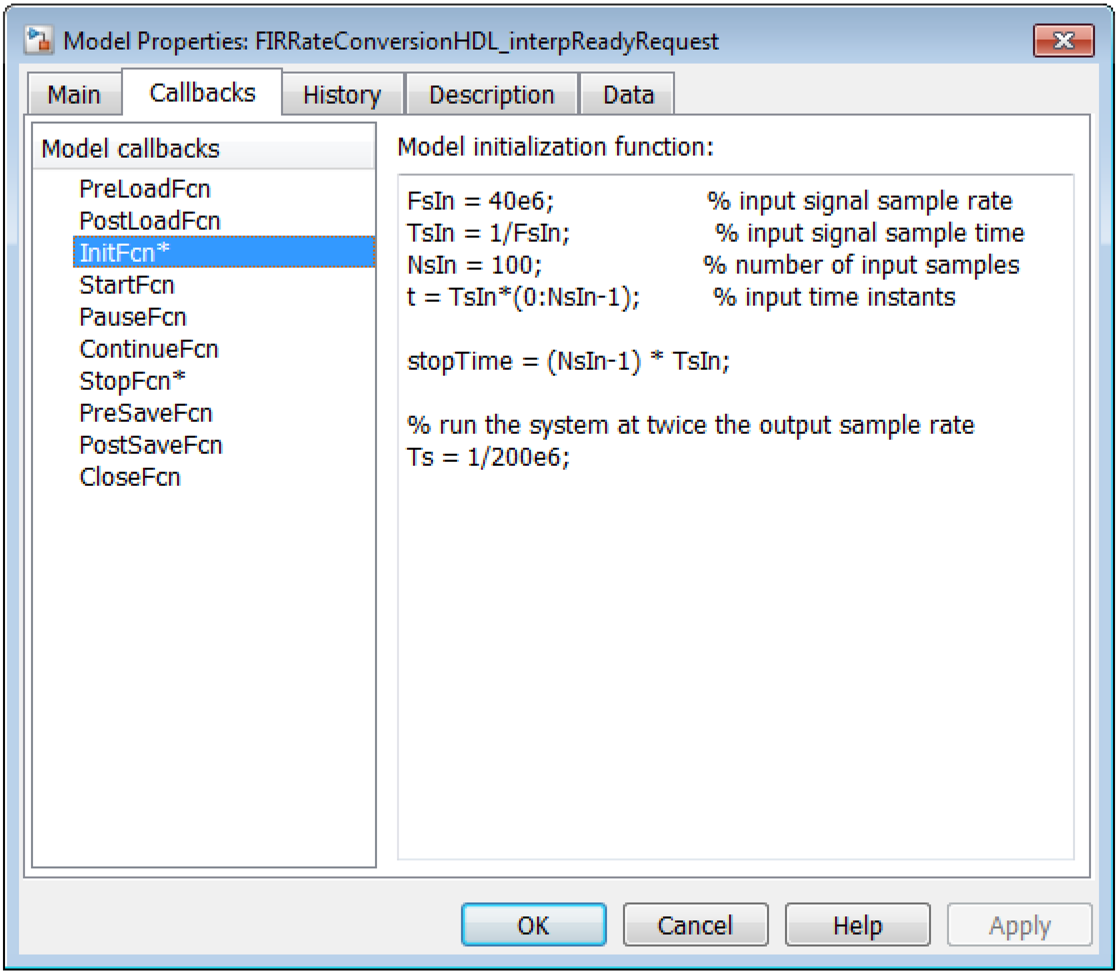
- When the block can accept a new input sample on the next time step, it sets the `ready` output signal to `true`. The model connects this signal to a waveform source that generates one sample at a time.

Open the Model



Configure the Model

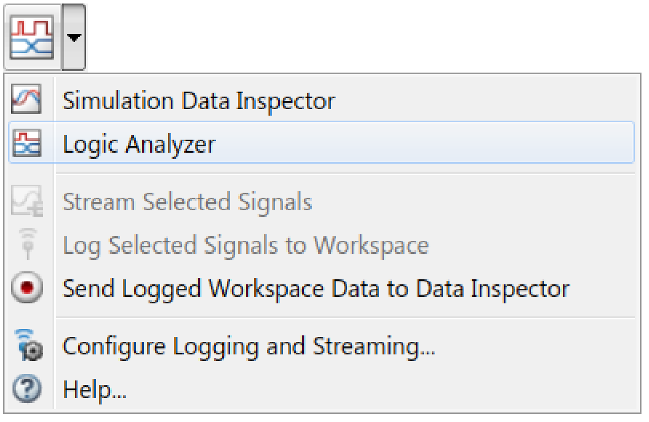
Define the data rate parameters in the `InitFcn` callback.



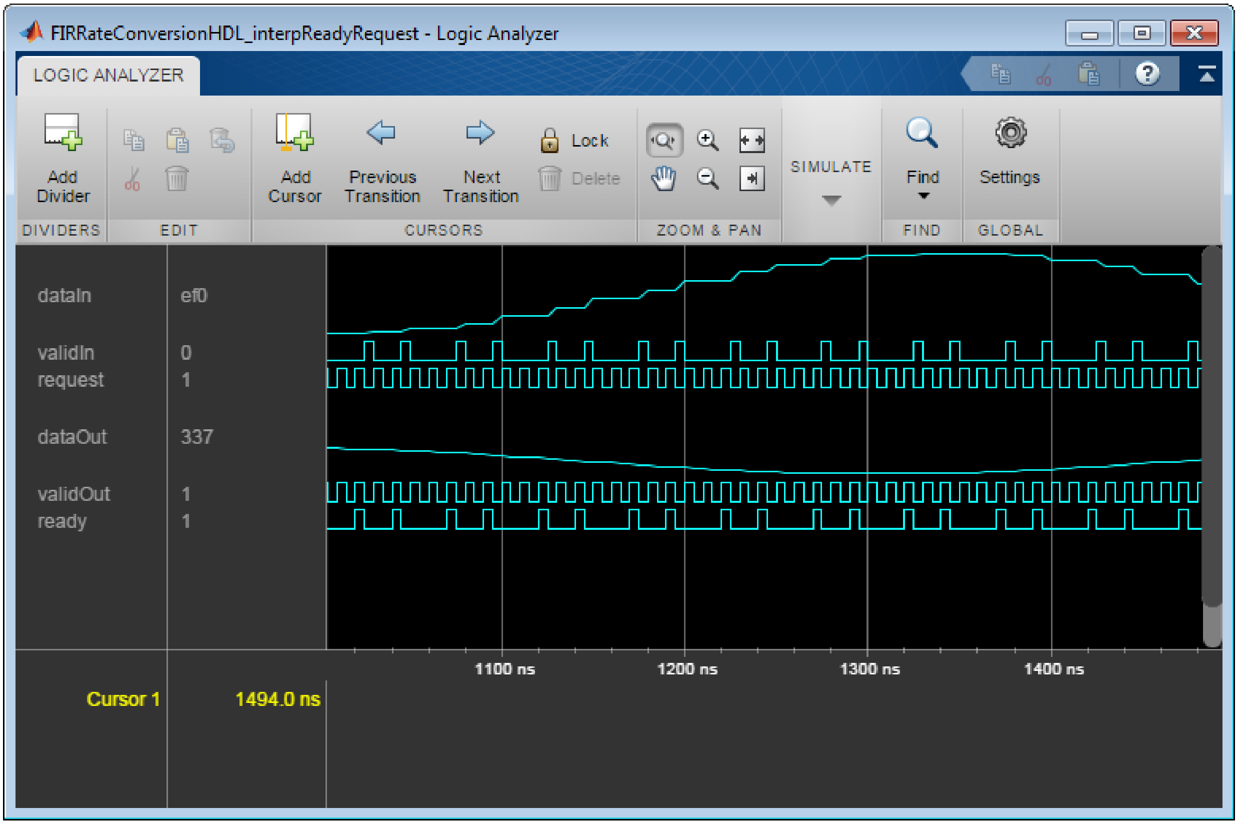
Configure the FIR Rate Conversion HDL Optimized block. Use an interpolation factor of 5 and a decimation factor of 2. Use the `firmpm` function to design an equiripple FIR filter. Select both check boxes to enable the `ready` and `request` ports. % In the **Data Types** group, set the **Coefficients** data type to `fixdt(1,16,15)` to accommodate your filter design.

Run the Model and Display Results

Run the model. Use the **Logic Analyzer** to view the input and output signals of the block. The blue icon in the model indicates streamed signals. Launch the Logic Analyzer from the model's toolbar.



In the **Logic Analyzer**, note the pattern of `request` and the resulting `validOut` signal, and the pattern of `ready` and the resulting `validIn` signal.

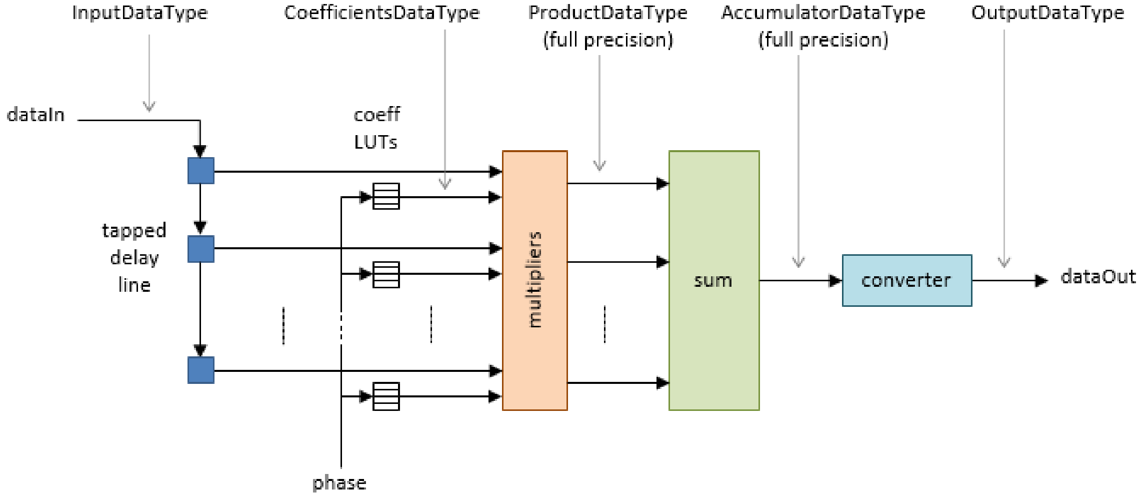


Generate HDL Code

To generate HDL code from the FIR Rate Converter HDL Optimized block, right-click the block and select **Create Subsystem from Selection**. Then right-click the subsystem and select **HDL Code** > **Generate HDL Code for Subsystem**.

Algorithm

The FIR Rate Conversion HDL Optimized block implements a fully parallel polyphase filter architecture. The diagram shows where the block casts the data types, according to your configuration.



Delay

The block models HDL pipeline latency, so there is an initial delay of several time steps before the object returns the first valid output sample. The latency depends on the filter coefficients and the resampling factors. To determine the latency from first sample in to first sample out, observe the `validOut` signal.

Performance

For a sample of design performance, generate HDL for the block as configured in the "Control Data Rate Using the Ready and Request Ports" on page 2-795 example. The example filter resamples at 5/2, and uses a symmetric 71-tap filter. The input samples and filter coefficients are 16 bits wide. The design was targeted to a Xilinx Virtex-6 FPGA, using Xilinx ISE synthesis and place and route tools.

After place and route, the design achieves 535 MHz clock frequency. It uses these resources.

Flip

Flip input vertically or horizontally

Library

Signal Management / Indexing

`dspindex`

Description

The Flip block vertically or horizontally reverses the M-by-N input matrix, u. The output always has the same dimensionality as the input.

When you set the **Flip along** parameter to `Columns`, the block flips the input *vertically* so the first row of the input becomes the last row of the output.

```
y = flipud(u)      % Equivalent MATLAB code
```

When flipping the input vertically, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

When you set the **Flip along** parameter to `Rows`, the block flips the input *horizontally* so the first column of the input becomes the last column of the output.

```
y = fliplr(u)      % Equivalent MATLAB code
```

When flipping the input horizontally, the block treats length-N unoriented vector inputs as 1-by-N row vectors.

This block supports Simulink virtual buses.

Parameters

Flip along

Specify the dimension along which to flip the input. When you set this parameter to `Columns`, the block flips the input vertically. When you set this parameter to `Rows`, the block flips the input horizontally.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

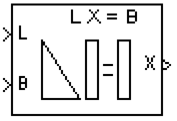
Forward Substitution

Solve $LX=B$ for X when L is lower triangular matrix



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The Forward Substitution block solves the linear system $LX=B$ by simple forward substitution of variables, where:

- L is the lower triangular M-by-M matrix input to the L port.
- B is the M-by-N matrix input to the B port.

The M-by-N matrix output X is the solution of the equations. The block does not check the rank of the inputs.

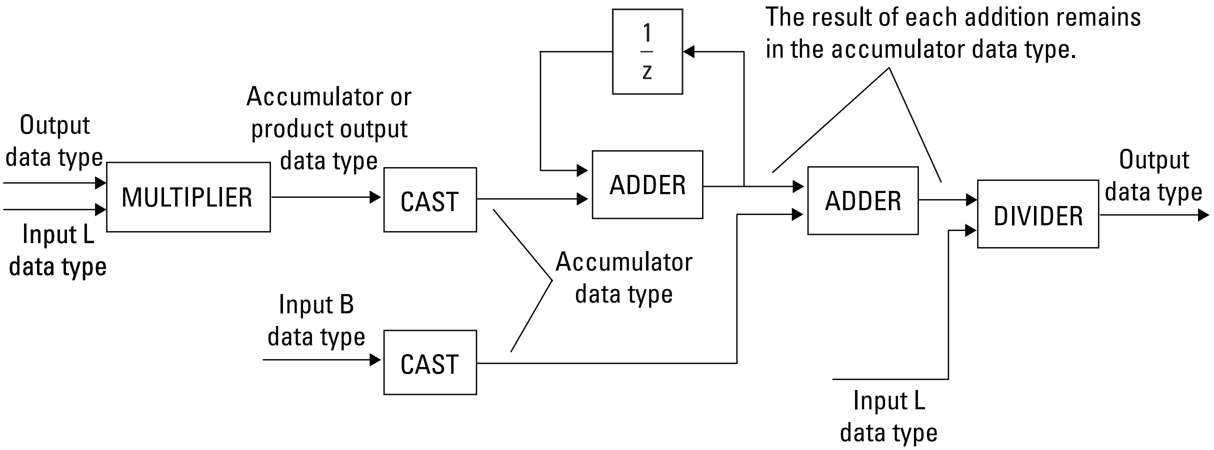
The block only uses the elements in the *lower triangle* of input L and ignores the upper elements. When you select **Input L is unit-lower triangular**, the block assumes the elements on the diagonal of L are 1s. This is useful when matrix L is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the D matrix.

The block treats a length-M vector input at port B as an M-by-1 matrix.

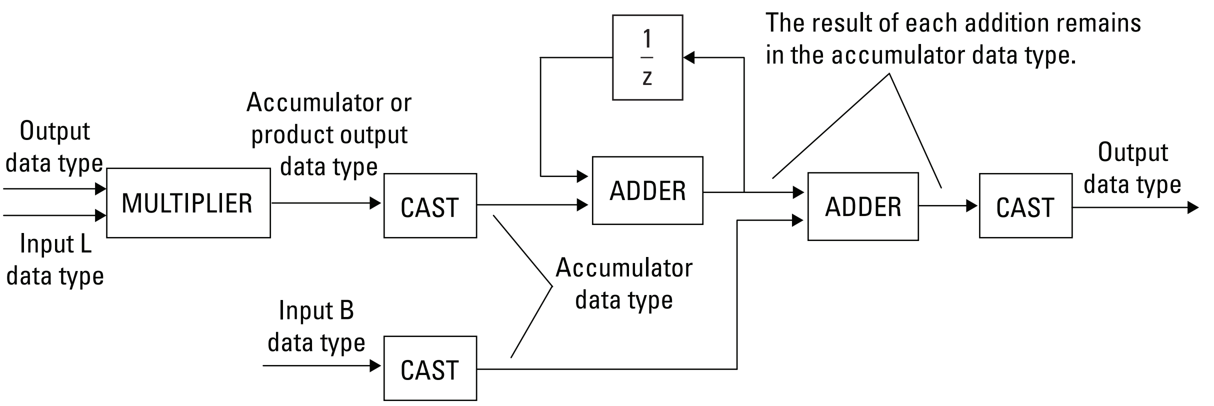
Fixed-Point Data Types

The following diagram shows the data types used within the Forward Substitution block for fixed-point signals.

When input L is not unit-lower triangular:



When input L is unit-lower triangular:

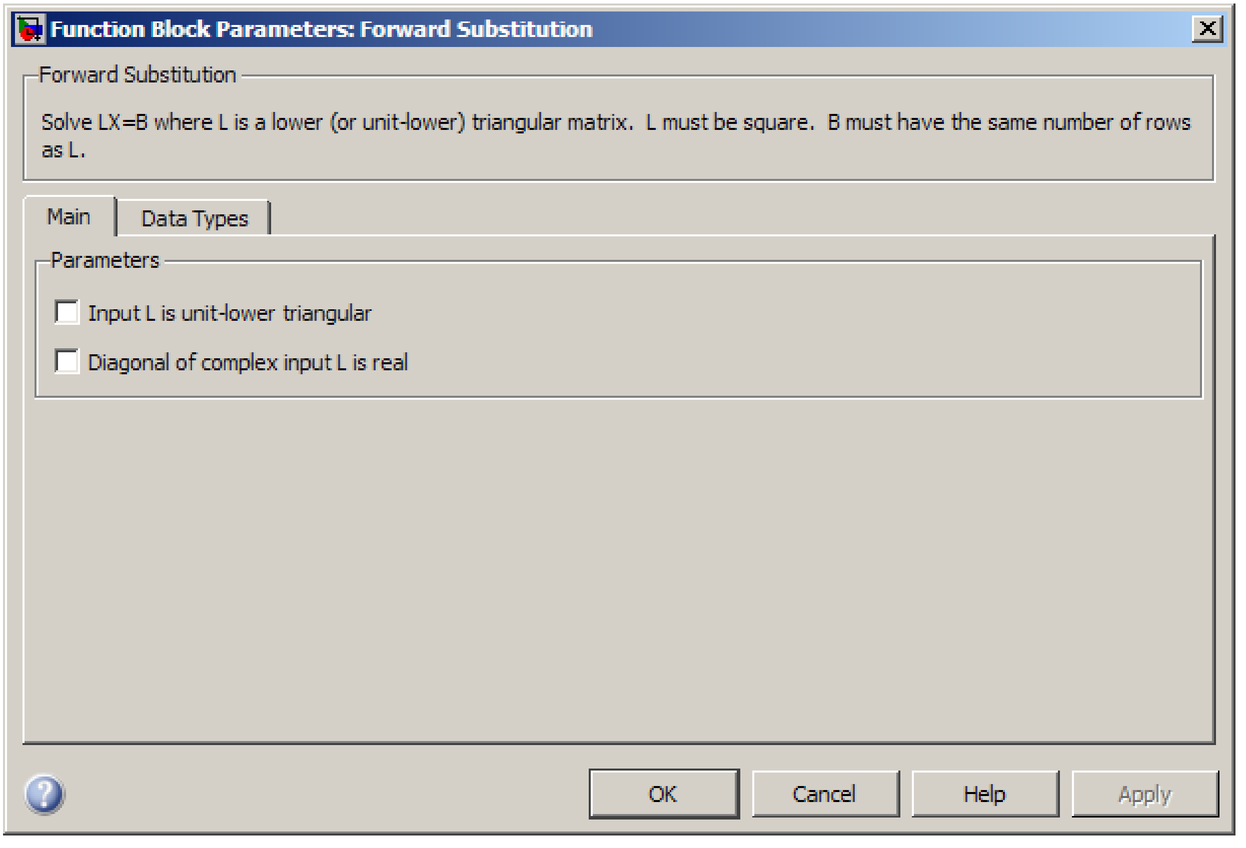


You can set the product output, accumulator, and output data types in the block dialog box, as discussed in the following section.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Dialog Box

The **Main** pane of the Forward Substitution block dialog box appears as follows.



Input L is unit-lower triangular

Select this check box only when all elements on the diagonal of L have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary divide operation.

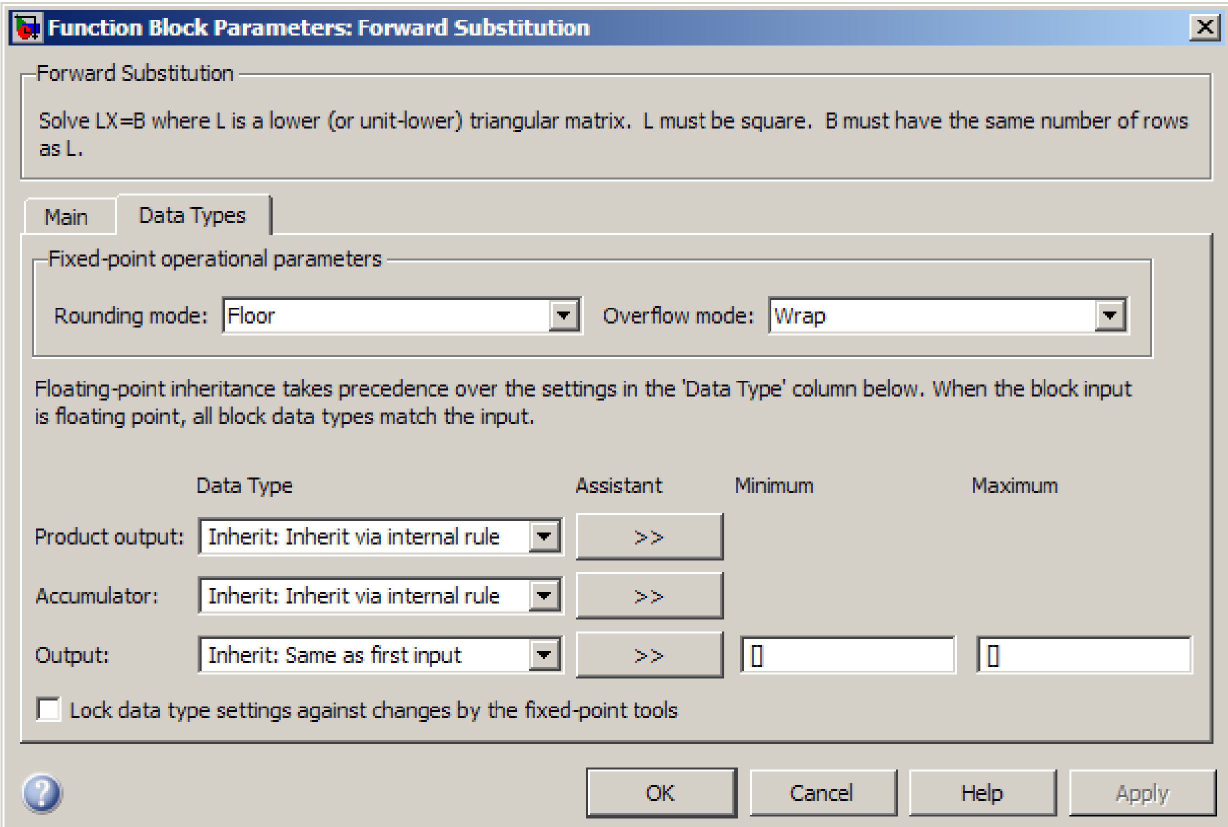
Do not select this check box if there are any elements on the diagonal of L that do not have a value of 1. When you clear the **Input L is unit-lower triangular** check box, the block always performs the necessary divide operation.

Diagonal of complex input L is real

Select to optimize simulation speed when the diagonal elements of complex input L are real. This parameter is only visible when **Input L is unit-upper triangular** is not selected.

Note: When L is a complex fixed-point signal, you must select either **Input L is unit-lower triangular** or **Diagonal of complex input L is real**. In such a case, the block ignores any imaginary part of the diagonal of L.

The **Data Types** pane of the Forward Substitution block dialog box appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-804 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-804 for illustrations depicting the use of the accumulator data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-804 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
L	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
X	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

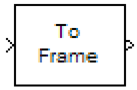
Frame Conversion

Specify sampling mode of output signal



Library

Signal Management / Signal Attributes

`dspsigattribs`

Description

The Frame Conversion block passes the input through to the output and sets the output sampling mode to the value of the **Sampling mode of output signal** parameter, which can be either `Frame-based` or `Sample-based`. The output sampling mode can also be inherited from the signal at the Ref (reference) input port, which you make visible by selecting the **Inherit output sampling mode from <Ref> input port** check box.

The Frame Conversion block does not make any changes to the input signal other than the sampling mode. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length-M 1-D vector and the block is in `Frame-based` mode, the output is a frame-based M-by-1 matrix — that is, a single channel.

Parameters

Inherit output sampling mode from <Ref> input port

Select to enable the Ref port from which the block inherits the output sampling mode.

Sampling mode of output signal

Specify the sampling mode of the output signal, `Frame-based` or `Sample-based`.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Frame Conversion.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Ref	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

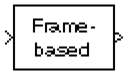
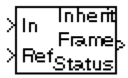
Frame Status Conversion (Obsolete)

Specify frame status of output as sample based or frame based





Library

`dspobslib`

Description

Note The Frame Status Conversion block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `Frame Conversion` block.

The Frame Status Conversion block passes the input through to the output, and sets the output frame status to the **Output signal** parameter, which can be either `Frame-based` or `Sample-based`. The output frame status can also be inherited from the signal at the `Ref` (reference) input port, which is made visible by selecting the **Inherit output frame status from Ref input port** check box.

When the **Output signal** parameter setting or the inherited signal's frame status differs from the input frame status, the block changes the input frame status accordingly, but does not otherwise alter the signal. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length-M 1-D vector, and the **Output signal** parameter is set to `Frame-based`, the output is a frame-based M-by-1 matrix (that is, a single channel).

When the **Output signal** parameter or the inherited signal's frame status matches the input frame status, the block passes the input through to the output unaltered.

Parameters

Inherit output frame status from Ref input port

When selected, enables the `Ref` input port from which the block inherits the output frame status.

Output signal

The output frame status, `Frame-based` or `Sample-based`.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Ref	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

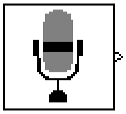
From Audio Device

Read audio data from computer's audio device



Note: The From Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Reader block from Audio System Toolbox instead.

Library

Sources

`dspsrcs4`

Description

The From Audio Device block reads audio data from an audio device in real time. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device from which to acquire audio. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update this list.

Use the **Number of channels** parameter to specify the number of audio channels in the signal. For example:

- Enter 2 if the audio source is two channels (stereo).
- Enter 1 if the audio source is single channel (mono).
- Enter 6 if you are working with a 5.1 speaker system.

The block's output is an M-by-N matrix, where M is the number of consecutive samples and N is the number of audio channels.

Use the **Sample rate (Hz)** parameter to specify the number of samples per second in the signal. If the audio data is processed in uncompressed pulse code modulation (PCM) format, it should typically be sampled at one of the standard audio device rates: 8000, 11025, 22050, 44100, or 48000 Hz.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** parameter to specify the data type of the audio data that the device is placing in the buffer. You can choose:

- `8-bit integer`
- `16-bit integer`
- `24-bit integer`
- `32-bit float`
- `Determine from output data type`

If you choose `Determine from output data type`, the following table summarizes the block's behavior.

Output Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

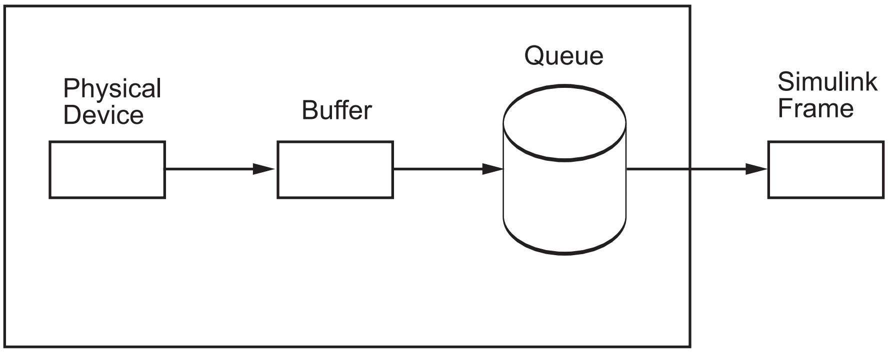
If you choose `Determine from output data type` and the device does not support a data type, the block uses the next lowest precision data type supported by the device.

Use the **Frame size (samples)** parameter to specify the number of samples in the block's output. Use the **Output data type** parameter to specify the data type of audio data output by the block.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Buffering

The From Audio Device block buffers the data from the audio device using the process illustrated by the following figure.



From Audio Device Block

1. At the start of the simulation, the audio device begins writing the input data to a buffer. This data has the data type specified by the **Device data type** parameter.
2. When the buffer is full, the From Audio Device block writes the contents of the buffer to the queue. Specify the size of this queue using the **Queue duration (seconds)** parameter.
3. As the audio device appends audio data to the bottom of the queue, the From Audio Device block pulls data from the top of the queue to fill the Simulink frame. This data has the data type specified by the **Output data type** parameter.

Select the **Automatically determine buffer size** check box to allow the block to calculate a conservative buffer size using the following equation:

$$size = 2^{\left\lfloor \log_2 \frac{sr}{10} \right\rfloor}$$

In this equation, *size* is the buffer size, and *sr* is the sample rate. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the buffer size in samples.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially empty, fills up. If the queue is full, the block drops the incoming data from the audio device. You can monitor dropped samples using the optional `Overrun` output port. When the simulation throughput rate is higher than the hardware throughput rate, the From Audio Device block waits for new samples to become available.

Channel Mapping

The term *Channel Mapping* refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. You can specify channel mapping as a vector of audio channel indices corresponding to each channel of data being read. The default value in the **Device Input Channels** parameter is 1:MAXINPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Input Channels** parameter in the dialog box.

Example: The selected input audio device contains 8 channels. You want to read data from only channels 2, 4, 6, and redirect the data as follows:

- Audio Device channel 2 to first data channel
- Audio Device channel 4 to second data channel
- Audio Device channel 6 to third data channel

Thus you would specify the **Device Input Channels** as [2 4 6].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue fills up and the block begins to lose audio data. Select the **Output number of samples by which the queue was overrun** check box to add an output port indicating when the queue was full. Here are several ways to deal with this situation:

- *Increase the queue duration.*

  The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data demand can lag behind the hardware's data supply.
- *Increase the buffer size.*

The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the queue. If the buffer is too big, Simulink must wait for the device to fill the buffer before it moves the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes and convert sample-based signals to frame-based signals throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see "Delay and Latency" and "Performance" (Simulink).

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`

Platform	Command
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/ bin/glnxa64 (Bash)`
Windows	`set PATH = $MATLABROOT\bin\win64; %PATH%`

Audio Hardware API

In order to communicate with the audio hardware on a given computer, the To Audio Device and From Audio Device blocks use the open-source PortAudio library. The PortAudio library supports a range of APIs designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows®: DirectSound, WDM—KS, ASIO™
- Linux®: OSS, ALSA
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp','portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp','portaudioHostApi',N)
```

where *N* is a scalar. Choose *N* based on the API choice above.

Parameters

Device

Specify the device from which to acquire audio data.

Use default mapping between Device Input Channels and Data

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Number of channels

Specify the number of audio channels. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is enabled.

Device Input Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Sample rate (Hz)

Specify the number of samples per second in the signal.

Device data type

Specify the data type used by the device to acquire audio data.

Automatically determine buffer size

Select this check box to enable the block to use a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer that the block uses to communicate with the audio device. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Output number of samples by which the queue was overrun

Select this check box to output the number of samples lost to queue overrun since the last transfer of a frame from the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-821.

Frame size (samples)

Specify the number of samples in the block's output signal.

Output data type

Select the data type of the block's output.

Supported Data Types

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Overrun	32-bit unsigned integer

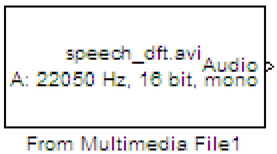
From Multimedia File

Stream from multimedia file



Library

Sources

`dspsrcs4`

Description

The From Multimedia File block reads audio samples, video frames, or both from a multimedia file. The block imports data from the file into a Simulink model.

Note: This block supports code generation for the host computer that has file I/O available. You cannot use this block with Simulink Desktop Real-Time™ software because that product does not support file I/O.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation” for details.

Supported Platforms and File Types

The supported file formats available to you depends on the codecs installed on your system.

Windows Platforms Supported File Formats

With the necessary Windows DirectShow codecs installed on your system, the From Multimedia File Block supports many video and audio file formats. This block performs best on platforms with Version 9.0 or later of DirectX® software.

The following table lists the most common file formats.

Multimedia Types	File Name Extensions
Image files	`.jpg`,`.bmp`,`.png`
Video files	`.qt`, `.mov`, `.avi`, `.asf`, `.asx`, `.wmv`, `.mpg`, `.mpeg`, `.mp2`, `.mp4`, `.m4v`
Audio files	`.wav`, `.wma`, `.avi`, `.aif`, `.aifc`, `.aiff`, `.mp3`, `.au`, `.snd, .mp4, .m4a, .flac, .ogg`

The default for image files is `.png`, , for video files is `.avi`, and for audio files is `.mp3`.

Windows XP x64 platform ships with a limited set of 64-bit video and audio codecs. If the From Multimedia File block cannot work on a compressed multimedia file, try one of the two alternatives:

- Run the 32-bit version of MATLAB on your Windows XP x64 platform. Windows XP x64 ships with many 32-bit codecs.
- Save the multimedia file to a file format supported by the From Multimedia File block.

If you use Windows, use Windows Media® Player Version 11 or later with this block for best results.

Non-Windows Platform Supported File Formats

The following table lists the most common file formats.

Multimedia Types	File Name Extensions
Video files	`.avi`, `.mj2`, `.mov`, `.mp4`,`.m4v`
Audio files	`.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff,`

The default for video files is `.avi`, and for audio files is `.mp3`.

Ports

The output ports of the From Multimedia File block change according to the content of the multimedia file. If the file contains only video frames, the **Image**, intensity **I**, or **R**,**G**,**B** ports appear on the block. If the file contains only audio samples, the **Audio** port appears on the block. If the file contains both audio and video, you can select the data to emit. The following table describes available ports.

Port	Description
Image	M-by-N-by-P color video signal where P is the number of color planes.
I	M-by-N matrix of intensity values.
R, **G**, **B**	Matrix that represents one plane of the RGB video stream. Outputs from the R, G, or B ports must have same dimensions.
Audio	Vector of audio data.
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, Cr ports produce the following outputs: Y: $M\ x\ N$ Cb: $M\ x\ \frac{N}{2}$ Cr: $M\ x\ \frac{N}{2}$

Sample Rates

The sample rate that the block uses depends on the audio and video sample rate. While the FMMF block operates at a single rate in Simulink, the underlying audio and video streams can produce different rates. In some cases, when the block outputs both audio and video, makes a small adjustment to the video rate.

Sample Time Calculations Used for Video and Audio Files

Sample time = $\dfrac{ceil(AudioSampleRate/FPS)}{AudioSampleRate}$.

When audio sample time, $\dfrac{AudioSampleRate}{FPS}$ is noninteger, the equation cannot reduce to $\dfrac{1}{FPS}$.

In this case, to prevent synchronization problems, the block drops the corresponding video frame when the audio stream leads the video stream by more than $\dfrac{1}{FPS}$.

In summary, the block outputs one video frame at each Simulink time step. To calculate the number of audio samples to output at each time step, the block divides the audio sample rate by the video frame rate (fps). If the audio sample rate does not divide evenly by the number of video frames per second, the block rounds the number of audio samples up to the nearest whole number. If necessary, the block periodically drops a video frame to maintain synchronization for large files.

Dialog Box

Main Tab

File name

Specify the name of the multimedia file from which to read. The block determines the type of file (audio and video, audio only, or video only) and provides the associated parameters.

If the location of the file does not appear on your MATLAB path, use the **Browse** button to specify the full path. Otherwise, if the location of this file appears on your MATLAB path, enter only the file name. On Windows platforms, this parameter supports URLs that point to MMS (Microsoft Media Server) streams.

Inherit sample time from file

Select the **Inherit sample time from file** check box if you want the block sample time to be the same as the multimedia file. If you clear this check box, enter the block sample time in the **Desired sample time** parameter field. The file that the From Multimedia File block references, determines the block default sample time. You can also set the sample time for this block manually. If you do not know the intended sample rate of the video, let the block inherit the sample rate from the multimedia file.

Desired sample time

Specify the block sample time. This parameter becomes available if you clear the **Inherit sample time from file** check box.

Number of times to play file

Enter a positive integer or `inf` to represent the number of times to play the file.

Output end-of-file indicator

Use this check box to determine whether the output is the last video frame or audio sample in the multimedia file. When you select this check box, a Boolean output port labeled EOF appears on the block. The output from the EOF port defaults to 1 when the last video frame or audio sample is output from the block. Otherwise, the output from the EOF port defaults to 0.

Multimedia outputs

Specify `Video and audio`, `Video only`, or `Audio only` output file type. This parameter becomes available only when a video signal has both audio and video.

Samples per audio channel

Specify number of samples per audio channel. This parameter becomes available for files containing audio.

Output color format

Specify whether you want the block to output `RGB`, `Intensity`, or `YCbCr 4:2:2` video frames. This parameter becomes available only for a signal that contains video. If you select `RGB`, use the **Image signal** parameter to specify how to output a color signal.

Image signal

Specify how to output a color video signal. If you select `One multidimensional signal`, the block outputs an M-by-N-by-P color video signal, where P is the number of color planes, at one port. If you select `Separate color signals`, additional ports appear on the block. Each port outputs one M-by-N plane of an RGB video stream. This parameter becomes available only if you set the **Image color space** parameter to `RGB` and the signal contains video.

Audio output sampling mode

Select Sample based or Frame based output. If the input to the block has 3 or more dimensions, you must select Sample based output. This parameter appears when you specify a file containing audio for the **File name** parameter.

Data Types Tab

Audio output data type

Set the data type of the audio samples output at the Audio port. This parameter becomes available only if the multimedia file contains audio. You can choose `double`, `single`, `int16`, or `uint8` types.

Video output data type

Set the data type of the video frames output at the **R**, **G**, **B**, or **Image** ports. This parameter becomes available only if the multimedia file contains video. You can choose `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `Inherit from file` types.

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH "${DYLD_LIBRARY_PATH}:$MATLABROOT/bin/maci64" (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH=$LD_LIBRARY_PATH:$MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:$MATLABROOT/bin/glnxa64 (csh/tcsh)`
	
	`export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH=%PATH%;%MATLABROOT%\bin\win64`

Supported Data Types

For source blocks to display video data properly, double- and single-precision floating-point pixel values must be between `0` and `1`. For other data types, the pixel values must be between the minimum and maximum values supported by their data type.

Port	Supported Data Types	Supports Complex Values?
Image	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers	No
R, G, B	Same as the Image port	No
Audio	• Double-precision floating point • Single-precision floating point • 16-bit signed integers • 8-bit unsigned integers	No
Y, Cb,Cr	Same as the Image port	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

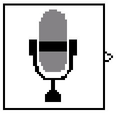
From Wave Device (Obsolete)

Read audio data from standard audio device in real-time (32-bit Windows operating systems only)



Library

`dspwin32`

Description

Note The From Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `From Audio Device` block.

The From Wave Device block reads audio data from a standard Windows audio device in real-time. It is compatible with most popular Windows hardware, including Sound Blaster cards. (Models that contain both this block and the To Wave Device block require a *duplex-capable* sound card.)

The **Use default audio device** parameter allows the block to detect and use the system's default audio hardware. This option should be selected on systems that have a single sound device installed, or when the default sound device on a multiple-device system is the desired source. In cases when the default sound device is not the desired input source, clear **Use default audio device**, and select the desired device in the **Audio device menu** parameter.

When the audio source contains two channels (stereo), the **Stereo** check box should be selected. When the audio source contains a single channel (mono), the **Stereo** check box should be cleared. For stereo input, the block's output is an M-by-2 matrix containing one frame (M consecutive samples) of audio data from each of the two channels. For mono input, the block's output is an M-by-1 matrix containing one frame (M consecutive samples) of audio data from the mono input. The frame size, M, is specified by the **Samples per frame** parameter. For M=1, the output is sample based; otherwise, the output is frame based.

The audio data is processed in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. You can select one of these rates from the **Sample rate** parameter. To specify a different rate, select the **User-defined** option and enter a value in the **User-defined sample rate** parameter.

The **Sample Width (bits)** parameter specifies the number of bits used to represent the signal samples read by the audio device. The following settings are available:

- 8 — allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — allocates 24 bits to each sample, allowing a resolution of 16777216 levels (only for use with 24-bit audio devices)

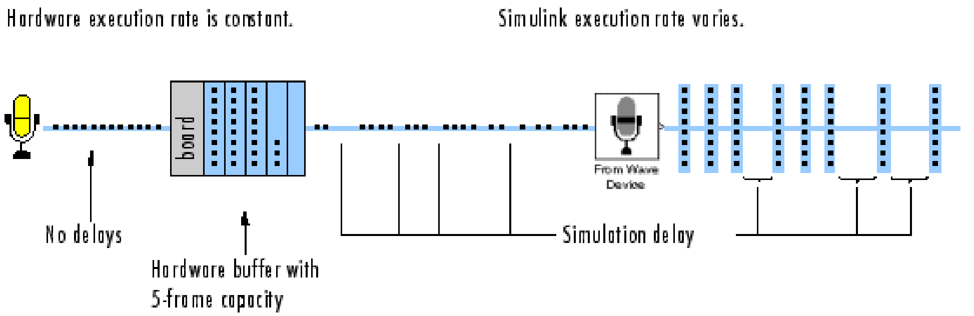
Higher sample width settings require more memory but yield better fidelity. The output from the block is independent of the **Sample width (bits)** setting. The output data type is determined by the **Data type** parameter setting.

Buffering

Since the audio device accepts real-time audio input, Simulink software must read a continuous stream of data from the device throughout the simulation. Delays in reading data from the audio hardware can result in hardware errors or distortion of the signal. This means that the From Wave Device block must read data from the audio hardware as quickly as the hardware itself acquires the signal. However, the block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running from within Simulink rather than as generated code. (Simulink operations are generally slower than comparable hardware operations, and execution speed routinely varies during the simulation as the host operating system services other processes.) The block must therefore rely on a buffering strategy to ensure that signal data can be read on schedule without losing samples.

At the start of the simulation, the audio device begins writing the input data to a (hardware) buffer with a capacity of T_b seconds. The From Wave Device block immediately begins pulling the earliest samples off the buffer (first in, first out) and collecting them in length-M frames for output. As the audio device continues to append inputs to the bottom of the buffer, the From Wave Device block continues to pull inputs off the top of the buffer at the best possible rate.

The following figure shows an audio signal being acquired and output with a frame size of 8 samples. The buffer of the sound board is approaching its five-frame capacity at the instant shown, which means that the hardware is adding samples to the buffer more rapidly than the block is pulling them off. (If the signal sample rate was 8 kHz, this small buffer could hold approximately 0.005 second of data.



When the simulation throughput rate is higher than the hardware throughput rate, the buffer remains empty throughout the simulation. If necessary, the From Wave Device block simply waits for new samples to become available on the buffer (the block does not interpolate between samples). More typically, the simulation throughput rate is lower than the hardware throughput rate, and the buffer tends to fill over the duration of the simulation.

Troubleshooting

When the buffer size is too small in relation to the simulation throughput rate, the buffer might fill before the entire length of signal is processed. This usually results in a device error or undesired device output. When this problem occurs, you can choose to either increase the buffer size or the simulation throughput rate:

- *Increase the buffer size*

  The **Queue duration** parameter specifies the duration of signal, T_b (in real-time seconds), that can be buffered in hardware during the simulation. Equivalently, this is the maximum length of time that the block's data acquisition can lag the hardware's data acquisition. The number of frames buffered is approximately

$$\frac{T_b F_s}{M}$$

where F_s is the sample rate of the signal and M is the number of samples per frame. The required buffer size for a given signal depends on the signal length, the frame size, and the speed of the simulation. Note that increasing the buffer size might increase model latency.

- *Increase the simulation throughput rate*

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes (and convert sample-based signals to frame-based signals) throughout the model to reduce the amount of block-to-block communication overhead. This can drastically increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder. Native code runs much faster than Simulink, and should provide rates adequate for real-time audio processing.

More general ways to improve throughput rates include simplifying the model, and running the simulation on a faster PC processor. See “Delay and Latency” and “Performance” (Simulink) for other ideas on improving simulation performance.

Parameters

Sample rate (Hz)

The sample rate of the audio data to be acquired. Select one of the standard Windows rates or the `User-defined` option.

User-defined sample rate (Hz)

The (nonstandard) sample rate of the audio data to be acquired.

Sample width (bits)

The number of bits used to represent each signal sample.

Stereo

Specifies stereo (two-channel) inputs when selected, mono (one-channel) inputs when cleared. Stereo output is M-by-2; mono output is M-by-1.

Samples per frame

The number of audio samples in each successive output frame, *M*. When the value of this parameter is 1, the block outputs a sample-based signal.

Queue duration (seconds)

The length of signal (in seconds) to buffer to the hardware at the start of the simulation.

Use default audio device

Reads audio input from the system's default audio device when selected. Clear to enable the **Audio device ID** parameter and select a device.

Audio device

The name of the audio device from which to read the audio output (lists the names of the installed audio device drivers). Select **Use default audio device** when the system has only a single audio card installed.

Data type

The data type of the output: double-precision, single-precision, signed 16-bit integer, or unsigned 8-bit integer.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

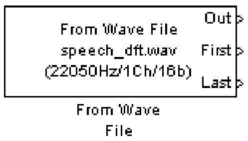
From Wave File (Obsolete)	DSP System Toolbox
To Wave Device (Obsolete)	DSP System Toolbox
`audiorecorder`	MATLAB

Introduced in R2008b

From Wave File (Obsolete)

Read audio data from Microsoft Wave (.wav) file



Library

dspwin32

Description

Note: The From Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `From Multimedia File` block.

The From Wave File block streams audio data from a Microsoft® Wave (.wav) file and generates a signal with one of the data types and amplitude ranges in the following table.

Note: AVI files are the only supported file type for non-Windows platforms.

Output Data Type	Output Amplitude Range
double	±1
single	±1
int16	-32768 to 32767 (-2^{15} to $2^{15} - 1$)
uint8	0 to 255

The audio data must be in uncompressed pulse code modulation (PCM) format.

```
y = wavread('filename')      % Equivalent MATLAB code
```

The block supports 8-, 16-, 24-, and 32-bit Microsoft Wave (`.wav`) files.

The **File name** parameter can specify an absolute or relative path to the file. When the file is on the MATLAB path or in the current folder (the folder returned by typing `pwd` at the MATLAB command line), you need only specify the file name. You do not need to specify the `.wav` extension.

Note: The From Wave File block does not support .wav file names that contain a `+` character. To read .wav files that have a `+` character in the file name, use the `From Multimedia File` block.

For an audio file containing C channels, the block's output is an M-by-C matrix containing one frame (M consecutive samples) of audio data from each channel. The frame size, M, is specified by the **Samples per output frame** parameter. For M=1, the output is sample based; otherwise, the output is frame based.

The output frame period, T_{fo}, is

$$T_{fo} = \frac{M}{F_s}$$

where F_s is the data sample rate in Hz.

To reduce the required number of file accesses, the block acquires L consecutive samples from the file during each access, where L is specified by the **Minimum number of samples for each read from file** parameter ($L \geq M$). For $L < M$, the block instead acquires M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Use the **Data type** parameter to specify the data type of the block's output. Your choices are `double`, `single`, `uint8`, or `int16`.

Select the **Loop** check box if you want to play the file more than once. Then, enter the number of times to play the file. The number you enter must be a positive integer or `inf`.

Use the **Number of times to play file** parameter to enter the number of times to play the file. The number you enter must be a positive integer or `inf`, to play the file until you stop the simulation.

The **Samples restart** parameter determines whether the samples from the audio file repeat immediately or repeat at the beginning of the next frame output from the output port. When you select `immediately after last sample`, the samples repeat immediately. When you select `at beginning of next frame`, the frame containing the last sample value from the audio file is zero padded until the frame is filled. The block then places the first sample of the audio file in the first position of the next output frame.

Use the **Output start-of-file indicator** parameter to determine when the first audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled SOF appears on the block. The output from the SOF port is 1 when the first audio sample in the file is output from the block. Otherwise, the output from the SOF port is 0.

Use the **Output end-of-file indicator** parameter to determine when the last audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled EOF appears on the block. The output from the EOF port is 1 when the last audio sample in the file is output from the block. Otherwise, the output from the EOF port is 0.

The block icon shows the name, sample rate (in Hz), number of channels (1 or 2), and sample width (in bits) of the data in the specified audio file. All sample rates are supported; the sample width must be either 8, 16, 24, or 32 bits.

Parameters

File name

Enter the path and name of the file to read. Paths can be relative or absolute.

Note: The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the `From Multimedia File` block.

Samples per output frame

Enter the number of samples in each output frame, *M*. When the value of this parameter is `1`, the block outputs a sample-based signal.

Minimum number of samples for each read from file

Enter the number of consecutive samples to acquire from the file with each file access, *L*.

Data type

Select the output data type: `double`, `single`, `uint8`, or `int16`. The data type setting determines the output's amplitude range.

Loop

Select this check box if you want to play the file more than once.

Number of times to play file

Enter the number of times you want to play the file.

Samples restart

Select `immediately after last sample` to repeat the audio file immediately. Select `at beginning of next frame` to place the first sample of the audio file in the first position of the next output frame.

Output start-of-file indicator

Use this check box to determine whether the output contains the first audio sample in the file.

Output end-of-file indicator

Use this check box to determine whether the output contains the last audio sample in the file.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

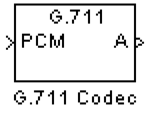
G711 Codec

Quantize narrowband speech input signals



Library

Quantizers

`dspquant2`

Description

The G711 Codec block is a logarithmic scalar quantizer designed for narrowband speech. Narrowband speech is defined as a voice signal with an analog bandwidth of 4 kHz and a Nyquist sampling frequency of 8 kHz. The block quantizes a narrowband speech input signal so that it can be transmitted using only 8-bits. The G711 Codec block has three modes of operation: encoding, decoding, and conversion. You can choose the block's mode of operation by setting the **Mode** parameter.

If, for the **Mode** parameter, you choose `Encode PCM to A-law`, the block assumes that the linear PCM input signal has a dynamic range of 13 bits. Because the block always operates in saturation mode, it assigns any input value above $2^{12}-1$ to $2^{12}-1$ and any input value below -2^{12} to -2^{12}. The block implements an A-law quantizer on the input signal and outputs A-law index values. When you choose `Encode PCM to mu-law`, the block assumes that the linear PCM input signal has a dynamic range of 14 bits. Because the block always operates in saturation mode, it assigns any input value above $2^{13}-1$ to $2^{13}-1$ and any input value below -2^{13} to -2^{13}. The block implements a mu-law quantizer on the input signal and outputs mu-law index values.

If, for the **Mode** parameter, you choose `Decode A-law to PCM`, the block decodes the input A-law index values into quantized output values using an A-law lookup table.

When you choose `Decode mu-law to PCM`, the block decodes the input mu-law index values into quantized output values using a mu-law lookup table.

If, for the **Mode** parameter, you choose `Convert A-law to mu-law`, the block converts the input A-law index values to mu-law index values. When you choose `Convert mu-law to A-law`, the block converts the input mu-law index values to A-law index values.

Note Set the **Mode** parameter to `Convert A-law to mu-law` or `Convert mu-law to A-law` only when the input to the block is A-law or mu-law index values.

If, for the **Mode** parameter, you choose `Encode PCM to A-law` or `Encode PCM to mu-law`, the **Overflow diagnostic** parameter appears on the block parameters dialog box. Use this parameter to determine the behavior of the block when overflow occurs. The following options are available:

- `Ignore` — Proceed with the computation and do not issue a warning message.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation.
- `Error` — Display an error dialog box and terminate the simulation.

Note Like all diagnostic parameters on the Configuration Parameters dialog box, **Overflow diagnostic** parameter is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Parameters

Mode

- When you choose `Encode PCM to A-law`, the block implements an A-law encoder.
- When you choose `Encode PCM to mu-law`, the block implements a mu-law encoder.
- When you choose `Decode A-law to PCM`, the block decodes the input index values into quantized output values using an A-law lookup table.
- When you choose `Decode mu-law to PCM`, the block decodes the input index values into quantized output values using a mu-law lookup table.

- When you choose `Convert A-law to mu-law`, the block converts the input A-law index values to mu-law index values.
- When you choose `Convert mu-law to A-law`, the block converts the input mu-law index values to A-law index values.

Overflow diagnostic

Use this parameter to determine the behavior of the block when overflow occurs.

- Select `Ignore` to proceed with the computation without a warning message.
- Select `Warning` to display a warning message in the MATLAB Command Window and continue the simulation.
- Select `Error` to display an error dialog box and terminate the simulation.

This parameter is only visible if, for the **Mode** parameter, you select `Encode PCM to A-law` or `Encode PCM to mu-law`.

Halfband Filter

Design halfband filter

Note: The Halfband Filter block has been removed from the DSP System Toolbox block library. Existing instances of the Halfband Filter block will continue to operate. To model FIR halfband decimators and interpolators, use the `FIR Halfband Decimator` and `FIR Halfband Interpolator` blocks. These blocks replace the functionality of the Halfband Filter block, when **Impulse response** is set to `FIR`, and **FilterType** is set to `Decimator` and `Interpolator`. To model IIR halfband decimators and interpolators, use the `IIR Halfband Decimator` and `IIR Halfband Interpolator` blocks. These blocks replace the functionality of the Halfband Filter block, when **Impulse response** is set to `IIR`, and **FilterType** is set to `Decimator` and `Interpolator`.

Library

Filtering / Filter Designs

`dspfdesign`

Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

See “Halfband Filter Design — Main Pane” on page 5-749 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter type and order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Specify the filter response as `Lowpass` (the default) or `Highpass`.

Filter type

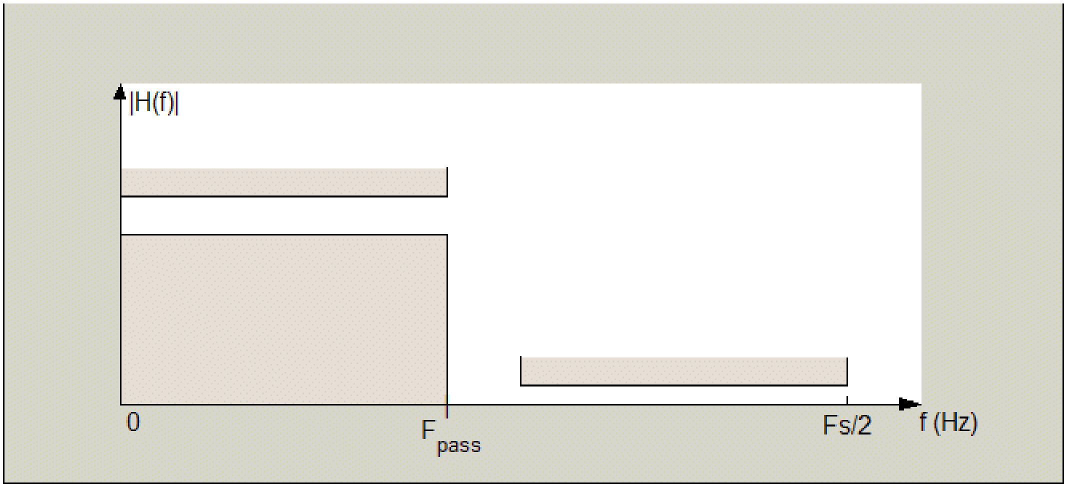
Select `Single-rate`, `Decimator`, or `Interpolator`. By default, the block specifies a single-rate filter.

Order

Enter the filter order. This option is enabled only when the **Filter order mode** is set to `Specify`.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.



In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

Frequency constraints

When **Order mode** is `Specify`, set this parameter to `Unconstrained` or `Transition width`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify `Unconstrained` (the default), or select `Stopband attenuation` to constrain the response in the stopband explicitly.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).

Astop

When **Magnitude units** is `Stopband attenuation`, enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are `equiripple`, and `Kaiser window`. For IIR halfband filters, the available design options are `Butterworth`, `elliptic`, and `IIR quasi-linear phase`.

Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

Minimum phase

Select the checkbox to specify a minimum-phase design.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

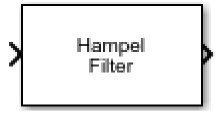
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2006b

Hampel Filter

Filter outliers using Hampel identifier
Library: DSP System Toolbox / Filtering / Filter Designs



Description

The Hampel Filter block detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the block computes the median of a window composed of the current sample and $\frac{Len-1}{2}$ adjacent samples on each side of current sample. *Len* is the window length you specify through the **Window length** parameter. The block also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see "Algorithms" on page 2-859.

Ports

Input

`Port_1` — Data input
vector | matrix

The block accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n \geq 1$. m is the number of samples in each frame (channel), and n is the number of channels. The block also accepts variable-size inputs. That is, you can change the size of each input channel during simulation. However, the number of channels cannot change.

Data Types: `single` | `double`

Output

y — Filtered output

vector | matrix

The size and data type of this output matches the size and data type of the input.

This port is unnamed until you select the **Output outlier status** check box.

Data Types: `single` | `double`

`outlier` — Output the outlier status

vector | matrix

A value of `1` in this output indicates that the corresponding element in the input is an outlier. This output has the same size as the input.

This port is unnamed until you select the **Output outlier status** check box.

Dependencies

To enable this port, select the **Output outlier status** check box.

Data Types: `Boolean`

Parameters

`Window length` — Length of the sliding window

`11` (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the block computes the median and median absolute deviation of the data in the window.

`Threshold for outlier detection (standard deviations)` — Threshold

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this parameter is used to detect the outlier, see “Algorithms” on page 2-859.

Tunable: Yes

`Output outlier status` — Flag to output the outlier status
off (default) | on

Select this parameter to output a matrix of Boolean values that has the same size as the input. Each element in this matrix indicates whether the corresponding element in the input is an outlier. A value of `1` indicates an outlier.

`Simulate using` — Type of simulation to run
`Interpreted execution` (default) | `Code generation`

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time and provides faster simulation speed than `Code generation`.
- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time and has slower simulation speed than `Interpreted execution`.

Definitions

Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence $x_1, x_2, x_3, \ldots, x_n$ and a sliding window of length k, define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}\left(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \ldots, x_i, \ldots, x_{i+k-2}, x_{i+k-1}, x_{i+k}\right)$
- Standard deviation — $\sigma_i = \kappa\,\text{median}\left(\left|x_{i-k} - m_i\right|, \ldots, \left|x_{i+k} - m_i\right|\right)$, where

  $$\kappa = \frac{1}{\sqrt{2}\,\text{erfc}^{-1}\,1/2} \approx 1.4826$$

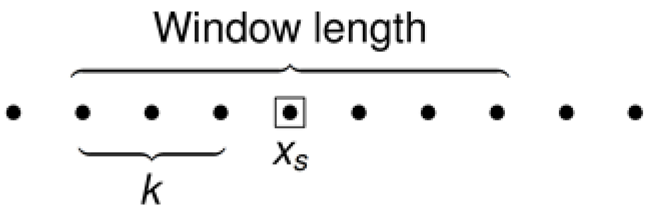
The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold n_σ, then the Hampel identifier declares x_i an outlier and replaces it with m_i. If n_σ is 0, then the Hampel filter behaves as a regular median filter.

Algorithms



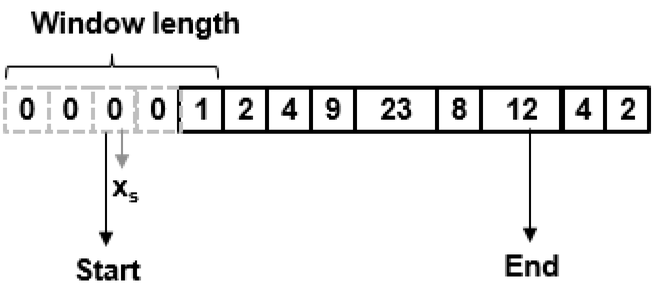
For a given sample of data, x_s, the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i, and standard deviation, σ_i, over the current window of data.
- Compares the current sample with $n_\sigma \times \sigma_i$, where n_σ is the threshold value. If $|x_s - m_i| > n_\sigma \times \sigma_i$, the filter identifies the current sample, x_s, as an outlier and replaces it with the median value, m_i.

Consider a frame of data that is passed into the Hampel filter.

1	2	4	9	23	8	12	4	2

In this example, the Hampel filter slides a window of length 5 (Len) over the data. The filter has a threshold value of 2 (n_σ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with $Len - 1$ zeros. To compute the first sample of the output, the window centers on the $\left[\frac{Len-1}{2}+1\right]^{th}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.



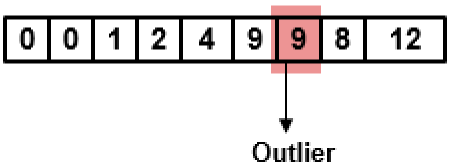
- Current sample: $x_s = 0$.
- Window of data: $win = [0\ 0\ 0\ 0\ 1]$.
- Local median: $m_i = \text{median}([0\ 0\ 0\ 0\ 1]) = 0$.
- Median absolute deviation: $mad_i = \text{median}\left(|x_{i-k} - m_i|, \ldots, |x_{i+k} - m_i|\right)$. For this window of data, $mad = \text{median}\left(|0-0|, \ldots, |1-0|\right) = 0$.
- Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2}\,\text{erfc}^{-1} 1/2} \approx 1.4826$.
- The current sample, $x_s = 0$, does not obey the relation for outlier detection.

  $$\left[|x_s - m_i| = 0\right] > \left[(n_\sigma \times \sigma_i) = 0\right]$$

  Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the window on the $\left[End - \frac{Len-1}{2}\right]^{th}$ sample, marked as End. Because the window centered on the last $\frac{Len-1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:



The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

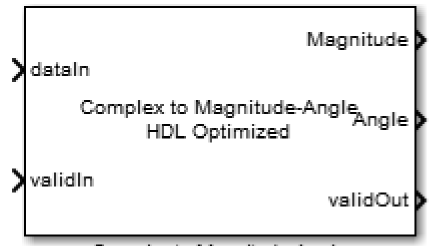
Complex to Magnitude-Angle HDL Optimized

Compute magnitude and/or phase angle of complex signal—optimized for HDL code generation using the CORDIC algorithm



Complex to Magnitude-Angle
HDL Optimized

Library

Math Operations

`dspmathops`

Description

The Complex to Magnitude-Angle HDL Optimized block computes the magnitude and/or phase angle of a complex signal. It provides hardware-friendly control signals. The block uses a pipelined Coordinate Rotation Digital Computer (CORDIC) algorithm to achieve an efficient HDL implementation.

Signal Attributes

Port	Direction	Description	Data Type
`dataIn`	Input	Complex scalar input data.	• `fixdt()` • `int32/16/8` • `uint32/16/8`

Port	Direction	Description	Data Type
			double/single are allowed for simulation but not for HDL code generation.
validIn	Input	Indicates that the input data is valid. When validIn is high, the block captures the dataIn value.	boolean
magnitude	Output	Scalar output data.	Same as dataIn
angle	Output	Scalar output data. Optional.	Same as dataIn
validOut	Output	Indicates that the output data is valid. When the magnitude or angle output is ready, the block sets validOut high .	boolean

Parameters

Number of iterations source

Specifies the source of **Number of iterations** for the CORDIC algorithm. Select Auto to set the number of iterations to the input word length − 1. If the input is double or single, Auto sets the number of iterations to 16. Select Property to set the number of iterations from **Number of iterations**. The default is Auto.

Number of iterations

Specifies the number of CORDIC iterations the block executes. This parameter is visible only when **Number of iterations source** is set to Property. The number of iterations must be less than or equal to the input data word length − 1.

The latency of the block depends on the number of iterations performed. See “Latency” on page 2-869.

Output format

Specifies which output ports are active. You can select Magnitude, Angle, or Magnitude and angle. The default is Magnitude and angle.

Angle format

Specifies the format of the angle output. You can select Normalized or Radians. Select Normalized to return output in a fixed-point format that normalizes the angles in the range [–1,1]. For more information see “Normalized Angle Format” on page 2-869. Select `Radians` to return output as a fixed-point value between π and −π. The default format is `Normalized`.

Scale output

Scales output by the inverse of the CORDIC gain factor. The default value is selected.

Note: If you turn off output scaling, and apply the CORDIC gain elsewhere in your design, you must exclude the π/4 term. The quadrant mapping algorithm replaces the first CORDIC iteration by mapping inputs onto the angle range [0,π/4]. Therefore, the initial rotation does not contribute a gain term.

Troubleshooting

If the input is 0+0i, the output angle is undefined. The block does not implement correction logic to force the output to 0. You can ignore this output angle.

Algorithm

CORDIC Algorithm

The CORDIC algorithm is a hardware-friendly method for performing trigonometric functions. It is an iterative algorithm that approximates the solution by converging toward the ideal point. The block uses CORDIC vectoring mode to iteratively rotate the input onto the real axis.

The Givens method for rotating a complex number $x+iy$ by an angle θ is as follows. The direction of rotation, d, is +1 for counterclockwise and −1 for clockwise.

$$x_r = x\cos\theta - dy\sin\theta$$
$$y_r = y\cos\theta + dx\sin\theta$$

For a hardware implementation, factor out the $\cos\theta$ to leave a $\tan\theta$ term.

$$x_r = \cos\theta\left(x - dy\tan\theta\right)$$
$$y_r = \cos\theta\left(y + dx\tan\theta\right)$$

To rotate the vector onto the real axis, choose a series of rotations of θ_n so that $\tan\theta_n = 2^{-n}$. Remove the $\cos\theta$ term so each iterative rotation uses only shift and add operations.

$$Rx_n = x_{n-1} - d_n y_{n-1} 2^{-n}$$
$$Ry_n = y_{n-1} + d_n x_{n-1} 2^{-n}$$

Combine the missing $\cos\theta$ terms from each iteration into a constant, and apply it with a single multiplier to the result of the final rotation. The output magnitude is the scaled final value of x. The output angle, z, is the sum of the rotation angles.

$$x_r = (\cos\theta_0 \cos\theta_1 \ldots \cos\theta_n) Rx_N$$
$$z = \sum_{0}^{N} d_n \theta_n$$

Modified CORDIC Algorithm

The convergence region for the standard CORDIC rotation is ≈±99.7°. To work around this limitation, before doing any rotation, the block maps the input into the [0,π/4] range using the following algorithm.

```
if abs(x) > abs(y)
  input_mapped = [abs(x), abs(y)];
else
  input_mapped = [abs(y), abs(x)];
end
```

At each iteration, the block rotates the vector towards the real axis. The rotation is counterclockwise when y is negative, and clockwise when y is positive.

Quadrant mapping saves hardware resources and reduces latency by reducing the number of CORDIC pipeline stages by one. The CORDIC gain factor, Kn, therefore does not include the n=0, or cos(π/4) term.

$$K_n = \cos\theta_1 \ldots \cos\theta_n = \cos(26.565) \cdot \cos(14.036) \cdot \cos(7.125) \cdot \cos(3.576)$$

After the CORDIC iterations are complete, the block corrects the angle back to its original location. First it adjusts the angle to the correct side of π/4.

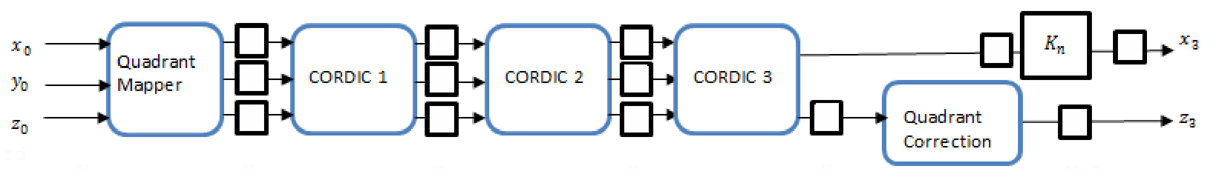
```
if abs(x) > abs(y)
  angle_unmapped = CORDIC_out;
else
  angle_unmapped = (pi/2) - CORDIC_out;
end
```

Then it flips the angle to the original quadrant.

```
if (x < 0)
  if (y < 0)
    output_angle = - pi + angle_unmapped;
  else
    output_angle = pi - angle_unmapped;
else
  if (y<0)
    output_angle = -angle_unmapped;
```

Architecture

The block generates a pipelined HDL architecture to maximize throughput. Each CORDIC iteration is done in one pipeline stage. The gain multiplier, if enabled, is implemented with Canonical Signed Digit (CSD) logic.

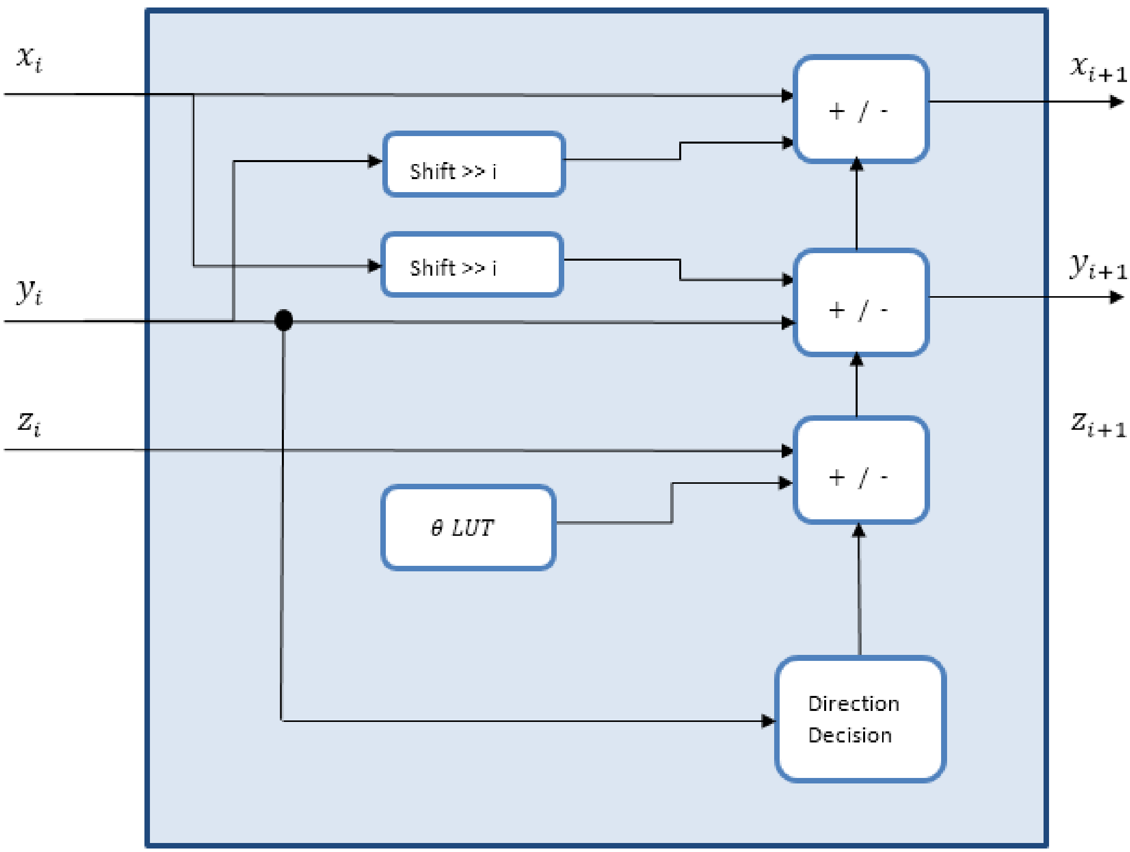


Input Word Length	Output Magnitude Word Length
fixdt(0,WL,FL)	fixdt(0,WL+2,FL)
fixdt(1,WL,FL)	fixdt(1,WL+1,FL)

Input Word Length	Output Angle Word Length	
fixdt([ ],WL,FL)	Radians	fixdt(1,WL+3,WL)

Input Word Length	Output Angle Word Length	
	Normalized	fixdt(1,WL+3,WL+2)

The CORDIC logic at each pipeline stage implements one iteration. For each pipeline stage, the shift and angle rotation are constants.

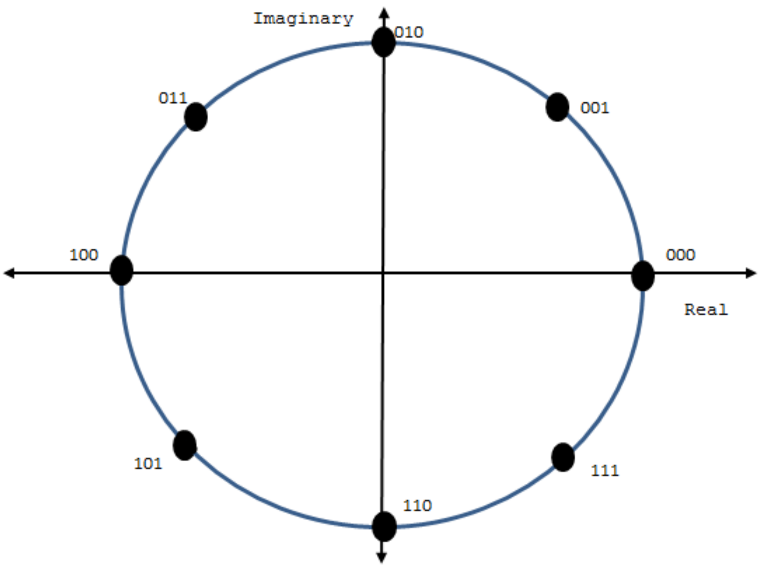


When you set **Output format** to `Magnitude`, the block does not generate HDL code for the angle accumulation and quadrant correction logic.

Normalized Angle Format

This format normalizes the fixed-point radian angle values around the unit circle. This is a more efficient use of bits than a range of [0,2π] radians. Normalized angle format also enables wraparound at 0/2π without additional detect and correct logic.

For example, representing the angle with 3 bits results in the following normalized values.



Using the mapping described in "Modified CORDIC Algorithm" on page 2-866, the block normalizes the angles across [0,π/4] and maps them to the correct octant at the end of the calculation.

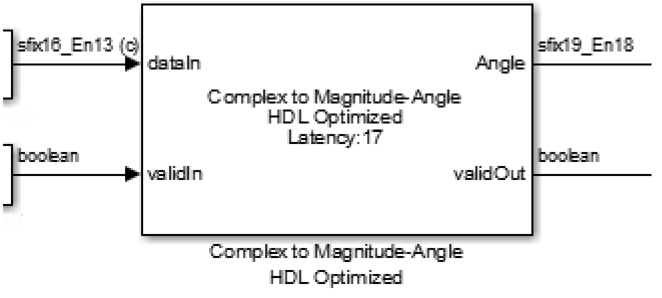
Control Signals

The `validIn` signal qualifies the input data. When the output data calculated from a valid input reaches the end of the pipeline, the block asserts the `validOut` signal.

Latency

The output is valid **Number of iterations** + 2 cycles after valid input.

When you set **Number of iterations source** to `Property`, the block shows the latency immediately. When you set **Number of iterations source** to `Auto`, the block calculates the latency based on the input port data type, and displays it when you update the model.



When you set **Number of iterations source** to `Auto`, the number of iterations is input word length − 1, and the latency is input word length + 1. If the input is `double` or `single` type, the number of iterations is 16, and the latency is 18.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Complex to Magnitude-Angle HDL Optimized in the HDL Coder documentation.

Performance

When generated HDL code for the default configuration, with output scaling disabled and `fixdt(1,16,12)` input, is synthesized into a Xilinx Virtex–6 (XC6VLX240T-1FFG1156) FPGA, the design achieves 260 MHz clock frequency. It uses the following resources.

Resource	Uses
LUT	882

Resource	Uses
FFS	792
Xilinx LogiCORE DSP48	0
Block RAM (16K)	0

Performance of the synthesized HDL code varies depending on your target and synthesis options.

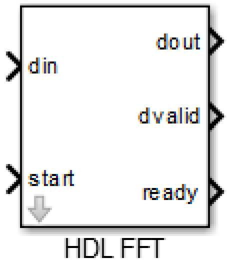
HDL Minimum Resource FFT

FFT— optimized for HDL code generation using minimum hardware resources



Library

Obsolete

`dspobs`

Description

The HDL Minimum Resource FFT block implements an FFT architecture that uses minimal hardware resources. The HDL Minimum Resource FFT block supports the Radix-2 with decimation-in-time (DIT) algorithm for FFT computation. See the FFT block for more information about this algorithm.

The results returned by the HDL Minimum Resource FFT block are bit-for-bit compatible with results returned by the FFT block. The operation of the HDL Minimum Resource FFT block differs from the FFT block, due to the requirements of hardware realization. The HDL Minimum Resource FFT block:

- Requires serial input
- Generates serial output

- Operates in burst I/O mode

The HDL Minimum Resource FFT block provides handshaking signals to support these features.

- “Block Inputs and Outputs” on page 2-873
- “Parameters” on page 2-875
- “Signal Processing with the HDL FFT Block” on page 2-877

Block Inputs and Outputs

As shown in the following figure, the HDL Minimum Resource FFT block has two input ports and three output ports. Two of these ports are for data input and output signals. The other ports are for control signals.

The input ports are:

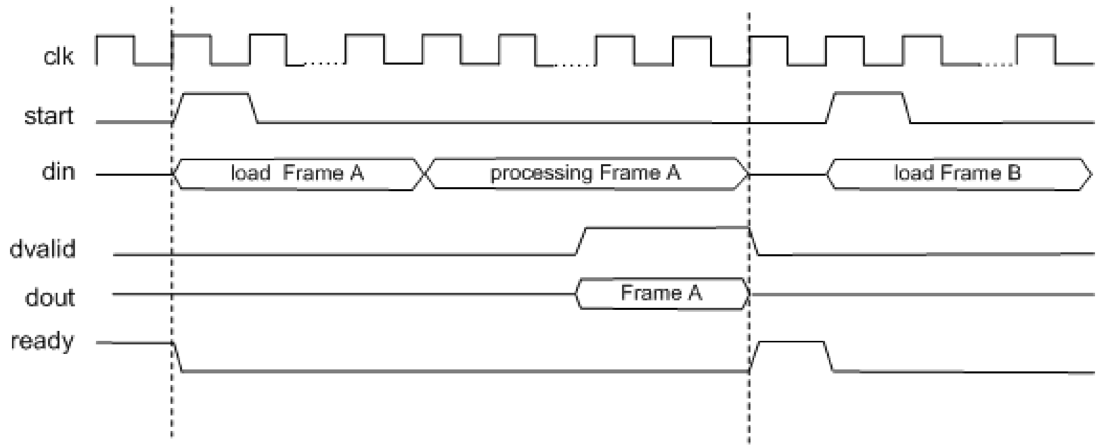
- `din`: The input data signal. A complex signal is required.
- `start`: Boolean control signal. When this signal is asserted true (1), the HDL Minimum Resource FFT block initiates processing of a data frame.

The output ports are:

- `dout`: Data output signal. The Radix-2 with DIT algorithm produces output with linear ordering.
- `dvalid`: Boolean control signal. The HDL Minimum Resource FFT block asserts this signal true (1) when a burst of valid output data is available at the `dout` port.
- `ready`: Boolean control signal. The HDL Minimum Resource FFT block asserts this signal true (1) to indicate that it is ready to process a new frame.

Configuring Control Signals

For efficient hardware deployment of the HDL Minimum Resource FFT block, the timing of the block's input and output data streams must be considered carefully. The following figure shows the timing relationships between the system clock and the `start`, `ready`, and `dvalid` signals.



When ready is asserted, the start signal (active high) triggers the block. The high cycle period of the start signal does not affect the behavior of the block.

One clock cycle after the start trigger, the block begins to load data and the ready signal is deasserted. During the interval when the block is loading, processing, and outputting data, ready is low and the start signal is ignored.

The dvalid signal is asserted high for N clock cycles (where N is the FFT length) after processing is complete. ready is asserted again after the N-point FFT outputs are sent out.

The expression Tcycle denotes the total number of clock cycles required by the HDL Minimum Resource FFT block to complete an FFT of length N. Tcycle is defined as follows:

- Where N >8

  ```
  Tcycle =  3N/2-2 + log2(N)*(N/2+3);
  ```
- Where N = 8

  ```
  Tcycle =  3N/2-1 +log2(N)*(N/2+3);
  ```

Given Tcycle, you can then define the period between assertions of the HDL Minimum Resource FFT start signal in a way that is suitable to your application. In the “Using the Minimum Resource HDL FFT” example, this period is computed and assigned to the variable startLen, as follows:

```
if (N<=8)
startLen = (ceil(Tcycle/N)+1)*N;
else
startLen = ceil(Tcycle/N)*N;
end
```

In the example model, `startLen` determines the period of a Pulse Generator that drives the HDL Minimum Resource FFT block's `start` input. These values are computed in the model's initialization function (`InitFcn`), which is defined in the **Callbacks** pane of the Simulink Model Explorer.

The HDL Minimum Resource FFT block asserts and deasserts the `ready` and `dvalid` signals automatically. These signals are routed to the model components that write to and read from the HDL Minimum Resource FFT block.

Parameters

FFT Length

Default: 8

The FFT length must be a power of 2, in the range 2^3 .. 2^{16}.

Rounding mode

Default: `Floor`

The HDL Minimum Resource FFT block supports all rounding modes of the FFT block. See also the FFT block reference section.

Overflow mode

Default: `Saturate`

The HDL Minimum Resource FFT block supports all overflow modes of the FFT block. See also the FFT block reference section.

Sine table

Default: `Same word length as input`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values is equal to the word length minus one.

- When you select `Same word length as input`, the word length of the sine table values match that of the input to the block.
- When you select `Specify word length`, you can enter the word length of the sine table values, in bits, in the **Sine table word length** field. The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters; they always saturate and round to `Nearest`.

Product output

Default: `Same as input`

Use this parameter to specify how you want to designate the product output word and fraction lengths:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits, in the **Product word length** and **Product fraction length** fields.

Accumulator

Default: `Same as input`

Use this parameter to specify how you want to designate the accumulator word and fraction lengths:

When you select `Same as product output`, these characteristics match those of the product output.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits, in the **Accumulator word length** and **Accumulator fraction length** fields.

Output

Default: `Same as input`

Choose how you specify the output word length and fraction length:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits, in the **Output word length** and **Output fraction length** fields.

Note: The HDL FFT block skips the divide-by-two operation on butterfly outputs for fixed-point signals.

Signal Processing with the HDL FFT Block

To get started with the HDL Minimum Resource FFT block, run the "Using the Minimum Resource HDL FFT" example, which is located in the HDL Coder/Signal Processing example library.

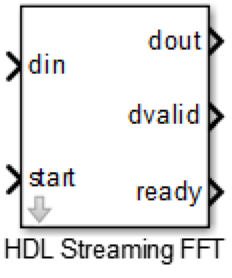
The example illustrates the use of the HDL Minimum Resource FFT block in simulation. The model includes buffering and control logic that handles serial input and output. In the example, a complex source signal is stored as a series of samples in a FIFO. Samples from the FIFO are processed serially by the HDL Minimum Resource FFT block, which emits a stream of scalar FFT data.

For comparison, the same source signal is also processed by the frame-based FFT block. The output frames from the FFT block are buffered into a FIFO and compared to the output of the HDL Minimum Resource FFT block. Examination of the results shows the outputs to be identical.

Introduced in R2014b

HDL Streaming FFT

Radix-2 FFT with decimation-in-frequency (DIF) — optimized for HDL code generation



Library

Obsolete

`dspobs`

Description

Note: The HDL Streaming FFT block will be deprecated in future releases. Use the FFT HDL Optimized block instead.

The HDL Streaming FFT block returns results identical to results returned by the Radix-2 DIF algorithm of the FFT block.

- "Block Inputs and Outputs" on page 2-879
- "Timing Description" on page 2-879
- "Parameters" on page 2-882

Block Inputs and Outputs

As shown in the following figure, the HDL Streaming FFT block has two input ports and three output ports. Two of these ports are for data input and output signals. The other ports are for control signals.

The block has the following input ports:

- `din`: The input data signal. The coder requires a complex fixed-point signal.
- `start`: Boolean control signal. When `start` asserts true (1), the HDL Streaming FFT block initiates processing of a data frame.

The block has the following output ports:

- `dout`: Data output signal.
- `dvalid`: Boolean control signal. The HDL Streaming FFT block asserts this signal true (1) when a stream of valid output data is available at the `dout` port.
- `ready`: Boolean control signal. The HDL Streaming FFT block asserts this signal true (1) to indicate that it is ready to process a new frame.

Timing Description

The HDL Streaming FFT block operates in one of two modes:

- *Continuous data streaming* mode: In this mode, the HDL Streaming FFT block expects to receive a continuous stream of data at `din`. After an initial delay, the block produces a continuous stream of data at `dout`.
- *Non-continuous data streaming* mode: In this mode, the HDL Streaming FFT block receives non-continuous bursts of streaming data at `din`. After an initial delay, the block produces non-continuous bursts of streaming data at `dout`.

The behavior of the control signals determines the timing mode of the block.

Continuous Data Streaming Timing

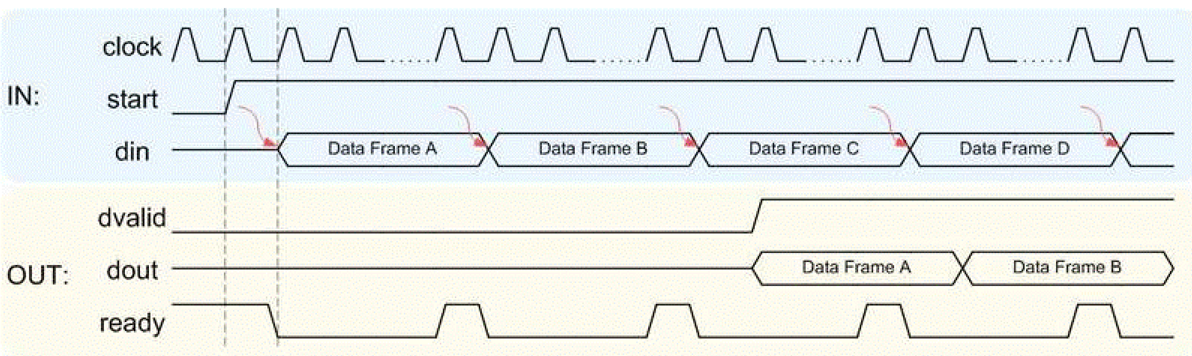
Assertion of the `start` signal (active high) triggers processing by the HDL Streaming FFT block. To initiate continuous data stream processing, assert the `start` signal in one of the following ways:

- Hold the start signal high (as shown in figure "Continuous Data Streaming With Start Signal Held High").
- Pulse the start signal every N clock cycles, where N is the FFT length (as shown in figure "Continuous Data Streaming With Pulsed Start Signal").

One clock cycle after the `start` trigger, the block begins to load data at `din`. After the first frame of streaming data, the block starts to receive the next frame of streaming data.

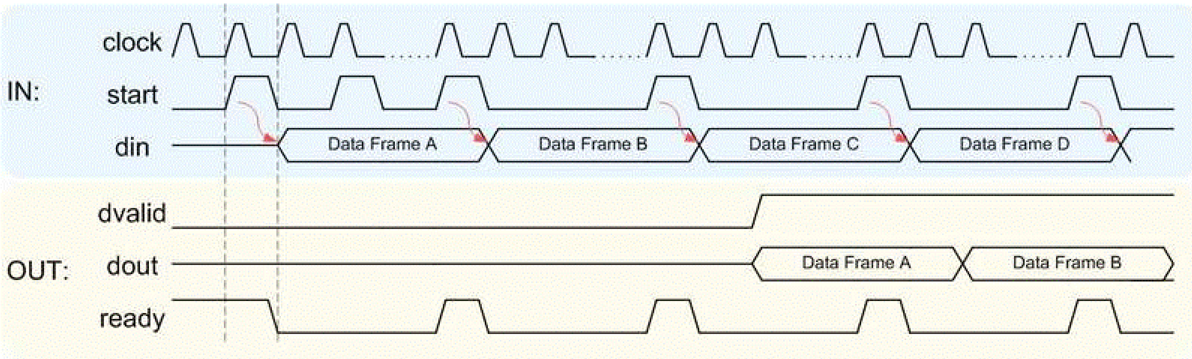
Meanwhile, the block performs the FFT calculation on the incoming data frames and outputs the results continuously at `dout`. The HDL Streaming FFT block asserts and deasserts the `ready` and `dvalid` signals automatically. The block asserts `dvalid` high whenever the output data stream is valid. The block asserts `ready` high to indicate that the block is ready to load a new data frame. When `ready` is low, the block ignores the `start` signal.

The following figures illustrate continuous data streaming. Each data frame corresponds to a stream of N input data values, where N is the FFT length.



Continuous Data Streaming With Start Signal Held High

Note: The `start` signal can be a single cycle pulse; it need not be held high for the entire data frame. When processing for a frame begins, further pulses on `start` do not affect processing of that frame. However, a `start` pulse must occur at the beginning of each data frame.



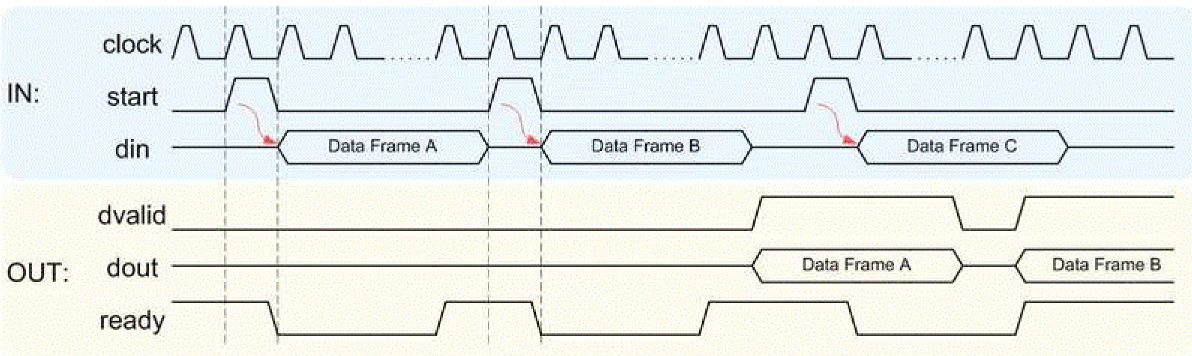
Continuous Data Streaming With Pulsed Start Signal

Non-Continuous Data Streaming Timing

In this mode, the HDL Streaming FFT block receives continuous bursts of streaming data at `din`. After an initial delay, the block produces non-continuous bursts of streaming data at `dout`. Breaks occur between data frames when the following condition exist:

- The `start` signal does not assert every N clock cycles (where N is the FFT length)
- The `start` signal is not continuously held high.

Non-continuous data streaming mode allows you more flexibility in determining the intervals between input data streams.

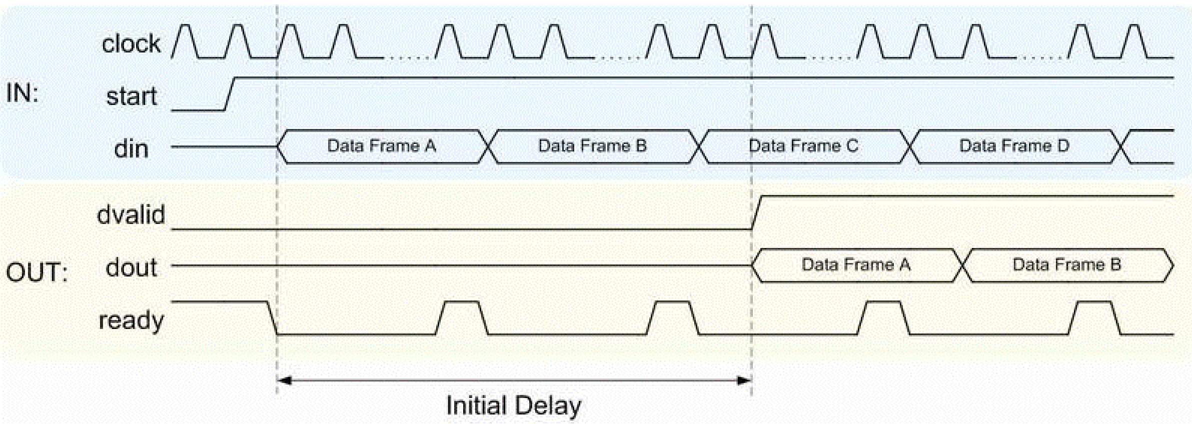


Initial Delay

The initial delay of the HDL Streaming FFT block is the interval between the following times:

- The time the block begins to receive the first frame of input data
- The time the block asserts `dvalid` and produces the first valid output data.

The initial delay represents the time the block uses to load a data frame, calculate the FFT, and output the beginning of the first output frame. The following figure illustrates the initial delay.



If you select the block option **Display computed initial delay on mask**, the block icon displays the initial delay. The display represents the delay time as Z^{-n}, where n is the delay time in samples.

Parameters

FFT Length

Default: 1024

The FFT length must be a power of 2, in the range 2^3 to 2^{16}.

Rounding mode

Default: `Floor`

The HDL Streaming FFT block supports all rounding modes of the FFT block. See also the FFT block reference.

Overflow mode

Default: `Wrap`

The HDL Streaming FFT block supports all overflow modes of the FFT block. See also the FFT block reference.

Sine table

Default: `Same word length as input`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values is equal to the word length minus one.

- When you select `Same word length as input`, the word lengths of the sine table values match the word lengths of the block inputs.
- When you select `Specify word length`, you can enter the word length of the sine table values, in bits, in the **Sine table word length** field. The sine table values do not obey the **Rounding mode** and **Overflow mode** parameters. They always saturate and round to `Nearest`.

Product output

Default: `Same as input`

Use this parameter to specify how you want to designate the product output word and fraction lengths:

- When you select `Same as input`, these characteristics match the characteristics of the input to the block.
- `Binary point scaling`: Enter the word length and the fraction length of the product output, in bits, in the **Product word length** and **Product fraction length** fields.

Accumulator

Default: `Same as input`

Use this parameter to specify how you want to designate the accumulator word and fraction lengths:

When you select Same as product output, these characteristics match the characteristics of the product output.

- When you select Same as input, these characteristics match the characteristics of the input to the block.
- Binary point scaling: Enter the word length and the fraction length of the accumulator, in bits, in the **Accumulator word length** and **Accumulator fraction length** fields.

Output

Default: Same as input

Choose how you specify the output word length and fraction length:

- Same as input: these characteristics match the characteristics of the input to the block.
- Binary point scaling: lets you enter the word length and fraction length of the output, in bits, in the **Output word length** and **Output fraction length** fields.

Output in bit-reversed order

Default: Off

- On: The output data stream is in bit-reversed order.
- Off: The output data stream is in natural order.

For more information about the effects of bit reversal, see "Linear and Bit-Reversed Output Order".

Display computed initial delay on mask

Default: Off

- On: The block icon displays the initial delay as Z^{-n}, where n is the delay time in samples.
- Off: The block icon does not display the initial delay.

Note: **Sine table**, **Product output**, **Accumulator**, and **Output** do not support:

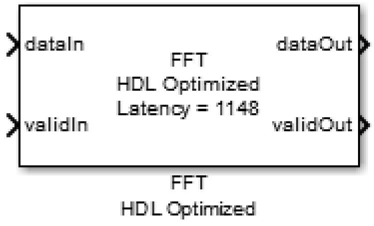
- Inherit via internal rule

- `Slope and bias scaling`

Introduced in R2014b

FFT HDL Optimized

Fast Fourier transform—optimized for HDL code generation



Library

Transforms

`dspxfrm3`

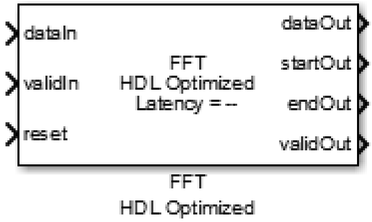
Description

The FFT HDL Optimized block implements a pipelined Radix 2^2 FFT algorithm that provides hardware speed and area optimization for streaming data applications. The block accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput using vector input.

The FFT HDL Optimized block replaces the `HDL Streaming FFT` block.

Signal Attributes

This FFT HDL Optimized block icon shows all optional ports.



Port	Direction	Description	Data Type
`dataIn`	Input	Scalar or column vector of real or complex input data. The vector size must be a power of 2 between 1 and 64, that is not greater than the FFT length.	• `fixdt()` • `int64/32/16/8` • `uint64/32/16/8` `double/single` are allowed for simulation but not for HDL code generation.
`validIn`	Input	Indicates that the input data is valid. When `validIn` is `true`, the block captures the value on `dataIn`.	`boolean`
`reset`	Input	Optional. Reset internal state. When `reset` is `true`, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `reset` is `false` and `validIn` starts a new frame.	`boolean`
`dataOut`	Output	Frequency channel output data. The output order is bit reversed by default.	Same as `dataIn`. If scaling is disabled, the word length grows by 2 bits per stage.
`validOut`	Output	Indicates that the output data is valid. The block sets `validOut` to `true` with each valid sample on `dataOut`.	`boolean`
`startOut`	Output	Optional. When this port is enabled, the block sets `startOut`	`boolean`

Port	Direction	Description	Data Type
		to `true`during the first valid cycle of a frame of output data.	
`endOut`	Output	Optional. When this port is enabled, the block sets `endOut` to `true` during the last valid cycle of a frame of output data.	`boolean`

Parameters

Main

Architecture

`Streaming Radix 2^2` (default) — An efficient architecture that has lower latency and uses fewer resources than the previous versions.

`Streaming Radix 2` — Versions before R2016a use this architecture. Use only for backward-compatibility purposes.

Complex Multiplication

Select the HDL implementation of complex multipliers. Each multiplication is implemented with either 3 multipliers and 5 adders, or 4 multipliers and 2 adders. Which option is faster or smaller depends on your synthesis tool and target device. This option applies only when you set **Architecture** to `Streaming Radix 2^2`.

Output in bit-reversed order

When you select this check box, the output elements are bit reversed relative to the input order. Clear the check box to output elements in linear order. By default, the check box is selected. The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so check only one of **Output in bit-reversed order** or **Input in bit-reversed order**. For more information, see “Linear and Bit-Reversed Output Order”.

Input in bit-reversed order

When you select this check box, the block expects input data in bit-reversed order. By default, the check box is clear and input is expected in linear order. The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so check only one of **Output in bit-reversed order** or **Input in bit-reversed order**. For more information, see “Linear and Bit-Reversed Output Order”.

Divide butterfly outputs by two

When you select this check box, the block implements an overall $1/N$ scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input. If scaling is disabled, the block avoids overflow by increasing the word length by 1 bit at each stage. By default, the check box is not selected.

FFT length

Specify the number of data points used for one FFT calculation. The default value is 1024. The FFT length must be a power of 2 between 2^3 and 2^{16} for HDL code generation.

Data Types

Rounding Method

The default rounding method for internal fixed point calculations is `Floor`. The FFT block uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is single or double type. Each stage rounds after the twiddle factor multiplication but before the butterflies.

Control Ports

Enable reset input port

When you select this check box, the `reset` port is present on the block icon. When `reset` is `true`, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `reset` is `false` and `validIn` starts a new frame. By default, the check box is not selected.

Enable start output port

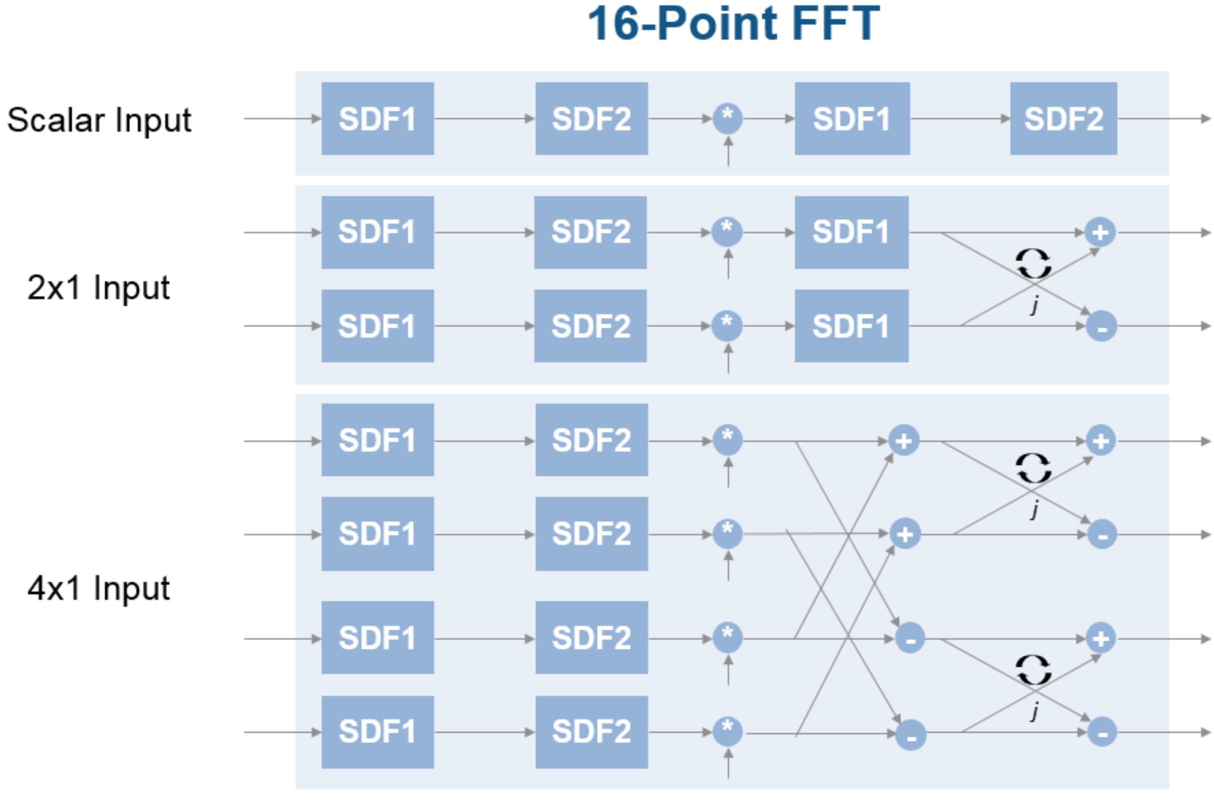
When you select this check box, the `startOut` port is present on the block icon, and this output signal is asserted (`true`) for the first cycle of an output frame. By default, the check box is not selected.

Enable end output port

When you select this check box, the `endOut` port is present on the block icon, and this output signal is asserted (`true`) for the last cycle of an output frame. By default, the check box is not selected.

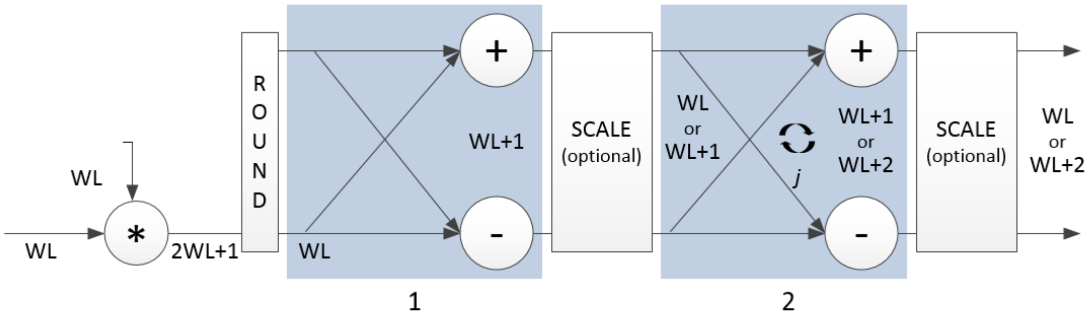
Algorithm

The Radix 2^2 architecture saves resources by factoring and grouping the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-path delay feedback (SDF) butterflies with memory controllers. If you use vector input, the results of twiddle factor multiplication are shared across multiple data points, without memory accesses.



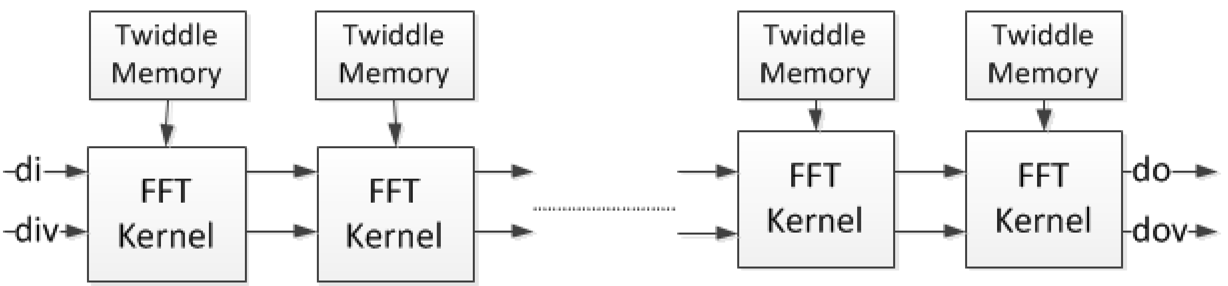
The first SDF stage is a regular butterfly, and the second stage multiplies by –*j* by swapping the real and imaginary parts of the input, and swapping the imaginary parts of the output. Each stage rounds the result of the twiddle factor multiplication to the input word length. This result is stored in memory for use by later stages. The twiddle factors have the same bit width as the input data. They use 2 integer bits and the remainder are fractional bits.

If you select **Divide butterfly outputs by two**, the block scales the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of $1/N$. If scaling is disabled, the block avoids overflow by increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.

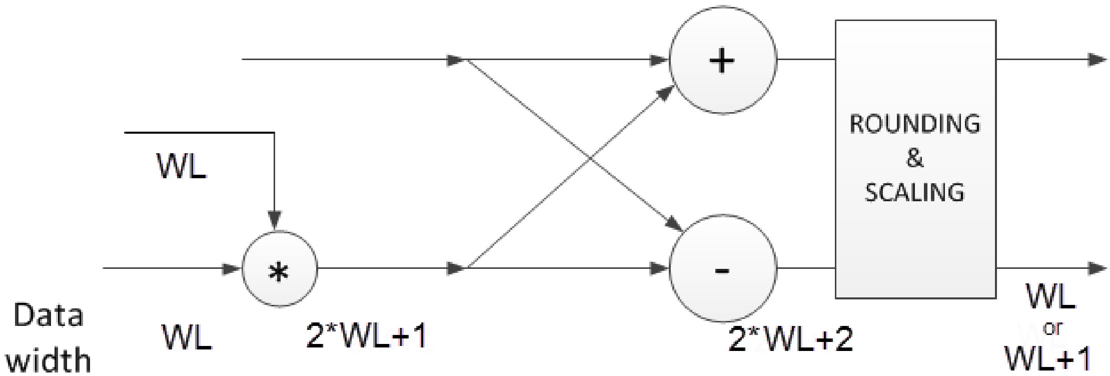


Radix 2 Architecture

In the Radix 2 architecture has $\log_2(N)$ pipeline stages. Each pipeline stage, or kernel, contains memory, a controller, and a complex Radix-2 butterfly.



Using decimation in time, each kernel multiplies by the twiddle factor and then adds samples in a butterfly. The kernel architecture minimizes the number of multipliers and adders. Within each kernel, data is processed in full precision. The kernel rounds to the output data width after the butterfly sum.



Control Signals

Input data is processed only when `validIn` is high. Output data is only valid when `validOut` is high.

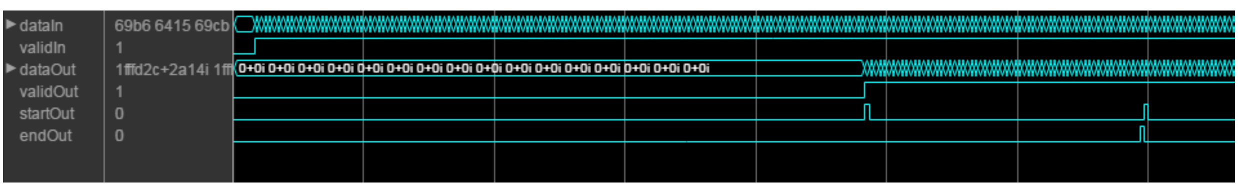
The block provides an optional reset port. When `reset` is high, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `reset` is low and `validIn` starts a new frame.

Timing Diagram

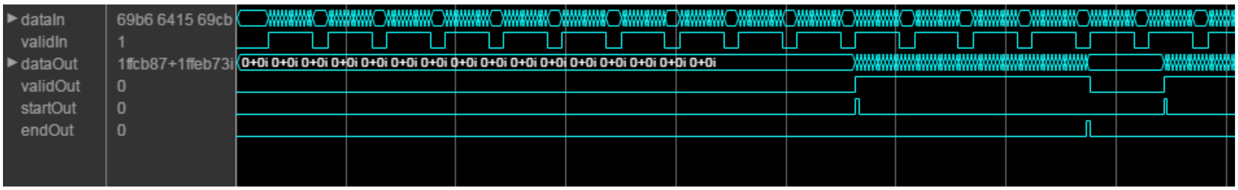
This diagram shows `validIn` and `validOut` signals for contiguous scalar input data and an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames, the output will also be continuous, after the initial latency.



The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is stored until a frame is filled, and output in a contiguous frame of *N* (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.



Latency

The latency varies with the FFT length and input vector size. After you update the model, the latency is displayed on the block icon. The displayed latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see FFT HDL Optimized in the HDL Coder documentation.

Performance

These resource and performance data are the synthesis results from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The three examples in the tables have this configuration:

- FFT length (default) — 1024
- Complex multiplication — 4 multipliers, 2 adders
- Output scaling — Enabled
- 16-bit complex input data
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, natural order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2^2 configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Uses
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2^2 implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Uses
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The Radix 2 implementation is supported with scalar input data only. The Radix 2 design achieves 295 MHz clock frequency. The latency is 1148 cycles. The design uses these resources.

Resource	Uses
LUT	4060
FFS	5160
Xilinx LogiCORE DSP48	16
Block RAM (16K)	6

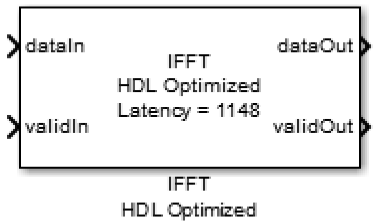
IFFT HDL Optimized

Inverse fast Fourier transform—optimized for HDL code generation



Library

Transforms

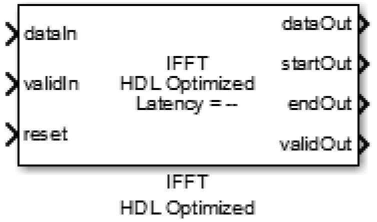
`dspxfrm3`

Description

The IFFT HDL Optimized block implements a pipelined Radix 2^2 IFFT algorithm that provides hardware speed and area optimization for streaming data applications. The block accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput using vector input.

Signal Attributes

This IFFT HDL Optimized block icon shows all optional ports available.



Port	Direction	Description	Data Type
`dataIn`	Input	Scalar or column vector of real or complex input data. The vector size must be a power of 2 between 1 and 64, that is not greater than the FFT length.	• `fixdt()` • `int64/32/16/8` • `uint64/32/16/8` `double/single` are allowed for simulation but not for HDL code generation.
`validIn`	Input	Indicates that the input data is valid. When `validIn` is `true`, the block captures the value on `dataIn`.	`boolean`
`reset`	Input	Optional. Reset internal state. When `reset` is `true`, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `reset` is `false` and `validIn` starts a new frame.	`boolean`
`dataOut`	Output	Frequency channel output data. The output order is bit reversed by default.	Same as `dataIn`. If scaling is disabled, the word length grows by 2 bits per stage.
`validOut`	Output	Indicates that the output data is valid. The block sets `validOut` to `true` with each valid sample on `dataOut`.	`boolean`
`startOut`	Output	Optional. When this port is enabled, the block sets `startOut`	`boolean`

Port	Direction	Description	Data Type
		to `true`during the first valid cycle of a frame of output data.	
`endOut`	Output	Optional. When this port is enabled, the block sets `endOut` to `true` during the last valid cycle of a frame of output data.	`boolean`

Parameters

Main

Architecture

`Streaming Radix 2^2` (default) — An efficient architecture that has lower latency and uses fewer resources than the previous versions.

`Streaming Radix 2` — Versions before R2016a use this architecture. Use only for backward-compatibility purposes.

Complex Multiplication

Select the HDL implementation of complex multipliers. Each multiplication is implemented with either 3 multipliers and 5 adders, or 4 multipliers and 2 adders. Which option is faster or smaller depends on your synthesis tool and target device. This option applies only if you set **Architecture** to `Streaming Radix 2^2`.

Output in bit-reversed order

When you select this check box, the output elements are bit reversed relative to the input order. Clear the check box to output elements in linear order. By default, the check box is selected. The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so check only one of **Output in bit-reversed order** or **Input in bit-reversed order**. For more information, see "Linear and Bit-Reversed Output Order".

Input in bit-reversed order

When you select this check box, the block expects input data in bit-reversed order. By default, the check box is clear and input is expected in linear order. The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so check only one of **Output in bit-reversed order** or **Input in bit-reversed order**. For more information, see "Linear and Bit-Reversed Output Order".

Divide butterfly outputs by two

When you select this check box, the block implements an overall $1/N$ scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the IFFT in the same amplitude range as its input. If scaling is disabled, the block avoids overflow by increasing the word length by 1 bit at each stage. By default, the check box is selected.

FFT length

Specify the number of data points used for one FFT calculation. The default value is 1024. The FFT length must be a power of 2 between 2^3 and 2^{16} for HDL code generation.

Data Types

Rounding Method

The default rounding method for internal fixed point calculations is `Floor`. The IFFT block uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is single or double type. Each stage rounds after the twiddle factor multiplication but before the butterflies.

Control Ports

Enable reset input port

When you select this check box, the `reset` port is present on the block icon. When `reset` is `true`, the block stops the current calculation and clears all internal state. The block begins fresh calculations when `reset` is `false` and `validIn` starts a new frame. By default, the check box is not selected.

Enable start output port

When you select this check box, the `startOut` port is present on the block icon, and this output signal is asserted (`true`) for the first cycle of an output frame. By default, the check box is not selected.

Enable end output port

When you select this check box, the endOut port is present on the block icon, and this output signal is asserted (true) for the last cycle of an output frame. By default, the check box is not selected.

Algorithm

The IFFT HDL Optimized block implements a pipelined Radix 2^2 (or Radix 2) algorithm. It implements the reverse function of the FFT HDL Optimized block. For more information, refer to the FFT HDL Optimized block page.

Control Signals

Input data is processed only when validIn is high. Output data is only valid when validOut is high.

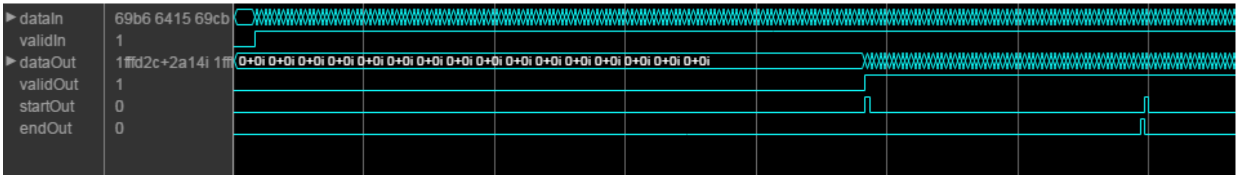
The block provides an optional reset port. When reset is high, the block stops the current calculation and clears all internal state. The block begins fresh calculations when reset is low and validIn starts a new frame.

Timing Diagram

This diagram shows validIn and validOut signals for contiguous scalar input data and an FFT length of 1024, and a vector size of 16.

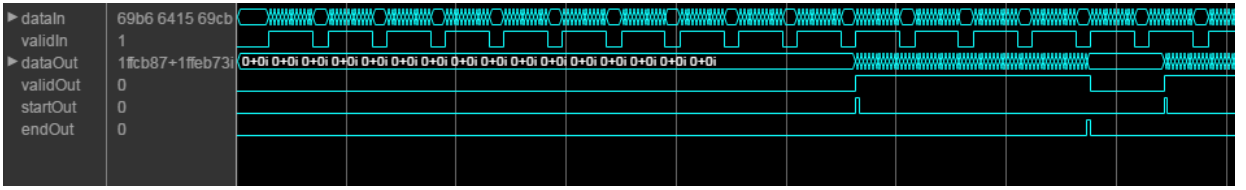
The diagram also shows the optional startOut and endOut signals that indicate frame boundaries. If you enable startOut, it pulses for one cycle with the first validOut of the frame. If you enable endOut, it pulses for one cycle with the last validOut of the frame.

If you apply continuous input frames, the output will also be continuous, after the initial latency.



The validIn signal can be noncontiguous. Data accompanied by a validIn signal is stored until a frame is filled, and output in a contiguous frame of N (FFT length) cycles.

This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.



Latency

The latency varies with the FFT length and input vector size. After you update the model, the latency is displayed on the block icon. The displayed latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see IFFT HDL Optimized in the HDL Coder documentation.

Performance

These resource and performance data are the synthesis results from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The three examples in the tables have this configuration:

- FFT length (default) — 1024
- Complex multiplication — 4 multipliers, 2 adders
- Output scaling — Enabled
- 16-bit complex input data
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, natural order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2^2 configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Uses
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2^2 implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Uses
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The Radix 2 implementation is supported with scalar input data only. The Radix 2 design achieves 295 MHz clock frequency. The latency is 1148 cycles. The design uses these resources.

Resource	Uses
LUT	4060
FFS	5160
Xilinx LogiCORE DSP48	16
Block RAM (16K)	6

dsp.HDLIFFT | `FFT HDL Optimized` | `IFFT`

Introduced in R2014a

Highpass Filter

Design FIR or IIR highpass filter

Library

Filtering / Filter Designs

`dspfdesign`

Description

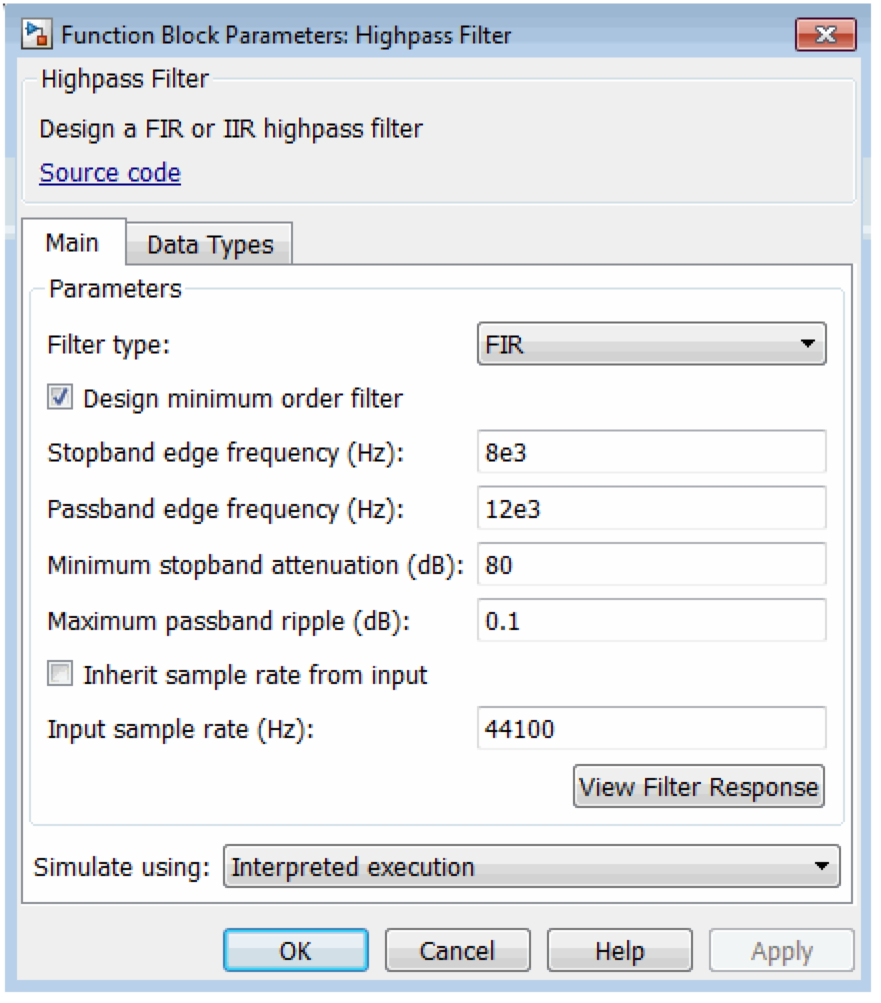
The Highpass Filter block independently filters each channel of the input signal over time using the given design specifications.

You can set the **Filter type** parameter of the block to design to implement the block as an FIR or IIR highpass filter. The block designs the filter based on the parameters specified in the block dialog box.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The block supports fixed-point operations, HDL code generation, and ARM Cortex code generation. To learn more about ARM Cortex code generation, see “ARM Cortex-M and ARM Cortex-A Optimization”

Dialog Box

Main Tab



Filter type

Type of highpass filter.

- `FIR` (default) — Design an FIR highpass filter.
- `IIR` — Design an IIR highpass filter.

Design minimum order filter

When you select this check box, the block designs a filter with the minimum order that the specified passband, stopband frequency, passband ripple, and stopband attenuation. Set these specifications using the corresponding parameters. When you clear this check box, specify the order of the filter in **Filter order**.

By default, this check box is selected.

Filter order

Filter order of highpass filter, specified as a positive scalar integer. You can specify a filter order only when the **Design minimum order filter** check box is not cleared. The default is `50`.

Stopband edge frequency (Hz)

Stopband edge frequency of the highpass filter, specified as a real positive scalar in Hz. The value of the stopband edge frequency in Hz must be less than the passband frequency. You can specify the stopband edge frequency only when the **Design minimum order filter** check box is selected. The default is `8e3`.

Passband edge frequency (Hz)

Passband edge frequency of the highpass filter, specified as a real positive scalar in Hz. The passband edge frequency must be less than half the value of the **Input sample rate (Hz)** and greater than the value of the **Stopband edge frequency (Hz)**. The default is `12e3`.

Minimum stopband attenuation (dB)

Minimum attenuation in the stopband, specified as a real positive scalar in dB. The default is `80`.

Maximum passband ripple (dB)

Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB. The default is `0.1`.

Inherit sample rate from input

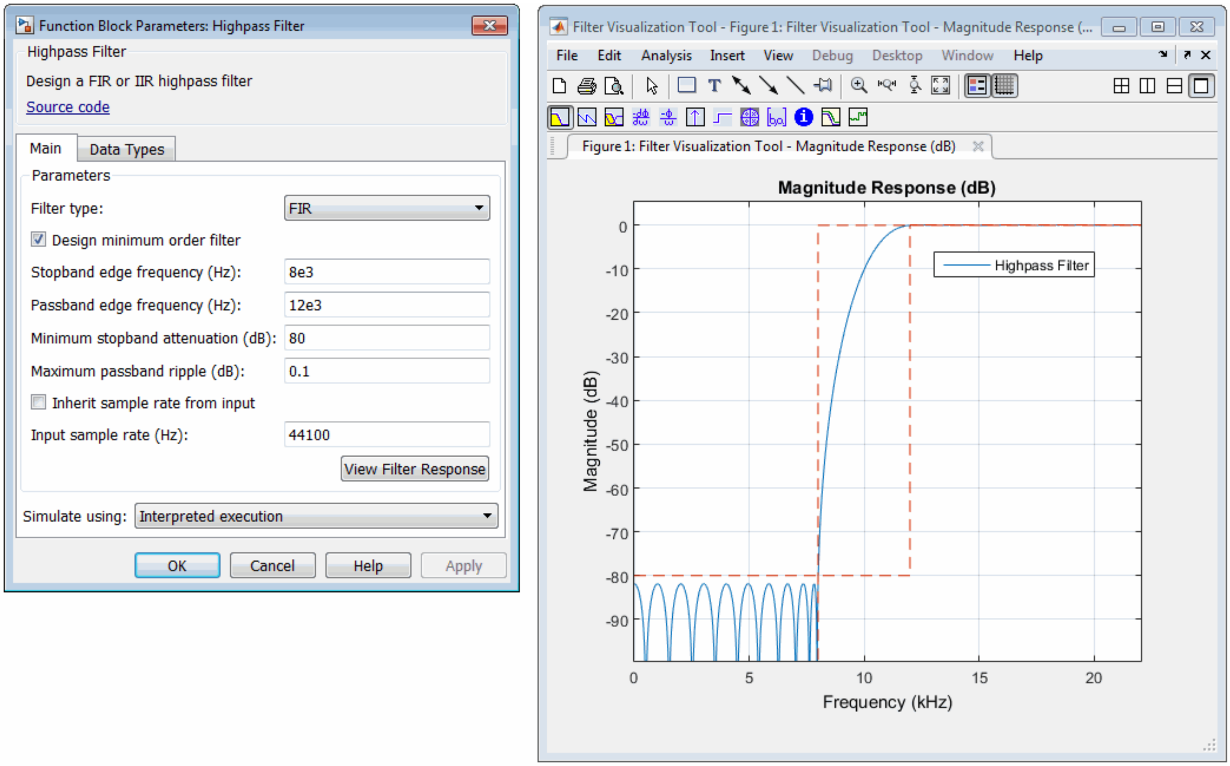
When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is `44100`.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Highpass Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

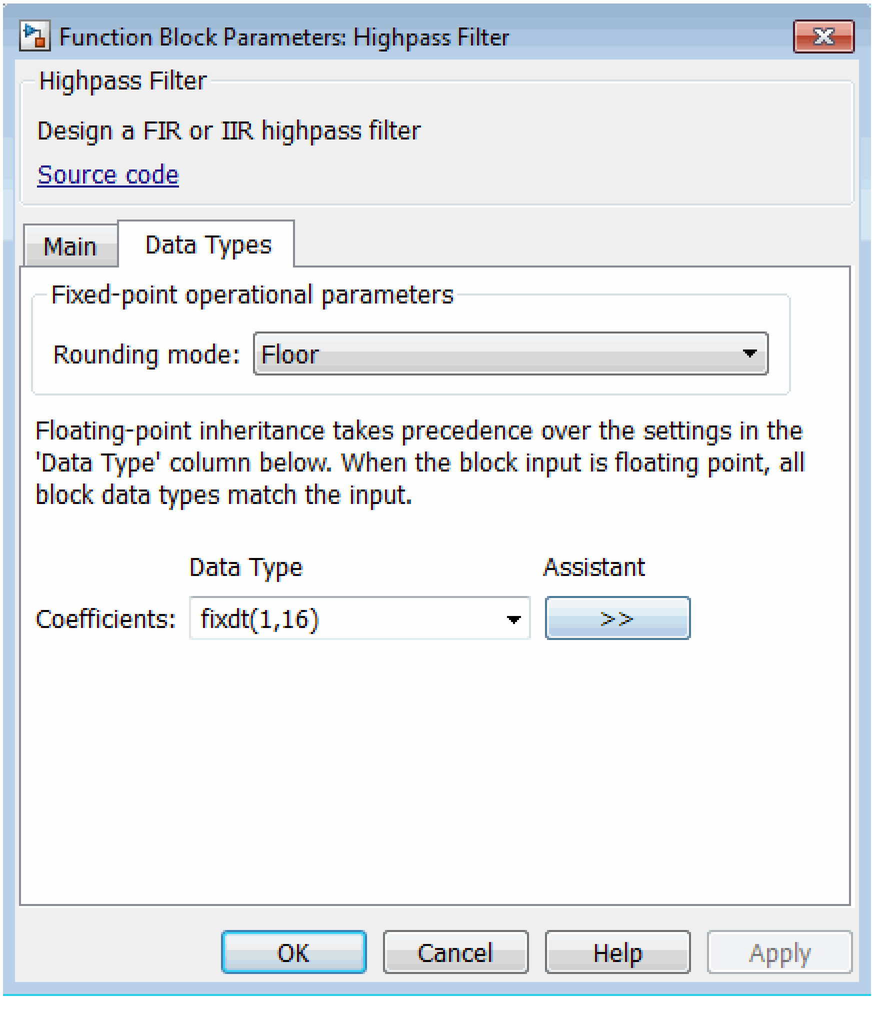
- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

- `Code generation`

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16` and fraction length, `0`. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16, 15)`). Specify the sign mode of this data type as `[ ]` or `true`.
- `Refresh Data Type` — Refresh to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

Decimation Factor

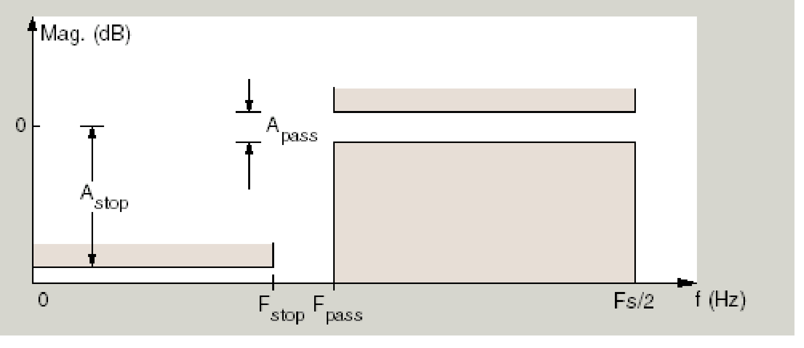
Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, the region between specification values Fstop and Fpass represents the transition region where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Stopband edge and passband edge` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edge` — Define the filter by specifying the edge of the passband.
- `Stopband edge` — Define the filter by specifying the edge of the stopband.
- `Stopband edge and 3 dB point` — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the stopband.
- `3 dB point` — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- `3 dB point and passband edge` — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the passband.
- `6 dB point` — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F3dB

When **Frequency constraints** is `3 dB point`, `Stopband edge and 3 dB point`, or `3 dB point and passband edge`, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

F6dB

When **Frequency constraints** is `6 dB point`, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, `Passband ripple`, `Passband ripple and stopband attenuation` or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterbuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

FIR Type

Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select either `3` or `4` from the drop-down list.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use `Direct-form FIR`, and IIR filters use `Cascade minimum-multiplier allpass`.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

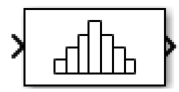
Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2006b

Histogram

Histogram of input or sequence of inputs

Library: DSP System Toolbox / Statistics



Description

The Histogram block computes the frequency distribution of the input elements along each column or along the entire input. You can specify the dimension using the **Find the histogram over** parameter. The block distributes the input elements based on their value into a number of discrete bins, which you specify through the **Number of bins** parameter. Specify the highest input value that the histogram can bin through the **Upper limit of histogram** parameter, B_M. Specify the lowest value through the **Lower limit of histogram** parameter, B_m. The width of each bin is equal and is given by:

$$\Delta = \frac{B_M - B_m}{n}$$

Each bin is centered at the following location:

$$B_m + \left(k + \frac{1}{2}\right)\Delta \qquad\qquad k = 0,1,2,\ldots,n-1$$

When the input data is real, the bin boundaries are cast into the double data type. When the input data is complex, bin boundaries for double-precision inputs are cast into the data type double and bin boundaries for integer inputs are cast into data type double and squared.

To track the frequency distribution of inputs over a period of time, select the **Running histogram** parameter.

When the input is complex, the block sorts the elements according to their magnitude.

Ports

Input

`In` — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

This port is unnamed until you select the **Running histogram** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

`Rst` — Reset port

scalar

Specify the reset event that causes the block to reset the running histogram. The reset signal and the input data signal must have the same rate.

Dependencies

To enable this port, select the **Running histogram** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — Histogram output

vector | matrix | *N*-D array

When you do not select the **Running histogram** parameter, the blocks computes the frequency distribution in each column of the input, or along the entire input. Consider a two-dimensional input signal of size *M*-by-*N*.

When you set **Find the histogram over** to:

- `Each column` — The block computes a histogram for each column of the input. The output is an n-by-N matrix, where n is the **Number of bins** you specify. The jth column of the output matrix contains the histogram for the data in the jth column of the M-by-N input matrix.
- `Entire input` — The block computes a histogram for the entire input vector, matrix, or N-D array. The output is an n-by-1 vector, where n is the **Number of bins** you specify.

When you select the **Running histogram** parameter, the block computes the frequency distribution of all inputs over a period of time. In this case, when you set **Find the histogram over** to:

- `Each column` — The block computes a running histogram for each column of the input. The output is an n-by-N matrix, where n is the **Number of bins** you specify. The jth column of the output matrix contains the running histogram for the data in the jth column of the M-by-N matrix input.
- `Entire input` — The block computes the running histogram for the entire input vector, matrix, or N-D array. The output is an n-by-1 vector, where n is the **Number of bins** you specify.

The output data type is `uint32` when the input has a data type other than `single` or `double`. The largest number that can be represented by `uint32` is $2^{32}-1$. If the range of any input exceeds this value, the block wraps the value back to `0`.

Data Types: `single` | `double` | `uint32`

Parameters

Main Tab

`Lower limit of histogram` — Lower boundary of the lowest-valued bin

scalar

Specify the lower boundary of the lowest-valued bin as a real scalar. This parameter does not accept `NaN` or `Inf`. If the input has a value less than **Lower limit of histogram**, the block places this element in the lowest-valued bin.

`Upper limit of histogram` — Upper boundary of the highest-valued bin
scalar

Specify the upper boundary of the highest-valued bin as a real scalar. This parameter does not accept `NaN` or `Inf`. If the input has a value greater than **Upper limit of histogram**, the block places this element in the highest-valued bin.

`Number of bins` — Number of histogram bins
positive integer

Specify the number of histogram bins as a positive integer.

`Find the histogram over` — Dimension over which the block computes the histogram
`Each column` (default) | `Entire input`

When you do not select the **Running histogram** parameter and you set **Find the histogram over** parameter to:

- `Each column` — The block computes the histogram over each column.
- `Entire input` — The block outputs the histogram over the entire input.

When you select the **Running histogram** parameter and you set **Find the histogram over** parameter to:

- `Each column` — The block computes the running histogram over each column.
- `Entire input` — The block outputs the running histogram over the entire input.

`Normalized` — Number of histogram bins
off (default) | on

When you select this parameter, the block output, y, is normalized, that is, `sum(y) = 1`. This parameter does not apply for fixed-point input signals.

`Running histogram` — Option to select running histogram
off (default) | on

When you select this parameter, the block tracks the frequency distribution of inputs over a period of time.

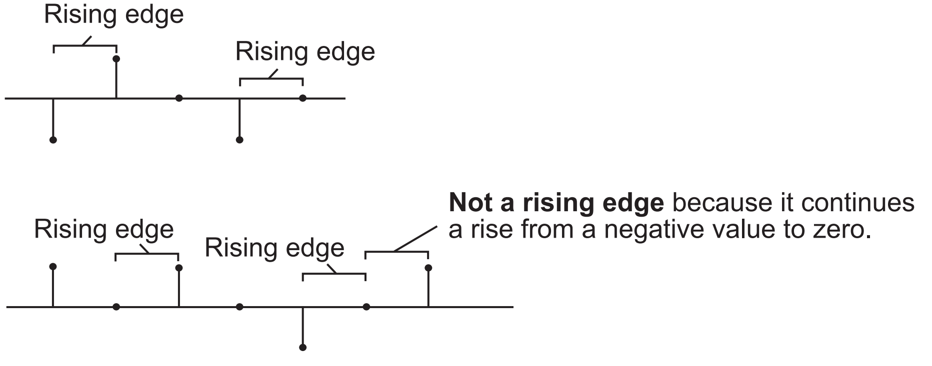
`Reset port` — Reset event
`Non-zero sample` (default) | `None` | `Rising edge` | `Falling edge` | `Either edge` |

The block resets the running histogram and empties all the bins whenever a reset event is detected at the optional **Rst** port. The reset sample time must equal the input sample time.

Use this parameter to specify the reset event.

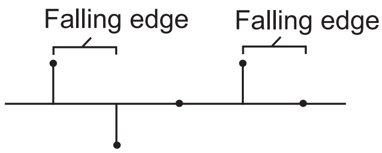
- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.
- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:

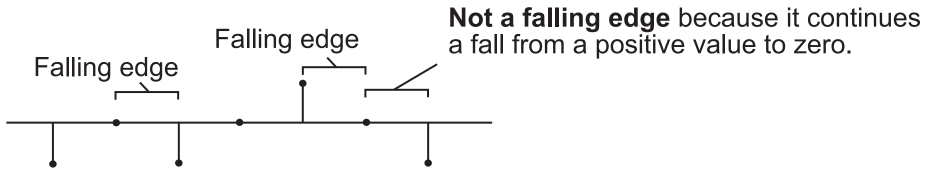
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:

  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.





- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.

Note: When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running histogram** parameter.

Data Types Tab

Note: To use these parameters, the data input must be complex and fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

`Overflow mode` — Method of overflow action

`Wrap` (default) | `Saturate`

Select the overflow mode for fixed-point operations.

`Product output` — Product output data type

`Inherit: Same as input` (default) | `fixdt([],16,0)`

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Same as input` (default) | `Inherit: Same as product output` | `fixdt([],16,0)`

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Model Examples

Algorithms

Histogram

The histogram value for a given bin represents the frequency of occurrence of the input values bracketed by that bin. **Upper limit of histogram** specifies the upper boundary of the highest-valued bin, B_M. **Lower limit of histogram** specifies the lower boundary of the lowest-valued bin, B_m. The bins have equal width, given by:

$$\Delta = \frac{B_M - B_m}{n}$$

The bins are centered at the following location:

$$B_m + \left(k + \frac{1}{2}\right)\Delta \qquad\qquad k = 0,1,2,...,n-1$$

n is the number of bins, specified through the **Number of bins** parameter.

Input values that fall on the border between two bins are placed into the lower valued bin. Each bin includes its upper boundary. For example, a bin of width 4 centered on the value 5 contains the input value 7, but not 3. Input values greater than the **Upper limit of histogram** parameter are placed in the highest valued bin. Similarly, values less than the **Lower limit of histogram** parameter are placed in the lowest valued bin.

The block sorts the complex data into bins according to the magnitude of the data. The magnitude is computed by taking the sum of the squares of the real and imaginary components of the complex data.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

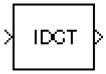
IDCT

Inverse discrete cosine transform (IDCT) of input



Library

Transforms

`dspxfrm3`

Description

The IDCT block computes the inverse discrete cosine transform (IDCT) of each channel in the M-by-N input matrix, `u`.

```
y = idct(u)     % Equivalent MATLAB code
```

For all N-D input arrays, the block computes the IDCT across the first dimension. The size of the first dimension (frame size), must be a power of two. To work with other frame sizes, use the `Pad` block to pad or truncate the frame size to a power-of-two length.

When the input is an M-by-N matrix, the block treats each input column as an independent channel containing M consecutive samples. The block outputs an M-by-N matrix whose lth column contains the length-M IDCT of the corresponding input column.

$$y(m,l) = \sum_{k=1}^{M} w(k)u(k,l)\cos\frac{\pi(2m-1)(k-1)}{2M}, \qquad m = 1,\ldots,M$$

where

$$w(k) = \begin{cases} \dfrac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\dfrac{2}{M}}, & 2 \le k \le M \end{cases}$$

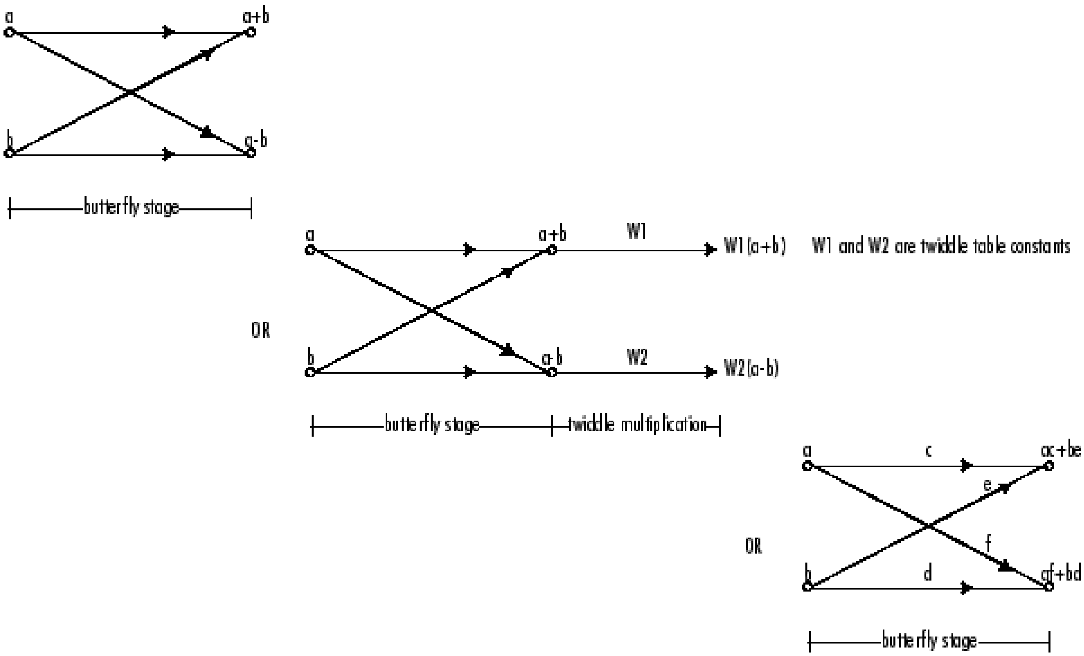
The **Sine and cosine computation** parameter determines how the block computes the necessary sine and cosine values. This parameter has two settings, each with its advantages and disadvantages, as described in the following table.

Sine and Cosine Computation Parameter Setting	Sine and Cosine Computation Method	Effect on Block Performance
`Table lookup`	The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.	The block usually runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.
`Trigonometric fcn`	The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.	The block usually runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

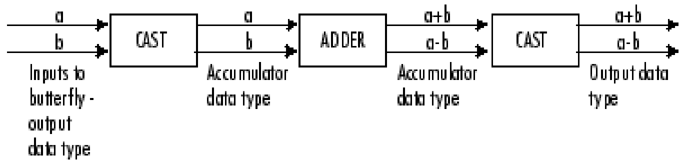
Fixed-Point Data Types

The following diagrams show the data types used within the IDCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IDCT block dialog as discussed in “Dialog Box” on page 2-940.

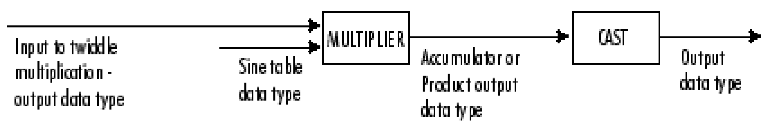
Inputs to the IDCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.



Butterfly Stage Data Types



Twiddle Multiplication Data Types

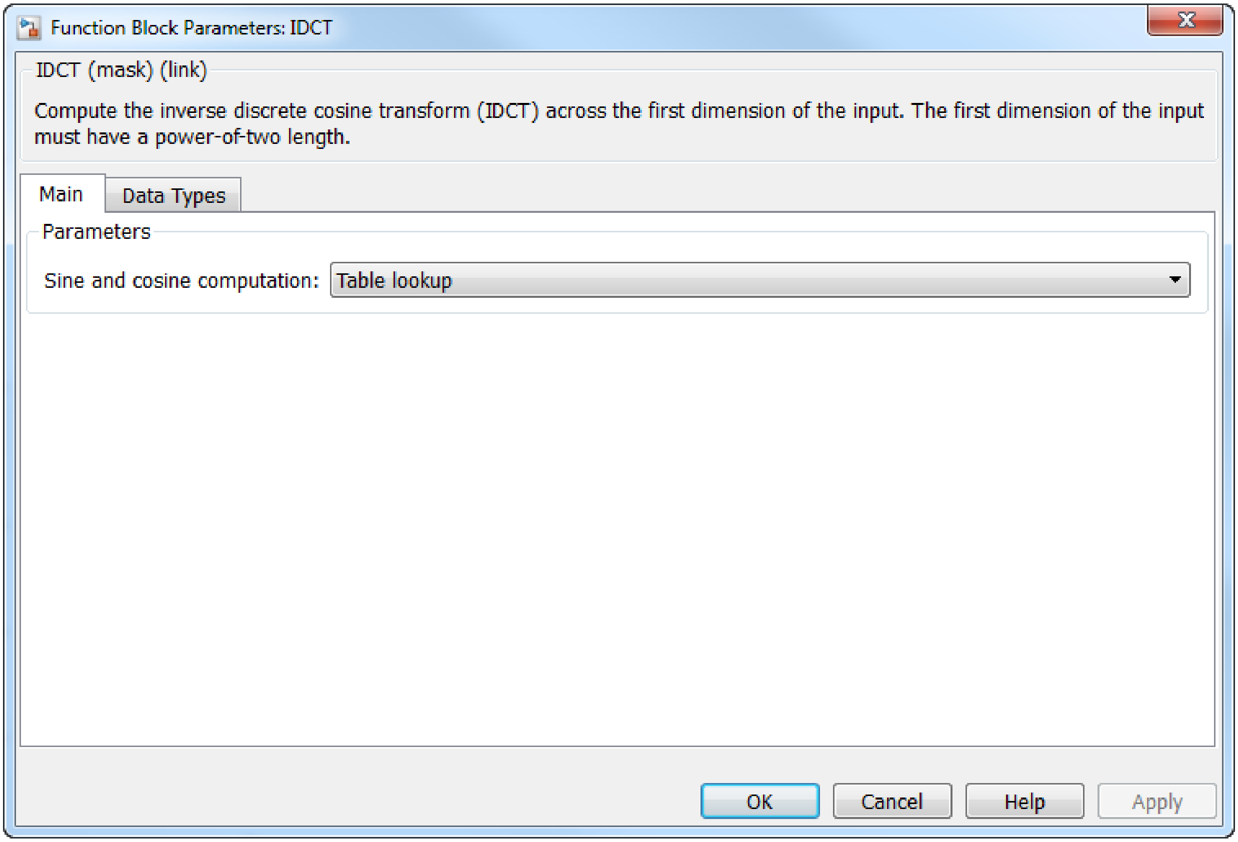


The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

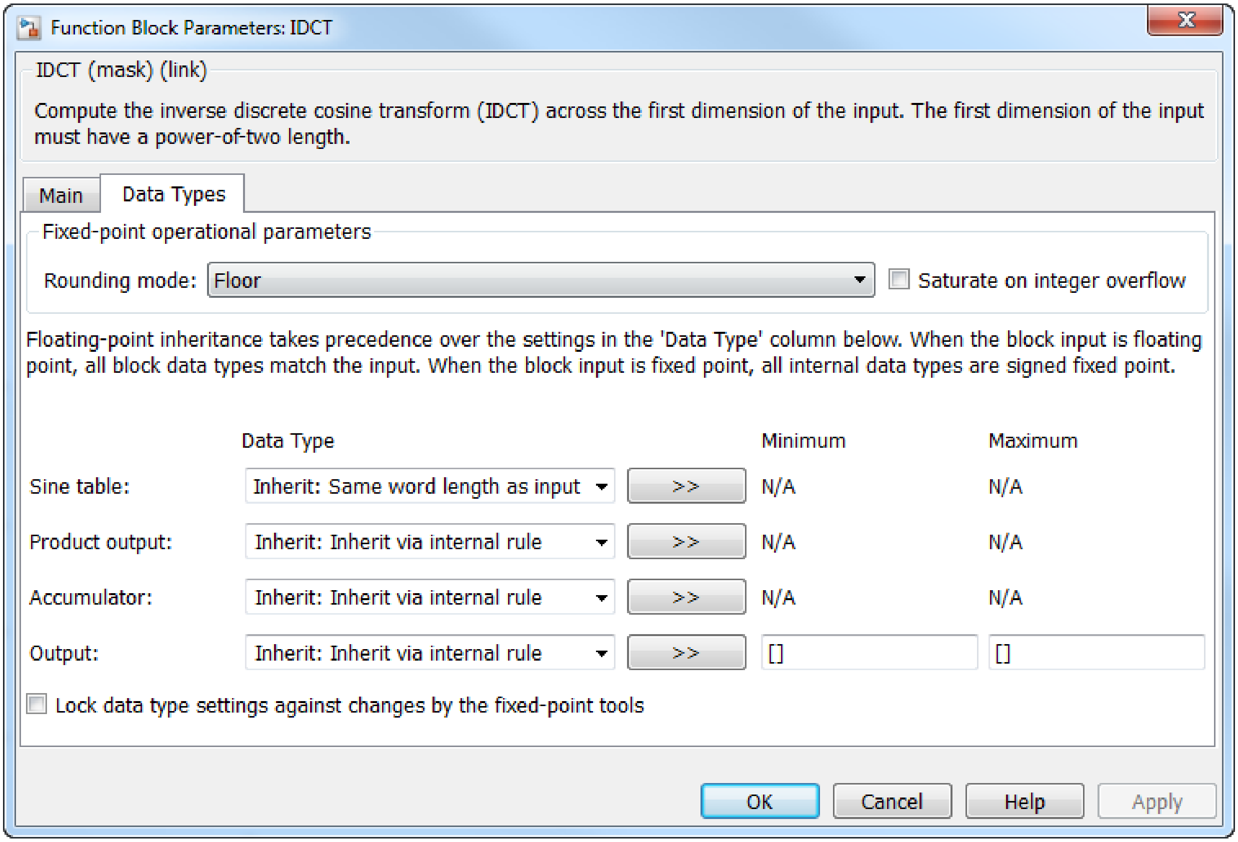
The **Main** pane of the IDCT block dialog appears as follows.



Sine and cosine computation

Sets the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (`Table lookup`), or by making sine and cosine function calls (`Trigonometric fcn`). See the table in the "Description" on page 2-937 section.

The **Data Types** pane of the IDCT block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; they always round to `Nearest`.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-938 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-938 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-938 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(DCT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see "Signal Ranges" (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

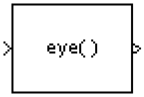
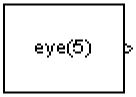
Identity Matrix

Generate matrix with ones on main diagonal and zeros elsewhere





Library

- Sources

  `dspsrcs4`
- Math Functions / Matrices and Linear Algebra / Matrix Operations

  `dspmtrx3`

Description

The Identity Matrix block generates a rectangular matrix with ones on the main diagonal and zeros elsewhere.

When you select the **Inherit output port attributes from input port** check box, the input port is enabled, and an *M*-by-*N* matrix input generates an *M*-by-*N* matrix output with the same sample period as the input. The values in the input matrix are ignored.

```
y = eye([M N])      % Equivalent MATLAB code
```

When you do not select the **Inherit output port attributes from input port** check box, the input port is disabled, and the dimensions of the output matrix are determined by the **Matrix size** parameter. A scalar value, *M*, specifies an *M*-by-*M* identity matrix, while a two-element vector, [*M N*], specifies an *M*-by-*N* unit-diagonal matrix. You can specify the output sample period using the **Sample time** parameter.

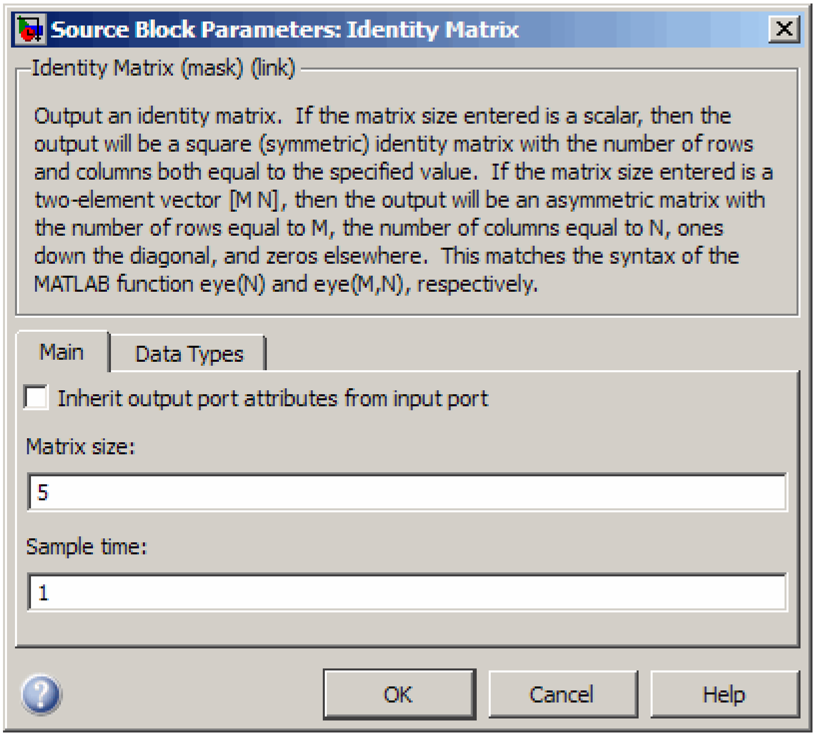
Examples

Set **Matrix size** to `[3 6]` to generate the 3-by-6 unit-diagonal matrix below.

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

Dialog Box

The **Main** pane of the Identity Matrix block dialog appears as follows.



Inherit output port attributes from input port

Enables the input port when selected. In this mode, the output inherits its dimensions, sample period, and data type from the input. The output is always real.

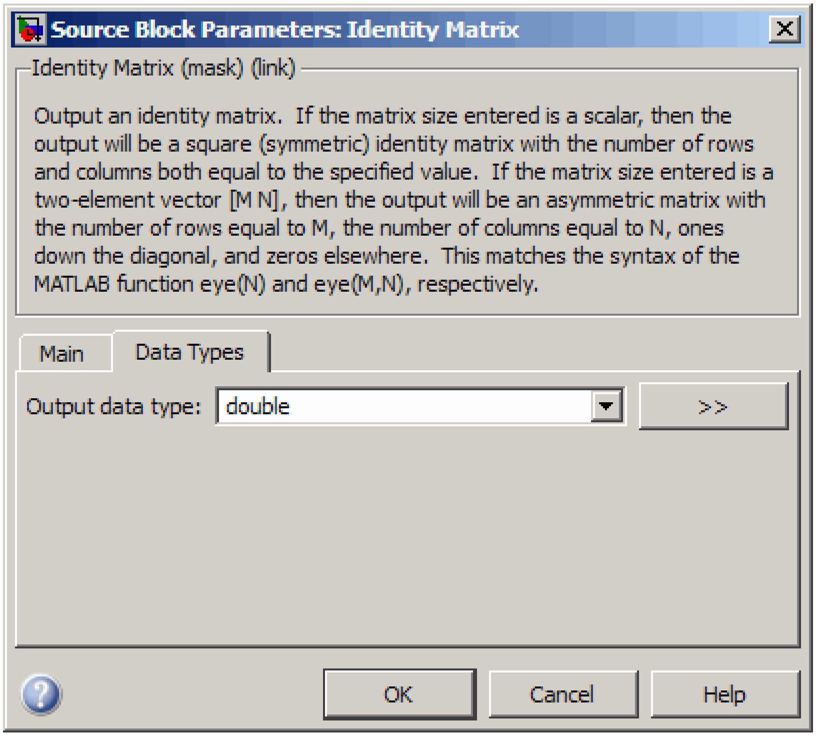
Matrix size

The number of rows and columns in the output matrix: a scalar *M* for a square *M*-by-*M* output, or a vector [*M N*] for an *M*-by-*N* output. This parameter is disabled when you select **Inherit input port attributes from input port**.

Sample time

The discrete sample period of the output. This parameter is disabled when you select **Inherit input port attributes from input port**.

The **Data Types** pane of the Identity Matrix block dialog appears as follows.



Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

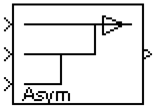
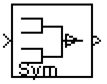
IDWT

Inverse discrete wavelet transform (IDWT) of input or reconstruct signals from subbands with smaller bandwidths and slower sample rates





Library

Transforms

`dspxfrm3`

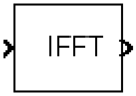
Description

The IDWT block is the same as the Dyadic Synthesis Filter Bank block in the Multirate Filters library, but with different default settings. See the `Dyadic Synthesis Filter Bank` block reference page for more information on how to use the block.

Introduced before R2006a

IFFT

Inverse fast Fourier transform (IFFT) of input



Library

Transforms

`dspxfrm3`

Description

The IFFT block computes the inverse fast Fourier transform (IFFT) across the first dimension of an *N-D* input array.

When you specify an FFT length not equal to the length of the input vector, (or first dimension of the input array), the block implements zero-padding, truncating, or modulo-*M*, (FFT length) data wrapping. This occurs before the IFFT operation.

```
y = ifft(u,M)  % P ≤ M
```

Wrapping:

```
y(:,l) = ifft(datawrap(u(:,l),M))  % P > M; l = 1,...,N
```

Truncating:

```
y (:,l) = ifft(u,M)     % P > M; l = 1,...,N
```

When the input length, *P*, is greater than the FFT length, *M*, you may see magnitude increases in your IFFT output. These magnitude increases occur because the IFFT block uses modulo-*M* data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample, *P*, to the FFT length, *M*. To do so, place a `Pad` block before the IFFT block in your model.

The kth entry of the lth output channel, $y(k, l)$, is equal to the kth point of the M-point inverse discrete Fourier transform (IDFT) of the lth input channel:

$$y(k,l) = \frac{1}{M}\sum_{p=1}^{P} u(p,l)e^{j2\pi(p-1)(k-1)/M} \qquad k = 1,\ldots,M$$

The output of this block has the same dimensions as the input. If the input signal has a floating-point data type, the data type of the output signal uses the same floating-point data type. Otherwise, the output can be any fixed-point data type. The block computes scaled and unscaled versions of the IFFT.

The input to this block can be floating-point or fixed-point, real or complex, and conjugate symmetric. The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library or an implementation based on a collection of Radix-2 algorithms. You can select `Auto` to allow the block to choose the implementation.

FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation will be restricted to MATLAB host computers. The data type must be floating-point. Refer to Simulink Coder for more details on generating code.

Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension M of the M-by-N input matrix, must be a power of two. To work with other input sizes, use the `Pad` block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

Radix-2 Algorithms for Real or Complex Input Complexity

Parameter Settings	Algorithms Used for IFFT Computation
☐ Input is in bit-reversed order ☐ Input is conjugate symmetric	Bit-reversal operation and radix-2 DIT
☑ Input is in bit-reversed order ☐ Input is conjugate symmetric	Radix-2 DIT
☐ Input is in bit-reversed order ☑ Input is conjugate symmetric	Bit-reversal operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms
☑ Input is in bit-reversed order ☑ Input is conjugate symmetric	Radix-2 DIT in conjunction with the half-length and double-signal algorithms

Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block's Radix–2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

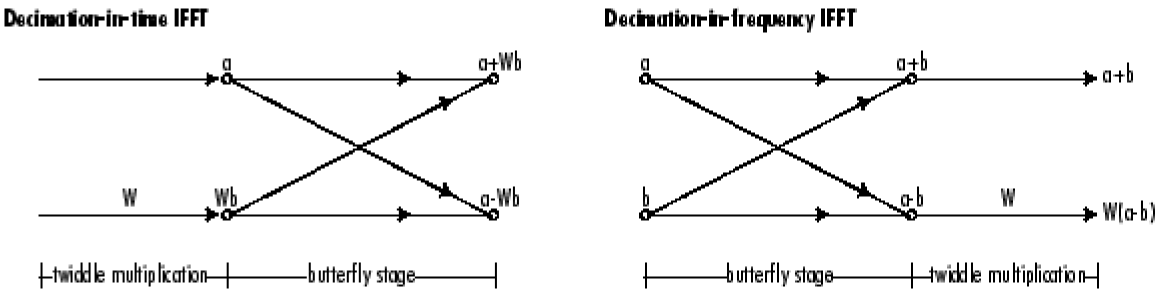
where K is the greater value of either M or N and $k = 0,\cdots,K-1$. The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

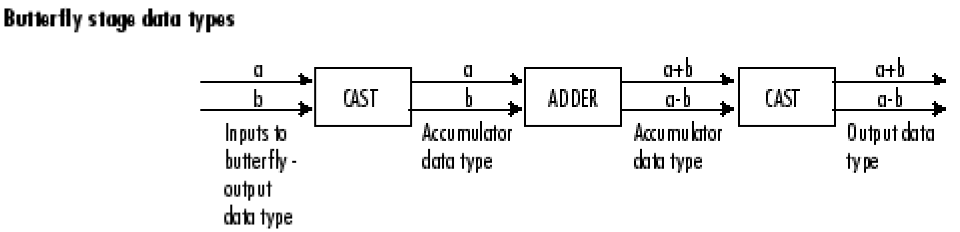
Number of Table Entries for N-Point FFT	
floating-point	3 N/4
fixed-point	N

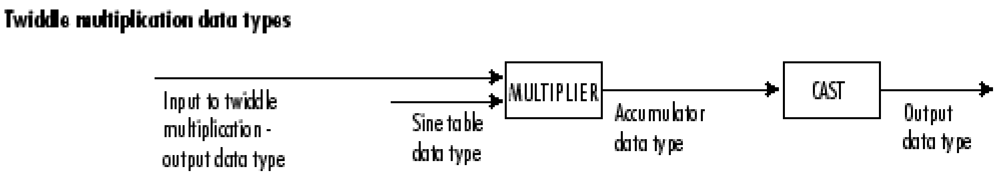
Fixed-Point Data Types

The following diagrams show the data types used in the IFFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IFFT dialog box as discussed in "Dialog Box" on page 2-957.

Inputs to the IFFT block are first cast to the output data type and stored in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time IFFT and after each butterfly stage in a decimation-in-frequency IFFT.





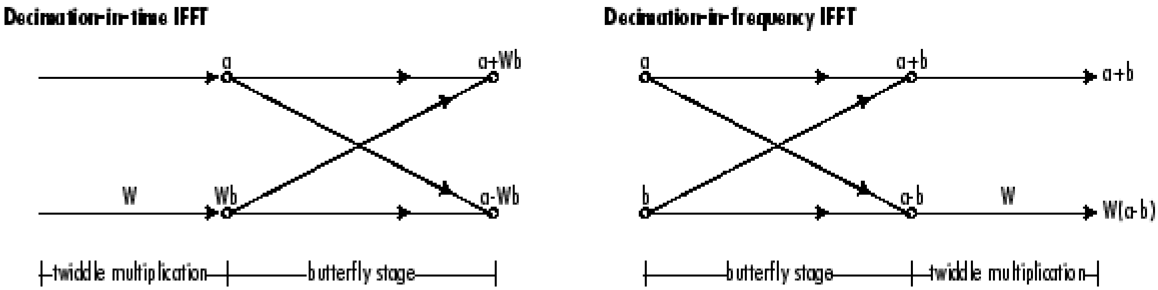


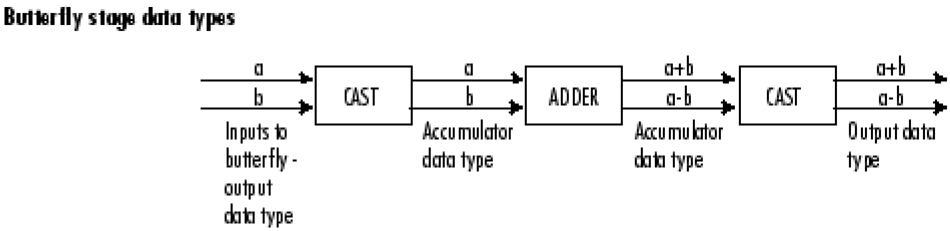
The multiplier output appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, refer to “Multiplication Data Types”.

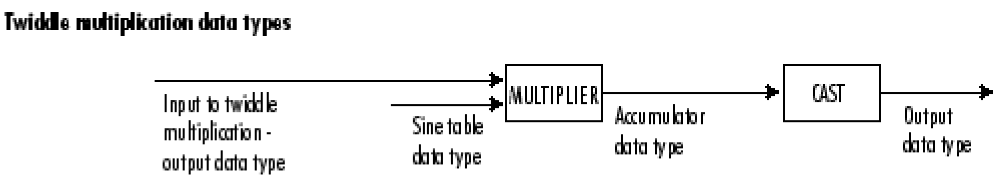
Fixed-Point Data Types

The following diagrams show the data types used within the IFFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IFFT block dialog, as discussed in "Dialog Box" on page 2-957.

The IFFT block first casts input to the output data type and then stores it in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time IFFT, and after each butterfly stage in a decimation-in-frequency IFFT.





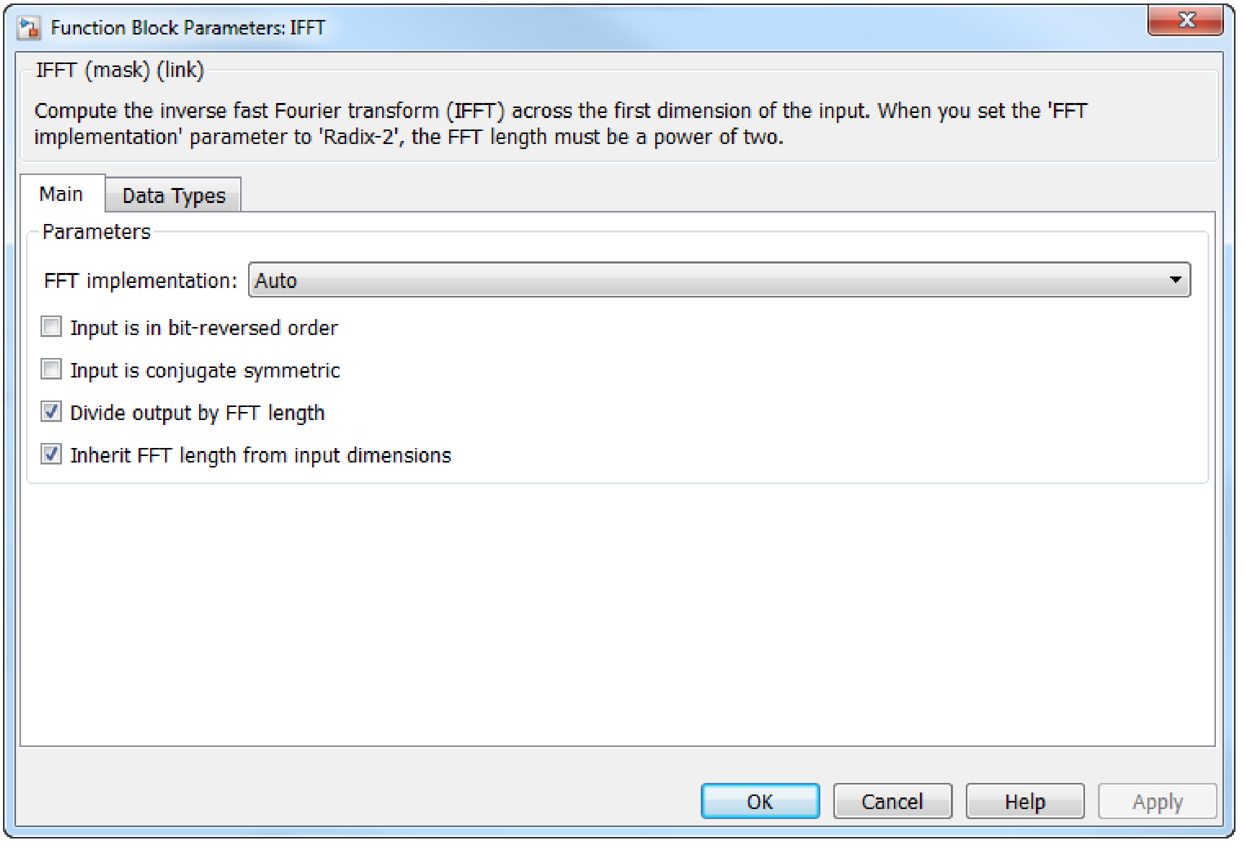


The output of the multiplier is in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

Note: When the block input is fixed point, all internal data types are signed fixed point.

Dialog Box

The **Main** pane of the IFFT block dialog appears as follows.



FFT implementation

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The dimension M of the M-by-N input matrix, must be a power of two. To work with other input sizes, use the `Pad` block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation. See "Radix-2 Implementation" on page 2-952.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Input is in bit-reversed order

Select or clear this check box to designate the order of the input channel elements. Select this check box when the input should appear in reversed order, and clear it when the input should appear in linear order. The block yields invalid outputs when you do not set this parameter correctly. This check box only appears when you set the **FFT implementation** parameter to `Radix-2` or `Auto`.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter. Also, it cannot be selected when you set the **FFT implementation** parameter to `FFTW`.

For more information on ordering of the output, see "Linear and Bit-Reversed Output Order".

Input is conjugate symmetric

Select this option when the block inputs conjugate symmetric data and you want real-valued outputs. Selecting this check box optimizes the block's computation method.

The FFT block yields conjugate symmetric output when you input real-valued data. Taking the IFFT of a conjugate symmetric input matrix produces real-valued output. Therefore, if the input to the block is both floating point and conjugate symmetric, and you select this check box, the block produces real-valued outputs.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter.

If you input conjugate symmetric data to the IFFT block and do not select this check box, the IFFT block outputs a complex-valued signal with small imaginary parts. The block outputs invalid data if you select this option with non conjugate symmetric input data.

Divide output by FFT length

When you select this check box, the block computes its output according to the IDFT equation, discussed in the Description section.

When you clear this check box, the block computes the output using a modified version of the IDFT: $M \cdot y(k,l)$, which is defined by the following equation:

$$M \cdot y(k,l) = \sum_{p=1}^{P} u(p,l) e^{j2\pi(p-1)(k-1)/M} \quad k = 1,\ldots,M$$

Notice, the modified IDFT equation does not include the multiplication factor of 1/*M*.

Inherit FFT length from input dimensions

Select to inherit the FFT length from the input dimensions. If you do not select this parameter, the **FFT length** parameter becomes available to specify the length. You cannot clear this parameter when you select either the **Input is in bit-reversed order** or the **Input is conjugate symmetric** parameter.

FFT length

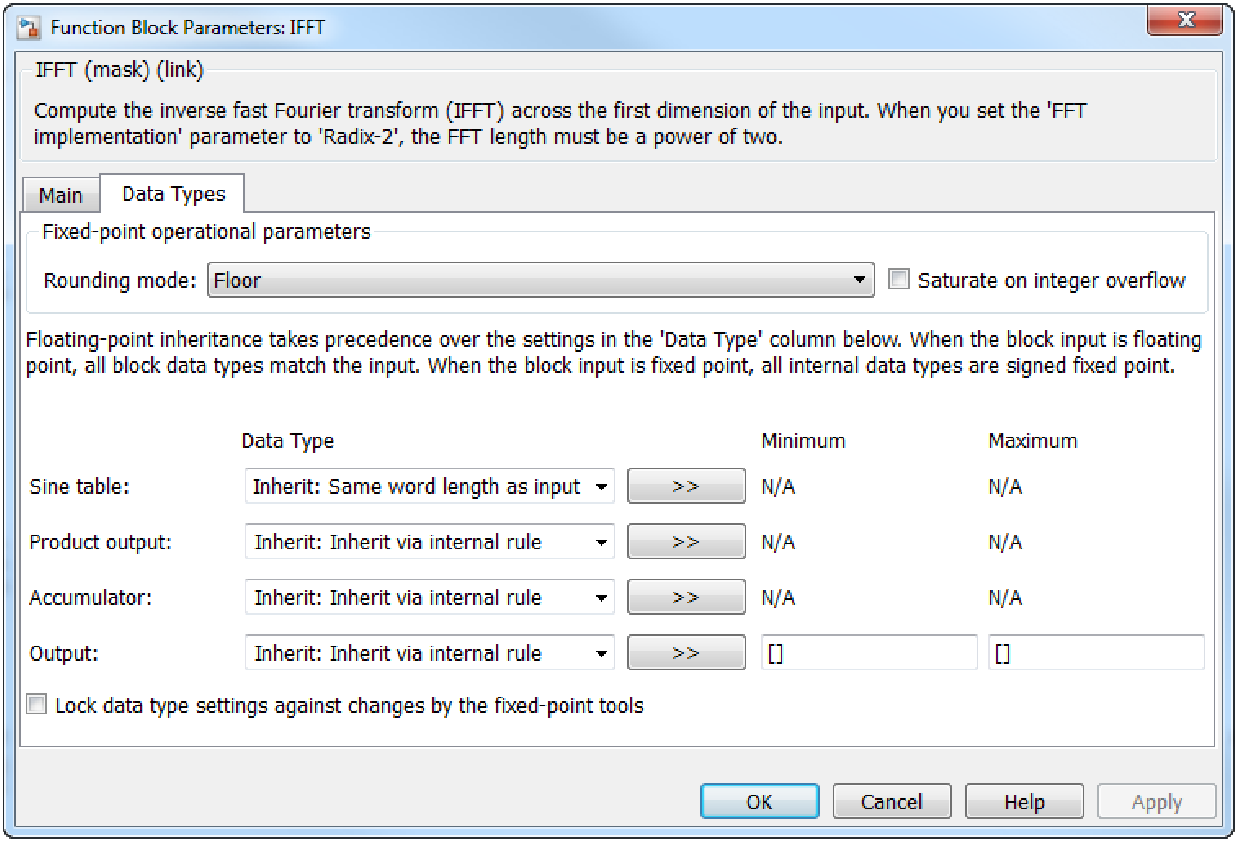
Specify FFT length. This parameter only becomes available if you do not select the **Inherit FFT length from input dimensions** parameter.

When you set the **FFT implementation** parameter to `Radix-2`, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the FFT length. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

The **Data Types** pane of the IFFT block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; instead, they always round to `Nearest`.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The sine table values do not obey this parameter; instead, they are always saturated.

Sine table data type

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to `Nearest`.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-955 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-955 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-955 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

  When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

  - When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
  - When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{ideal\ output} = WL_{input} + floor(\log_2(FFT\ length - 1)) + 1$$

$$FL_{ideal\ output} = FL_{input}$$

  Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Examples

See “Transform Frequency-Domain Data into Time Domain” in the *DSP System Toolbox User's Guide*.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only)

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - **FFT implementation** is set to `FFTW`.
  - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

  Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

IIR Halfband Interpolator

Interpolate signal using polyphase IIR halfband filter

Library

Filtering/Filter Designs

`dspfdesign`

Description

The IIR Halfband Interpolator block performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the block to use an elliptic design or a quasi-linear phase design. The block uses these design methods to compute the filter coefficients. To filter the inputs, the block uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the block to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Parameters

Filter specification

Parameters used to design the IIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of the three parameters:

- `Transition width and stopband attenuation` (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- `Filter order and transition width` — Design the filter using **Filter order** and **Transition width (Hz)**.
- `Filter order and stopband attenuation` — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- `Coefficients`— Specify the filter coefficients directly using the enabled parameters.

Transition width (Hz)

Transition width of the IIR halfband filter, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate.This parameter applies when **Filter specification** is set to `Filter order and transition width` or `Transition width and stopband attenuation`. The default is `4.1e3`.

Filter order

Filter order, specified as a finite positive integer. If you set **Design method** to `Elliptic`, then **Filter order** must be an odd integer greater than one. If you set **Design method** to `Quasi-linear phase`, then **Filter order** must be a multiple of four. This parameter applies when **Filter specification** is set to `Filter order and transition width` or `Filter order and stopband attenuation`. The default is `9`.

Stopband attenuation (dB)

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a real positive scalar in dB. This parameter applies when **Filter specification** is set to `Filter order and stopband attenuation` or `Transition width and stopband attenuation`. The default is `80`.

Design method

Design method for the IIR halfband filter.

- `Elliptic` (default) — The filter has nonlinear phase and uses few coefficients.
- `Quasi-linear phase` — The first branch of the polyphase filter structure is a pure delay, which results in an approximately linear phase response.

This parameter applies when you set **Filter specification** to any option except `Coefficients`.

Internal allpass structure

Internal allpass filter implementation structure, specified as `Minimum multiplier` or `Wave Digital Filter`. This parameter applies when you set **Filter specification** to `Coefficients`. Each structure uses a different coefficients set, independently stored in the corresponding coefficients property. The default is `Minimum multiplier`.

Make the first branch a pure delay

When you select this check box, the first branch of the polyphase filter structure becomes a pure delay, and the **Branch 1 allpass polynomial coefficients** and **Branch 1 Wave Digital coefficients** parameters do not apply. This parameter applies when you set **Filter specification** to `Coefficients`.

By default, this check box is selected.

Delay length in samples for branch 1

Length of the first branch delay, specified as a finite positive scalar. This parameter applies when you set **Filter specification** to `Coefficients` and select **Make the first branch a pure delay**. The default is `1`.

Branch 1 allpass polynomial coefficients

Allpass polynomial filter coefficients of the first branch, specified as an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Minimum multiplier`. The default is [`0.1284563; 0.7906755`].

Branch 2 allpass polynomial coefficients

Allpass polynomial filter coefficients of the second branch, specified as an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Minimum multiplier`. The default is `0.4295667`.

Branch 1 Wave Digital coefficients

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Wave Digital Filter`. The default is `[0.1284563; 0.7906755]`.

Branch 2 Wave Digital coefficients

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Wave Digital Filter`. The default is `0.4295667`.

Last section of branch 2 is first order

When you select this check box, the last section of the second branch is treated as a first order section. This parameter applies only when you set **Filter specification** to `Coefficients`. When the coefficients of the second branch are in an *N*-by-2 matrix, the block ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section.

When this check box is cleared, the last section of the second branch is treated as a second-order section. When the coefficients of the second branch are in an *N*-by-1 matrix, the block ignores this parameter.

By default, this check box is cleared.

Input highpass subband

When you select this check box, the block acts as a synthesis filter bank. The block accepts two inputs to synthesize: lowpass and highpass subbands. When you clear this check box, the block acts as an IIR half band interpolator and accepts a single vector or matrix as input. By default, this check box is cleared.

Inherit sample rate from input

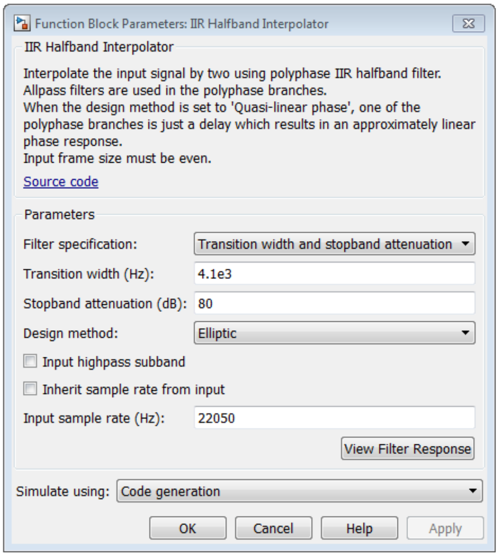
When you select this check box, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

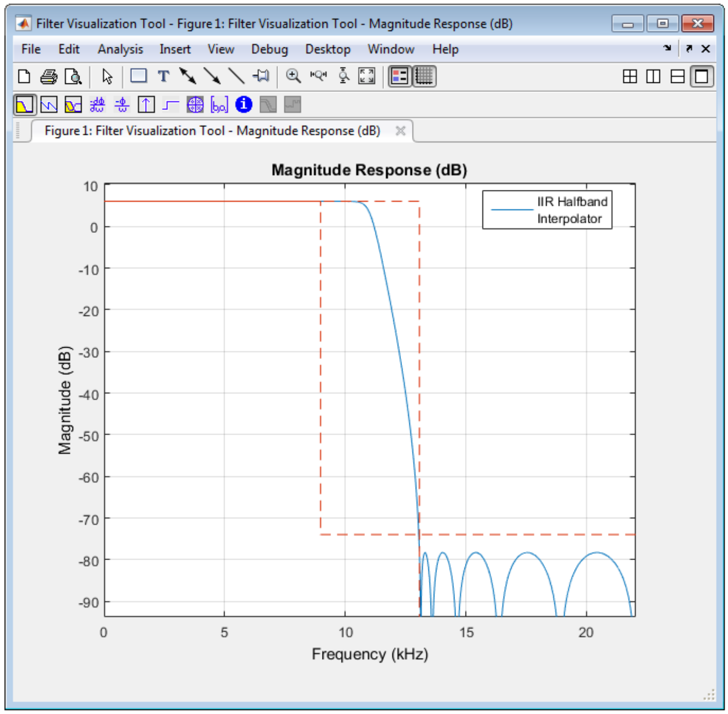
Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is `44100`. You can specify an input sample rate when the **Inherit sample rate from input** check box is cleared.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the IIR Halfband Interpolator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

IIR Halfband Decimator

Decimate signal using polyphase IIR halfband filter

Library

Filtering/Filter Designs

`dspfdesign`

Description

The IIR Halfband Decimator block performs polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the block to use an elliptic design or a quasi-linear phase design. The block uses these design methods to compute the filter coefficients. To filter the inputs, the block uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the block to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

Parameters

Filter specification

Parameters used to design the IIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of the three parameters:

- `Transition width and stopband attenuation` (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- `Filter order and transition width` — Design the filter using **Filter order** and **Transition width (Hz)**.
- `Filter order and stopband attenuation` — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- `Coefficients`— Specify the filter coefficients directly using the enabled parameters.

Transition width (Hz)

Transition width of the IIR halfband filter, specified as a real positive scalar in Hz. The transition width must be less than half the input sample rate. This parameter applies when **Filter specification** is set to `Filter order and transition width` or `Transition width and stopband attenuation`. The default is `4.1e3`.

Filter order

Filter order, specified as a finite positive integer. If you set **Design method** to `Elliptic`, then **Filter order** must be an odd integer greater than one. If you set **Design method** to `Quasi-linear phase`, then **Filter order** must be a multiple of four. This parameter applies when **Filter specification** is set to `Filter order and transition width` or `Filter order and stopband attenuation`. The default is `9`.

Stopband attenuation (dB)

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a real positive scalar in dB. This parameter applies when **Filter specification** is set to `Filter order and stopband attenuation` or `Transition width and stopband attenuation`. The default is `80`.

Design method

Design method for the IIR halfband filter.

- `Elliptic` (default) — The filter has nonlinear phase and uses few coefficients.
- `Quasi-linear phase` — The first branch of the polyphase filter structure is a pure delay, which results in an approximately linear phase response.

This parameter applies when you set **Filter specification** to any option except `Coefficients`.

Internal allpass structure

Internal allpass filter implementation structure, specified as `Minimum multiplier` or `Wave Digital Filter`. This parameter applies when you set **Filter specification** to `Coefficients`. Each structure uses a different coefficients set, independently stored in the corresponding coefficients property. The default is `Minimum multiplier`.

Make the first branch a pure delay

When you select this check box, the first branch of the polyphase filter structure becomes a pure delay, and the **Branch 1 allpass polynomial coefficients** and **Branch 1 Wave Digital coefficients** parameters do not apply. This parameter applies when you set **Filter specification** to `Coefficients`.

By default, this check box is selected.

Delay length in samples for branch 1

Length of the first branch delay, specified as a finite positive scalar. This parameter applies when you set **Filter specification** to `Coefficients` and select **Make the first branch a pure delay**. The default is `1`.

Branch 1 allpass polynomial coefficients

Allpass polynomial filter coefficients of the first branch, specified as an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Minimum multiplier`. The default is [`0.1284563; 0.7906755`].

Branch 2 allpass polynomial coefficients

Allpass polynomial filter coefficients of the second branch, specified as an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Minimum multiplier`. The default is `0.4295667`.

Branch 1 Wave Digital coefficients

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Wave Digital Filter`. The default is [`0.1284563; 0.7906755`].

Branch 2 Wave Digital coefficients

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. This parameter applies only when you set **Filter specification** to `Coefficients` and **Internal allpass structure** to `Wave Digital Filter`. The default is `0.4295667`.

Last section of branch 2 is first order

When you select this check box, the last section of the second branch is treated as a first order section. This parameter applies only when you set **Filter specification** to `Coefficients`. When the coefficients of the second branch are in an *N*-by-2 matrix, the block ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section.

When this check box is cleared, the last section of the second branch is treated as a second-order section. When the coefficients of the second branch are in an *N*-by-1 matrix, the block ignores this parameter.

By default, this check box is cleared.

Output highpass subband

When you select this check box, the block acts as an analysis filter bank, producing two power-complementary outputs. When you clear this check box, the block acts as an IIR halfband decimator and accepts a single vector or matrix as input. By default, this check box is cleared.

Inherit sample rate from input

When you select this check box, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

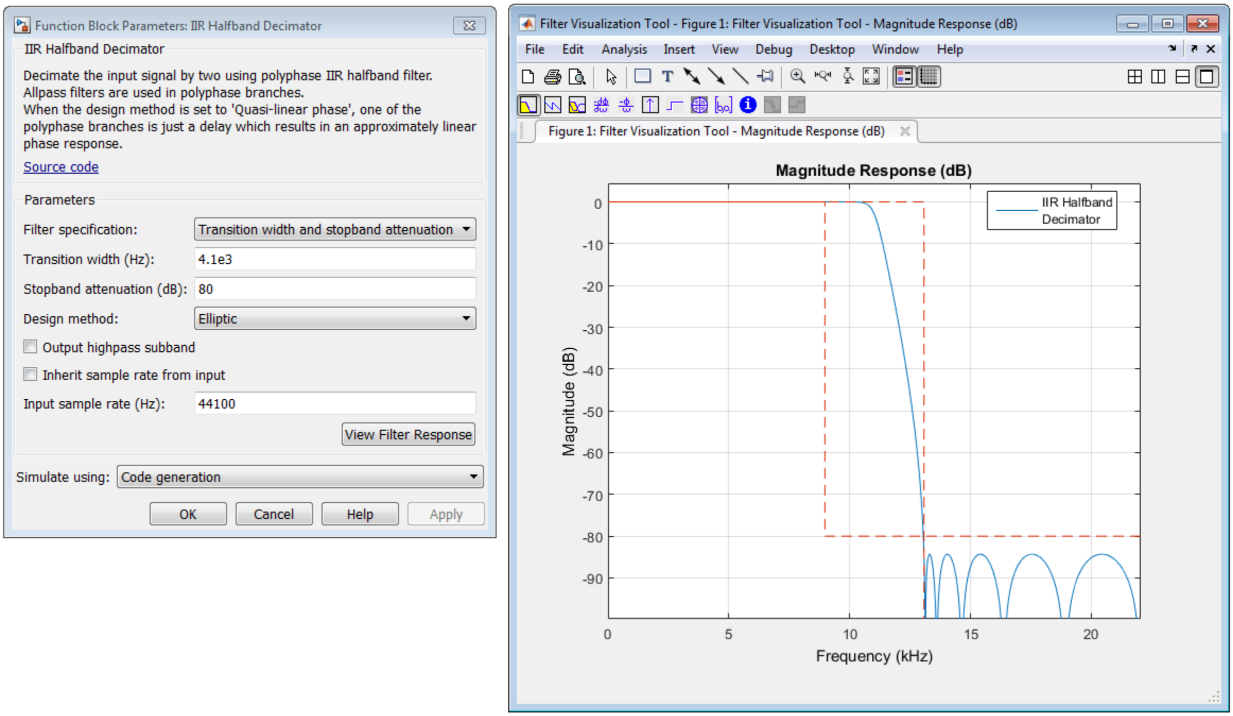
This parameter applies when you set **Filter specification** to any coefficients except `Coefficients`.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is `44100`. You can specify an input sample rate when the **Inherit sample rate from input** check box is cleared.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the IIR Halfband Decimator. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

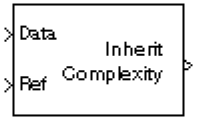
Introduced in R2015b

Inherit Complexity

Change complexity of input to match reference signal



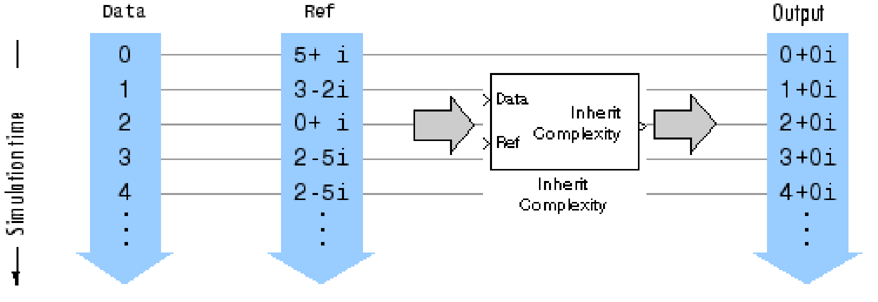
Library

Signal Management / Signal Attributes

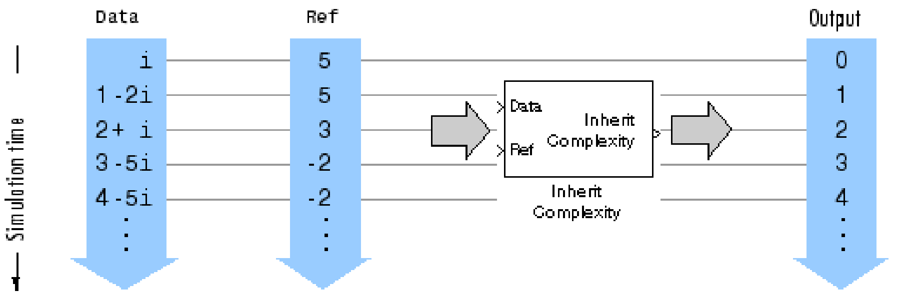
`dspsigattribs`

Description

The Inherit Complexity block alters the input data at the Data port to match the complexity of the reference input at the Ref port. When the Data input is real, and the Ref input is complex, the block appends a zero-valued imaginary component, `0i`, to each element of the Data input.



When the `Data` input is complex, and the `Ref` input is real, the block outputs the real component of the `Data` input.



When both the `Data` input and `Ref` input are real, or when both the `Data` input and `Ref` input are complex, the block propagates the `Data` input with no change.

Supported Data Types

Port	Supported Data Types
Data	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

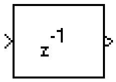
Integer Delay (Obsolete)

Delay input by integer number of sample periods



Library

`dspobslib`

Description

Note: The Integer Delay block will be removed from the product in a future release. We strongly recommend replacing this block with the `Delay` block.

The Integer Delay block delays a discrete-time input by the number of sample intervals specified in the **Delay** parameter. Noninteger delay values are rounded to the nearest integer, and negative delays are clipped at 0.

Sample-Based Operation

When the input is a sample-based M-by-N matrix, the block treats each of the $M*N$ matrix elements as an independent channel. The **Delay** parameter, v, can be an M-by-N matrix of positive integers that specifies the number of sample intervals to delay each channel of the input, or a scalar integer by which to equally delay all channels.

For example, when the input is M-by-1 and v is the matrix `[v(1) v(2) ... v(M)]'`, the first channel is delayed by `v(1)` sample intervals, the second channel is delayed by `v(2)` sample intervals, and so on. Note that when a channel is delayed for Δ sample-time units, the output sample at time t is the input sample at time $t - \Delta$. When $t - \Delta$ is negative, then the output is the corresponding value specified by the **Initial conditions** parameter.

A 1-D vector of length M is treated as an M-by-1 matrix, and the output is 1-D.

The **Initial conditions** parameter specifies the output of the block during the initial delay in each channel. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input.

Fixed Initial Conditions

A fixed initial condition in sample-based mode can be specified as one of the following:

- Scalar value to be repeated at each sample time of the initial delay (for every channel). For a 2-by-2 input with the parameter settings below,

  
  the block generates the following sequence of matrices at the start of the simulation,

  $$\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^2 & u_{12}^1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^3 & u_{12}^2 \\ u_{21}^1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^4 & u_{12}^3 \\ u_{21}^2 & u_{22}^1 \end{bmatrix}, \ldots$$

  where u_{ij}^k is the *i,j*th element of the *k*th matrix in the input sequence.

- Array of size *M*-by-*N*-by-*d*. In this case, you can set different fixed initial conditions for each element of a sample-based input. This setting is explained further in the Array bullet in "Time-Varying Initial Conditions" on page 2-984.

Initial conditions cannot be specified by full matrices.

Time-Varying Initial Conditions

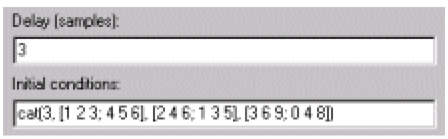
A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector of length *d*, where *d* is the maximum value specified for any channel in the **Delay** parameter. The vector can be a *L*-by-*d*, 1-by-*d*, or 1-by-1-by-*d*. The d elements of the vector are output in sequence, one at each sample time of the initial delay.

For a scalar input and the parameters shown below,

the block outputs the sequence `-1, -1, -1, 0, 1,...` at the start of the simulation.

- Array of dimension M-by-N-by-d, where d is the value specified for the **Delay** parameter (the maximum value when the **Delay** is a vector) and M and N are the number of rows and columns, respectively, in the input matrix. The d pages of the array are output in sequence, one at each sample time of the initial delay. For a 2-by-3 input, and the parameters below,



the block outputs the matrix sequence

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}, \begin{bmatrix} 2 & 4 & 6 \\ 1 & 3 & 5 \end{bmatrix}, \begin{bmatrix} 3 & 6 & 9 \\ 0 & 4 & 8 \end{bmatrix}$$

at the start of the simulation. Note that setting **Initial conditions** to an array with the same matrix for each entry implements constant initial conditions; a different constant initial condition for each input matrix element (channel).

Initial conditions cannot be specified by full matrices.

Frame-Based Operation

When the input is a frame-based M-by-N matrix, the block treats each of the N columns as an independent channel, and delays each channel as specified by the **Delay** parameter.

For frame-based inputs, the **Delay** parameter can be a scalar integer by which to equally delay all channels. It can also be a 1-by-N row vector, each element of which serves as the delay for the corresponding channel of the N-channel input. Likewise, it can also be an M-by-1 column vector, each element of which serves as the delay for one of the corresponding M samples for each channel. The **Delay** parameter can be an M-by-N matrix of positive integers as well; in this case, each element of each channel is delayed by the corresponding element in the delay matrix. For instance, if the fifth element of the third column of the delay matrix was 3, then the fifth element of the third channel of the input matrix is always delayed by three sample-time units.

When a channel is delayed for Δ sample-time units, the output sample at time t is the input sample at time $t - \Delta$. When $t - \Delta$ is negative, then the output is the corresponding value specified in the **Initial conditions** parameter.

The **Initial conditions** parameter specifies the output during the initial delay. Both fixed and time-varying initial conditions can be specified. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output.

Fixed Initial Conditions

The settings shown below specify fixed initial conditions. The value entered in the **Initial conditions** parameter is repeated at the output for each sample time of the initial delay. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value to be repeated for all channels of the output at each sample time of the initial delay. For a general M-by-N input with the parameter settings below,

  
  the first five samples in each of the N channels are zero. Notice that when the frame size is larger than the delay, all of these zeros are all included in the first output from the block.
- Array of size 1-by-N-by-D. In this case, you can also specify different fixed initial conditions for each channel. See “Time-Varying Initial Conditions” on page 2-987 for details.

Initial conditions cannot be specified by full matrices.

Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For time-varying initial conditions, the values specified in the **Initial conditions** parameter are output in sequence during the initial delay. A time-varying initial condition in frame-based mode can be specified in the following ways:

- Vector of length D, where each of the N channels have the same initial conditions sequence specified in the vector. D is defined as follows:
  - When an element of the delay entry is less than the frame size,

    $D = d + 1$

    where d is the maximum delay.
  - When the all elements of the delay entry are greater than the input frame size,

    $D = d +$ `input frame size` $- 1$

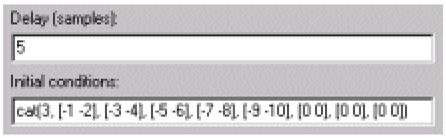
  Only the first d entries of the initial condition vector are used; the rest of the values are ignored, but you must include them nonetheless. For a two-channel ramp input `[1:100; 1:100]'` with a frame size of 4 and the parameter settings below,

  
  the block outputs the following sequence of frames at the start of the simulation.

  $$\begin{bmatrix} -4 & -1 \\ -5 & -2 \\ 1 & -3 \\ 2 & -4 \end{bmatrix}, \begin{bmatrix} 3 & -5 \\ 4 & 1 \\ 5 & 2 \\ 6 & 3 \end{bmatrix}, \begin{bmatrix} 7 & 4 \\ 8 & 5 \\ 9 & 6 \\ 10 & 7 \end{bmatrix}, \ldots$$

  Note that since one of the delays, 2, is less than the frame size of the input, 4, the length of the **Initial conditions** vector is the sum of the maximum delay and 1 (5+1), which is 6. The first five entries of the initial conditions vector are used by the channel with the maximum delay, and the rest of the entries are ignored. Since the first channel is delayed for less than the maximum delay (2 sample time units), it only makes use of two of the initial condition entries.

- Array of size 1-by-N-by-D, where D is defined in "Time-Varying Initial Conditions" on page 2-987. In this case, the kth entry of each 1-by-N entry in the array corresponds to an initial condition for the kth channel of the input matrix. Thus, a 1-by-N-by-D initial conditions input allows you to specify different initial conditions for each channel. For instance, for a two-channel ramp input `[1:100; 1:100]'` with a frame size of 4 and the parameter settings below,



the block outputs the following sequence of frames at the start of the simulation.

$$\begin{bmatrix} -1 & -2 \\ -3 & -4 \\ -5 & -6 \\ -7 & -8 \end{bmatrix}, \begin{bmatrix} -9 & -10 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \ldots$$

Note that the channels have distinct time varying initial conditions; the initial conditions for channel 1 correspond to the first entry of each length-2 row vector in the initial conditions array, and the initial conditions for channel 2 correspond to the second entry of each row vector in the initial conditions array. Only the first five entries in the initial conditions array are used; the rest are ignored.

The 1-by-N-by-D array entry can also specify different fixed initial conditions for every channel; in this case, every 1-by-N entry in the array would be identical, so that the initial conditions for each column are fixed over time.

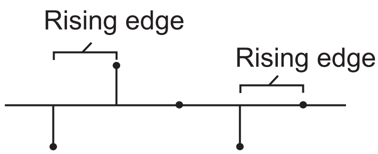
Initial conditions cannot be specified by full matrices.

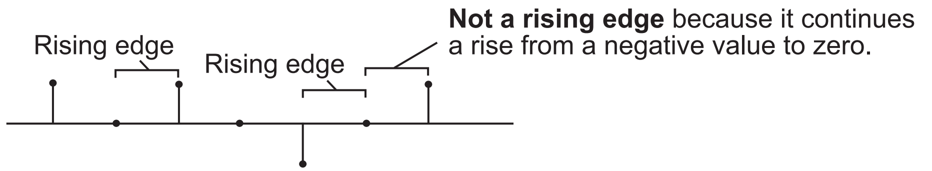
Resetting the Delay

The block resets the delay whenever it detects a reset event at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

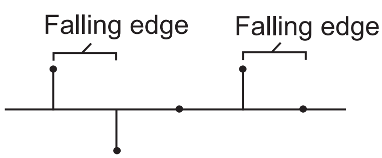
You specify the reset event in the **Reset port** parameter:

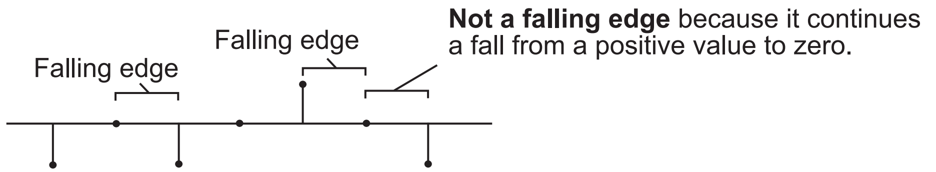
- `None` disables the Rst port.
- `Rising edge` — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)





- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero.

Note When running simulations in the Simulink `MultiTasking` mode, sample-based reset signals have a one-sample latency, and frame-based reset signals have one frame of latency. Thus, there is a one-sample or one-frame delay between the time the block detects a reset event, and when it applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Examples

The dspafxr example illustrates an audio reverberation system built around the Integer Delay block.

Parameters

Delay

The number of sample periods to delay the input signal.

Initial conditions

The value of the block's output during the initial delay.

Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 2-988.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)

- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled by the **Reset port** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

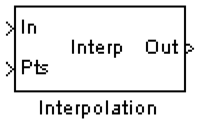
Introduced in R2008b

Interpolation

Interpolate values of real input samples



Library

Signal Operations

`dspsigops`

Description

The Interpolation block interpolates discrete, real, inputs using linear or FIR interpolation. The block accepts both sample- and frame-based input data in the form of a vector, matrix, or sample-based N-D array. The block outputs a scalar, vector, matrix, or N-D array of the interpolated values, which has the same frame status as the input data.

You must specify the interpolation points (times at which to interpolate values) in a one-based interpolation array, I_{Pts}. An entry of 1 in I_{Pts} refers to the first sample of the input data, an entry of 2.5 refers to the sample half-way between the second and third input sample, and so on. Depending on the dimensions of the input data, I_{Pts} can be a scalar, a length-P row or column vector, a P-by-N frame-based matrix, or a sample-based N-D array where P is the size of the first dimension of the N-D array. In most cases, P can be any positive integer. For more information about valid interpolation arrays, refer to the tables in "How the Block Applies Interpolation Arrays to Inputs" on page 2-993.

In most cases, the block applies I_{Pts} across the first dimension of an N-D input array, or to each input vector. You can set the block to apply the same interpolation array for all input data (static interpolation points entered on the block mask) or to use a different interpolation array for each N-D array, matrix, or vector input (time-varying interpolation points received via the Pts input port).

Specifying Static Interpolation Points

To supply the block with a static interpolation array (an interpolation array applied to every vector or N-D array of input data), perform the following steps:

- Set the **Source of interpolation points** parameter to `Specify via dialog`.
- Enter the interpolation array in the **Interpolation points** parameter. To learn about interpolation arrays, see "How the Block Applies Interpolation Arrays to Inputs" on page 2-993.

Specifying Time-Varying Interpolation Points

To supply the block with time-varying interpolation arrays (where the block uses a different interpolation array for each vector or N-D array input), perform the following steps:

1. Set the **Source of interpolation points** parameter to `Input port`, the **Pts** port appears on the block.
2. Generate a signal of interpolation arrays, and supply it to the Pts port. The block uses the input to this port as the interpolation points. To learn about interpolation arrays, see "How the Block Applies Interpolation Arrays to Inputs" on page 2-993.

How the Block Applies Interpolation Arrays to Inputs

The interpolation array I_{Pts} represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{Pts} refers to the first sample of the input, an entry of

2.5 refers to the sample half-way between the second and third input sample, and so on. In most cases, when I_{Pts} is a vector, it can be of any length.

Valid values in the interpolation array, I_{Pts}, range from 1 to the number of samples in each channel of the input. To learn how the block handles out of range interpolation values, see “Handling Out-of-Range Interpolation Points” on page 2-997.

Depending on the dimension and frame status of the input and the dimension of I_{Pts}, the block usually applies I_{Pts} to the input in one of the following ways:

- Applies the I_{Pts} array across the first dimension of a sample-based N-D array or frame-based matrix input, resulting in a sample-based N-D array or frame-based matrix output.
- Applies the vector I_{Pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the block applies the interpolation array I_{Pts} to all the possible types of sample- and frame-based inputs, and show the resulting output dimensions.

The first table describes the block's behavior when the **Source of interpolation points** is `Specify via dialog` and the input is sample based.

Input Dimensions (Sample Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Sample Based)
N-D Array (ex. M-by-N-by-Q)	1-by-P row	Applies I_{Pts} to the first dimension of the input array	P-by-N-by-Q array
	P-by-1 column		
	P-by-N-by-Q array	Applies the columns of I_{Pts} to the corresponding columns of the input array	
M-by-1 column	1-by-P row (block treats I_n as a column)	Applies I_{Pts} to the input column	P-by-1 column
	P-by-1 column		

Input Dimensions (Sample Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Sample Based)
1-by-N row	1-by-P row	Applies I_n to the input row	1-by-P row
	P-by-1 column (block treats I_{Pts} as a row)		

The next table describes the block's behavior when the **Source of interpolation points** is `Specify via dialog` and the input is frame based.

Input Dimensions (Frame Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame Based)
M-by-N matrix	1-by-N row	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	1-by-N row
	P-by-1 column	Applies I_{Pts} to each input column	P-by-N matrix
	P-by-N matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M-by-1 column	1-by-P row (block treats I_{Pts} as a column)	Applies I_{Pts} to the input column	P-by-1 column
	P-by-1 column		
1-by-N row (not recommended)	1-by-N row	Not Applicable. Block copies input vector	1-by-N row, a copy of the input vector
	P-by-1 column		P-by-N matrix where each row is a copy of the input vector
	P-by-N matrix		

The next table describes the block's behavior when the **Source of interpolation points** is `Input port` and the input is sample based.

Input Dimensions (Sample Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Sample Based)
N-D Array (ex. M-by-N-by-Q)	Sample-based 1-by-P row	Applies I_{Pts} to the first dimension of the input array	P-by-N-by-Q array
	Sample- or frame-based P-by-1 column		
	Sample-based P-by-N-by-Q array	Applies the columns of I_{Pts} to the corresponding columns of the input array	
M-by-1 column	Sample-based 1-by-P row	Applies I_{Pts} to the input column	P-by-1 column
	Sample- or frame-based P-by-1 column		
1-by-N row	Sample-based 1-by-P row	Applies I_{Pts} to the input row	1-by-P row
	Sample or frame-based P-by-1 column		

The next table describes the block's behavior when the **Source of interpolation points** is `Input port` and the input is frame based.

Input Dimensions (Frame Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame Based)
M-by-N matrix	Frame-based 1-by-N row	Applies each column of I_{Pts} (each element of I_{Pts}) to the corresponding column of the input matrix	1-by-N row
	Sample-based 1-by-P row	Applies I_{Pts} to each input column	P-by-N matrix

Input Dimensions (Frame Based)	Valid Dimensions of Interpolation Array I_{Pts}	How Block Applies I_{Pts} to Input	Output Dimensions (Frame Based)
	Frame- or sample-based P-by-1 column		
	Frame- or sample-based P-by-N matrix	Applies the columns of I_{Pts} to the corresponding columns of the input matrix	
M-by-1 column	Sample-based 1-by-P row	Applies I_{Pts} to the input column	P-by-1 column
	Frame- or sample-based P-by-1 column		
1-by-N row (not recommended)	Frame-based 1-by-N row	Not Applicable. Block copies input vector	1-by-N row, a copy of the input vector
	Sample-based 1-by-P row		P-by-N matrix where each row is a copy of the input vector
	Frame- or sample-based P-by-1 column		
	Frame- or sample-based P-by-N matrix		

Handling Out-of-Range Interpolation Points

Valid values in the interpolation array I_{Pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector `D`, all entries of I_{Pts} must range from 1 to 5. I_{Pts} cannot contain entries such as 7 or -9, since there is no 7th or -9th entry in `D`.

The **Out of range interpolation points** parameter sets how the block handles interpolation points that are fall outside the valid range, and has the following settings:

- `Clip` — The block replaces any out-of-range values in I_{Pts} with the closest value in the valid range (from 1 to the number of input samples), and then proceeds with computations using the clipped version of I_{Pts}.

- `Clip and warn` — In addition to `Clip`, the block issues a warning at the MATLAB command line every time clipping occurs.
- `Error` — When the block encounters an out-of-range value in I_{Pts}, the simulation stops, and the block issues an error at the MATLAB command line.

Example of Clipping

Suppose the block is set to clip out-of-range interpolation points, and gets the following input vector and interpolation points:

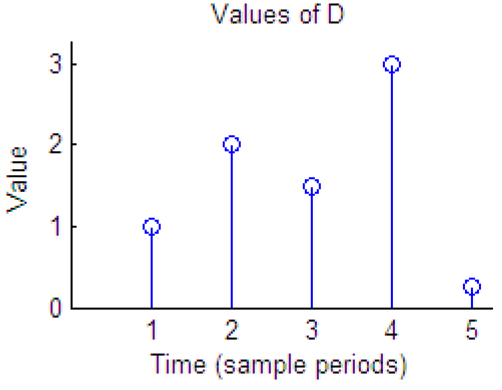
- `D = [11 22 33 44]'`
- $\mathtt{I_{Pts}}$ `= [10 2.6 -3]'`

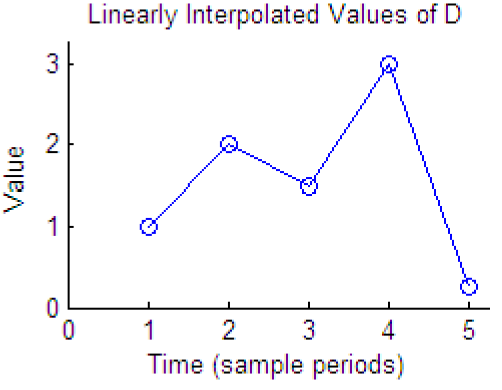
Because *D* has four samples, valid interpolation points range from 1 to 4. The block clips the interpolation point 10 to 4 and the point -3 to 1, resulting in the clipped interpolation vector $\mathtt{I_{PtsClipped}}$ `= [4 2.6 1]'`.

Linear Interpolation Mode

When **Interpolation Mode** is set to `Linear`, the block interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

For instance, if the input signal *D* = [1 2 1.5 3 0.25]', the following plot on the left shows the samples in *D*, and the plot on the right shows the linearly interpolated values between the samples in *D*.



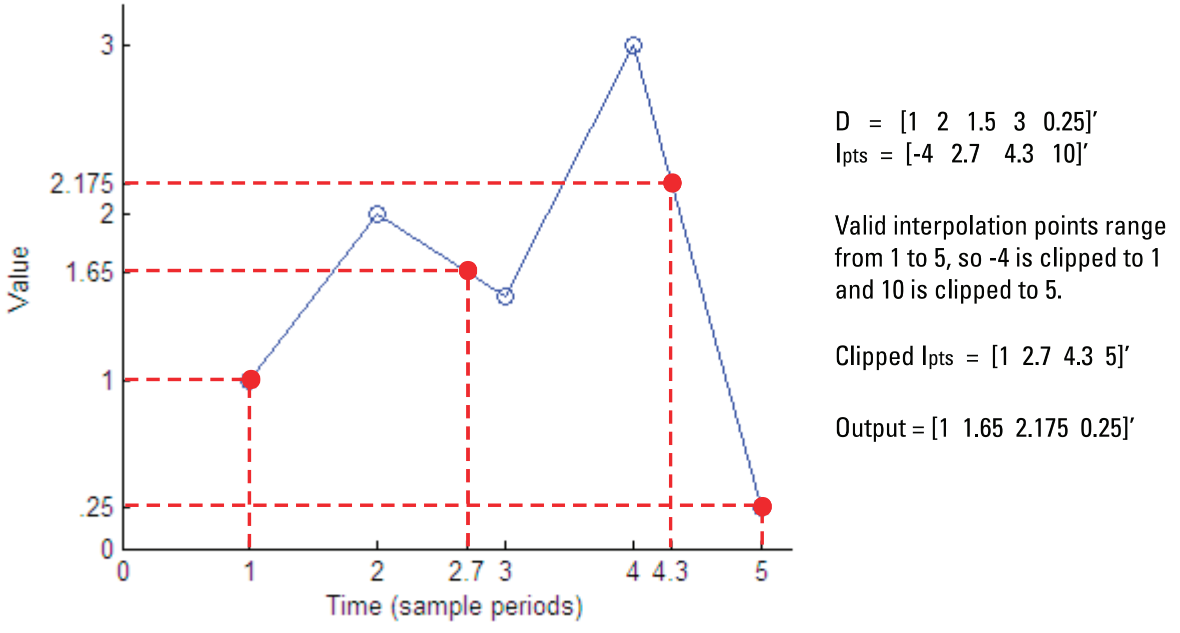


The following figure illustrates the case of a block in linear interpolation mode that is set to clip out-of-range interpolation points. The vector D supplies the input data and the vector I_{Pts} supplies the interpolation points:

- `D = [1 2 1.5 3 0.25]'`
- `I`$_{Pts}$` = [-4 2.7 4.3 10]'`

The block clips the invalid interpolation points, and outputs the linearly interpolated values in a vector, `[1 1.65 2.175 0.25]'`.

Interpolated Values of D at Clipped Interpolation Points



FIR Interpolation Mode

When **Interpolation Mode** is set to `FIR`, the block interpolates data values using an FIR interpolation filter, specified by various block parameters. See in the Variable Fractional Delay block reference for more information.

Parameters

Source of interpolation points

Choose how you want to specify the interpolation points. If you select `Specify via dialog`, the **Interpolation points** parameter become available. Use this option for static interpolation points. If you select `Input port`, the Pts port appears on the block. The block uses the input to this port as the interpolation points. Use this option for time-varying interpolation points. For more information, see "Specifying Static Interpolation Points" on page 2-993 and "Specifying Time-Varying Interpolation Points" on page 2-993.

Interpolation points

The array of points in time at which to interpolate the input signal (I_{Pts}). An entry of 1 in I_{Pts} refers to the first sample of the input, an entry of 2.5 refers to the sample half-way between the second and third input sample, and so on. See "How the Block Applies Interpolation Arrays to Inputs" on page 2-993. Tunable (Simulink).

Interpolation mode

Sets the block to interpolate by either linear or FIR interpolation. For more information, see "Linear Interpolation Mode" on page 2-998 and "FIR Interpolation Mode" on page 2-999.

Interpolation filter half-length

Specify the half-length of the FIR interpolation filter (`P`). To perform the interpolation in `FIR` mode, the block uses the nearest 2*`P` low-rate samples. In most cases, `P` low-rate samples must appear below and above each interpolation point. However, if you interpolate at a low-rate sample point, the block includes that low-rate sample in the required 2*`P` samples and requires only 2*`P`–1 neighboring low-rate samples. If an interpolation point does not have the required number of neighboring low-rate samples, the block interpolates that point using linear interpolation.

This parameter becomes available only when the **Interpolation mode** is set to `FIR`. For more information, see "FIR Interpolation Mode" on page 2-999.

Interpolation points per input sample

Also known as the *upsampling factor*, this parameter defines the number of points per input sample (`L`) at which the block computes a unique FIR interpolation filter. To perform the FIR Interpolation, the block uses a polyphase structure with `L` filter arms of length 2*`P`.

For example, if `L=4`, the block constructs a polyphase filter with four arms. The block then interpolates at points corresponding to 1 +*i*/**L**, 2 +*i*/**L**, 3 +*i*/**L**..., where the integers

1, 2, and 3 represent the low-rate samples, and *i*=`0,1,2,3`. To interpolate at a point that does not directly correspond to an arm of the polyphase filter requires an extra computation. The block first rounds that point down to the nearest value that does correspond to an arm of the polyphase filter. Thus, to interpolate at the point 2.2, the block rounds 2.2 down to 2, and computes the FIR interpolation using the first arm of the polyphase filter structure. Similarly, to interpolate the point 2.65, the block rounds the value down to 2.5 and uses the third arm of the polyphase filter structure.

This parameter becomes available only when the **Interpolation mode** is set to `FIR`. For more information, see "FIR Interpolation Mode" on page 2-999.

Normalized input bandwidth

The bandwidth of the input divided by Fs/2 (half the input sample frequency).

This parameter is only available when the **Interpolation mode** is set to `FIR`. For more information, see "FIR Interpolation Mode" on page 2-999.

Out of range interpolation points

When an interpolation point is out of range, this parameter sets the block to either clip the interpolation point, clip the value and issue a warning at the MATLAB command line, or stop the simulation and issue an error at the MATLAB command line. For more information, see "Handling Out-of-Range Interpolation Points" on page 2-997.

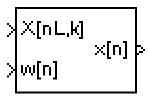
Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point
Pts	• Double-precision floating point • Single-precision floating point
Out	• Double-precision floating point • Single-precision floating point

Introduced before R2006a

Inverse Short-Time FFT

Recover time-domain signals by performing inverse short-time, fast Fourier transform (FFT)



Inverse
Short-Time FFT

Library

Transforms

`dspxfrm3`

Description

The Inverse Short-Time FFT block reconstructs the time-domain signal from the frequency-domain output of the Short-Time FFT block using a two-step process. First, the block performs the overlap add algorithm shown below.

$$x[n] = \frac{L}{W(0)} \sum_{p=-\infty}^{\infty} \left[\frac{1}{N} \sum_{k=0}^{N-1} X[pL,k] e^{j2\pi kn/N} \right]$$

Then, the block rebuffers the signal in order to reconstruct the time-domain signal. Depending on the analysis window used by the Short-Time FFT block, the Inverse Short-Time FFT block might or might not achieve perfect reconstruction of the time domain signal.

Connect your complex-valued, single-channel or multichannel input signal to the X(n,k) port. The block accepts unoriented vector, column vector and matrix input. The block outputs the real or complex-valued, single-channel or multichannel inverse short-time FFT at port x(n).

Connect your complex-valued, single-channel analysis window to the w(n) port. When you select the **Assert if analysis window does not support perfect signal**

reconstruction check box, the block displays an error when the input signal cannot be perfectly reconstructed. The block uses the values you enter for the **Analysis window length (W)** and **Reconstruction error tolerance**, or maximum amount of allowable error in the reconstruction process, to determine if the signal can be perfectly reconstructed.

Examples

The dspstsa example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal. To open the `dspstsa` model, type `dspstsa` in the MATLAB command prompt.

Parameters

Analysis window length

Enter the length of the analysis window. This parameter is visible when you select the **Assert if analysis window does not support perfect signal reconstruction** check box.

Overlap between consecutive STFFT frames (in samples)

Enter the number of samples of overlap for each frame of the Short-Time FFT block's input signal. This value should be the same as the **Overlap between consecutive windows (in samples)** parameter in the Short-Time FFT block parameters dialog.

Samples per output frame

Enter the desired frame size of the output signal.

Input is conjugate symmetric

Select this check box when the input to the block is both floating point and conjugate symmetric, and you want real-valued outputs. When you select this check box when the input is not conjugate symmetric, the output of the block is invalid. This parameter cannot be used for fixed-point signals.

Assert if analysis window does not support perfect signal reconstruction

Select this check box to display an error when the analysis window used by the Short-Time FFT block does not support perfect signal reconstruction.

Reconstruction error tolerance

Enter the amount of acceptable error in the reconstruction of the original signal. This parameter is visible when you select the **Assert if analysis window does not support perfect signal reconstruction** check box.

Supported Data Types

Port	Supported Data Types
X(n,k)	• Double-precision floating point • Single-precision floating point
w(n)	• Double-precision floating point • Single-precision floating point
x(n)	• Double-precision floating point • Single-precision floating point

References

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

When the input length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

When the input length is a power of two, you can generate standalone C and C++ code from this block.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Select `Lowpass` or `Highpass` to design an inverse sinc lowpass or highpass filter.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Regions between specification values such as **Fpass** and **Fstop** represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- `6 dB point` — For FIR filters, define the filter response by specifying the locations of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

F6dB

When **Frequency constraints** is `6 dB point`, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is `Equiripple`.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set **Stopband shape**, **Stopband decay** specifies the amount of decay applied to the stopband. the following conditions apply to **Stopband decay** based on the value of **Stopband Shape**:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Sinc frequency factor

A frequency dilation factor. The **Sinc frequency factor**, *C* , parameterizes the passband magnitude response for a lowpass design through H(ω) = sinc(Cω)^(-P) and through H(ω) = sinc(C(1-ω))^(-P) for a highpass design.

Sinc power

Negative power of passband magnitude response. The **Sinc power**, *P*, parameterizes the passband magnitude response for a lowpass design through H(ω) = sinc(Cω)^(-P) and through H(ω) = sinc(C(1-ω))^(-P) for a highpass design.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure.

Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

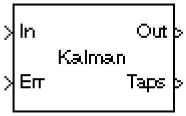
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2006b

Kalman Adaptive Filter (Obsolete)

Compute filter estimates for inputs using Kalman adaptive filter algorithm



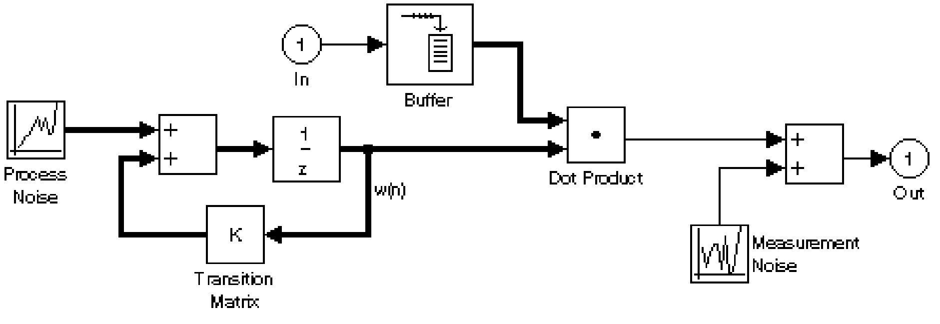
Library

`dspobslib`

Description

Note The Kalman Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `Kalman Filter` block.

The Kalman Adaptive Filter block computes the optimal linear minimum mean-square estimate (MMSE) of the FIR filter coefficients using a one-step predictor algorithm. This Kalman filter algorithm is based on the following physical realization of a dynamic system.



The Kalman filter assumes that there are no deterministic changes to the filter taps over time (that is, the transition matrix is identity), and that the only observable output from the system is the filter output with additive noise. The corresponding Kalman filter is expressed in matrix form as

$$g(n) = \frac{K(n-1)u(n)}{u^H(n)K(n-1)u(n) + Q_M}$$
$$y(n) = u^H(n)\hat{w}(n)$$
$$e(n) = d(n) - y(n)$$
$$\hat{w}(n+1) = \hat{w}(n) + e(n)g(n)$$
$$K(n) = K(n-1) - g(n)u^H(n)K(n-1) + Q_p$$

The variables are as follows

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$K(n)$	The correlation matrix of the state estimation error
$g(n)$	The vector of Kalman gains at step n
$\hat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
Q_M	The correlation matrix of the measurement noise
Q_P	The correlation matrix of the process noise

The correlation matrices, Q_M and Q_P, are specified in the parameter dialog by scalar variance terms to be placed along the matrix diagonals, thus ensuring that these matrices are symmetric. The filter algorithm based on this constraint is also known as the random-walk Kalman filter.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the input covariance matrix $K(n)$. This decreases the total number of computations by a factor of two.

The block icon has port labels corresponding to the inputs and outputs of the Kalman algorithm. Note that inputs to the In and Err ports must be sample-based scalars with the same complexity. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

Block Ports	Corresponding Variables
In	u, the scalar input, which is internally buffered into the vector $u(n)$
Out	$y(n)$, the filtered scalar output
Err	$e(n)$, the scalar estimation error
Taps	$\hat{w}(n)$, the vector of filter-tap estimates

An optional Adapt input port is added when you select the **Adapt port** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the Adapt input is nonzero. A zero-valued input to the `Adapt` port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero Adapt input.

The **FIR filter length** parameter specifies the length of the filter that the Kalman algorithm estimates. The **Measurement noise variance** and the **Process noise variance** parameters specify the correlation matrices of the measurement and process noise, respectively. The **Measurement noise variance** must be a scalar, while the **Process noise variance** can be a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The **Initial error correlation matrix** specifies the initial value $K(0)$, and can be a diagonal matrix, a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

Parameters

FIR filter length

The length of the FIR filter.

Measurement noise variance

The value to appear along the diagonal of the measurement noise correlation matrix. Tunable (Simulink).

Process noise variance

The value to appear along the diagonal of the process noise correlation matrix. Tunable (Simulink).

Initial value of filter taps

The initial FIR filter coefficients.

Initial error correlation matrix

The initial value of the error correlation matrix.

Adapt port

Enables the `Adapt` port.

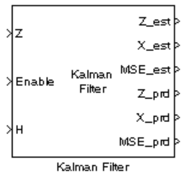
Kalman Filter

Predict or estimate states of dynamic systems



Library

Filtering/Adaptive Filters

`dspadpt3`

Description

Use the Kalman Filter block to predict or estimate the state of a dynamic system from a series of incomplete and/or noisy measurements. Suppose you have a noisy linear system that is defined by the following equations:

$$x_k = Ax_{k-1} + w_{k-1}$$
$$z_k = Hx_k + v_k$$

This block can use the previously estimated state, $\hat{x}_{k-1}$, to predict the current state at time k, x_k^-, as shown by the following equation:

$$x_k^- = A\hat{x}_{k-1}$$
$$P_k^- = A\hat{P}_{k-1}A^T + Q$$

The block can also use the current measurement, z_k, and the predicted state, x_k^-, to estimate the current state value at time k, $\hat{x}_k$, so that it is a more accurate approximation:

$$K_k = P_k^- H^T \left(H P_k^- H^T + R \right)^{-1}$$

$$\hat{x}_k = x_k^- + K_k \left(z_k - H x_k^- \right)$$

$$\hat{P}_k = \left(I - K_k H \right) P_k^-$$

The variables in the previous equations are defined in the following table.

Variable	Definition	Default Value or Initial Condition
x	State	N/A
$\hat{x}$	Estimated state	`zeros([6, 1])`
x^-	Predicted state	N/A
A	State transition matrix	$\begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$
w	Process noise	N/A
z	Measurement	N/A
H	Measurement matrix	$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$
v	Measurement noise	N/A
$\hat{P}$	Estimated error covariance	`10*eye(6)`
P^-	Predicted error covariance	N/A
Q	Process noise covariance	`0.05*eye(6)`
K	Kalman gain	N/A

Variable	Definition	Default Value or Initial Condition
R	Measurement noise covariance	`eye(4)`
I	Identity matrix	N/A

In the previous equations, z is a vector of measurement values. Most of the time, the block processes Z, an M-by-N matrix, where M is the number of measurement values and N is the number of filters.

Use the **Number of filters** parameter to specify the number of filters to use to predict or estimate the current value.

Use the **Enable filters** parameter to specify which filters are enabled or disabled at each time step. If you select `Always`, the filters are always enabled. If you choose `Specify via input port <Enable>`, the Enable port appears on the block. The input to this port must be a row vector of 1s and 0s whose length is equal to the number of filters. For example, if there are 3 filters and the input to the Enable port is [1 0 1], only the first and third filter are enabled at this time step. If you select the **Reset the estimated state and estimated error covariance when filters are disabled** check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values.

Note: All filters have the same state transition matrix, measurement matrix, initial conditions, and noise covariance, but their state, measurement, enable, and MSE signals are unique. Within the state, measurement, enable, and MSE signals, each column corresponds to a filter.

Use the **Measurement matrix source** parameter to specify how to enter the measurement matrix values. If you select `Specify via dialog`, the **Measurement matrix** parameter appears in the dialog box. If you select `Input port <H>`, the H port appears on the block. Use this port to specify your measurement matrix.

See the Radar Tracking example for a demonstration of how to use this block. You can open this example by typing

```
aero_radmod_dsp
```

at the MATLAB command prompt.

Parameters

Number of filters

Specify the number of filters to use to predict or estimate the current value.

Enable filters

Specify which filters are enabled or disabled at each time step. If you select `Always`, the filters are always enabled. If you choose `Specify via input port <Enable>`, the Enable port appears on the block.

Reset the estimated state and estimated error covariance when filters are disabled

If you select this check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values. This parameter is visible if, for the **Enable filters** parameter, you select `Specify via input port <Enable>`.

Initial condition for estimated state

Enter the initial condition for the estimated state.

Initial condition for estimated error covariance

Enter the initial condition for the estimated error covariance.

State transition matrix

Enter the state transition matrix.

Process noise covariance

Enter the process noise covariance.

Measurement matrix source

Specify how to enter the measurement matrix values. If you select `Specify via dialog`, the **Measurement matrix** parameter appears in the dialog box. If you select `Input port <H>`, the H port appears on the block.

Measurement matrix

Enter the measurement matrix values. This parameter is visible if you select `Specify via dialog` for the **Measurement matrix source** parameter.

Measurement noise covariance

Enter the measurement noise covariance.

Output estimated measurement <Z_est>

Select this check box if you want the block to output the estimated measurement.

Output estimated state <X_est>

Select this check box if you want the block to output the estimated state.

Output MSE of estimated state <MSE_est>

Select this check box if you want the block to output the mean-squared error of the estimated state.

Output predicted measurement <Z_prd>

Select this check box if you want the block to output the predicted measurement.

Output predicted state <X_prd>

Select this check box if you want the block to output the predicted state.

Output MSE of predicted state <MSE_prb>

Select this check box if you want the block to output the mean-squared error of the predicted state.

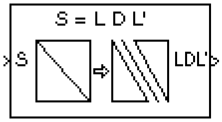
`LDL Solver`	DSP System Toolbox

Introduced in R2007a

LDL Factorization

Factor square Hermitian positive definite matrices into lower, upper, and diagonal components



Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`

Description

The LDL Factorization block uniquely factors the square Hermitian positive definite input matrix S as

$$S = LDL^*$$

where L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L. Only the diagonal and lower triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded.

The block's output is a composite matrix with lower triangle elements l_{ij} from L, diagonal elements d_{ij} from D, and upper triangle elements u_{ij} from L^*. The output format is shown below for a 5-by-5 matrix.

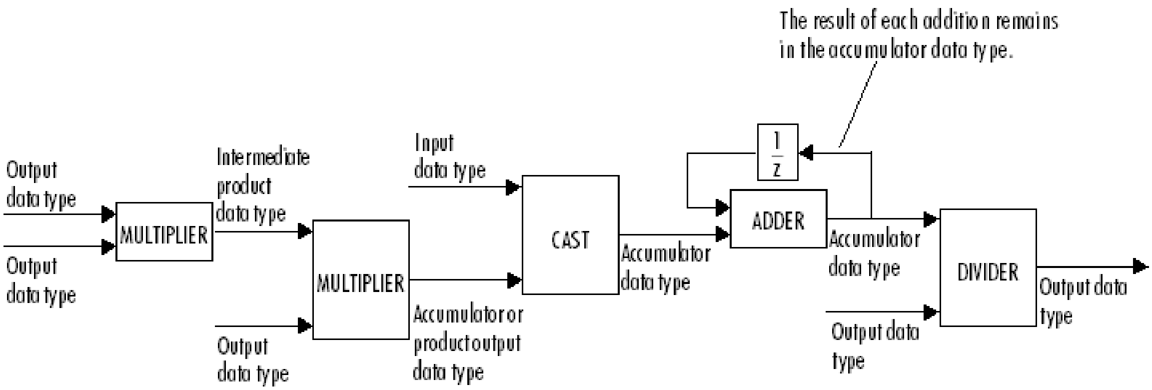
$$\begin{bmatrix} d_{11} & u_{12} & u_{13} & u_{14} & u_{15} \\ l_{21} & d_{22} & u_{23} & u_{24} & u_{25} \\ l_{31} & l_{32} & d_{33} & u_{34} & u_{35} \\ l_{41} & l_{42} & l_{43} & d_{44} & u_{45} \\ l_{51} & l_{52} & l_{53} & l_{54} & d_{55} \end{bmatrix} \qquad u_{ij} = l_{ji}^*$$

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

The algorithm requires that the input be square and Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter.

Fixed-Point Data Types

The following diagram shows the data types used within the LDL Factorization block for fixed-point signals.

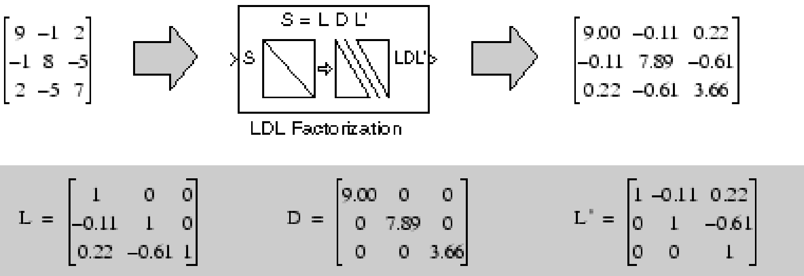


You can set the intermediate product, product output, accumulator, and output data types in the block dialog as discussed below.

The output of the second multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

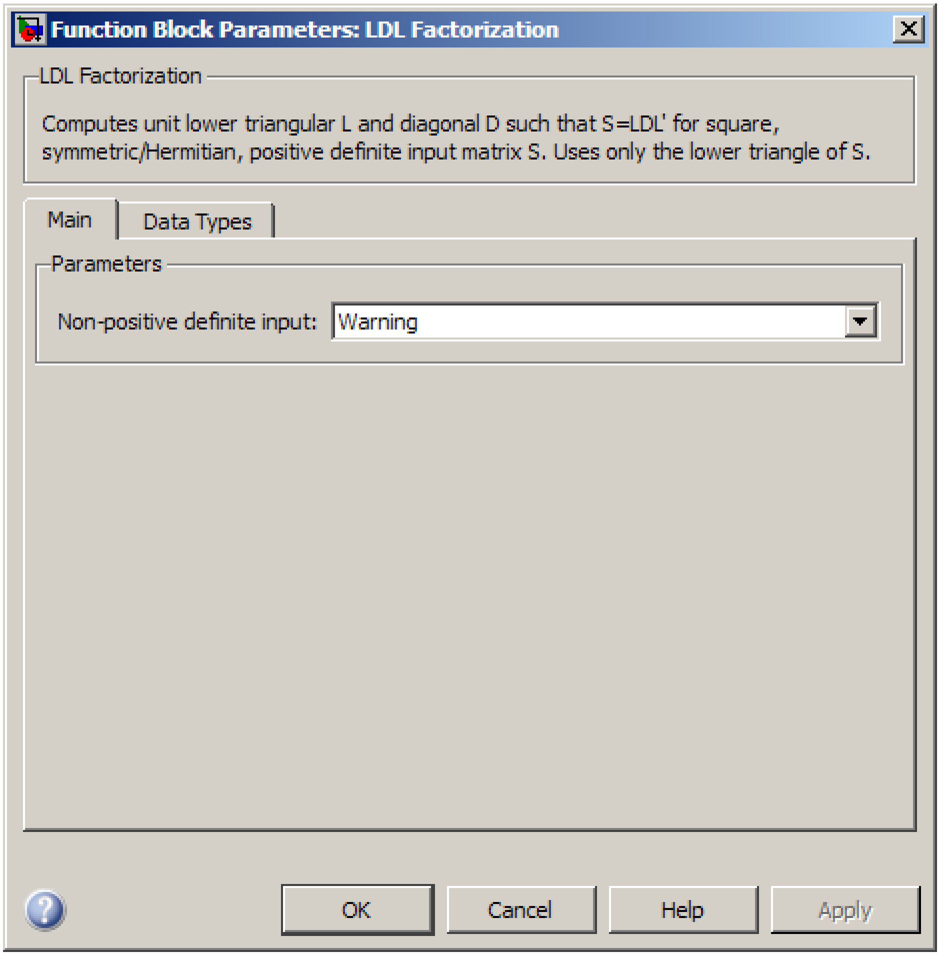
Examples

LDL decomposition of a 3-by-3 Hermitian positive definite matrix:



Dialog Box

The **Main** pane of the LDL Factorization block dialog appears as follows.



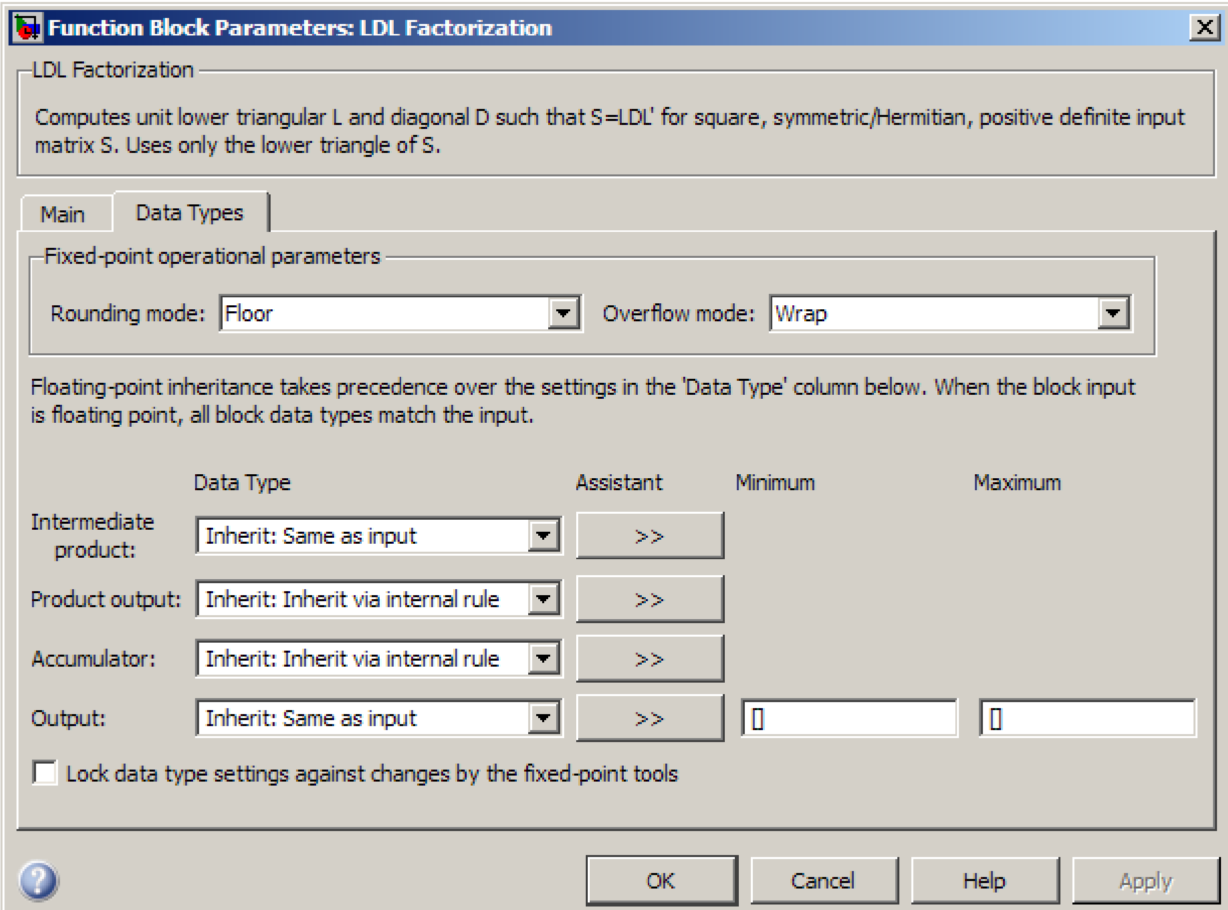
Non-positive definite input

Specify the action when nonpositive definite matrix inputs occur:

- `Ignore` — Proceed with the computation and do not issue an alert. The output is not a valid factorization. A partial factorization is present in the upper left corner of the output.
- `Warning` — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is not a valid factorization. A partial factorization is present in the upper left corner of the output.

- `Error` — Display an error dialog and terminate the simulation.

The **Data Types** pane of the LDL Factorization block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-1026, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1026 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1026 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1026 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

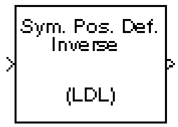
LDL Inverse

Compute inverse of Hermitian positive definite matrix using LDL factorization



Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

`dspinverses`

Description

The LDL Inverse block computes the inverse of the Hermitian positive definite input matrix S by performing an LDL factorization.

$$S^{-1} = \left(LDL^{*}\right)^{-1}$$

L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^{*} is the Hermitian (complex conjugate) transpose of L. Only the diagonal and lower triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded.

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and do not issue an alert. The output is not a valid inverse.

- `Warning` — Display a warning message in the MATLAB command window, and continue the simulation. The output is not a valid inverse.
- `Error` — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs.

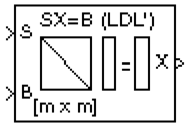
LDL Solver

Solve *SX*=*B* for *X* when *S* is square Hermitian positive definite matrix



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The LDL Solver block solves the linear system *S*X=*B* by applying LDL factorization to the matrix at the S port, which must be square (*M*-by-*M*) and Hermitian positive definite. Only the diagonal and lower triangle of the matrix are used, and any imaginary component of the diagonal entries is disregarded. The input to the B port is the right side *M*-by-*N* matrix, *B*. The *M*-by-*N* output matrix *X* is the unique solution of the equations.

A length-*M* unoriented vector input for right side *B* is treated as an *M*-by-1 matrix.

When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- `Ignore` — Proceed with the computation and do not issue an alert. The output is not a valid solution.
- `Warning` — Proceed with the computation and display a warning message in the MATLAB Command Window. The output is not a valid solution.
- `Error` — Display an error dialog and terminate the simulation.

Note The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

Algorithm

The LDL algorithm uniquely factors the Hermitian positive definite input matrix S as
$S = LDL^*$

where L is a lower triangular square matrix with unity diagonal elements, D is a diagonal matrix, and L^* is the Hermitian (complex conjugate) transpose of L.

The equation
$LDL^*X = B$

is solved for X by the following steps:

1 Substitute
  $Y = DL^*X$
2 Substitute
  $Z = L^*X$
3 Solve one diagonal and two triangular systems.
  $LY = B$
  $DZ = Y$
  $L^*X = Z$

Parameters

Non-positive definite input

Response to nonpositive definite matrix inputs.

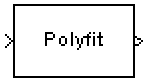
Least Squares Polynomial Fit

Compute polynomial coefficients that best fit input data in least-squares sense



Library

Math Functions / Polynomial Functions

`dsppolyfun`

Description

The Least Squares Polynomial Fit block computes the coefficients of the nth order polynomial that best fits the input data in the least-squares sense, where you specify n in the **Polynomial order** parameter. A distinct set of n+1 coefficients is computed for each column of the M-by-N input, u.

For a given input column, the block computes the set of coefficients, c_1, c_2, ..., c_{n+1}, that minimizes the quantity

$$\sum_{i=1}^{M} (u_i - \hat{u}_i)^2$$

where u_i is the ith element in the input column, and

$$\hat{u}_i = f(x_i) = c_1 x_i^n + c_2 x_i^{n-1} + \ \ldots \ + c_{n+1}$$

The values of the independent variable, x_1, x_2, ..., x_M, are specified as a length-M vector by the **Control points** parameter. The same M control points are used for all N polynomial fits, and can be equally or unequally spaced. The equivalent MATLAB code is shown below.

```
c = polyfit(x,u,n)      % Equivalent MATLAB code
```

For convenience, the block treats length-M unoriented vector input as an M-by-1 matrix.

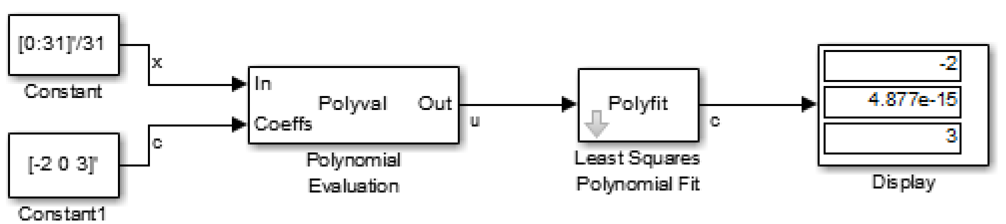
Each column of the (n+1)-by-N output matrix, c, represents a set of n+1 coefficients describing the best-fit polynomial for the corresponding column of the input. The coefficients in each column are arranged in order of descending exponents, c_1, c_2, ..., c_{n+1}.

Examples

In the ex_leastsquarespolyfit_ref model below, the Polynomial Evaluation block uses the second-order polynomial

$$y = -2u^2 + 3$$

to generate four values of dependent variable y from four values of independent variable u, received at the top port. The polynomial coefficients are supplied in the vector `[-2 0 3]` at the bottom port. Note that the coefficient of the first-order term is zero.



The **Control points** parameter of the Least Squares Polynomial Fit block is configured with the same four values of independent variable u that are used as input to the Polynomial Evaluation block, `[1 2 3 4]`. The Least Squares Polynomial Fit block uses these values together with the input values of dependent variable y to reconstruct the original polynomial coefficients.

Parameters

Control points

The values of the independent variable to which the data in each input column correspond. For an M-by-N input, this parameter must be a length-M vector. Tunable (Simulink).

Polynomial order

The order, n, of the polynomial to be used in constructing the best fit. The number of coefficients is n+1.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

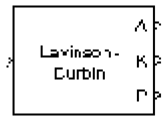
`polyfit`	MATLAB

Introduced before R2006a

Levinson-Durbin

Solve linear system of equations using Levinson-Durbin recursion



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The Levinson-Durbin block solves the nth-order system of linear equations
$Ra = b$

in the cases where:

- R is a Hermitian, positive-definite, Toeplitz matrix.
- b is identical to the first column of R shifted by one element and with the opposite sign.

$$\begin{bmatrix} r(1) & r^*(2) & \cdots & r^*(n) \\ r(2) & r(1) & \cdots & r^*(n-1) \\ \vdots & \vdots & \ddots & \vdots \\ r(n) & r(n-1) & \cdots & r(1) \end{bmatrix} \begin{bmatrix} a(2) \\ a(3) \\ \vdots \\ a(n+1) \end{bmatrix} = \begin{bmatrix} -r(2) \\ -r(3) \\ \vdots \\ -r(n+1) \end{bmatrix}$$

The input to the block, `r = [r(1) r(2) ... r(n+1)]`, can be a vector or a matrix. If the input is a matrix, the block treats each column as an independent channel and solves it separately. Each channel of the input contains lags *0* through *n* of an autocorrelation sequence, which appear in the matrix *R*.

The block can output the polynomial coefficients, *A*, the reflection coefficients, *K*, and the prediction error power, *P*, in various combinations. The **Output(s)** parameter allows you to enable the *A* and *K* outputs by selecting one of the following settings:

- `A` — For each channel, port A outputs `A = [1 a(2) a(3) ... a(n+1)]`, the solution to the Levinson-Durbin equation. *A* has the same dimension as the input. You can also view the elements of each output channel as the coefficients of an *n*th-order autoregressive (AR) process.
- `K` — For each channel, port K outputs `K = [k(1) k(2) ... k(n)]`, which contains *n* reflection coefficients and has the same dimension as the input, less one element. A scalar input channel causes an error when you select `K`. You can use reflection coefficients to realize a lattice representation of the AR process described later in this page.
- `A and K` — The block outputs both representations at their respective ports. A scalar input channel causes an error when you select `A and K`.

Select the **Output prediction error power (P)** check box to output the prediction error power for each channel, *P*. For each channel, *P* represents the power of the output of an FIR filter with taps *A* and input autocorrelation described by *r*, where *A* represents a prediction error filter and *r* is the input to the block. In this case, *A* is a whitening filter. *P* has one element per input channel.

When you select the **If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0** check box (default), an input channel whose `r(1)` element is zero generates a zero-valued output. When you clear this check box, an input with `r(1) = 0` generates `NaN`s in the output. In general, an input with `r(1) = 0` is invalid because it does not construct a positive-definite matrix *R*. Often, however, blocks receive zero-valued inputs at the start of a simulation. The check box allows you to avoid propagating `NaN`s during this period.

Applications

One application of the Levinson-Durbin formulation implemented by this block is in the Yule-Walker AR problem, which concerns modeling an unknown system as an autoregressive process. You would model such a process as the output of an all-pole IIR filter with white Gaussian noise input. In the Yule-Walker problem, the use of the signal's autocorrelation sequence to obtain an optimal estimate leads to an $Ra = b$ equation of the type shown above, which is most efficiently solved by Levinson-Durbin recursion. In this case, the input to the block represents the autocorrelation sequence, with `r(1)` being the zero-lag value. The output at the block's A port then contains the coefficients of the autoregressive process that optimally models the system. The coefficients are ordered in descending powers of z, and the AR process is minimum phase. The prediction error, G, defines the gain for the unknown system, where $G = \sqrt{P}$:

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ \ldots \ + a(n+1)z^{-n}}$$

The output at the block's K port contains the corresponding reflection coefficients, [k(1) k(2) ... k(n)], for the lattice realization of this IIR filter. The Yule-Walker AR Estimator block implements this autocorrelation-based method for AR model estimation, while the Yule-Walker Method block extends the method to spectral estimation.

Another common application of the Levinson-Durbin algorithm is in linear predictive coding, which is concerned with finding the coefficients of a moving average (MA) process (or FIR filter) that predicts the next value of a signal from the current signal sample and a finite number of past samples. In this case, the input to the block represents the signal's autocorrelation sequence, with r(1) being the zero-lag value, and the output at the block's A port contains the coefficients of the predictive MA process (in descending powers of z).

$$H(z) = A(z) = 1 + a(2)z^{-1} + \ \ldots \ a(n+1)z^{-n}$$

These coefficients solve the following optimization problem:

$$\min_{\{a_i\}}$$

$$E\left[\left|x_n - \sum_{i=1}^{N} a_i x_{n-i}\right|^2\right]$$

Again, the output at the block's K port contains the corresponding reflection coefficients, `[k(1) k(2) ... k(n)]`, for the lattice realization of this FIR filter.

The Autocorrelation LPC block in the Linear Prediction library implements this autocorrelation-based prediction method.

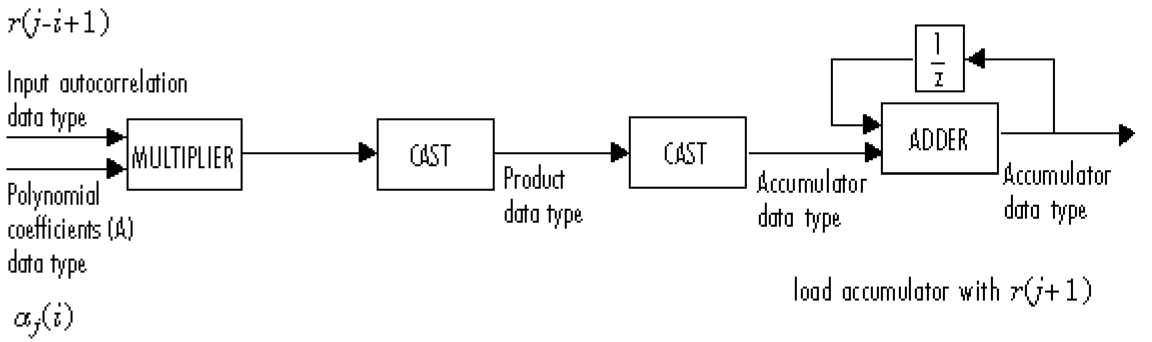
Fixed-Point Data Types

The diagrams in this section show the data types used within the Levinson-Durbin block for fixed-point signals.

After initialization the block performs n updates. At the (j+1) update,

$$\text{value in accumulator } = r(j+1) + \sum a_j(i) \times r(j-i+1)$$

The following diagram displays the fixed-point data types used in this calculation:



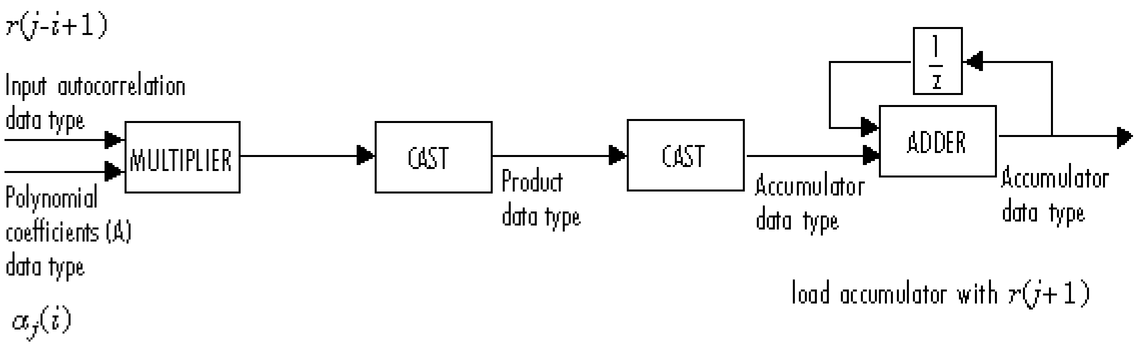
The block then updates the reflection coefficients K according to

$$K_{j+1} = \text{ value in accumulator } / P_j$$

The block then updates the prediction error power P according to

$$P_{j+1} = P_j - P_j \times K_{j+1} \times \text{conj}(K_{j+1})$$

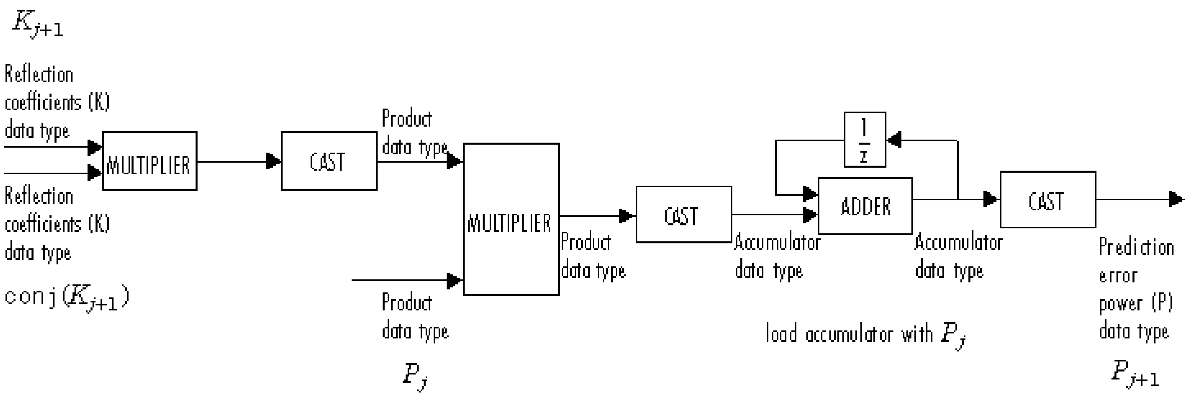
The next diagram displays the fixed-point data types used in this calculation:



The polynomial coefficients A are then updated according to

$$a_{j+1}(i) = a_j(i) + K_{j+1} \times \mathrm{conj}\left(\mathrm{a}_\mathrm{j}(j-1+i)\right)$$

This diagram displays the fixed-point data types used in this calculation:

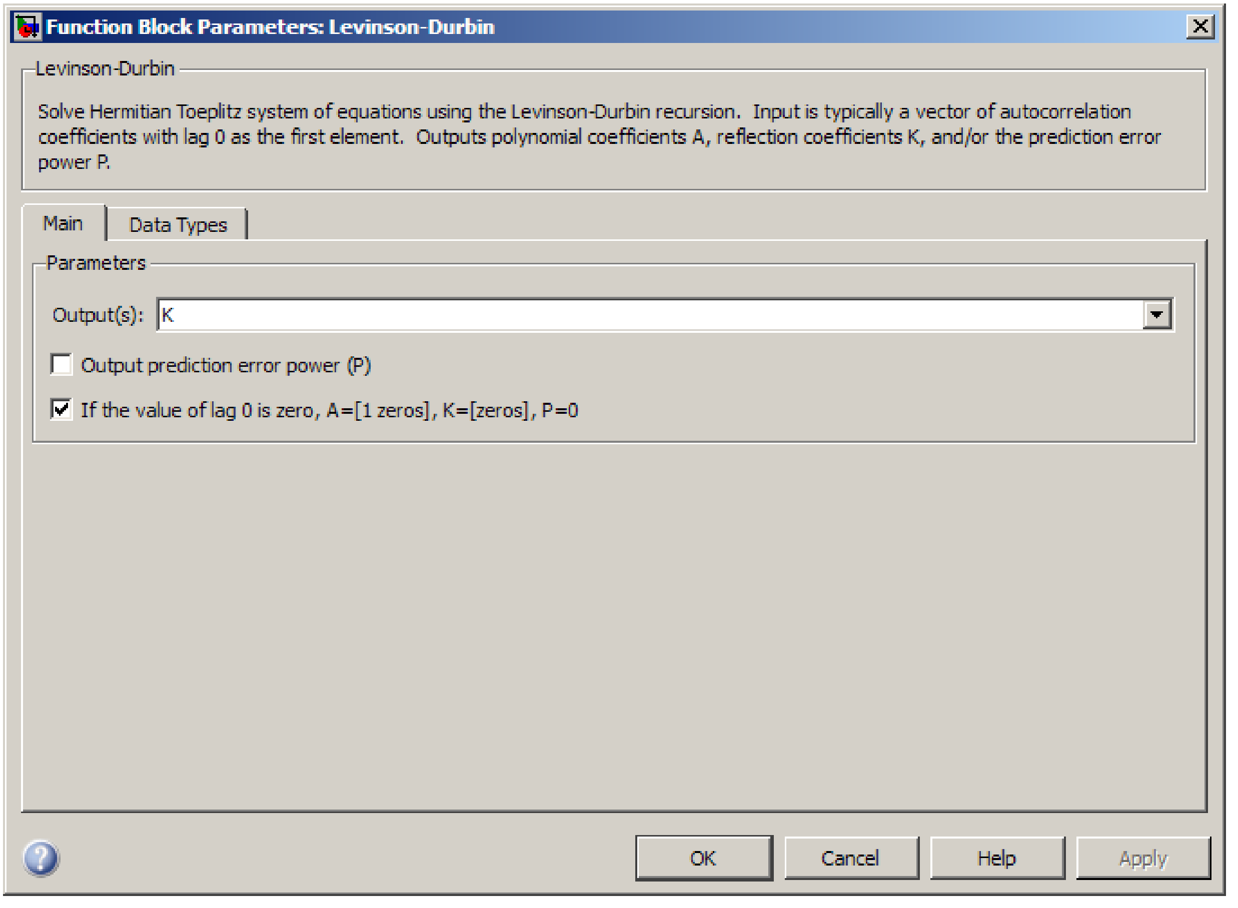


Algorithm

The algorithm requires $O(n^2)$ operations for each input channel. This implementation is therefore much more efficient for large n than standard Gaussian elimination, which requires $O(n^3)$ operations per channel.

Dialog Box

The **Main** pane of the Levinson-Durbin block dialog box appears as follows.



Output(s)

Specify the solution representation of $Ra = b$ to output: model coefficients (A), reflection coefficients (K), or both (A and K). When the input is a scalar or row vector, you must set this parameter to A.

Output prediction error power (P)

Select to output the prediction error at port P.

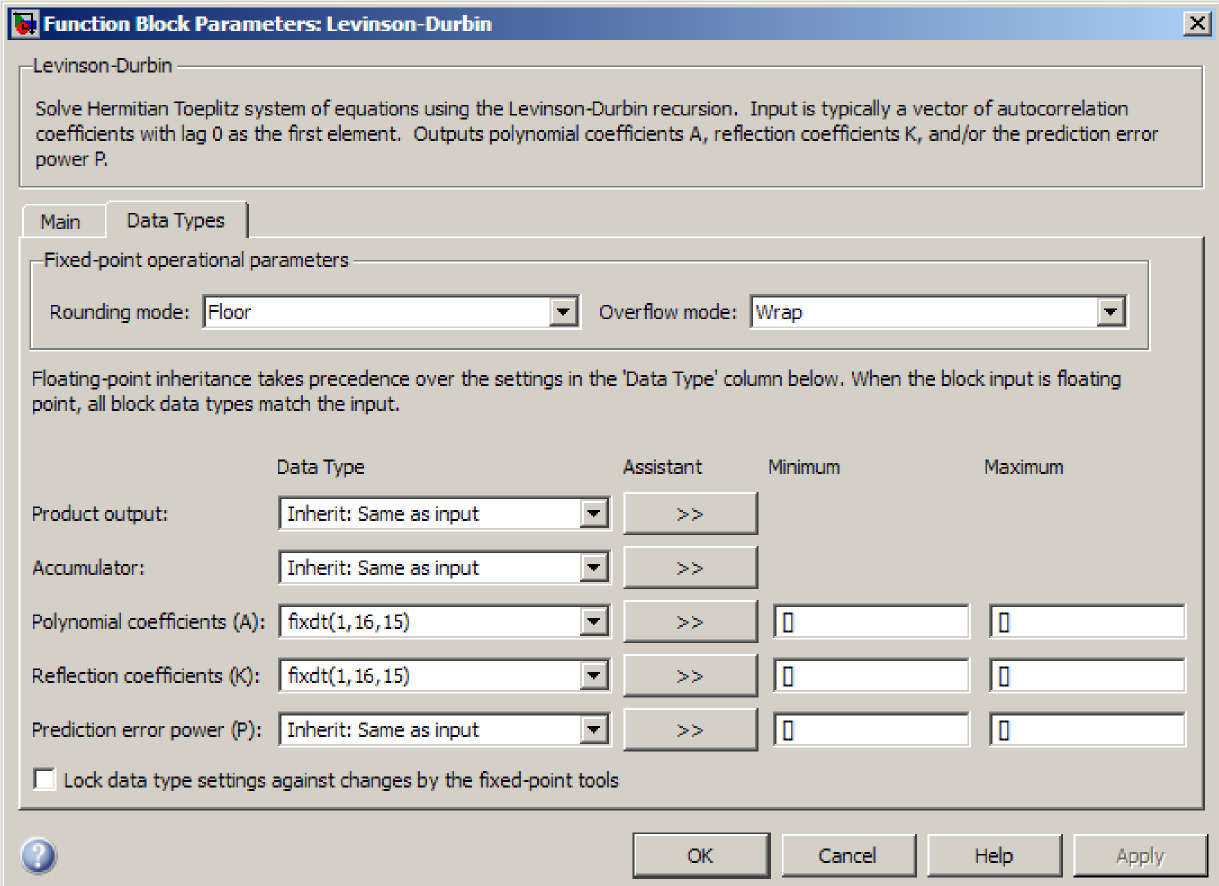
If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0

When you select this check box and the first element of the input, `r(1)`, is zero, the block outputs the following vectors, as appropriate:

- `A = [1 zeros(1,n)]`
- `K = [zeros(1,n)]`
- `P = 0`

When you clear this check box, the block outputs a vector of `NaN`s for each channel whose `r(1)` element is zero.

The **Data Types** pane of the Levinson-Durbin block dialog box appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1045 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1045 for illustrations depicting the use of the accumulator data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Polynomial coefficients (A)

Specify the polynomial coefficients (*A*) data type. See “Fixed-Point Data Types” on page 2-1045 for illustrations depicting the use of the A data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **A** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Reflection coefficients (K)

Specify the polynomial coefficients (*A*) data type. See “Fixed-Point Data Types” on page 2-1045 for illustrations depicting the use of the K data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **K** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Prediction error power (P)

Specify the prediction error power (*P*) data type. See “Fixed-Point Data Types” on page 2-1045 for illustrations depicting the use of the P data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **P** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified).Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see "Specify Minimum and Maximum Values for Block Parameters" (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

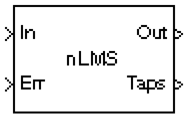
LMS Adaptive Filter (Obsolete)

Compute filter estimates for input using LMS adaptive filter algorithm



Library

`dspobslib`

Description

Note The LMS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `LMS Filter` block.

The LMS Adaptive Filter block implements an adaptive FIR filter using the stochastic gradient algorithm known as the normalized least mean-square (LMS) algorithm.

$$y(n) = \hat{w}^H(n-1)u(n)$$

$$e(n) = d(n) - y(n)$$

$$\hat{w}(n) = \hat{w}(n-1) + \frac{u(n)}{a + u^H(n)u(n)}\mu e^*(n)$$

The variables are as follows.

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$\hat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size

To overcome potential numerical instability in the tap-weight update, a small positive constant (a = 1e-10) has been added in the denominator.

To turn off normalization, clear the **Use normalization** check box in the parameter dialog. The block then computes the filter-tap estimate as

$$\hat{w}(n) = \hat{w}(n-1) + u(n)\mu e^*(n)$$

The block icon has port labels corresponding to the inputs and outputs of the LMS algorithm. Note that inputs to the In and Err ports must be sample-based scalars. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

Block Ports	Corresponding Variables
`In`	u, the scalar input, which is internally buffered into the vector $u(n)$
`Out`	$y(n)$, the filtered scalar output
`Err`	$e(n)$, the scalar estimation error
`Taps`	$\hat{w}(n)$, the vector of filter-tap estimates

An optional `Adapt` input port is added when you select the **Adapt input** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the `Adapt` input is nonzero. A zero-valued input to the Adapt port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero `Adapt` input.

The **FIR filter length** parameter specifies the length of the filter that the LMS algorithm estimates. The **Step size** parameter corresponds to μ in the equations. Typically, for convergence in the mean square, μ must be greater than 0 and less than 2. The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The **Leakage factor** specifies the value of the leakage factor, 1 –μ α, in the leaky LMS algorithm below. This parameter must be between 0 and 1.

$$\hat{w}(n+1) = (1-\mu\alpha)\hat{w}(n) + \frac{u(n)}{u^H(n)u(n)}\mu e^*(n)$$

Examples

See the lmsadeq and lmsadtde demos.

Parameters

FIR filter length

The length of the FIR filter.

Step-size

The step-size, usually in the range (0, 2). Tunable (Simulink).

Initial value of filter taps

The initial FIR filter coefficients.

Leakage factor

The leakage factor, in the range [0, 1]. Tunable (Simulink).

Use normalization

Select this check box to compute the filter-tap estimate using the normalized equations.

Adapt input

Enables the Adapt port when selected.

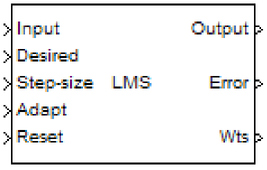
LMS Filter

Compute output, error, and weights using LMS adaptive algorithm



Library

Filtering / Adaptive Filters

`dspadpt3`

Description

The LMS Filter block can implement an adaptive FIR filter using five different algorithms. The block estimates the filter weights, or coefficients, needed to minimize the error, *e(n)*, between the output signal *y(n)* and the desired signal, *d(n)*. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the desired signal to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal, which is the estimate of the desired signal. The Error port outputs the result of subtracting the output signal from the desired signal.

When you select `LMS` for the **Algorithm** parameter, the block calculates the filter weights using the least mean-square (LMS) algorithm. This algorithm is defined by the following equations.

$$
\begin{aligned}
y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\
e(n) &= d(n) - y(n) \\
\mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)
\end{aligned}
$$

The various LMS adaptive filter algorithms available in this block are defined as:

- LMS:

$$f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS:

$$f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

- Sign-Error LMS:

$$f(\mathbf{u}(n),e(n),\mu) = \mu\, sign(e(n))\mathbf{u}^*(n)$$

- Sign-Data LMS:

$$f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\, sign(\mathbf{u}(n))$$

  where **u**(n) is real.
- Sign-Sign LMS:

$$f(\mathbf{u}(n),e(n),\mu) = \mu\, sign(e(n))\, sign(\mathbf{u}(n))$$

  where **u**(n) is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n

Variable	Description
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)

In NMLS, to overcome potential numerical instability in the update of the weights, a small positive constant, epsilon, has been added in the denominator. For double-precision floating-point input, epsilon is 2.2204460492503131e-016. For single-precision floating-point input, epsilon is 1.192092896e-07. For fixed-point input, epsilon is 0.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Step size (mu)** parameter corresponds to μ in the equations. For convergence of the normalized LMS equations, $0<\mu<2$. You can either specify a step size using the input port, Step-size, or by entering a value in the Block Parameters: LMS Filter dialog.

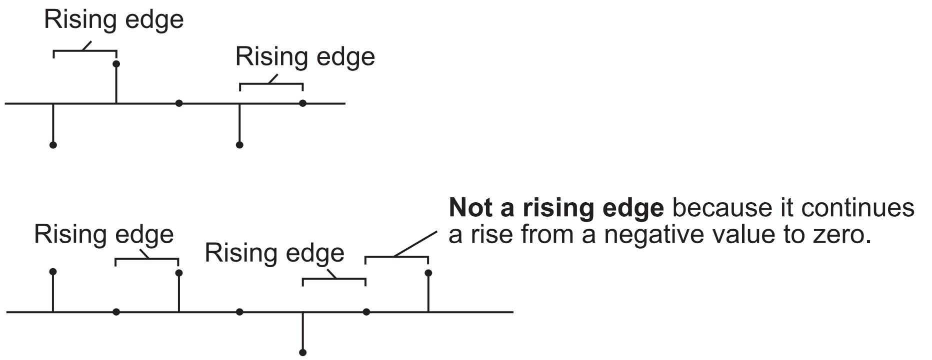
Enter the initial filter weights **w**(0) as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is less than or equal to zero, the filter weights remain at their current values.

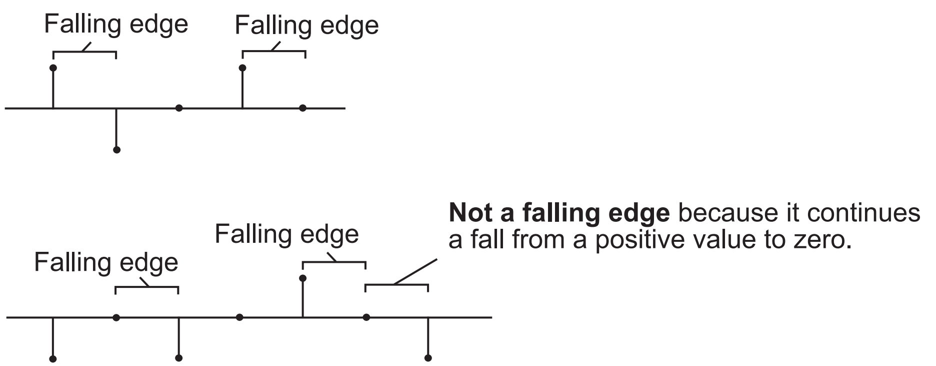
When you want to reset the value of the filter weights to their initial values, use the **Reset port** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset port** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset port** list:

- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge` (as described above)
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

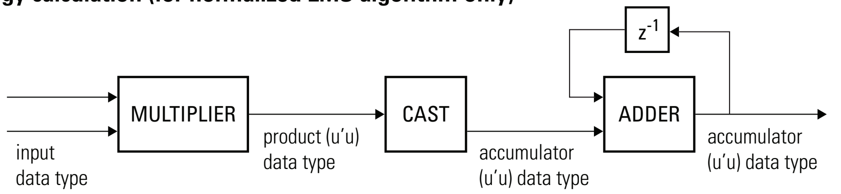
Fixed-Point Data Types

The following diagrams show the data types used within the LMS Filter block for fixed-point signals; the table summarizes the definitions of variables used in the diagrams:

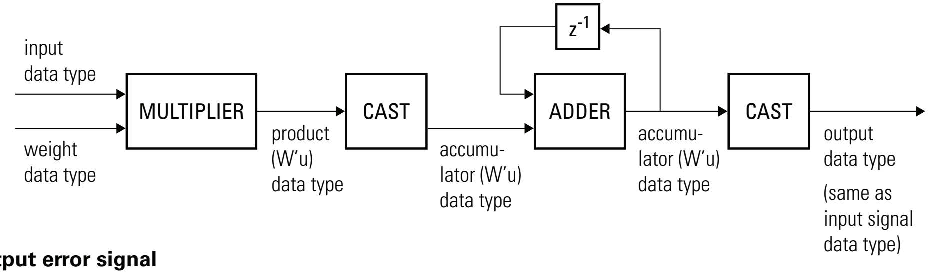
Variable	Definition
u	Input vector
W	Vector of filter weights
μ	Step size
e	Error
Q	Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$
Product **u'u**	Product data type in Energy calculation diagram
Accumulator **u'u**	Accumulator data type in Energy calculation diagram
Product **W'u**	Product data type in Convolution diagram
Accumulator **W'u**	Accumulator data type in Convolution diagram
Product $\mu \cdot e$	Product data type in Product of step size and error diagram
Product $Q \cdot \mathbf{u}$	Product and accumulator data type in Weight update diagram. [1]

[1]The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

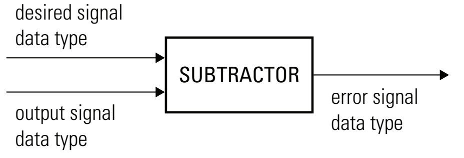
Energy calculation (for normalized LMS algorithm only)



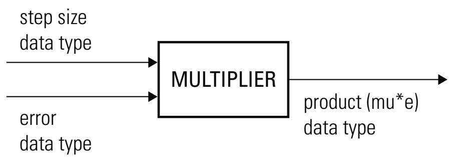
Convolution



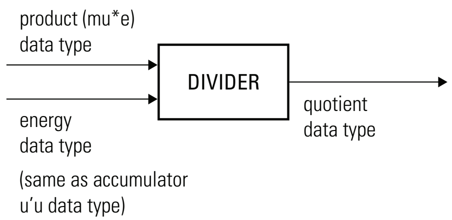
Output error signal



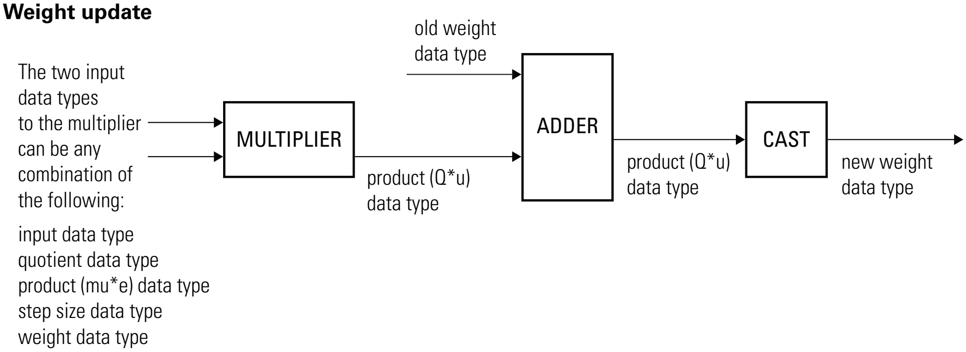
Product of step size and error (for LMS and Sign-Data LMS algorithms only)



Quotient (for normalized LMS only)



Weight update



You can set the data type of the parameters, weights, products, quotient, and accumulators in the block mask. Fixed-point inputs, outputs, and mask parameters of this block must have the following characteristics:

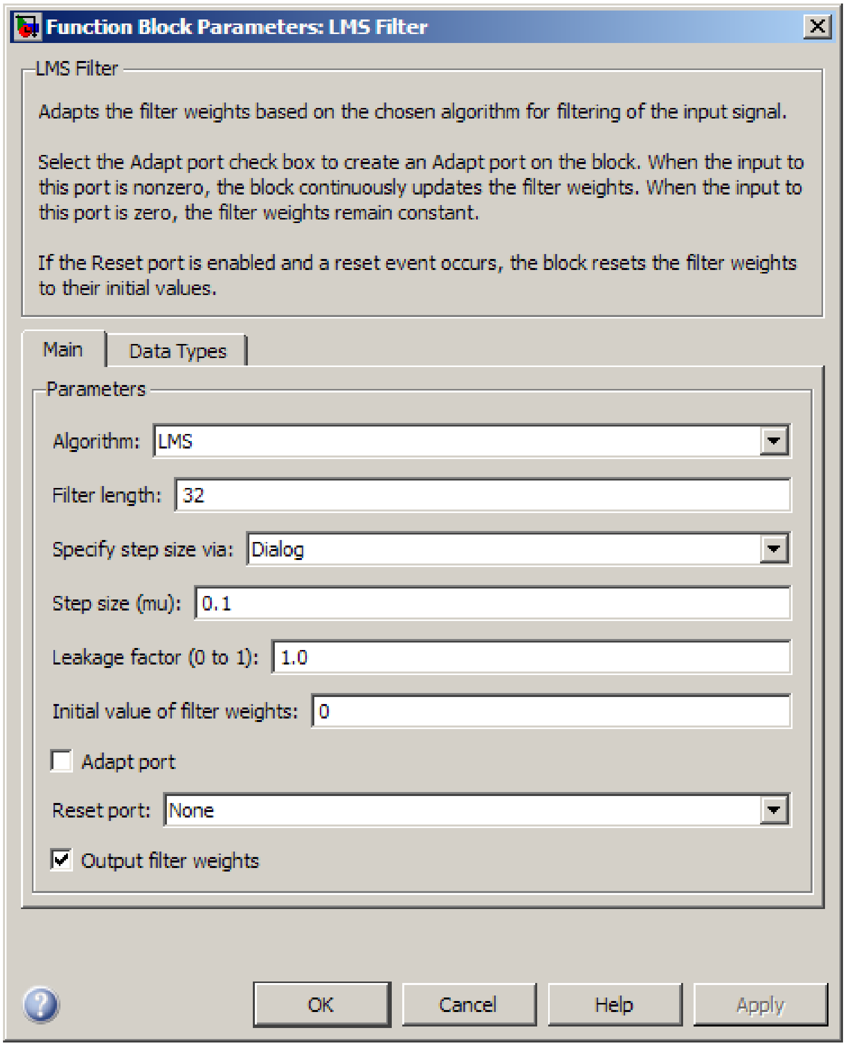
- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.

- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the **u'u**, **W'u**, $\mu \cdot e$, and $Q \cdot \mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the **u'u** and **W'u** operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Dialog Box

The **Main** pane of the LMS Filter block dialog appears as follows.



Algorithm

Choose the algorithm used to calculate the filter weights.

Filter length

Enter the length of the FIR filter weights vector.

Specify step size via

Select `Dialog` to enter a value for step size in the Block parameters: LMS Filter dialog. Select `Input port` to specify step size using the Step-size input port.

Step size (mu)

Enter the step size μ. Tunable (Simulink).

Leakage factor (0 to 1)

Enter the leakage factor, $0 < 1 - \mu\alpha \leq 1$. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Adapt port

Select this check box to enable the Adapt input port.

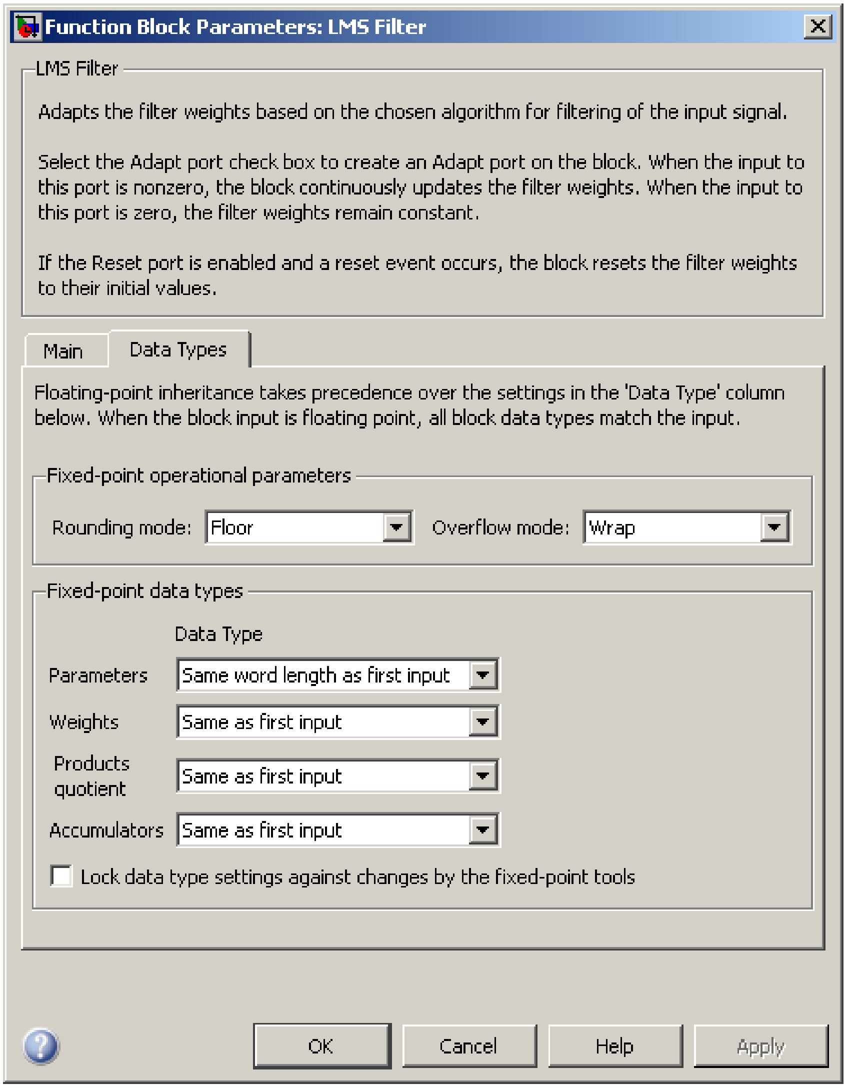
Reset port

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

The **Data Types** pane of the LMS Filter block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Parameters

This parameter is visible if, for the **Specify step size via** parameter, you choose `Dialog`. Choose how you specify the word length and the fraction length of the leakage factor and step size:

- When you select `Same word length as first input`, the word length of the leakage factor and step size match that of the first input to the block. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Specify word length`, you can enter the word length of the leakage factor and step size, in bits. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the leakage factor and step size, in bits. The leakage factor and the step size must have the same word length, but the fraction lengths can differ.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the leakage factor and step size. The leakage factor and the step size must have the same word length, but the slopes can differ. This block requires a power-of-two slope and a bias of zero.

If, for the **Specify step size via** parameter, you choose `Input port`, the word length of the leakage factor is the same as the word length of the step size input at the Step size port. The fraction length of the leakage factor is automatically set to the best precision possible based on the word length of the leakage factor.

Weights

Choose how you specify the word length and fraction length of the filter weights of the block:

- When you select `Same as first input`, the word length and fraction length of the filter weights match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the filter weights, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the filter weights. This block requires a power-of-two slope and a bias of zero.

Products & quotient

Choose how you specify the word length and fraction length of **u'u**, **W'u**, $\mu \cdot e$, $Q \cdot \mathbf{u}$, and the quotient, Q. Here, **u** is the input vector, **W** is the vector of filter weights, μ is the step size, e is the error, and Q is the quotient, which is defined as $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$

- When you select `Same as first input`, the word length and fraction length of these quantities match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of these quantities, in bits. The word length of the quantities must be the same, but the fraction lengths can differ.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of these quantities. The word length of the quantities must be the same, but the slopes can differ. This block requires a power-of-two slope and a bias of zero.

Accumulators

Use this parameter to specify how you would like to designate the word and fraction lengths of the accumulators for the **u'u** and **W'u** operations.

Note This parameter is *not* used to designate the word and fraction lengths of the accumulator for the $Q \cdot \mathbf{u}$ operation. The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

See “Fixed-Point Data Types” on page 2-1062 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as first input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulators, in bits. The word length of both the accumulators must be the same, but the fraction lengths can differ.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulators. The word length of both the accumulators

must be the same, but the slopes can differ. This block requires a power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see LMS Filter.

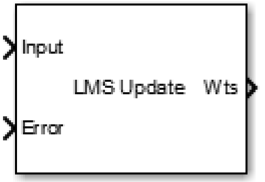
LMS Update

Estimate weights of LMS adaptive filter

Library: DSP System Toolbox / Filtering / Adaptive Filters



Description

The LMS Update block estimates the weights of an LMS adaptive filter. The block accepts the data and error as inputs and computes the filter weights based on the algorithm the block chooses. For more details on the algorithms, see “Algorithms” on page 2-1076.

You can use this block to compute the adaptive filter weights in applications such as system identification, inverse modeling, and filtered-x LMS algorithms, which are used in acoustic noise cancellation. For more details, see Bibliography.

Ports

Input

`Input` — Data input

scalar

Data input to the adaptive filter. The block accepts single-precision or double-precision floating point inputs. All inputs must be scalars and must have the same data type and precision.

Data Types: `single | double`

Complex Number Support: Yes

`Error` — Error

scalar

Error between the output signal and the desired signal.

Data Types: `single` | `double`
Complex Number Support: Yes

`Mu` — Filter adaptation step size
0.1 (default) | scalar in the range [0,1]

To enable this port, set **Step size source** to `Input port`.

Data Types: `single` | `double`

`Adapt` — Update filter weights
real scalar

When the input to this port is not zero, the block updates the filter weights. When the input to this port is 0, the filter weights do not change.

Data Types: `single` | `double` | `Boolean` | `int16` | `int32` | `int64` | `int8` | `uint16` | `uint32` | `uint64` | `uint8`

`Reset` — Reset filter weights
real scalar

When the input to this port is not zero, the block resets the filter weights to their initial values. When the input to this port is 0, the filter weights do not change.

Data Types: `single` | `double` | `Boolean` | `int16` | `int32` | `int64` | `int8` | `uint16` | `uint32` | `uint64` | `uint8`

Output

`Wts` — Filter weights
1-by-*n* row vector

The length of the filter weights vector is the value in the **Filter length** parameter.

Data Types: `single` | `double`

Parameters

`Algorithm` — LMS adaptive algorithm
`LMS` (default) | `Normalized LMS` | `Sign-Error LMS` | `Sign-Data LMS` | `Sign-Sign LMS`

The block uses one of the listed algorithms to compute the filter weights. For more details on the algorithms, see “Algorithms” on page 2-1076.

`Filter length` — Length of the filter

32 (default) | positive integer

Filter length specifies the length of the weights vector the block generates through the **Wts** output port.

`Step size source` — Method to specify the step size

`Property` (default) | `Input port`

- `Property` — Specify the filter adaptation size using the **Step size (mu)** parameter.
- `Input port` — Pass filter adaptation size using the **Mu** input port.

`Step size (mu)` — Size of the adaptation step

0.1 (default) | nonnegative scalar

Step size (mu) indicates the amount by which the filter weights are updated in each iteration. Choose an optimal step size so that the filter is stable and the convergence speed is optimal.

To enable this parameter, set **Step size source** to `Property`.

This parameter is tunable. You can change its value even during the simulation.

`Leakage factor (0 to 1)` — Leakage factor

1.0 (default) | real scalar in the range [0,1]

Leakage factor (0 to 1) prevents unbounded growth of the filter coefficients by reducing the drift of the coefficients from their optimum values. A leakage factor of `1.0` indicates no leakage. If you encounter coefficient drift, that is, large fluctuation about the optimum solution, decrease the leakage factor until the coefficient fluctuation becomes small.

This parameter is tunable. You can change its value even during the simulation.

`Initial value of filter weights` — Initial value of filter weights

0 (default) | real scalar

This parameter specifies the initial value of the filter weights, *w(n-1)*. The block uses this value to compute the weights, *w(n)*, when n = 1. For more details, see “Algorithms” on page 2-1076.

`Enable adapt input` — Update the filter weights
off (default) | on

When you select this check box, the **Adapt** input port appears on the block. When the input to this port is greater than 0, the block updates the filter weights. When the input to this port is less than or equal to 0, the filter weights do not change.

`Enable reset input` — Reset the filter weights
off (default) | on

When you select this check box, the **Reset** input port appears on the block. When the input to this port is greater than 0, the block resets the filter weights to their initial values. When the input to this port is less than or equal to 0, the filter weights do not change.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Model Examples

Algorithms

The block computes filter weight estimates using $\mathbf{w}(n) = \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$.

The function $f(\mathbf{u}(n), e(n), \mu)$ is defined according to the LMS algorithm you specify through the **Algorithm** parameter:

- **`LMS`** — $f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\mathbf{u}^*(n)$
- **`Normalized LMS`** — $$f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

  In the `Normalized LMS` algorithm, ε is a small positive constant that overcomes the potential numerical instability in the update of weights.

  For double-precision floating-point inputs, ε is `2.2204460492503131e-016`. For single-precision floating-point inputs, ε is `1.192092896e-07`. For fixed-point input, ε is 0.
- **`Sign-Error LMS`** — $f(\mathbf{u}(n),e(n),\mu) = \mu\, sign(e(n))\mathbf{u}^*(n)$
- **`Sign-Data LMS`** — $f(\mathbf{u}(n),e(n),\mu) = \mu e(n)\, sign(\mathbf{u}(n))$, where **u**(n) is real
- **`Sign-Sign LMS`** — $f(\mathbf{u}(n),e(n),\mu) = \mu\, sign(e(n))\, sign(\mathbf{u}(n))$, where **u**(n) is real

In the previous equations:

- n — The current time index
- $\mathbf{u}(n)$ — The vector of buffered input samples at step n
- $\mathbf{u}^*(n)$ — The complex conjugate of the vector of buffered input samples at step n
- $\mathbf{w}(n)$ — The vector of filter weight estimates at step n
- $e(n)$ — The estimation error at step n
- μ — The adaptation step size
- α — The leakage factor ($0 \le \alpha \le 1$)

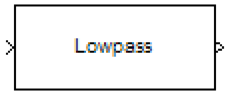
Lowpass Filter

Design FIR or IIR lowpass filter



Library

Filtering / Filter Designs

`dspfdesign`

Description

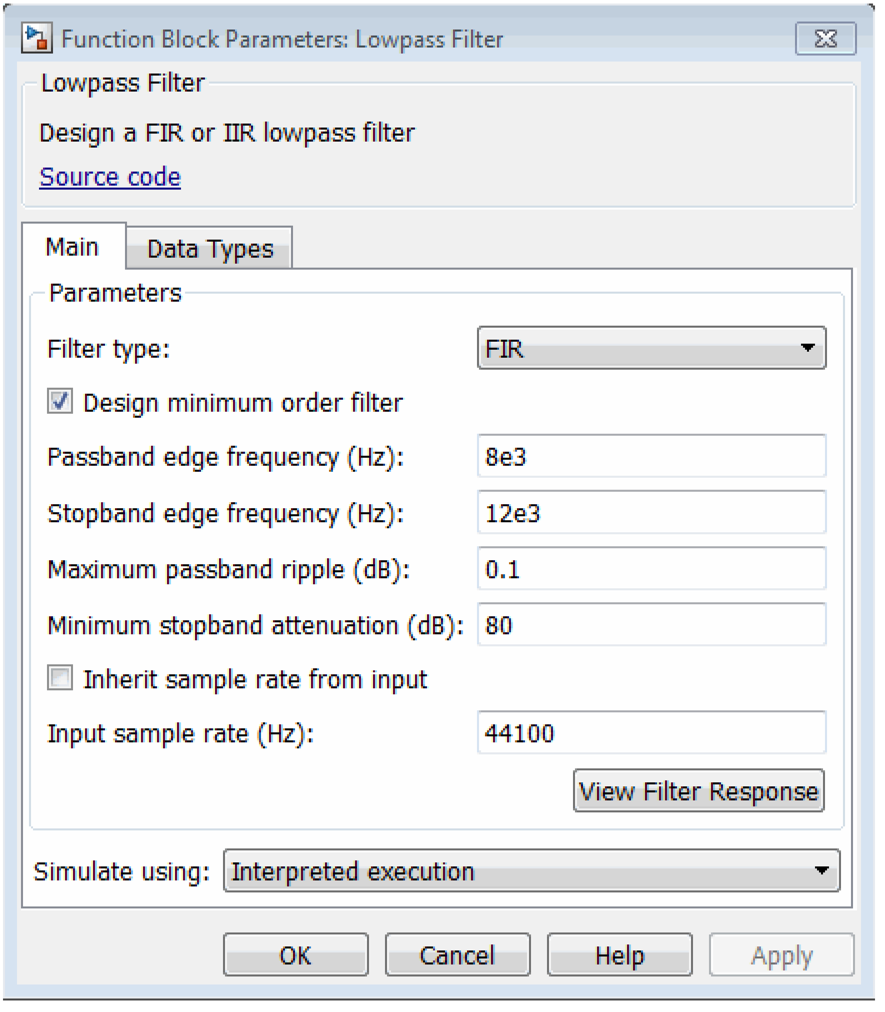
The Lowpass Filter block independently filters each channel of the input signal over time using the given design specifications.

You can set the **Filter type** parameter of the block to implement the block as an FIR or IIR lowpass filter. The block design the filter based on the parameters specified in the block dialog box.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.
The block supports fixed-point operations, HDL code generation, and ARM Cortex code generation. To learn more about ARM Cortex code generation, see "ARM Cortex-M and ARM Cortex-A Optimization"

Dialog Box

Main Tab



Parameters

Filter type

Type of lowpass filter.

- `FIR` (default) — Design an FIR lowpass filter.
- `IIR` — Design an IIR lowpass filter.

Design minimum order filter

When you select this check box, the block designs a filter with the minimum order and the specified passband, stopband frequency, passband ripple, and stopband attenuation. Set these specifications using the corresponding parameters. When you clear this check box, specify the order of the filter in **Filter order**.

By default, this check box is selected.

Filter order

Filter order of lowpass filter, specified as a positive scalar integer. You can specify the filter order only when **Design minimum order filter** check box is cleared. The default is `50`.

Passband edge frequency (Hz)

Passband edge frequency of the lowpass filter, specified as a real positive scalar in Hz. The passband edge frequency must be less than half the value of the **Input sample rate (Hz)**. The default is `8e3`.

Stopband edge frequency (Hz)

Stopband edge frequency of the lowpass filter, specified as a real positive scalar in Hz. The stopband edge frequency must be less than half the value of the **Input sample rate (Hz)**. You can specify the stopband edge frequency only when the **Design minimum order filter** is selected. The default is `12e3`.

Maximum passband ripple (dB)

Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB. The default is `0.1`.

Minimum stopband attenuation (dB)

Minimum attenuation in the stopband, specified as a real positive scalar in dB. The default is `80`.

Inherit sample rate from input

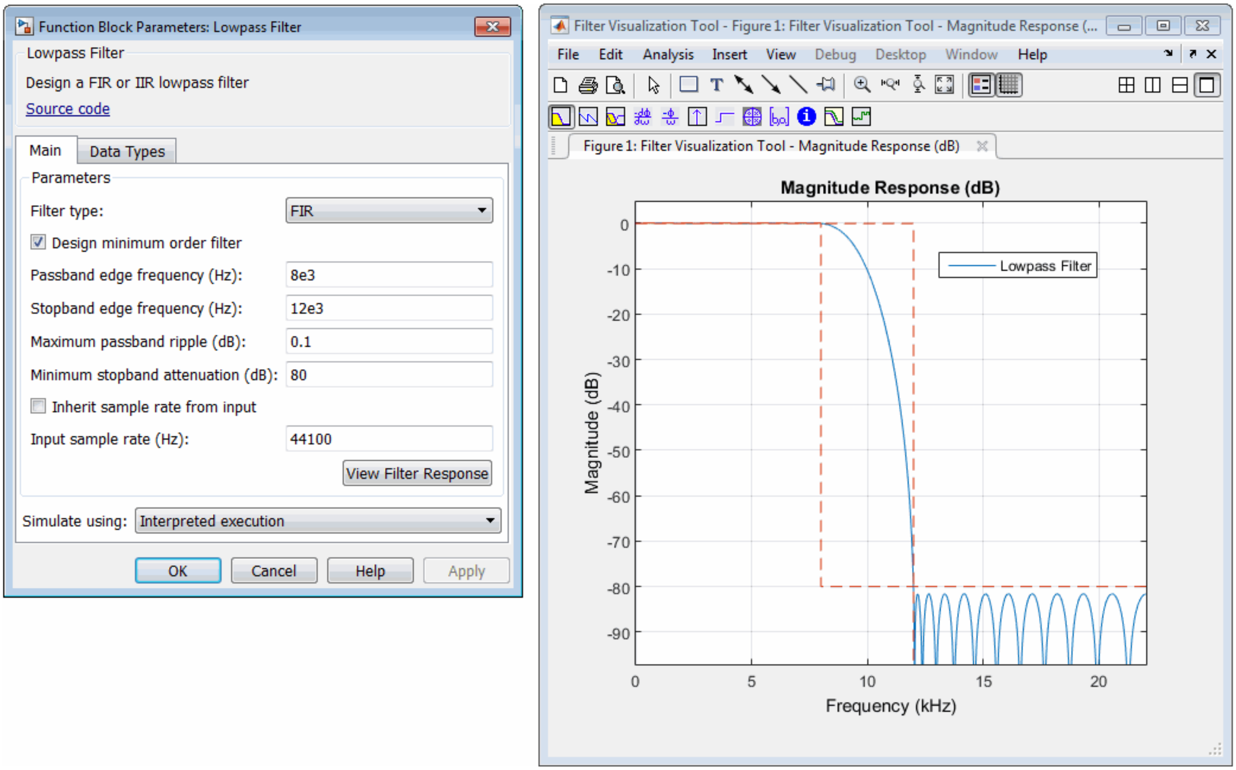
When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

Input sample rate (Hz)

Input sample rate, specified as a scalar in Hz. The default is `44100`.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Lowpass Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.



To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

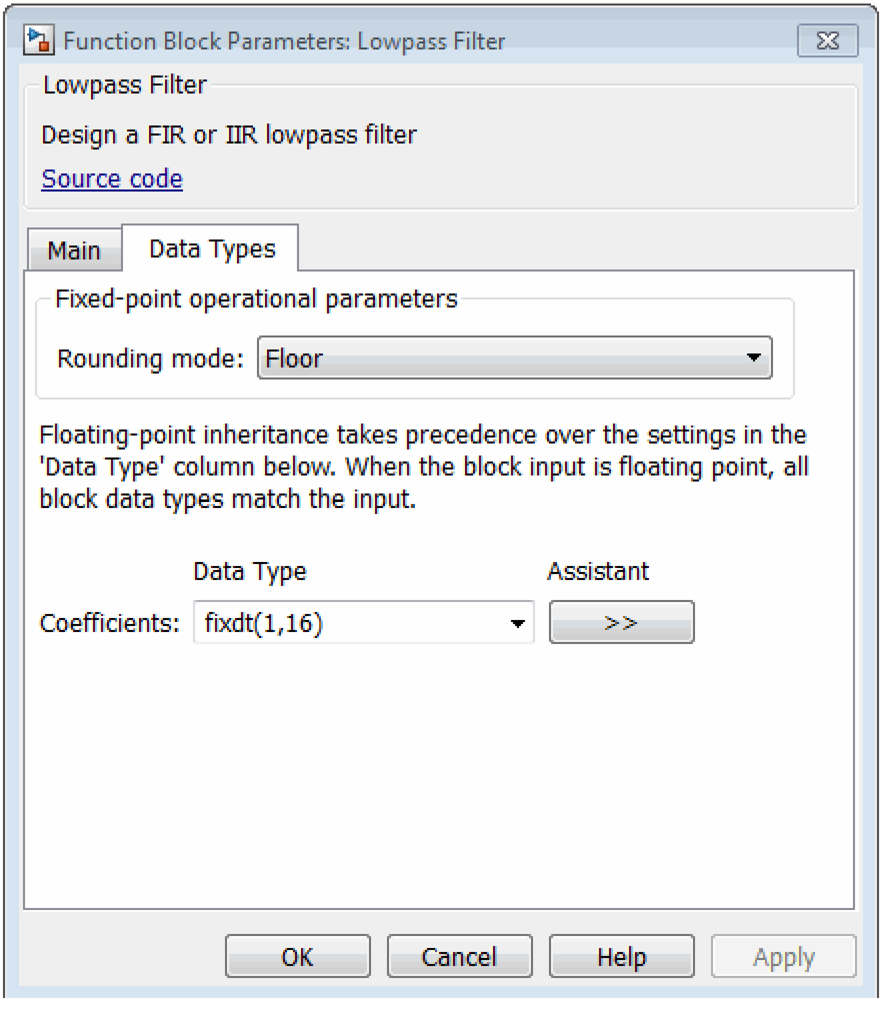
- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

- `Code generation`

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

Data Types Tab



Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, and `Zero`. The default is `Floor`.

Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length `16`, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length `16` and fraction length, `0`. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16, 15)`). Specify the sign mode of this data type as `[ ]` or `true`.
- `Refresh Data Type` — Refresh to the default data type.

Click the **Show data type assistant** button >> to display the data type assistant, which helps you set the stage input parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed or unsigned)

Algorithm

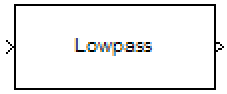
This block brings the capabilities of the dsp.LowpassFilter System object to the Simulink environment.

For information on the algorithms used by this block, see the Algorithms on page 4-1191 section of `dsp.LowpassFilter` system object.

Introduced in R2015b

Lowpass Filter (Obsolete)

Design lowpass filter



Note: The Lowpass Filter (Obsolete) block has been replaced by the `Lowpass Filter` block. Existing instances of the Lowpass Filter (Obsolete) block will continue to operate. For new models, use the Lowpass Filter block.

Library

Filtering / Filter Designs

`dspfdesign`

Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Parameters

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify`. Selecting `Specify` enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to `IIR`, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

Order

Enter the filter order. This option is enabled only if you set the **Order mode** to `Specify`.

Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to `IIR` and the **Order mode** to `Specify`.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting `Sample-rate converter` activates both factors.

Decimation Factor

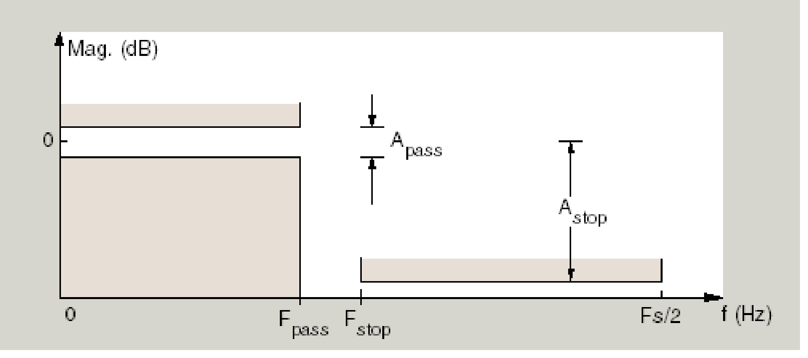
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.



In the figure, regions between specification values such as F_{pass} and F_{stop} represent transition regions where the filter response is not constrained.

Frequency constraints

When **Order mode** is `Specify`, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and Stopband frequencies` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband frequency` — Define the filter by specifying the edge of the passband.
- `Stopband frequency` — Define the filter by specifying the edge of the stopband.

- `Hafband power (3dB) frequency` — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- `Cutoff (6dB) frequency` — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input sample rate** parameter.

Input sample rate

Input sample rate, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Half power (3dB) frequency

When **Frequency constraints** is `Half power (3dB) frequency`, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Cutoff (6dB) frequency

When **Frequency constraints** is `Cutoff (6dB) frequency`, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: `Unconstrained`, and `Passband ripple and stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)

Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually `Elliptic`, and the default FIR method is `Equiripple`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Specify the phase constraint of the filter as `Linear`, `Maximum`, or `Minimum`.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters (Impulse response: IIR).

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

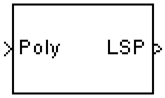
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2006b

LPC to LSF/LSP Conversion

Convert linear prediction coefficients to line spectral pairs or line spectral frequencies



Library

Estimation / Linear Prediction

`dsplp`

Description

The LPC to LSF/LSP Conversion block takes a vector or matrix of linear prediction coefficients (LPCs) and converts it to a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs). When converting LPCs to LSFs, the block outputs match those of the `poly2lsf` function.

The block input must be either a matrix, a column vector, or an unoriented vector. Each channel of the input must have at least two samples.

The input LPCs for each channel, 1, a_1, a_2, ..., a_m, must be the denominator of the transfer function of a stable all-pole filter with the form given in the first equation of “Requirements for Valid Outputs” on page 2-1095. A length-M+1 input channel yields a length-M output channel.

See other sections of this reference page to learn about how to ensure that you get valid outputs, how to detect invalid outputs, how the block computes the LSF/LSP values, and more.

Requirements for Valid Outputs

To get valid outputs, your inputs and the **Root finding coarse grid points** parameter value must meet these requirements:

- The input LPCs for each channel, 1, a_1, a_2, ..., a_m, must come from the denominator of the following transfer function, *H(z)*, of a stable all-pole filter (all roots of *H(z)* must be inside the unit circle). Note that the first term in *H(z)*'s denominator must be 1. When the input LPCs do not come from a transfer function of the following form, the block outputs are invalid.

$$H(z) = \frac{1}{1 + a_1 z^{-1} + a_2 z^{-2} + \ \ldots \ + a_m z^{-m}}$$

- The **Root finding coarse grid points** parameter value must be large enough so that the block can find all the LSP or LSF values. (The output LSFs and LSPs are roots of polynomials related to the input LPC polynomial; the block looks for these roots to produce the output. For details, see "LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding" on page 2-1101.) When you do not set **Root finding coarse grid points** to a high enough value relative to the number of LPCs, the block might not find all the LSPs or LSFs and yield invalid outputs as described in "Root Finding Method Limitations: Failure to Find Roots" on page 2-1105.

To learn about recognizing invalid inputs and outputs and parameters for dealing with them, see "Handling and Recognizing Invalid Inputs and Outputs" on page 2-1097.

Setting Outputs to LSFs or LSPs

Set the **Output** parameter to one of the following settings to determine whether the block outputs LSFs or LSPs:

- `LSF in radians (0 pi)` — Block outputs the LSF values between 0 and π radians in increasing order. The block does not output the guaranteed LSF values, 0 and π.
- `LSF normalized in range (0 0.5)` — Block outputs normalized LSF values in increasing order, computed by dividing the LSF values between 0 and π radians by 2π. The block does not output the guaranteed normalized LSF values, 0 and 0.5.
- `LSP in range (-1 1)` — Block outputs LSP values in decreasing order, equal to the cosine of the LSF values between 0 and π radians. The block does not output the guaranteed LSP values, -1 and 1.

Adjusting Output Computation Time and Accuracy with Root Finding Parameters

The values n and k determine the block's output computation time and accuracy, where

- n is the value of the **Root finding coarse grid points** parameter (choose this value with care; see the note below).
- k is the value of the **Root finding bisection refinement** parameter.
- Decreasing the values of n and k decreases the output computation time, but also decreases output accuracy:
  - The upper bound of block's computation time is proportional to $k \cdot (n-1)$.
  - Each LSP output is within $1/(n \cdot 2^k)$ of the actual LSP value.
  - Each LSF output is within ΔLSF of the actual LSF value, LSF_{act}, where

$$\Delta LSF = \left| a\cos\left(LSF_{act}\right) - a\cos\left(LSF_{act} + 1/\left(n \cdot 2^k\right)\right)\right|$$

Note When the value of the **Root finding coarse grid points** parameter is too small relative to the number of LPCs, the block might output invalid data as described in "Requirements for Valid Outputs" on page 2-1095. Also see "Handling and Recognizing Invalid Inputs and Outputs" on page 2-1097.

Notable Input and Output Properties

- To get valid outputs, your input LPCs and the value of the **Root finding coarse grid points** parameter must meet the requirements described in "Requirements for Valid Outputs" on page 2-1095.
- Length-L+1 input channel yields length-L output channel
- **Output** parameter determines the output type (see "Setting Outputs to LSFs or LSPs" on page 2-1096):
  - LSFs — frequencies, w_k, where $0 < w_k < \pi$ and $w_k < w_{k+1}$
  - Normalized LSFs — $w_k / 2\pi$
  - LSPs — $\cos(w_k)$

Handling and Recognizing Invalid Inputs and Outputs

The block outputs invalid data when your input LPCs and the value of the **Root finding coarse grid points** parameter do not meet the requirements described in

“Requirements for Valid Outputs” on page 2-1095. The following topics describe what invalid outputs look like, and how to set the block parameters provided for handling invalid inputs and outputs:

- “What Invalid Outputs Look Like” on page 2-1098
- “Parameters for Handling Invalid Inputs and Outputs” on page 2-1098

What Invalid Outputs Look Like

The channels of an invalid output have the same dimensions, sizes, and frame statues as the channels of a valid output. However, invalid output channels do not contain all the LSP or LSF values. Instead, they contain none or some of the LSP and LSF values and the rest of the output is filled with place holder values (-1, 0.5, or π) depending on the **Output** parameter setting).

In short, all invalid outputs in a channel end in one of the place holder values (-1, 0.5, or π) as illustrated in the following table. To learn how to use the block's parameters for handling invalid inputs and outputs, see the next section.

Output Parameter Setting	Place Holder	Sample Invalid Outputs
`LSF in radians (0 pi)`	π	$\begin{bmatrix} w_1 & w_2 & w_3 & \pi & \pi & \pi & \pi & \pi \end{bmatrix}$
`LSF normalized in range (0 0.5)`	`0.5`	$\begin{bmatrix} w_1 \\ w_2 \\ 0.5 \end{bmatrix}$
`LSP in range (-1 1)`	`-1`	$\begin{bmatrix} \cos(w_{13}) \\ \cos(w_{23}) \\ -1 \\ -1 \\ -1 \end{bmatrix}$

Parameters for Handling Invalid Inputs and Outputs

You must set how the block handles invalid inputs and outputs by setting these parameters:

- **Show output validity status (1=valid, 0=invalid)** — Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; `1` when the output of the corresponding channel is valid, and `0` when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see "Requirements for Valid Outputs" on page 2-1095). See the previous section to learn how to recognize invalid outputs.
- **If current output is invalid, overwrite with previous output** — Select this check box to cause the block to overwrite invalid outputs with the previous output. When you set this parameter you also need to consider these parameters:
  - **When first output is invalid, overwrite with user-defined values** — When the first input is unstable, you can overwrite the invalid first output with either
    - The default values, by clearing this check box
    - Values you specify, by selecting this check box

    The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state.
  - **User-defined LSP/LSF values for overwriting invalid first output** — Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.
- **If first input value is not 1** — The block output in any channel is invalid when the first coefficient in an LPC vector is not 1; this parameter determines what the block does when given such inputs:
  - `Ignore` — Proceed with computations as if the first coefficient is 1.
  - `Normalize` — Divide the input LPCs by the value of the first coefficient before computing the output.
  - `Normalize and warn` — In addition to `Normalize`, display a warning message at the MATLAB command line.
  - `Error` — Stop the simulation and display an error message at the MATLAB command line.

Parameters

Output

Specifies whether to convert the input linear prediction polynomial coefficients (LPCs) to `LSP in range (-1 1)`, `LSF in radians (0 pi)`, or `LSF normalized in range (0 0.5)`. See "Setting Outputs to LSFs or LSPs" on page 2-1096 for descriptions of the three settings.

Root finding coarse grid points

The value n, where the block divides the interval (-1, 1) into n subintervals of equal length, and looks for roots (LSP values) in each subinterval. You must pick n large enough or the block output might be invalid as described in "Requirements for Valid Outputs" on page 2-1095. To learn how the block uses this parameter to compute the output, see "LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding" on page 2-1101. Also see "Adjusting Output Computation Time and Accuracy with Root Finding Parameters" on page 2-1096. Tunable (Simulink).

Root finding bisection refinement

The value k, where each LSP output is within $1/(n \cdot 2^k)$ of the actual LSP value, where n is the value of the **Root finding coarse grid points** parameter. To learn how the block uses this parameter to compute the output, see "LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding" on page 2-1101. Also see "Adjusting Output Computation Time and Accuracy with Root Finding Parameters" on page 2-1096. Tunable (Simulink).

Show output validity status

Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; `1` when the output of the corresponding channel is valid, and `0` when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see "Requirements for Valid Outputs" on page 2-1095).

If current output is invalid, overwrite with previous output

Selecting this check box causes the block to overwrite invalid outputs with the previous output. Setting this parameter activates other parameters for taking care of initial overwrite values (when the very first output of the block is invalid). For more information, see "Parameters for Handling Invalid Inputs and Outputs" on page 2-1098.

When first output is invalid, overwrite with user-defined values

When the first input is unstable, you can overwrite the invalid first output with either

- The default values, by clearing this check box
- Values you specify, by selecting this check box

The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state. For more information, see "Parameters for Handling Invalid Inputs and Outputs" on page 2-1098.

User-defined LSP/LSF values for overwriting invalid first output

Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.

If first input value is not 1

Determines what the block does when the first coefficient of an input is not `1`. The block can either proceed with computations as when the first coefficient is 1 (`Ignore`); divide the input LPCs by the value of the first coefficient before computing the output (`Normalize`); in addition to `Normalize`, display a warning message at the MATLAB command line (`Normalize and warn`); stop the simulation and display an error message at the MATLAB command line (`Error`). For more information, see "Parameters for Handling Invalid Inputs and Outputs" on page 2-1098.

Theory

LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding

---

Note To learn the principles on which the block's LSP and LSF computation method is based, see the reference listed in "References" on page 2-1107.

To compute LSP outputs for each channel, the block relies on the fact that LSP values are the roots of two particular polynomials related to the input LPC polynomial; the block finds these roots using the Chebyshev polynomial root finding method, described next. To compute LSF outputs, the block computes the arc cosine of the LSPs, outputting values ranging from 0 to π radians.

Root Finding Method

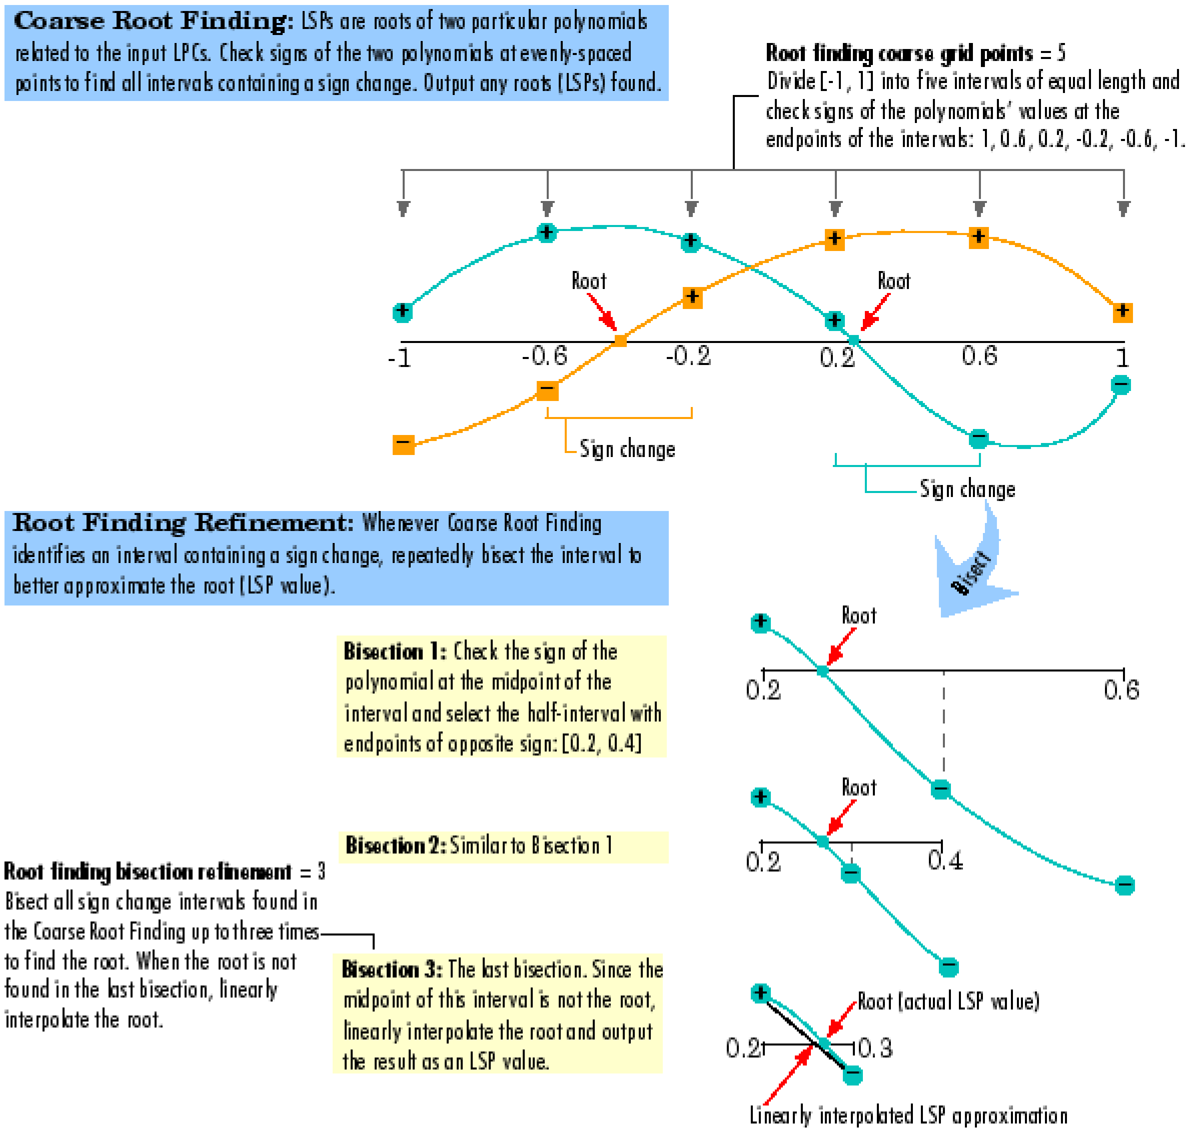
LSPs, which are the roots of two particular polynomials, always lie in the range (-1, 1). (The guaranteed roots at 1 and -1 are factored out.) The block finds the LSPs by looking for a sign change of the two polynomials' values between points in the range (-1, 1). The block searches a maximum of $k(n-1)$ points, where

- n is the value of the **Root finding coarse grid points** parameter.
- k is the value of the **Root finding bisection refinement** parameter.

The block's method for choosing which points to check consists of the following two steps:

1. **Coarse Root Finding** —- The block divides the interval [-1, 1] into n intervals, each of length $2/n$, and checks the signs of both polynomials' values at the endpoints of the intervals. The block starts checking signs at 1, and continues checking signs at $1 - 4/n$, $1 - 6/n$, and so on at steps of length $2/n$, outputting any point if it is a root. The block stops searching in these situations:
   a. The block finds a sign change of a polynomial's values between two adjacent points. An interval containing a sign change is guaranteed to contain a root, so the block further searches the interval as described in Step 2, Root Finding Refinement.
   b. The block finds and outputs all M roots (given a length-M+1 LPC input).
   c. The block fails to find all M roots and yields invalid outputs as described in "Handling and Recognizing Invalid Inputs and Outputs" on page 2-1097.
2. **Root Finding Refinement** — When the block finds a sign change in an interval, $[a, b]$, it searches for the root guaranteed to lie in the interval by following these steps:
   a. **Check if Midpoint Is a Root** — The block checks the sign of the midpoint of the interval $[a, b]$. The block outputs the midpoint if it is a root, and continues Step 1, Coarse Root Finding, at the next point, $a - 2/n$. Otherwise, the block selects the half-interval with endpoints of opposite sign (either $[a, (a + b)/2]$ or $[(a + b)/2, b]$) and executes Step 2b, Stop or Continue Root Finding Refinement.

b **Stop or Continue Root Finding Refinement** — When the block has repeated Step 2a k times (k is the value of the **Root finding bisection refinement** parameter), the block linearly interpolates the root by using the half-interval's endpoints, outputs the result as an LSP value, and returns to Step 1, Coarse Root Finding. Otherwise, the block repeats Step 2a using the half-interval.



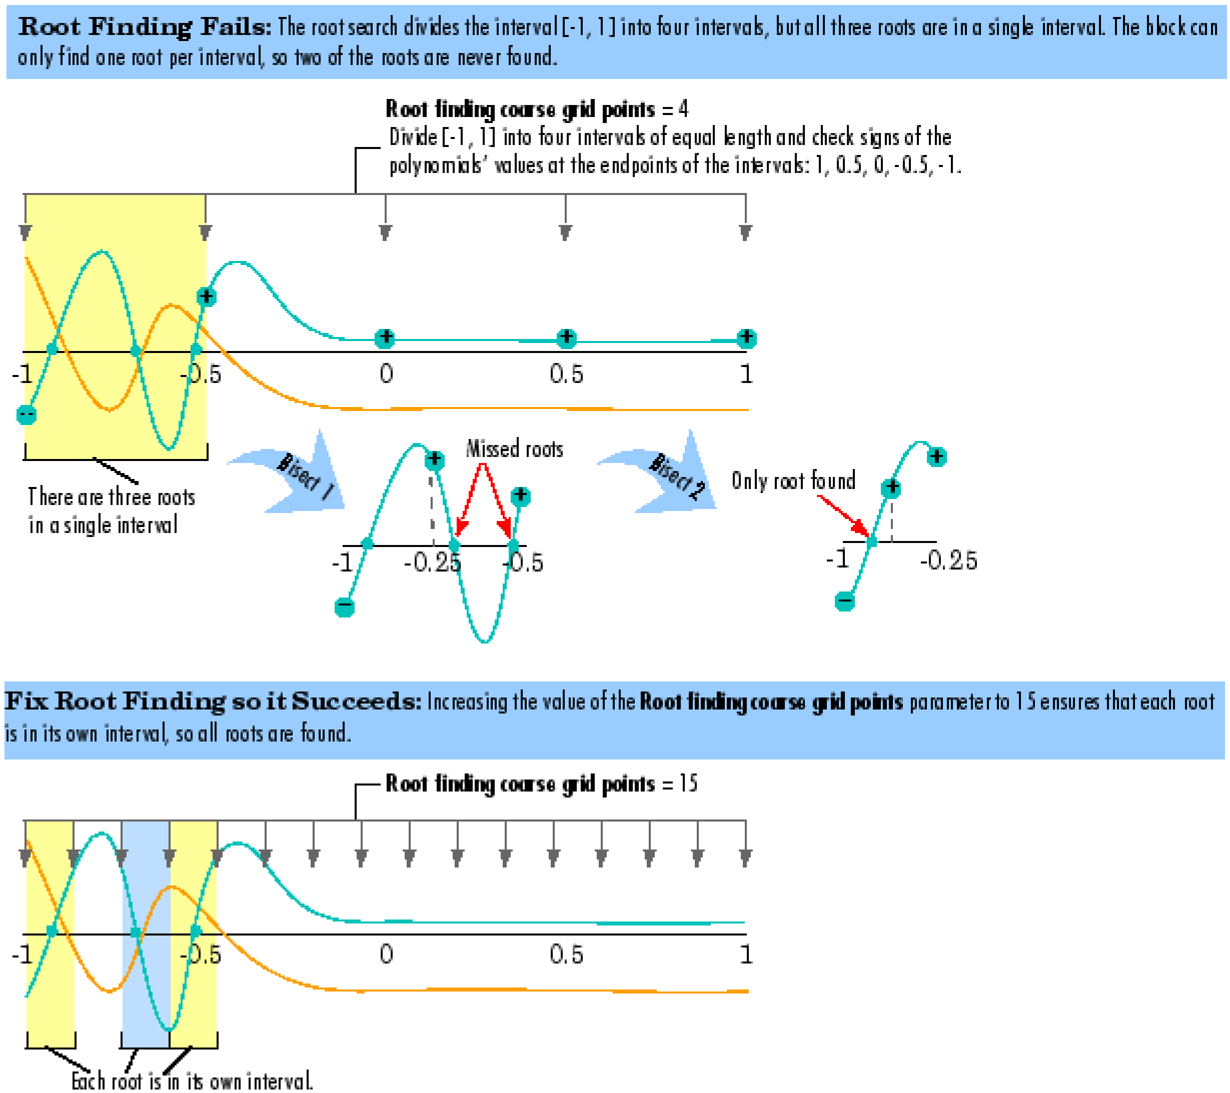
Coarse Root Finding and Root Finding Refinement

Root Finding Method Limitations: Failure to Find Roots

The block root finding method described above can fail, causing the block to produce invalid outputs (for details on invalid outputs, see "Handling and Recognizing Invalid Inputs and Outputs" on page 2-1097).

In particular, the block can fail to find some roots if the value of the **Root finding coarse grid points** parameter, *n*, is too small. If the polynomials oscillate quickly and have roots that are very close together, the root finding might be too coarse to identify roots that are very close to each other, as illustrated in Fixing a Failed Root Finding.

For higher-order input LPC polynomials, you should increase the **Root finding coarse grid points** value to ensure the block finds all the roots and produces valid outputs.



Fixing a Failed Root Finding

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Supported only by the optional output port that appears when you set the parameter, **Show output validity status (1=valid, 0=invalid)**

LSF/LSP to LPC Conversion

Convert line spectral frequencies or line spectral pairs to linear prediction coefficients

Library

Estimation / Linear Prediction

`dsplp`

Description

The LSF/LSP to LPC Conversion block takes a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs) and converts it to a vector or matrix of linear prediction polynomial coefficients (LPCs). When converting LSFs to LPCs, the block outputs match those of the `lsf2poly` function.

The block input can be an N-by-M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel. Each input channel must be in the same format, which you specify in the **Input** parameter:

- `LSF in range (0 pi)` — Vector of LSF values between 0 and π radians in increasing order. Do not include the guaranteed LSF values, 0 and π.
- `LSF normalized in range (0 0.5)` — Vector of normalized LSF values in increasing order, (compute by dividing the LSF values between 0 and π radians by 2π). Do not include the guaranteed normalized LSF values, 0 and 0.5.
- `LSP in range (-1 1)` — Vector of LSP values in decreasing order, equal to the cosine of the LSF values between 0 and π radians. Do not include the guaranteed LSP values, -1 and 1.

Parameters

Input

Specifies whether to convert `LSP in range (-1 1)`, `LSF in range (0 pi)`, or `LSF normalized in range (0 0.5)` to linear prediction coefficients (LPCs).

Supported Data Types

- Double-precision floating point
- Single-precision floating point

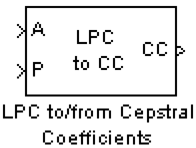
LPC to/from Cepstral Coefficients

Convert linear prediction coefficients to cepstral coefficients or cepstral coefficients to linear prediction coefficients



Library

Estimation / Linear Prediction

`dsplp`

Description

The LPC to/from Cepstral Coefficients block either converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs) or cepstral coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to select the domain into which you want to convert your coefficients. The LPC port corresponds to LPCs, and the CC port corresponds to the CCs. For more information, see "Algorithm" on page 2-1111.

The block input can be an N-by-M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Consider a signal $x(n)$ as the input to an FIR analysis filter represented by LPCs. The output of this analysis filter, $e(n)$, is known as the prediction error signal. The power of this error signal is denoted by P, the prediction error power.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can specify the prediction error power in two ways. From the **Specify P** list, choose `via input port` to input the prediction error power using input port P. The input to the port must be a vector with length equal to the number of input channels. Select `assume P equals 1` to set the prediction error power equal to 1 for all channels.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, the **Output size same as input size** check box appears. When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs. When you do not select this check box, enter a positive scalar for the **Length of output cepstral coefficients** parameter.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can use the **If first input value is not 1** parameter to specify the behavior of the block when the first coefficient of the LPC vector is not 1. The following options are available:

- `Replace it with 1` —- Changes the first value of the coefficient vector to 1. The other coefficient values are unchanged.
- `Normalize` — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1.
- `Normalize and Warn` — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- `Error` — Displays an error telling you that the first coefficient of the LPC vector is not 1.

When you select `Cepstral coefficients to LPCs` from the **Type of conversion** list, the **Output P** check box appears on the block. Select this check box when you want to output the prediction error power from output port P.

Algorithm

The cepstral coefficients are the coefficients of the Fourier transform representation of the logarithm magnitude spectrum. Consider a sequence, $x(n)$, having a Fourier transform $X(\omega)$. The cepstrum, $c_x(n)$, is defined by the inverse Fourier transform of $C_x(\omega)$, where $C_x(\omega) = \log_e X(\omega)$. See the Real Cepstrum block reference page for information on computing cepstrum coefficients from time-domain signals.

LPC to CC

When in this mode, this block uses a recursion technique to convert LPCs to CCs. The LPC vector is defined by $\begin{bmatrix} a_0 & a_1 & a_2 & \dots & a_p \end{bmatrix}$ and the CC vector is defined by $\begin{bmatrix} c_0 & c_1 & c_2 & \dots & c_p & \dots & c_{n-1} \end{bmatrix}$. The recursion is defined by the following equations:

$$c_0 = \log_e P$$

$$c_m = -a_m + \frac{1}{m} \sum_{k=1}^{m-1} \left[-(m-k) \cdot a_k \cdot c_{(m-k)} \right], 1 \le m \le p$$

$$c_m = \sum_{k=1}^{p} \left[\frac{-(m-k)}{m} \cdot a_k \cdot c_{(m-k)} \right], p < m < n$$

CC to LPC

When in this mode, this block uses a recursion technique to convert CCs to LPCs. The CC vector is defined by $\begin{bmatrix} c_0 & c_1 & c_2 & \dots & c_p & \dots & c_n \end{bmatrix}$ and the LPC vector is defined by $\begin{bmatrix} a_0 & a_1 & a_2 & \dots & a_p \end{bmatrix}$. The recursion is defined by the following equations

$$a_m = -c_m - \frac{1}{m} \sum_{k=1}^{m-1} \left[(m-k) \cdot c_{(m-k)} \cdot a_k \right]$$

$$P = \exp(C_0)$$

where $m = 1, 2, \dots, p$.

Parameters

Type of conversion

Choose `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to specify the domain into which you want to convert your coefficients.

Specify P

Choose `via input port` to input the values of prediction error power using input port P. Select `assume P equals 1` to set the prediction error power equal to 1.

Output size same as input size

When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs.

Length of output cepstral coefficients

Enter a positive scalar that is the length of each output channel of CCs.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

Output P

Select this check box to output the prediction error power for each channel from output port P.

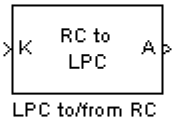
LPC to/from RC

Convert linear prediction coefficients to reflection coefficients or reflection coefficients to linear prediction coefficients



Library

Estimation / Linear Prediction

`dsplp`

Description

The LPC to/from RC block either converts linear prediction coefficients (LPCs) to reflection coefficients (RCs) or reflection coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to `LPC to RC` or `RC to LPC` to select the domain into which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients. For more information, see "Algorithm" on page 2-1116.

The block input can be an N-by-M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Consider a signal $x(n)$ as the input to an FIR analysis filter represented by LPC coefficients. The output of the analysis filter, $e(n)$, is known as the prediction error signal. The power of this error signal is denoted by P. When the zero lag autocorrelation coefficient of $x(n)$ is one, the autocorrelation sequence and prediction error power are said to be normalized.

Select the **Output normalized prediction error power** check box to enable port P. The normalized prediction error power output at `P` is a vector with one element per input channel. Each element varies between zero and one.

Select the **Output LPC filter stability** check box to output the stability of the filter represented by the LPCs or RCs. The synthesis filter represented by the LPCs is stable when the absolute value of each of the roots of the LPC polynomial is less than one. The lattice filter represented by the RCs is stable when the absolute value of each reflection coefficient is less than 1. When the filter is stable, the block outputs a Boolean value of `1` for each input channel at the S port. When the filter is unstable, the block outputs a Boolean value of `0` for each input channel at the S port.

If first input value is not 1 parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector in any channel is not 1. The following options are available:

- `Replace it with 1` — Changes the first value of the coefficient channel to 1. The other coefficient values are unchanged.
- `Normalize` — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.
- `Normalize and Warn` — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- `Error` — Displays an error telling you that the first coefficient of the LPC coefficient channel is not 1.

Algorithm

LPC to RC

When in this mode, this block uses backward Levinson recursion to convert linear prediction coefficients (LPCs) to reflection coefficients (RCs). For a given Nth order LPC vector $LPC_N = [\; 1 \quad a_{N1} \quad a_{N2} \quad \ldots \quad a_{NN} \;]$, the block calculates the Nth reflection coefficient value using the formula $\gamma_N = -a_{NN}$. The block then finds the lower order LPC vectors , LPC_{N-1}, LPC_{N-2}, ..., LPC_1, using the following recursion.

for $p = N, N-1, \ldots, 2,$

$$\gamma_p = a_{pp}$$
$$F = 1 - {\gamma_p}^2$$
$$a_{p-1,m} = \frac{a_{p,m}}{F} - \frac{\gamma_p a_{p,p-m}}{F}, \quad 1 \le m < p$$

end

Finally, $\gamma_1 = -a_{11}$. The reflection coefficient vector is $[\gamma_1, \quad \gamma_2, \quad \ldots, \quad \gamma_N]$.

RC to LPC

When in this mode, this block uses Levinson recursion to convert reflection coefficients (RCs) to linear prediction coefficients (LPCs). In this case, the input to the block is $RC = [\gamma_1 \quad \gamma_2 \quad \ldots \quad \gamma_N]$. The zeroth order LPC vector term is 1. Starting with this term, the block uses recursion to calculate the higher order LPC vectors, $LPC_2, LPC_3, \ldots LPC_N$, until it has calculated the entire LPC matrix.

$$LPC_{matrix} = \begin{bmatrix} LPC_0 \\ LPC_1 \\ LPC_2 \\ \ldots \\ LPC_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots & 0 \\ 1 & a_{11} & 0 & 0 & \cdots & 0 \\ 1 & a_{21} & a_{22} & 0 & \cdots & 0 \\ 1 & a_{31} & a_{32} & a_{33} & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & a_{N1} & a_{N2} & a_{N3} & \cdots & a_{NN} \end{bmatrix}$$

This LPC matrix consists of LPC vectors of order 0 through N found by using the Levinson recursion. The following are the formulas for the recursion steps, for $p = 0$, 1, ...,$N - 1$.

$$a_{p+1,m} = a_{p,m} + \gamma_{p+1} a_{p,p+1-m}, \quad 1 \le m \le p$$
$$a_{p+1,p+1} = \gamma_{p+1}$$

Parameters

Type of conversion

Select `LPC to RC` or `RC to LPC` to select the domain into which you want to convert your coefficients.

Output normalized prediction error power

Select this check box to output the normalized prediction error power at port P.

Output LPC filter stability

Select this check box to output the stability of the filter. When the filter represented by the LPCs or RCs is stable, the block outputs a Boolean value of `1` for each input channel at the S port. When the filter represented by the LPCs or RCs is unstable, the block outputs a Boolean value of `0` for each input channel at the S port.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

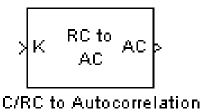
LPC/RC to Autocorrelation

Convert linear prediction coefficients or reflection coefficients to autocorrelation coefficients



Library

Estimation / Linear Prediction

`dsplp`

Description

The LPC/RC to Autocorrelation block either converts linear prediction coefficients (LPCs) to autocorrelation coefficients (ACs) or reflection coefficients (RCs) to autocorrelation coefficients (ACs). Set the **Type of conversion** parameter to `LPC to autocorrelation` or `RC to autocorrelation` to select the domain from which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients.

The block input can be an N-by-M matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Use the **Specify P** parameter to set the value of the prediction error power. You can set this parameter to 1 by selecting `Assume P=1`. When you select `Via input port`, a P port appears on the block. You can use this port to input the value of the actual, non-unity prediction error power for each channel. The length of this vector must equal the number of channels in the input.

The **If first input value is not 1** parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector is not 1. The following options are available:

- `Replace it with 1` — The block changes the first value of the coefficient vector to 1. The rest of the coefficient values are unchanged.

- `Normalize` — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.
- `Normalize and Warn` — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- `Error` — The block displays an error telling you that the first coefficient of the LPC coefficient vector is not 1.

Parameters

Type of conversion

From the list select `LPC to autocorrelation` or `RC to autocorrelation` to specify the domain from which you want to convert your coefficients.

Specify P

From the list select `Assume P=1` or `Via input port` to specify the value of prediction error power.

If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

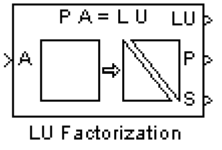
LU Factorization

Factor square matrix into lower and upper triangular components



Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`

Description

The LU Factorization block factors a row-permuted version of the square input matrix A as $A_p = L*U$, where L is a unit-lower triangular matrix, U is an upper triangular matrix, and A_p contains the rows of A permuted as indicated by the permutation index vector P. The block uses the pivot matrix A_p instead of the exact input matrix A because it improves the numerical accuracy of the factorization. You can determine the singularity of the input matrix A by enabling the optional output port S. When A is singular, the block outputs a `1` at port S; when A is nonsingular, it outputs a `0`.

To improve efficiency, the output of the LU Factorization block at port LU is a composite matrix containing both the lower triangle elements of L and the upper triangle elements of U. Thus, the output is in a different format than the output of the MATLAB `lu` function, which returns L and U as separate matrices. To convert the output from the block's `LU` port to separate L and U matrices, use the following code:

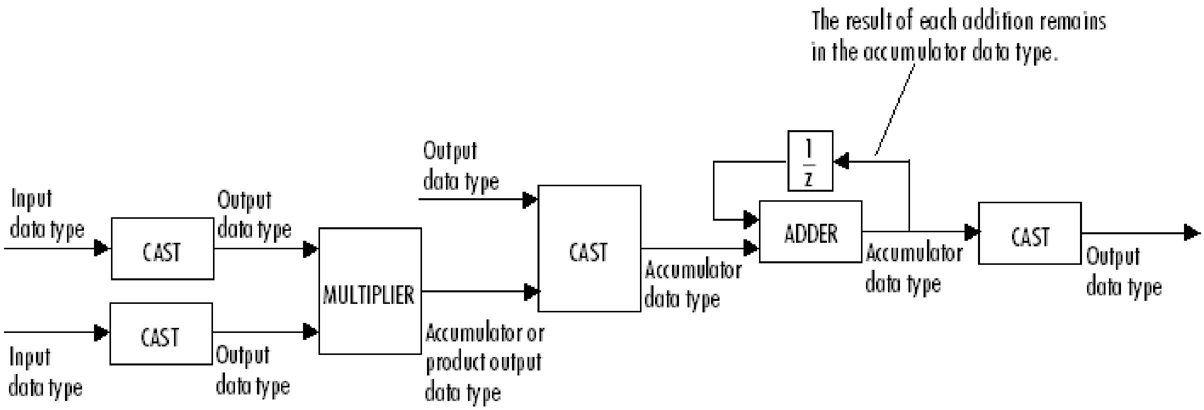
```
L = tril(LU,-1)+eye(size(LU));
U = triu(LU);
```

If you compare the results produced by these equations to the actual output of the MATLAB `lu` function, you may see slightly different values. These differences are due to rounding error, and are expected.

See the `lu` function reference page in the MATLAB documentation for more information about LU factorizations.

Fixed-Point Data Types

The following diagram shows the data types used within the LU Factorization block for fixed-point signals.



You can set the product output, accumulator, and output data types in the block dialog as discussed below.

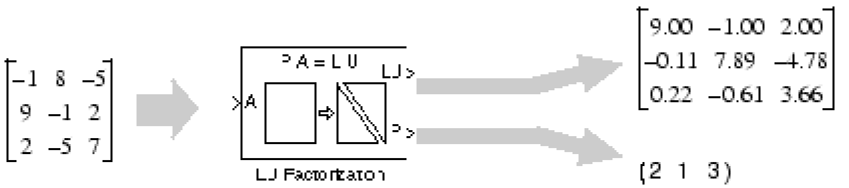
The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

Examples

The row-pivoted matrix A_p and permutation index vector P computed by the block are shown below for 3-by-3 input matrix A.

$$A = \begin{bmatrix} -1 & 8 & -5 \\ 9 & -1 & 2 \\ 2 & -5 & 7 \end{bmatrix} \qquad P = \begin{pmatrix} 2 & 1 & 3 \end{pmatrix} \qquad A_P = \begin{bmatrix} 9 & -1 & 2 \\ -1 & 8 & -5 \\ 2 & -5 & 7 \end{bmatrix}$$

The LU output is a composite matrix whose lower subtriangle forms *L* and whose upper triangle forms *U*.

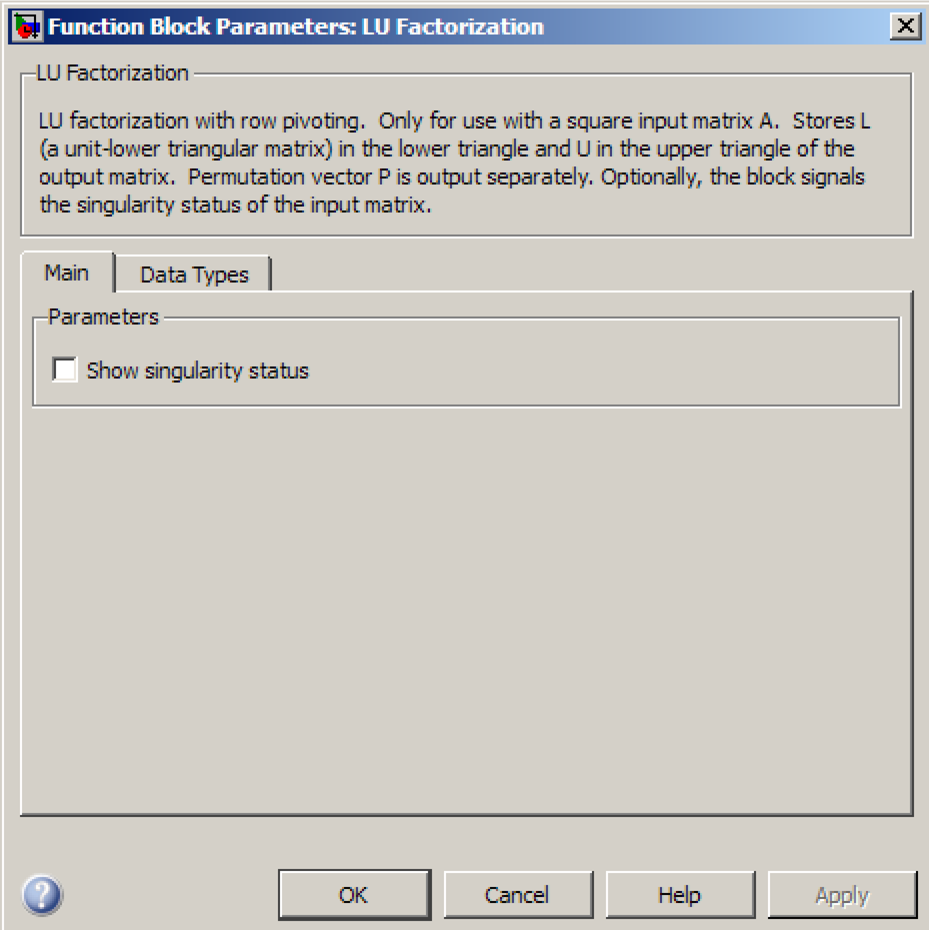


$$L = \begin{bmatrix} 1 & 0 & 0 \\ -0.11 & 1 & 0 \\ 0.22 & -0.61 & 1 \end{bmatrix} \qquad U = \begin{bmatrix} 9.00 & -1.00 & 2.00 \\ 0 & 7.89 & -4.78 \\ 0 & 0 & 3.66 \end{bmatrix}$$

See “Matrix Factorizations” in the *DSP System Toolbox User's Guide* for another example using the LU Factorization block.

Dialog Box

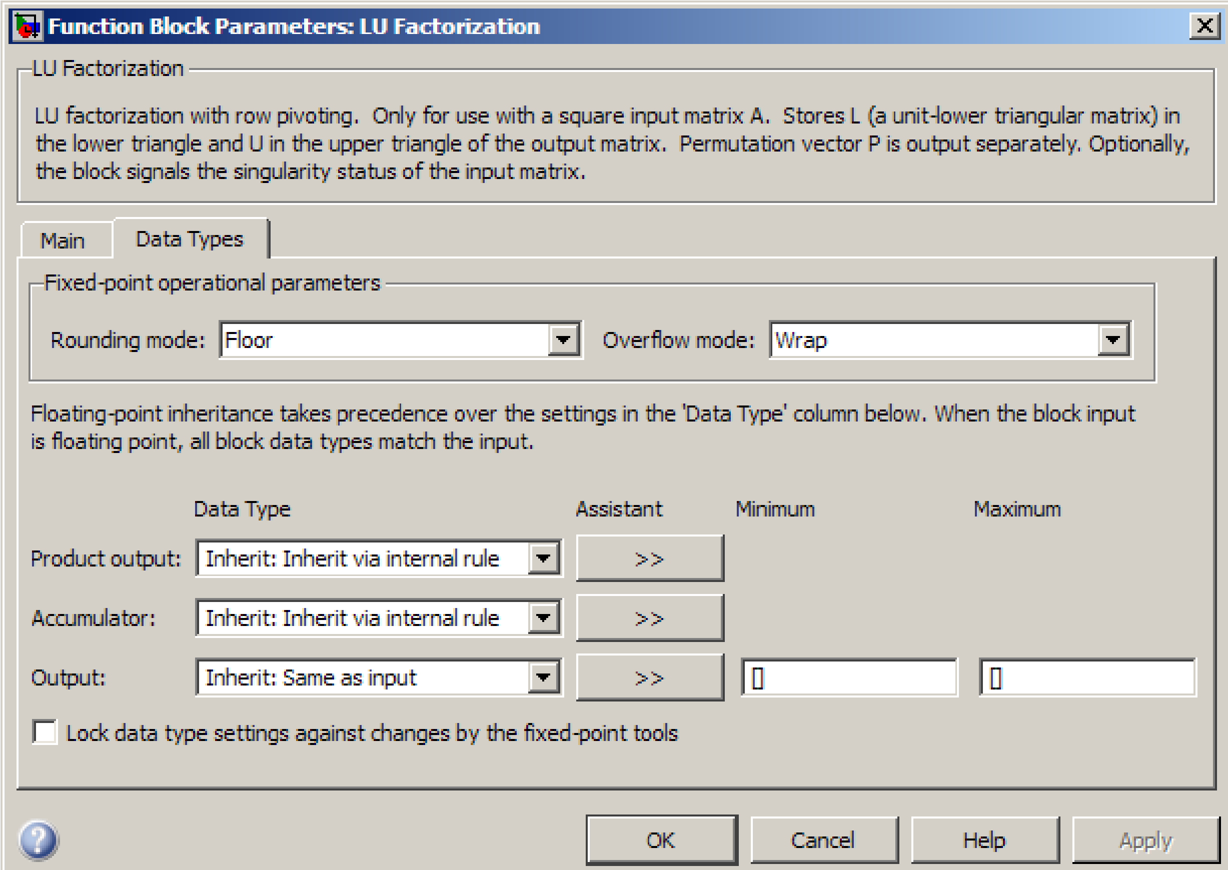
The **Main** pane of the LU Factorization block dialog appears as follows.



Show singularity status

Select to output the singularity of the input at port S, which outputs Boolean data type values of 1 or 0. An output of 1 indicates that the current input is singular, and an output of 0 indicates the current input is nonsingular.

The **Data Types** pane of the LU Factorization block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1124 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1124 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1124 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

LU Inverse

Compute inverse of square matrix using LU factorization

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

`dspinverses`

Description

The LU Inverse block computes the inverse of the square input matrix A by factoring and inverting row-pivoted variant A_p.

$$A_p^{-1} = (LU)^{-1}$$

L is a lower triangular square matrix with unity diagonal elements, and U is an upper triangular square matrix. The block outputs the inverse matrix A^{-1}.

Examples

See “Matrix Inverses” for an example that uses the LU Inverse block.

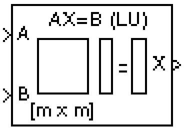
LU Solver

Solve AX=B for X when A is square matrix



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The LU Solver block solves the linear system AX=B by applying LU factorization to the M-by-M matrix at the A port. The input to the B port is the right side M-by-N matrix, B. The M-by-N matrix output X is the unique solution of the equations.

The block treats length-M unoriented vector input to the input port B as an M-by-1 matrix.

Algorithm

The LU algorithm factors a row-permuted variant (A_p) of the square input matrix A as

$$A_p = LU$$

where L is a lower triangular square matrix with unity diagonal elements, and U is an upper triangular square matrix.

The matrix factors are substituted for A_p in

$$A_pX = B_p$$

where B_p is the row-permuted variant of B, and the resulting equation

$$LUX = B_p$$

is solved for X by making the substitution $Y = UX$, and solving two triangular systems.

$$LY = B_p$$
$$UX = Y$$

Examples

See “Linear System Solvers” for an example that uses the LU Solver block.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

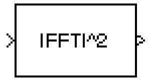
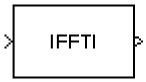
Magnitude FFT

Compute nonparametric estimate of spectrum using periodogram method





Library

- Estimation / Power Spectrum Estimation

  `dspspect3`
- Transforms

  `dspxfrm3`

Description

The Magnitude FFT block computes a nonparametric estimate of the spectrum using the periodogram method.

When the **Output** parameter is set to `Magnitude squared`, the block output for an M-by-N input u is equivalent to

```
y = abs(fft(u,nfft)).^2       % M ≤ nfft
```

When the **Output** parameter is set to `Magnitude`, the block output for an input u is equivalent to

```
y = abs(fft(u,nfft))          % M ≤ nfft
```

When $M > N_{fft}$, the block wraps the input to N_{fft} before computing the FFT using one of the above equations:

```
y(:,k)=datawrap(u(:,k),nfft)     % 1 ≤ k ≤ N
```

When $M > N_{fft}$, the block can also truncate the input:

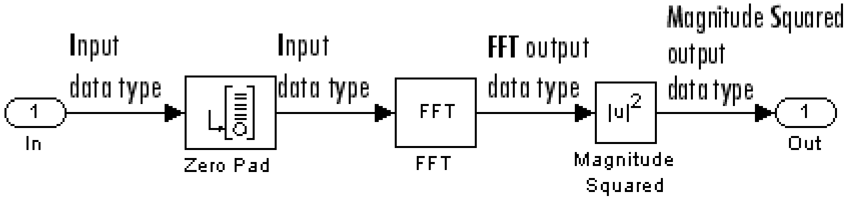
```
y(:,k)=abs(fft(u,nfft))        % 1 ≤ k ≤ N
```

The block treats an M-by-N matrix input as M sequential time samples from N independent channels. The block computes a separate estimate for each of the N independent channels and generates an N_{fft}-by-N matrix output. Each column of the output matrix contains the estimate of the corresponding input column's power spectral density at N_{fft} equally spaced frequency points in the range $[0,F_s)$, where F_s represents the signal's sample frequency. The block always outputs sample–based data.

The Magnitude FFT block supports real and complex floating-point inputs. The block also supports real fixed-point inputs in both `Magnitude` and `Magnitude squared` modes, and complex fixed-point inputs in the `Magnitude squared` mode.

Fixed-Point Data Types

The following diagram shows the data types used within the Magnitude FFT subsystem block for fixed-point signals.



The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- Sine table — `Same word length as input`
- Integer rounding mode — `Floor`
- Saturate on integer overflow — unchecked
- Product output — `Inherit via internal rule`
- Accumulator — `Inherit via internal rule`
- Output — `Inherit via internal rule`

The settings for the fixed-point parameters of the Magnitude Squared block in the diagram above are as follows:

- Integer rounding mode — `Floor`
- Saturate on integer overflow — checked
- Output — `Inherit via internal rule`

Examples

The dspsacomp example compares the periodogram method with several other spectral estimation methods.

Parameters

Output

Specify whether the block computes the magnitude FFT or magnitude-squared FFT of the input.

FFT implementation

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The first dimension M, of the input matrix must be a power of two. To work with other input sizes, use the `Pad` block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW algorithm.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Inherit FFT length from input dimensions

Select to use the input frame size as the number of data points, on which to perform the FFT. When you select this check box, this number must be a power of two. When you do not select this check box, the **FFT length** parameter specifies the number of data points.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, each frame is zero-padded as needed. When N_{fft} is smaller than the input frame size, each frame is wrapped as needed. This parameter is enabled when you clear the **Inherit FFT length from input dimensions** check box.

When you set the **FFT implementation** parameter to `Radix-2`, this value must be a power of two.

Wrap input data when FFT length is shorter than input length

Choose to wrap or truncate the input, depending on the **FFT length**. If this parameter is checked, modulo-length data wrapping occurs before the FFT operation, given **FFT length** is shorter than the input length. If this property is unchecked, truncation of the input data to the FFT length occurs before the FFT operation. The default is checked.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:

  - **FFT implementation** is set to `FFTW`.
  - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

  Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Matrix 1-Norm

Compute 1-norm of matrix

Matrix
1-Norm

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

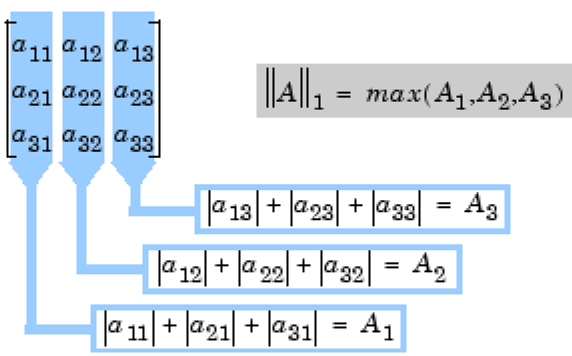
Description

The Matrix 1-Norm block computes the 1-norm, or maximum column-sum, of an M-by-N input matrix, A.

$$y = \|A\|_1 = \max_{1 \le j \le N} \sum_{i=1}^{M} |a_{ij}|$$

This is equivalent to

```
y = max(sum(abs(A)))      % Equivalent
MATLAB code
```

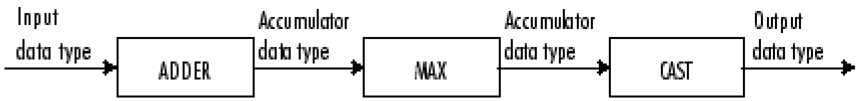


The block treats length-M unoriented vector input as an M-by-1 matrix. The output, y, is always a scalar.

The Matrix 1-Norm block supports real and complex floating-point inputs, and real fixed-point inputs.

Fixed-Point Data Types

The following diagram shows the data types used within the Matrix 1-Norm block for fixed-point signals.

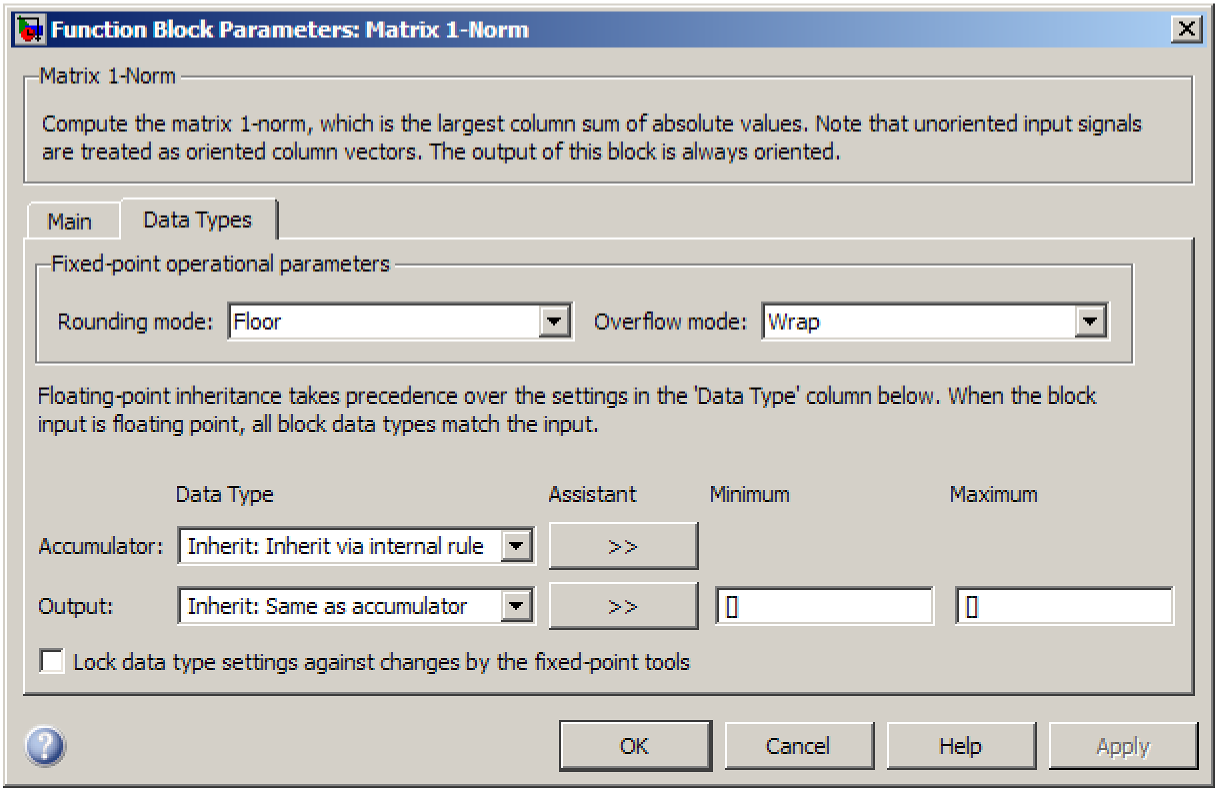


The block calculations are all done in the accumulator data type until the `max` is performed. The result is then cast to the output data type. You can set the accumulator and output data types in the block dialog as discussed in "Dialog Box" on page 2-1142 below.

Dialog Box

There are no parameters on the **Main** pane of this dialog.

The **Data types** pane of the Matrix 1-Norm block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1142 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1142 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))

- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

`dspmtrx3`

Description

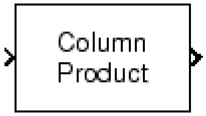
The Matrix Multiply block is an implementation of the Simulink Product block. See Product for more information.

Introduced before R2006a

Matrix Product

Multiply matrix elements along rows, columns, or entire input



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Matrix Product block multiplies the elements of an M-by-N input matrix u along its rows, its columns, or over all its elements.

When the **Multiply over** parameter is set to `Rows`, the block multiplies across the elements of each row and outputs the resulting M-by-1 matrix. The block treats length-N unoriented vector input as a 1-by-N matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left(\prod_{j=1}^{3} u_{1j} \right) \\ \left(\prod_{j=1}^{3} u_{2j} \right) \\ \left(\prod_{j=1}^{3} u_{3j} \right) \end{bmatrix}$$

When the **Multiply over** parameter is set to `Columns`, the block multiplies down the elements of each column and outputs the resulting 1-by-N matrix. The block treats length-M unoriented vector input as an M-by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix}$$

$$\Downarrow$$

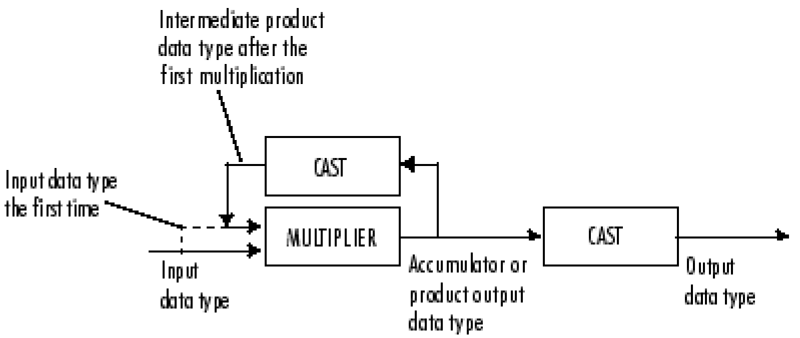
$$\begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} = \left[\left(\prod_{i=1}^{3} u_{i1} \right) \left(\prod_{i=1}^{3} u_{i2} \right) \left(\prod_{i=1}^{3} u_{i3} \right) \right]$$

When the **Multiply over** parameter is set to `Entire input`, the block multiplies all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow y = \left(\prod_{i=1}^{3} \prod_{j=1}^{3} u_{ij} \right)$$

Fixed-Point Data Types

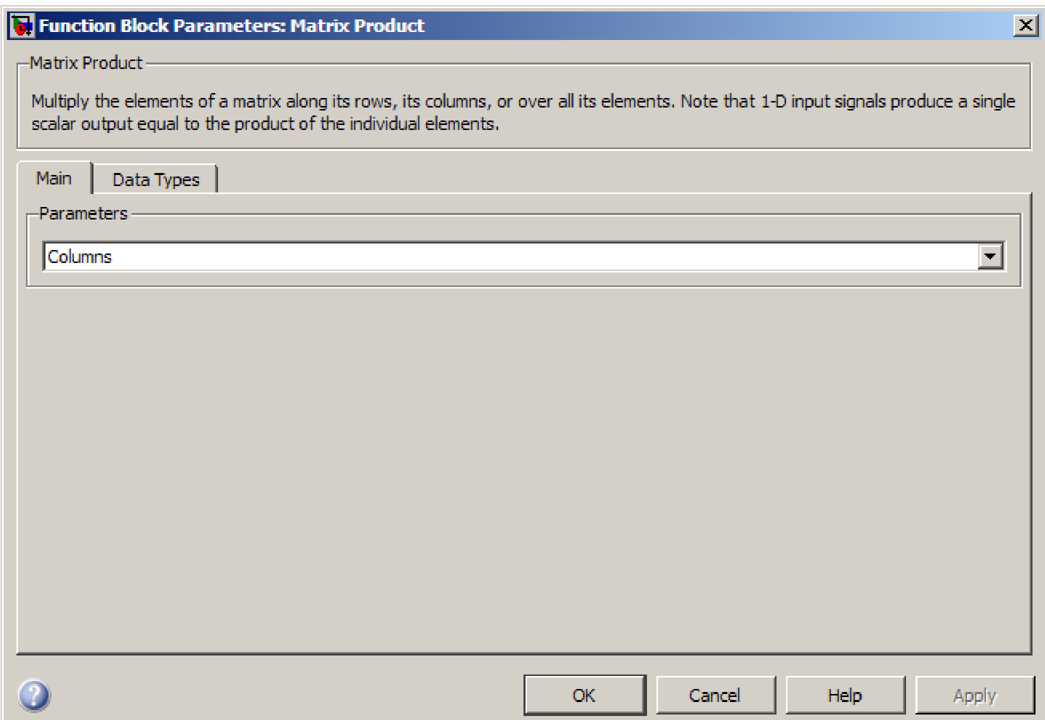
The following diagram shows the data types used within the Matrix Product block for fixed-point signals.



The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in "Dialog Box" on page 2-1152 below.

Dialog Box

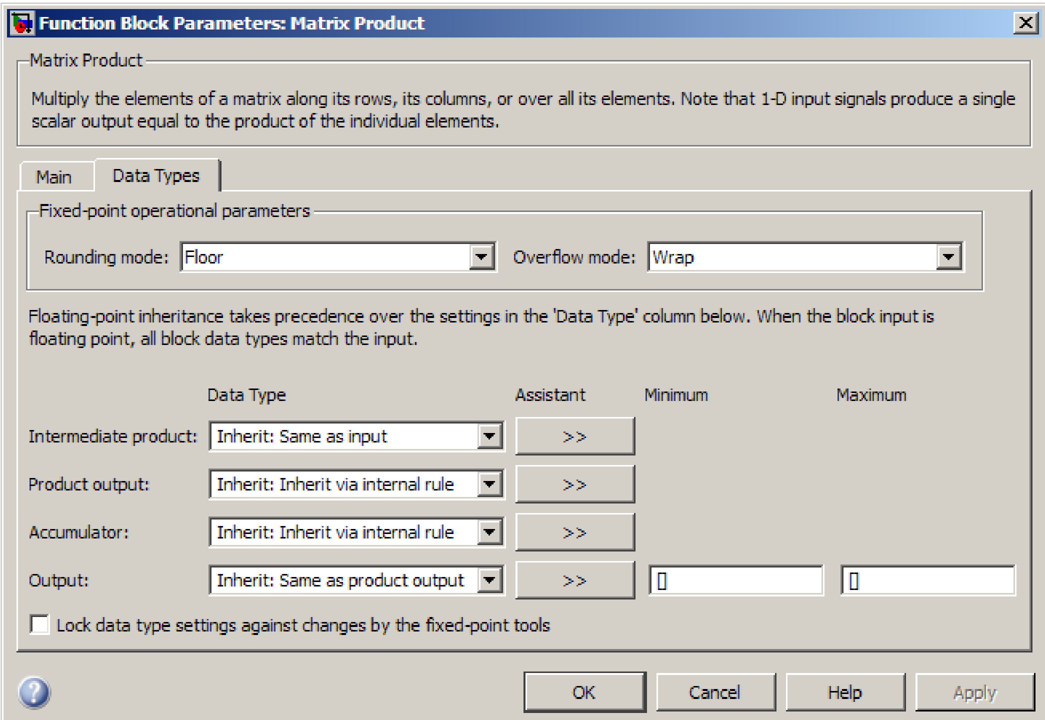
The **Main** pane of the Matrix Product block dialog appears as follows.



Multiply over

Indicate whether to multiply together the elements of each row, each column, or the entire input.

The **Data Types** pane of the Matrix Product block dialog appears as follows.



Note: Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-1151, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1151 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1151 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1151 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

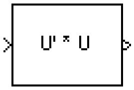
`Matrix Sum`	DSP System Toolbox
`prod`	MATLAB

Introduced before R2006a

Matrix Square

Compute square of input matrix



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Matrix Square block computes the square of an M-by-N input matrix, u, by premultiplying with the Hermitian transpose.

```
y = u' * u     % Equivalent MATLAB code
```

The block treats length-M unoriented vector inputs as an M-by-1 matrix. When the input is an M-by-N matrix, the output of the block is an N-by-N matrix.

Applications

The Matrix Square block is useful in a variety of applications:

- General matrix squares — The Matrix Square block computes the output matrix, y, without explicitly forming u'. It is therefore more efficient than other methods for computing the matrix square.
- Sum of squares — When the input is a column vector (N=1), the block's operation is equivalent to a multiply-accumulate (MAC) process, or inner product. The output is the sum of the squares of the input, and is always a real scalar.
- Correlation matrix — When the input is a row vector (M=1), the output, y, is the symmetric autocorrelation matrix, or outer product.

Parameters

Output minimum

Specify the minimum value the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output maximum

Specify the maximum value the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output data type

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Lock output data type setting against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the **Output data type** you specify on the block mask.

Integer rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select this check box to have overflows saturate to the maximum or minimum value that the data type can represent. If you clear this check box, the block wraps all overflows. See overflow mode for more information.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code

Supported Data Types

- Double-precision floating point
- Single-precision floating point

Matrix Sum

Sum matrix elements along rows, columns, or entire input

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

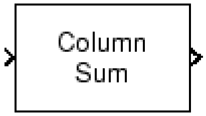
Description

The Matrix Sum block is an implementation of the Simulink Sum block. See Sum for more information.

Introduced before R2006a

Matrix Sum (Obsolete)

Sum matrix elements along rows, columns, or entire input



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspobslib`

Description

The Matrix Sum block sums the elements of an M-by-N input matrix u along its rows, its columns, or over all its elements.

When the **Sum over** parameter is set to `Rows`, the block sums across the elements of each row and outputs the resulting M-by-1 matrix. A length-N 1-D vector input is treated as a 1-by-N matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left(\sum_{j=1}^{3} u_{1j} \right) \\ \left(\sum_{j=1}^{3} u_{2j} \right) \\ \left(\sum_{j=1}^{3} u_{3j} \right) \end{bmatrix}$$

When the **Sum over** parameter is set to `Columns`, the block sums down the elements of each column and outputs the resulting 1-by-N matrix. A length-M 1-D vector input is treated as a M-by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix}$$

$$\Downarrow$$

$$\begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} = \left[\left(\sum_{i=1}^{3} u_{i1} \right) \left(\sum_{i=1}^{3} u_{i2} \right) \left(\sum_{i=1}^{3} u_{i3} \right) \right]$$

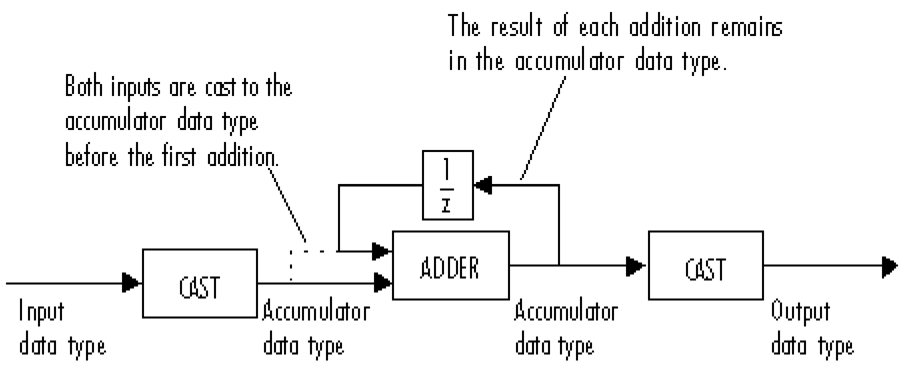
When the **Sum over** parameter is set to `Entire input`, the block sums all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \Rightarrow y = \left(\sum_{i=1}^{3} \sum_{j=1}^{3} u_{ij} \right)$$

The output of the Matrix Sum block has the same frame status as the input. This block accepts real and complex fixed-point and floating-point inputs except for complex unsigned fixed-point inputs.

Fixed-Point Data Types

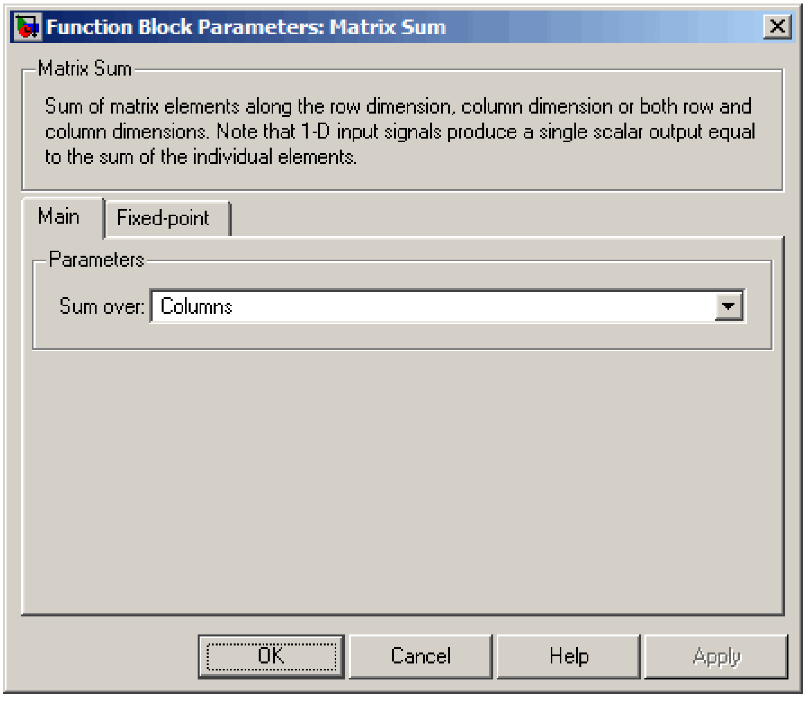
The following diagram shows the data types used within the Matrix Sum block for fixed-point signals.



You can set the accumulator and output data types in the block dialog as discussed in "Dialog Box" on page 2-1163 below.

Dialog Box

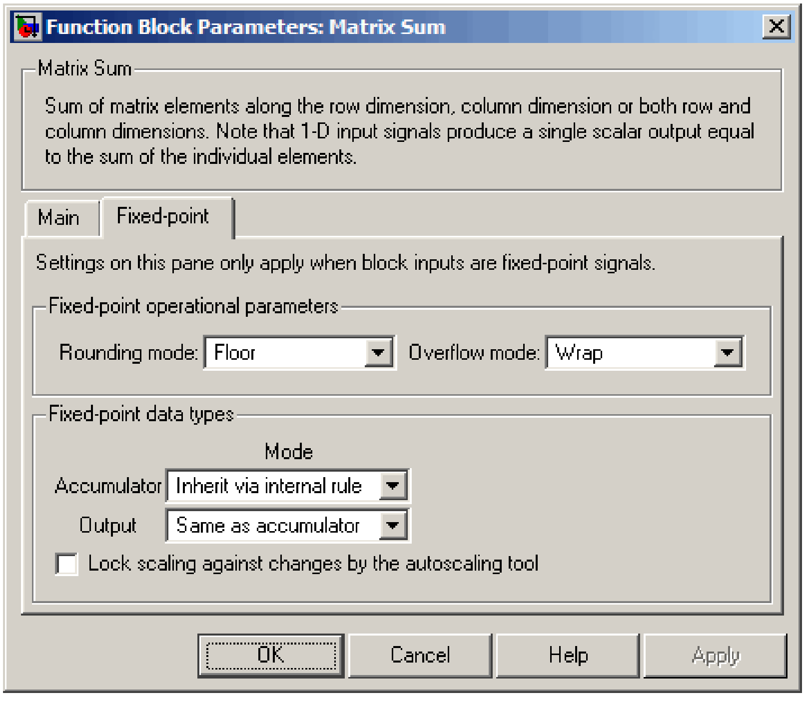
The **Main** pane of the Matrix Sum block dialog appears as follows.



Sum over

Indicate whether to sum the elements of each row, each column, or of the entire input.

The **Fixed-point** pane of the Matrix Sum block dialog appears as follows.



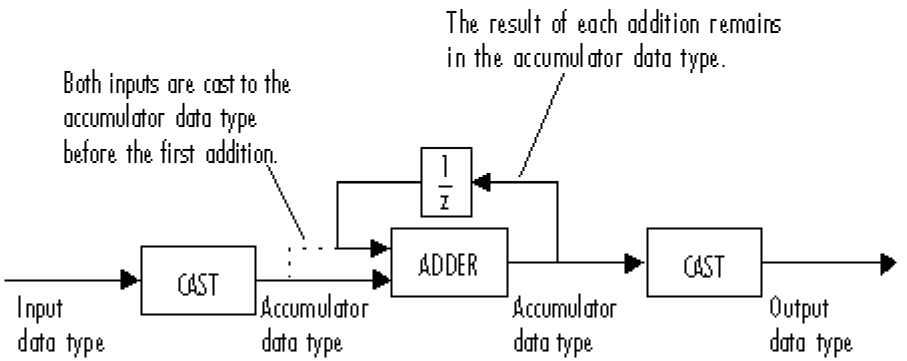
Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Accumulator



As depicted above, the elements of the block input are cast to the accumulator data type before they are added together. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate this accumulator word and fraction lengths:

- When you select `Inherit via internal rule`, the accumulator word length and fraction length are calculated automatically. For information about how the accumulator word and fraction lengths are calculated when an internal rule is used, see "Inherit via Internal Rule".
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.

- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling feature of the Fixed-Point Tool. See the `fxptdlg` reference page for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

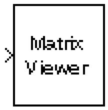
Introduced in R2008b

Matrix Viewer

Display matrices as color images



Library

Sinks

`dspsnks4`

Description

The Matrix Viewer block displays an *M*-by-*N* matrix input by mapping the matrix element values to a specified range of colors. The display is updated as each new input is received. This block treats an unoriented length *M* vector input as an *M*-by-1 matrix.

You can use the Matrix Viewer block in models running in Normal or Accelerator simulation modes. The software does not support this block in models running in Rapid Accelerator or External mode. For more information about these modes, see “How Acceleration Modes Work” (Simulink) in the *Simulink User's Guide*.

Image Properties

Select the **Image Properties** tab to show the image property parameters, which control the colormap and display.

You specify the mapping of matrix element values to colors in the **Colormap matrix**, **Minimum input value**, and **Maximum input value** parameters. For a colormap with *L* colors, the colormap matrix has dimension *L*-by-3, with one row for each color and one column for each element of the RGB triple that defines the color. Examples of RGB triples are

```
[ 1   0   0 ]   (red)
[ 0   0   1 ]   (blue)
[0.8 0.8 0.8]   (light gray)
```

See the `ColorSpec` property in the MATLAB documentation for complete information about defining RGB triples.

MATLAB provides a number of functions for generating predefined colormaps, such as `hot`, `cool`, `bone`, and `autumn`. Each of these functions accepts the colormap size as an argument, and can be used in the **Colormap matrix** parameter. For example, when you specify `gray(128)` for the **Colormap matrix** parameter, the matrix is displayed in 128 shades of gray. The color in the first row of the colormap matrix represents the value specified by the **Minimum input value** parameter, and the color in the last row represents the value specified by the **Maximum input value** parameter. Values between the minimum and maximum are quantized and mapped to the intermediate rows of the colormap matrix.

The documentation for the MATLAB `colormap` function provides complete information about specifying colormap matrices, and includes a complete list of the available colormap functions.

Axis Properties

Select the **Axis Properties** tab to show the axis property parameters, which control labeling and positioning.

The **Axis origin** parameter determines where the first element of the input matrix, $U(1,1)$, is displayed. When you specify `Upper left corner`, the matrix is displayed in matrix orientation, with $U(1,1)$ in the upper-left corner.

$$\begin{bmatrix} U_{11} & U_{12} & U_{13} & U_{14} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{41} & U_{42} & U_{43} & U_{44} \end{bmatrix}$$

When you specify `Lower left corner`, the matrix is flipped vertically to image orientation, with $U(1,1)$ in the lower-left corner.

$$\begin{bmatrix} U_{41} & U_{42} & U_{43} & U_{44} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{11} & U_{12} & U_{13} & U_{14} \end{bmatrix}$$

Axis zoom, when selected, causes the image display to completely fill the figure window. Axis titles are not displayed. This option can also be selected from the pop-up menu that is displayed when you right-click in the figure window. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the image axes.

To customize the axis tick range, set **Axis tick mode** to `User-defined` and specify a two-element row vector, [`Minvalue Maxvalue`], in **X-tick range** and **Y-tick range**. The matrix data does not change even when the axes ticks change. For example, consider displaying a matrix on axes with ticks ranging from 0 to 10. When you set **X-tick range** and **Y-tick range** to [0 1], the range of ticks changes from [0 10] to [0 1].

Figure Window

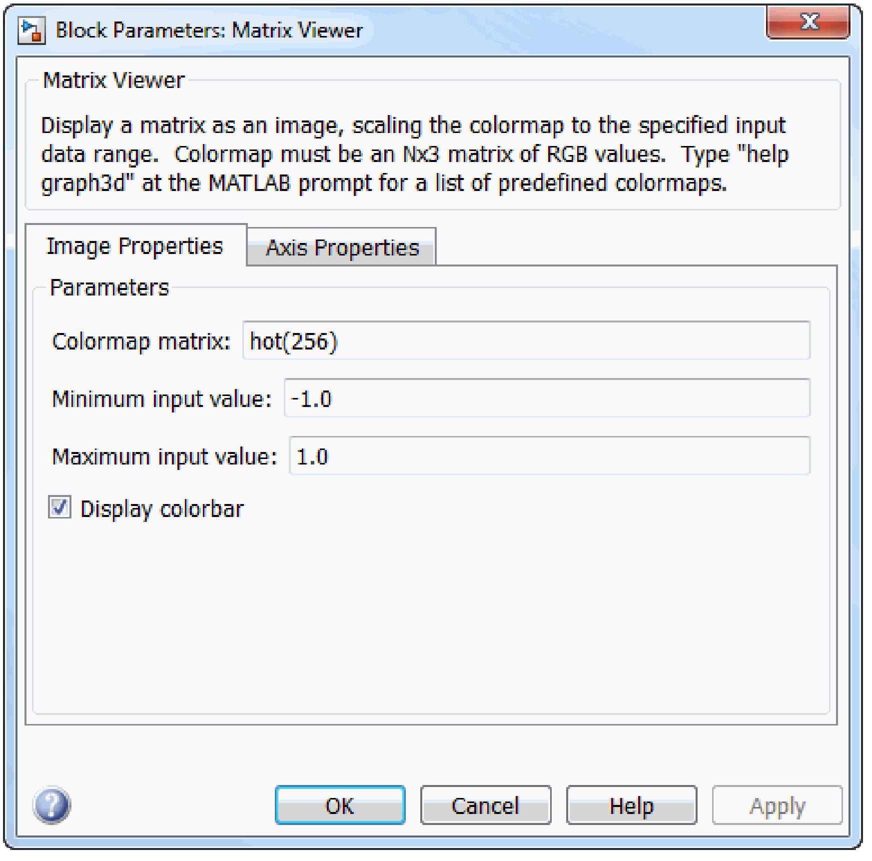
The image title in the figure title bar is the same as the block title. The axis tick marks reflect the size of the input matrix; the x-axis is numbered from 1 to N (number of columns), and the y-axis is numbered from 1 to M (number of rows).

Right-click the image in the figure window to access the following menu items:

- **Refresh** erases all data on the scope display except for the most recent image.
- **Autoscale** recomputes the minimum and maximum input values to fit the range of values observed in a series of 10 consecutive inputs. The numerical limits selected by the autoscale feature are shown in the **Minimum input value** and **Maximum input value** parameters, where you can make further adjustments to them manually.
- **Axis zoom**, when selected, causes the image to completely fill the figure window. Axis titles are not displayed. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the scope axes. This option can also be set in the Axis Properties pane of the parameter dialog box.
- **Colorbar**, when selected, displays a bar with the specified colormap to the right of the image axes.
- **Save Position** automatically updates the **Figure position** parameter in the **Axis Properties** pane to reflect the figure window's current position and size on the screen. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Position**. The parameter dialog box must be closed when you select **Save Position** for the **Figure position** parameter to be updated.

Dialog Box

The **Image Properties** pane of the Matrix Viewer block appears as follows.



Colormap matrix

A 3-column matrix defining the colormap as a set of RGB triples, or a call to a colormap-generating function such as `hot` or `spring`. See the `ColorSpec` property for complete information about defining RGB triples, and the MATLAB `colormap` function for a list of colormap-generating functions. Tunable (Simulink).

Minimum input value

The input value to be mapped to the color defined in the first row of the colormap matrix. Right-click in the figure window and select `Autoscale` from pop-up menu to set this parameter to the minimum value observed in a series of 10 consecutive matrix inputs. Tunable (Simulink).

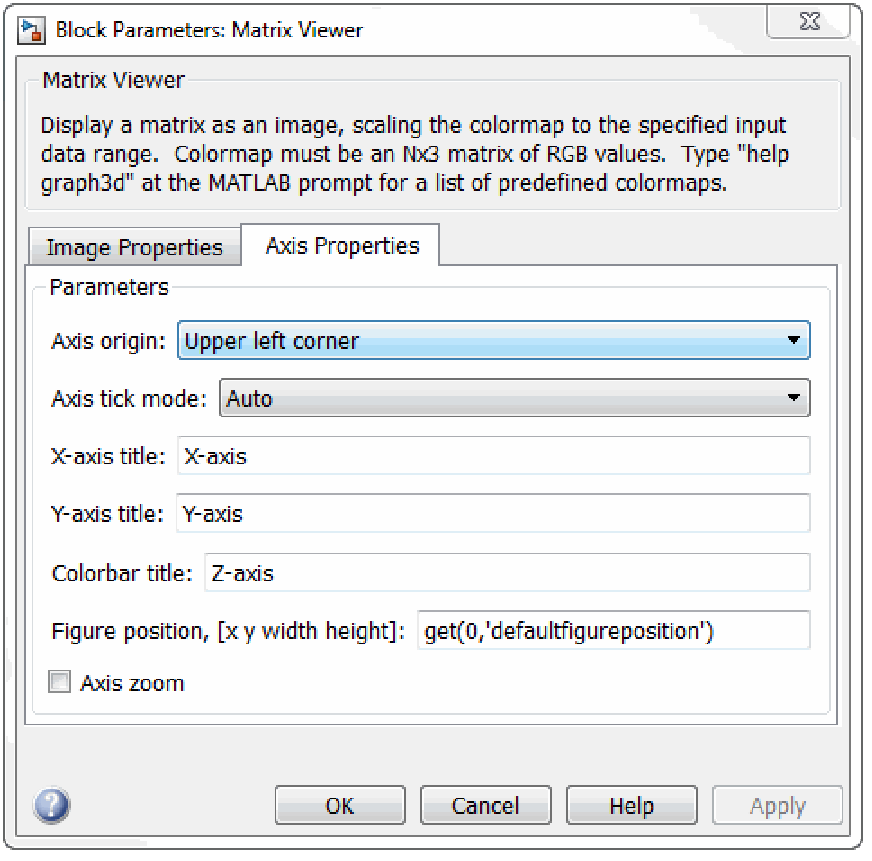
Maximum input value

The input value to be mapped to the color defined in the last row of the colormap matrix. Right-click in the figure window and select `Autoscale` from the pop-up menu to set this parameter to the maximum value observed in a series of 10 consecutive matrix inputs. Tunable (Simulink).

Display colorbar

Select to display a bar with the selected colormap to the right of the image axes. Tunable (Simulink).

The **Axis Properties** pane of the Matrix Viewer block appears as follows.



Axis origin

The position within the axes where the first element of the input matrix, $U(1,1)$, is plotted; bottom left or top left. Tunable (Simulink).

Axis tick mode

The mode used to specify the axis tick range. When you select `Auto`, the *x*-axis tick range and *y*-axis tick range are chosen based on the input signal. When you select `User-defined`, the axis tick range is set based on the values you specify in **X-tick range** and **Y-tick range**. The default is `Auto`.

X-tick range

x-axis tick range, specified as a two-element row vector of real scalars, [X_{min} X_{max}]. This parameter applies only when you set **Axis tick mode** to `User-defined`. When you change **X-tick range** during simulation, the axis range on the Matrix Viewer block updates in real time. The default is `[0 1]`.

Y-tick range

y-axis tick range, specified as a two-element row vector of real scalars, [Y_{min} Y_{max}]. This parameter applies only when you set **Axis tick mode** to `User-defined`. When you change **Y-tick range** during simulation, the axis range on the Matrix Viewer block updates in real time. The default is `[0 1]`.

X-axis title

The text to be displayed below the *x*-axis. Tunable (Simulink).

Y-axis title

The text to be displayed to the left of the *y*-axis. Tunable (Simulink).

Colorbar title

The text to be displayed to the right of the color bar, when **Display colorbar** is currently selected. Tunable (Simulink).

Figure position, [x y width height]

A 4-element vector of the form `[x y width height]` specifying the position of the figure window, where `(0,0)` is the lower-left corner of the display. Tunable (Simulink).

Axis zoom

Resizes the image to fill the figure window. Tunable (Simulink).

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

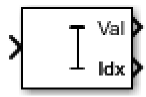
Maximum

Maximum values of input or sequence of inputs
Library: DSP System Toolbox / Statistics



Description

The Maximum block identifies the value and position of the largest element in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the maximum value of the entire input. The Maximum block can also track the maximum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to one of the following:

- `Value` — The block outputs the maximum values in the specified dimension.
- `Index` — The block outputs the index array of the maximum values in the specified dimension.
- `Value and Index` — The block outputs the maximum values and the corresponding index array in the specified dimension.
- `Running` — The block tracks the maximum values in a sequence of inputs over a period of time.

You can specify the dimension using the **Find the maximum value over** parameter.

Note: The **Running** mode in the Maximum block will be removed in a future release. To compute the running maximum in Simulink, use the `Moving Maximum` block instead.

Ports

Input

`In` — Data input
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be floating-point, fixed-point, or Boolean. Real fixed-point inputs can be either signed or unsigned. Complex fixed-point inputs must be signed.

This port is unnamed until you set the **Mode** parameter to `Running` and the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point`
Complex Number Support: Yes

`Rst` — Reset port
scalar

Specify the reset event that causes the block to reset the running maximum. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to `Running` and the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Val` — Maximum values along the specified dimension
scalar | vector | matrix | *N*-D array

The data type of the maximum value matches the data type of the input.

When the **Mode** parameter is set to either `Value and Index` or `Value`, the following applies:

- The size of the dimension for which the block computes the maximum value is 1. The sizes of all other dimensions match those of the input array. For example, when the input is an M-by-N-by-P array, with the dimension set to `1`, the block outputs a 1-by-N-by-P array. When the dimension is set to `3`, the block outputs a two-dimensional M-by-N matrix.

- When the input is an M-by-N matrix, with the dimension set to 1, the block outputs a 1-by-N matrix.

If you specify the block to compute the maximum value over the entire input, the block outputs a scalar.

When the **Mode** parameter is set `Running`, the block tracks the maximum value of each channel in a time sequence of M-by-N inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each y_{ijk} element of the output contains the maximum value observed in element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running maximum y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the maximum value observed in the jth column of all inputs since the last reset, up to and including element u_{ij} of the current input.

  When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to either `Value and Index` or `Value`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point`
Complex Number Support: Yes

`Idx` — Index of the maximum values along the specified dimension
scalar | vector | matrix | *N*-D array

When the input is `double`, the index values are also `double`. Otherwise, the index values are `uint32`.

Dependencies

To enable this port, set the **Mode** parameter to either `Value and Index` or `Index`.

Data Types: `double` | `uint32`

Parameters

Main Tab

`Mode` — Mode in which the block operates
`Value and Index` (default) | `Value` | `Index` | `Running`

When the **Mode** parameter is set to:

- `Value` — The block computes the maximum value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the maximum value of the entire input at each sample time, and outputs the array, *y*. Each element in the output is the maximum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the maximum value over** parameter. Consider a three dimensional input signal of size *M*-by-*N*-by-*P*. Set **Find the maximum value over** to:

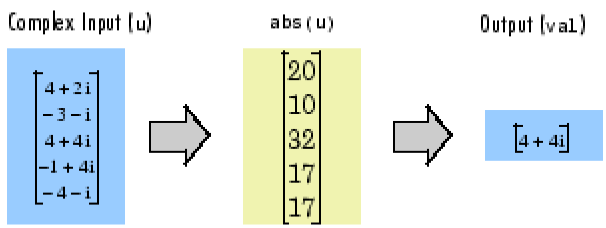
  - `Each row` — The output *y* at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the maximum value of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
  - `Each column` — The output *y* at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the maximum value of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Entire input` — The output y at each sample time is a scalar that contains the maximum value in the M-by-N-by-P input matrix.
- `Specified dimension` — The output y at each sample time depends on **Dimension**. If **Dimension** is set to `1`, the output is the same as when you select `Each column`. If **Dimension** is set to `2`, the output is the same as when you select `Each row`. If **Dimension** is set to `3`, the output at each sample time is an M-by-N matrix containing the maximum value of each vector over the third dimension of the input.

Complex Inputs

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the maximum magnitude squared as shown in the following figure. For complex value $u = a + bi$, the magnitude squared is $a^2 + b^2$.



- `Index` — The block computes the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array I. Each element in I is an integer indexing the maximum value in the corresponding column, row, vector, or entire input. The output I depends on the setting of the **Find the maximum value over** parameter. Consider a three-dimensional input signal of size M-by-N-by-P:
  - `Each row` — The output I at each sample time consists of an M-by-1-by-P array, where each element contains the index of the maximum value of each vector over the second dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is an M-by-1 column vector.
  - `Each column` — The output I at each sample time consists of a 1-by-N-by-P array, where each element contains the index of the maximum value of each vector over

the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

- `Entire input` — The output *I* at each sample time is a 1-by-3 vector that contains the location of the maximum value in the *M*-by-*N*-by-*P* input matrix. For an input that is an *M*-by-*N* matrix, the output is a 1-by-2 vector.
- `Specified dimension` — The output *I* at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select `Each column`. If **Dimension** is set to 2, the output is the same as when you select `Each row`. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the indices of the maximum values of each vector over the third dimension of the input.

When a maximum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector `[3 2 1 2 3]'`, the computed one-based index of the maximum value is `1`, rather than `5` when `Each column` is selected.

- `Value and Index` — The block outputs the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and the corresponding index array *I*.
- `Running` — The block tracks the maximum value of each channel in a time sequence of *M*-by-*N* inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

  - `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each y_{ijk} element of the output contains the maximum value observed in element u_{ijk} for all inputs since the last reset.

    When a reset event occurs, the running maximum y_{ijk} in the current frame is reset to the element u_{ijk}.
  - `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the

maximum value observed in the *j*th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Running Mode for Variable-Size Inputs

When the input is a variable-size signal, and you set the **Mode** to `Running`, then:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
  - When the input size difference is in the number of channels (columns), the state is reset.
  - When the input size difference is in the length of channels (rows), there is no reset and the running operation is carried out as usual.

`Index base` — Base of the maximum value index

`One` (default) | `Zero`

Specify whether the index of the maximum value is reported using one-based or zero-based numbering.

Dependencies

To enable this parameter, set **Mode** to either `Index` or `Value and Index`.

`Find the maximum value over` — Dimension over which the block computes the maximum value

`Each column` (default) | `Each row` | `Entire input` | `Specified dimension`

- `Each column` — The block outputs the maximum value over each column.

- `Each row` — The block outputs the maximum value over each row.
- `Entire input` — The block outputs the maximum value over the entire input.
- `Specified dimension` — The block outputs the maximum value over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, set **Mode** to `Value and Index`, `Value`, or `Index`.

`Dimension` — Custom dimension

`1` (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the maximum. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the maximum value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the maximum value observed in the *j*th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

  When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.
- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each y_{ijk} element of the output

contains the maximum value observed in element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running maximum y_{ijk} in the current frame is reset to the element u_{ijk}.

Dependencies

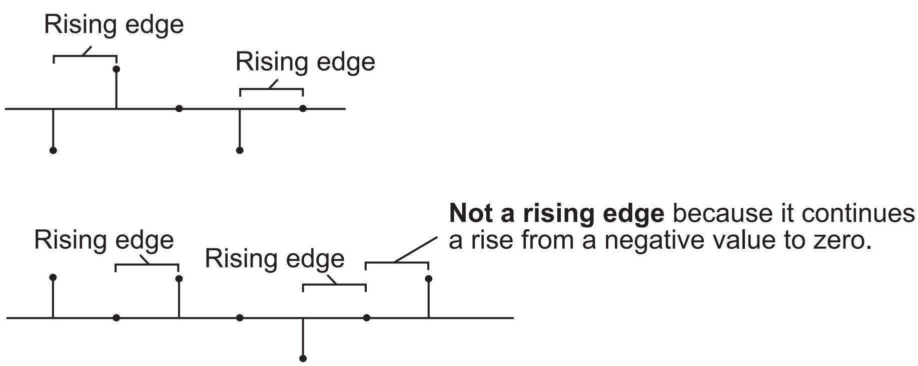
To enable this parameter, set **Mode** to `Running`.

`Reset port` — Reset event

`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

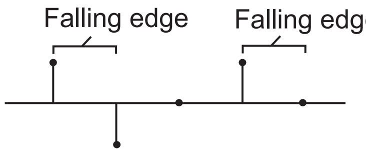
The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer, which is a multiple of the input sample time.

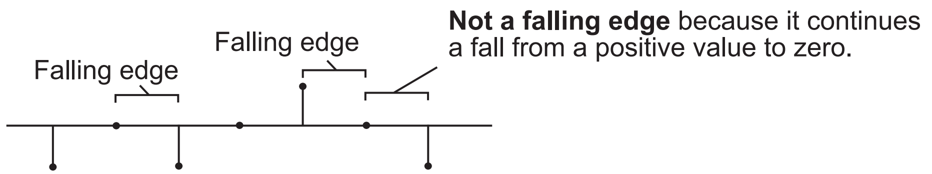
- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.





- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time that the **Rst** input is not zero.

Note: When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Dependencies

To enable this parameter, set **Mode** to `Running`.

Data Types Tab

Note To use these parameters, the data input must be complex and fixed-point.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

`Saturate on integer overflow` — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

`Product output` — Product output data type

`Inherit: Same as input` (default) | `fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the Maximum block. For more information on the product output data type, see “Multiplication Data Types”.

- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.

- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Same as product output` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Maximum block.

- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Model Examples

Algorithms

Maximum

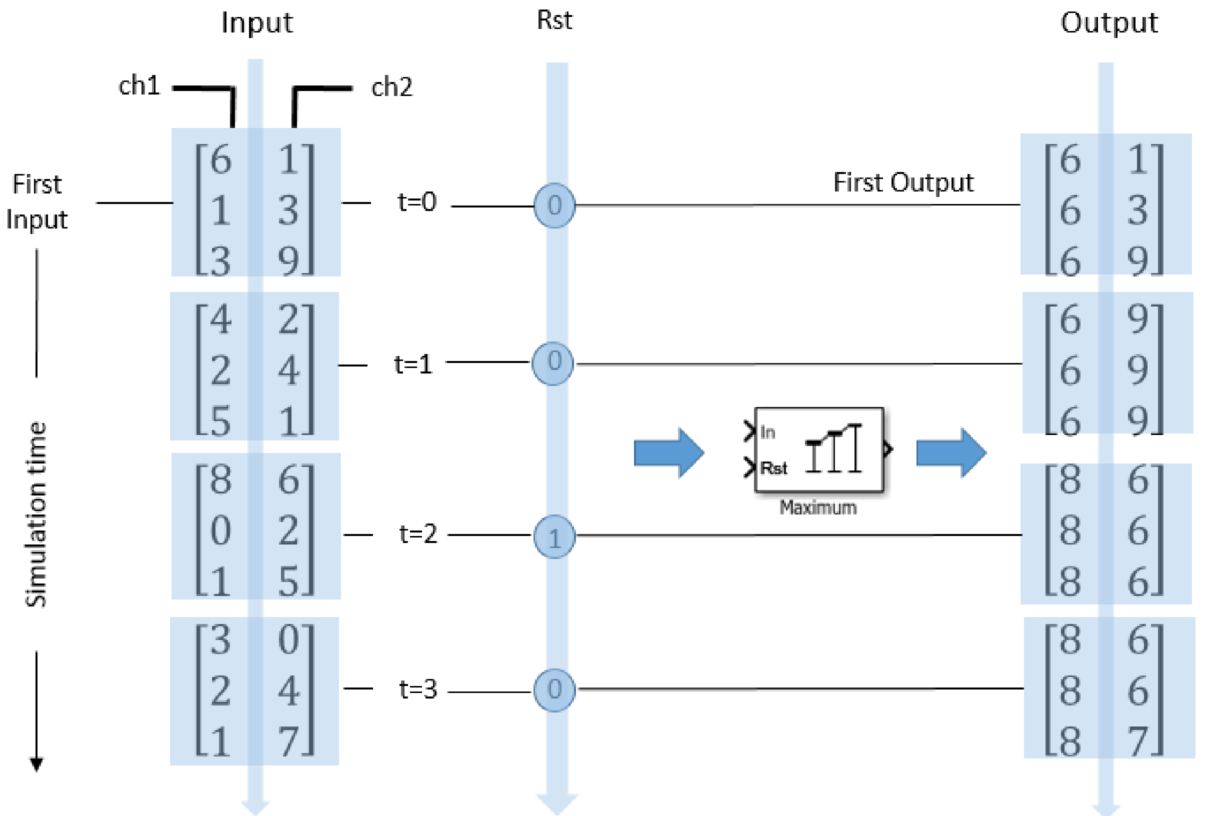
When you set **Mode** to one of `Value`, `Index`, or `Value and Index`, and specify a dimension, the block produces results identical to the MATLAB `max` function, when it is called as `[y,I] = max(u,[],D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the maximum value.
- `I` is the index of the maximum value.

The maximum value along the entire input is identical to calling the `max` function as `[y,I] = max(u(:))`.

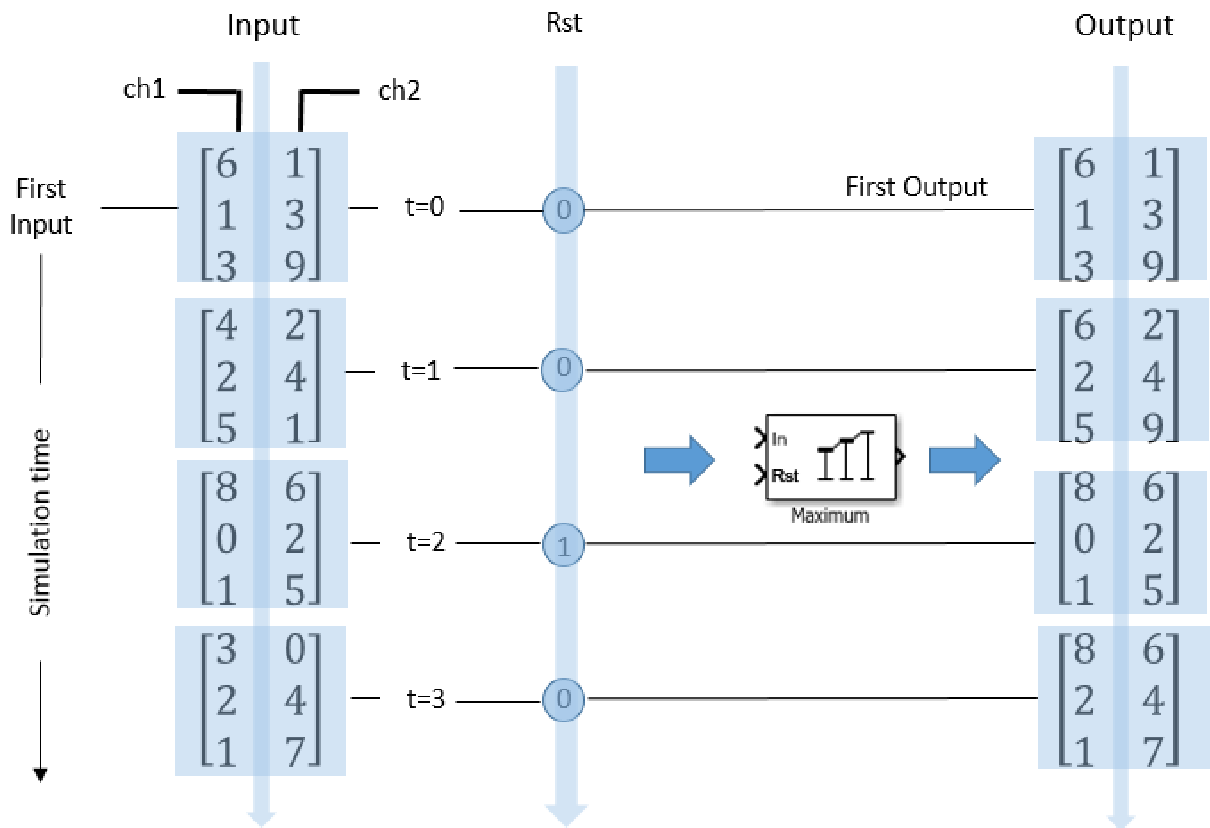
Running Maximum

When you set **Mode** to `Running`, and **Input processing** to `Columns as channels (frame based)`, the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.



The block outputs the maximum value over each channel since the last reset. At $t = 2$, the reset event occurs. The maximum value in the second column changes to 6, even though 6 is less than 9, which was the maximum value since the previous reset event.

When you set **Mode** to `Running`, and **Input processing** to `Elements as channels (sample based)`, the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.



Each y_{ij} element of the output contains the maximum value observed in element u_{ij} for all inputs since the last reset. The reset event occurs at $t = 2$. When a reset event occurs, the running maximum, y_{ij}, in the current frame is reset to element u_{ij}.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Maximum.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The parameters on the **Data Types Tab** of the block are used only for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described under the 'Mode' parameter in “Main Tab” on page 2-1177. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

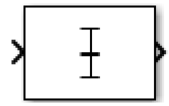
Blocks

`Mean` | `Minimum` | `Moving Maximum` | `Moving Minimum`

Introduced before R2006a

Mean

Find mean value of input or sequence of inputs
Library: DSP System Toolbox / Statistics



Description

The Mean block computes the mean of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the mean of the entire input. You can specify the dimension using the **Find the mean value over** parameter. The Mean block can also track the mean value in a sequence of inputs over a period of time. To track the mean value in a sequence of inputs, select the **Running mean** parameter.

Note: The **Running** mode in the Mean block will be removed in a future release. To compute the running mean in Simulink, use the `Moving Average` block instead.

Ports

Input

`I` — Data input
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point with power-of-two slope and zero bias.

This port is unnamed until you select the **Running mean** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

Complex Number Support: Yes

`Rst` — Reset port
scalar

Specify the reset event that causes the block to reset the running mean. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running mean** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — Mean value along the specified dimension
scalar | vector | matrix | *N*-D array

The data type of the output matches the data type of the input.

When you do not select the **Running mean** parameter, the block computes the mean value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the mean of the entire input at each individual sample time. Each element in the output array `y` is the mean value of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the mean value over** parameter. Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the mean value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the mean value of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the mean value of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the mean value of each vector over the first dimension

of the input. For an M-by-N matrix input, the output at each sample time is a 1-by-N row vector.

In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an M-by-N matrix containing the mean value of each vector over the third dimension of the input.

When you select **Running mean**, the block tracks the mean value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each element y_{ijk} of the output contains the mean value of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running mean y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the mean of the values in the jth column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

Parameters

Main Tab

`Running mean` — Option to select running mean

off (default) | on

When you select the **Running mean** parameter, the block tracks the mean value of each channel in a time sequence of inputs.

`Find the mean value over` — Dimension over which the block computes the mean value

`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the mean value over each column.
- `Each row` — The block outputs the mean value over each row.
- `Entire input` — The block outputs the mean value over the entire input.
- `Specified dimension` — The block outputs the mean value over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running mean** parameter.

`Dimension` — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the mean is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the mean value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the mean of the values in the *j*th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.
- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the mean value of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running mean y_{ijk} in the current frame is reset to the element u_{ijk}.

  Variable-Size Inputs

  When your inputs are of variable size, and you select the **Running mean** parameter, then:

  - If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
  - If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
    - When the input size difference is in the number of channels (number of columns), the state is reset.
    - When the input size difference is in the length of channels (number of rows), there is no reset and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running mean** parameter.

`Reset port` — Reset event

`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

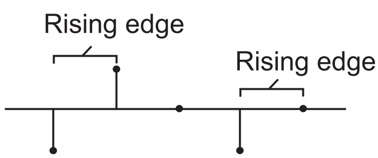
The block resets the running mean whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

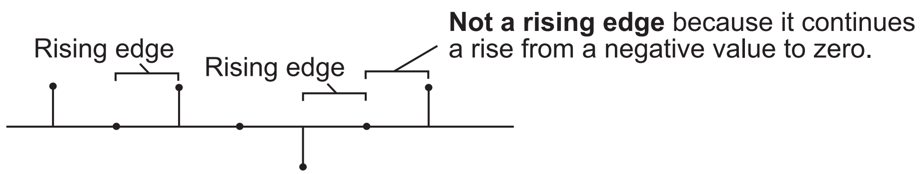
When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running mean for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:

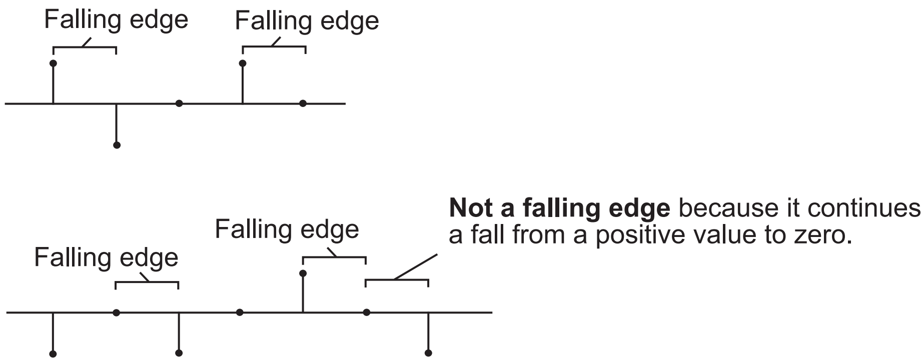
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.





- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:

  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note: When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Dependencies

To enable this parameter, select the **Running mean** parameter.

Data Types Tab

Note: To use these parameters, the data input must be fixed-point. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

`Overflow mode` — Method of overflow action

`Wrap` (default) | `Saturate`

Select the overflow mode for fixed-point operations.

`Accumulator` — Accumulator data type

`Inherit: Same as input` (default) | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Mean block. See “Fixed Point” on page 2- for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button 

.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Output` — Output data type

`Inherit: Same as accumulator` (default) | `fixdt([],16,0)`

Output specifies the data type of the output of the Mean block. See “Fixed Point” on page 2- for illustrations depicting the use of the output data type in this block. You can set it to:

- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button 

.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Output Minimum` — Minimum value the block can output

[ ] (default) | scalar

Specify the minimum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

`Output Maximum` — Maximum value the block can output

[ ] (default) | scalar

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Model Examples

Algorithms

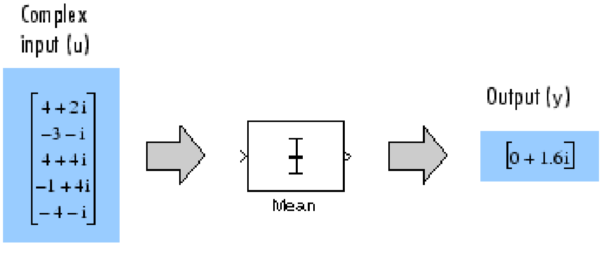
Mean

When you clear the **Running mean** parameter and specify a dimension, the block produces results identical to the MATLAB `mean` function, when it is called as `y = mean(u,D)`.

- u is the data input.
- D is the dimension.
- y is the mean value.

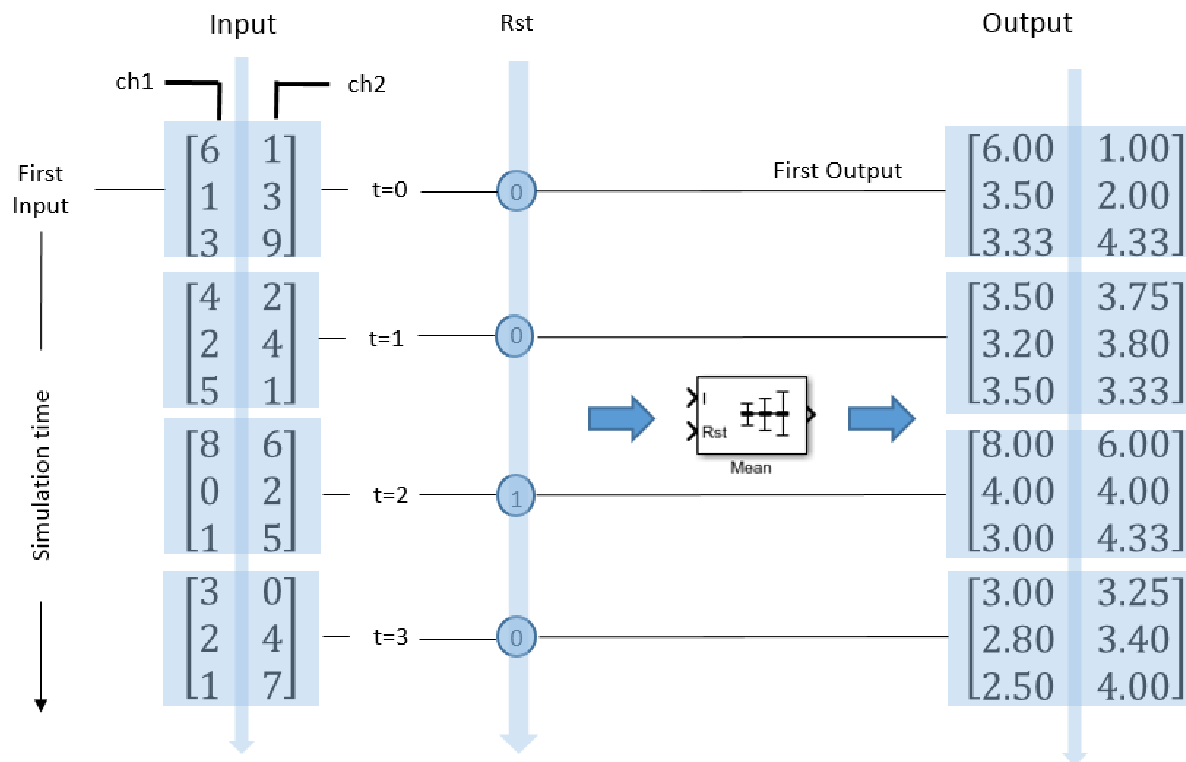
The mean value along the entire input is identical to calling the mean function as y = mean(u(:)).

The mean of a complex input is computed independently for the real and imaginary components.



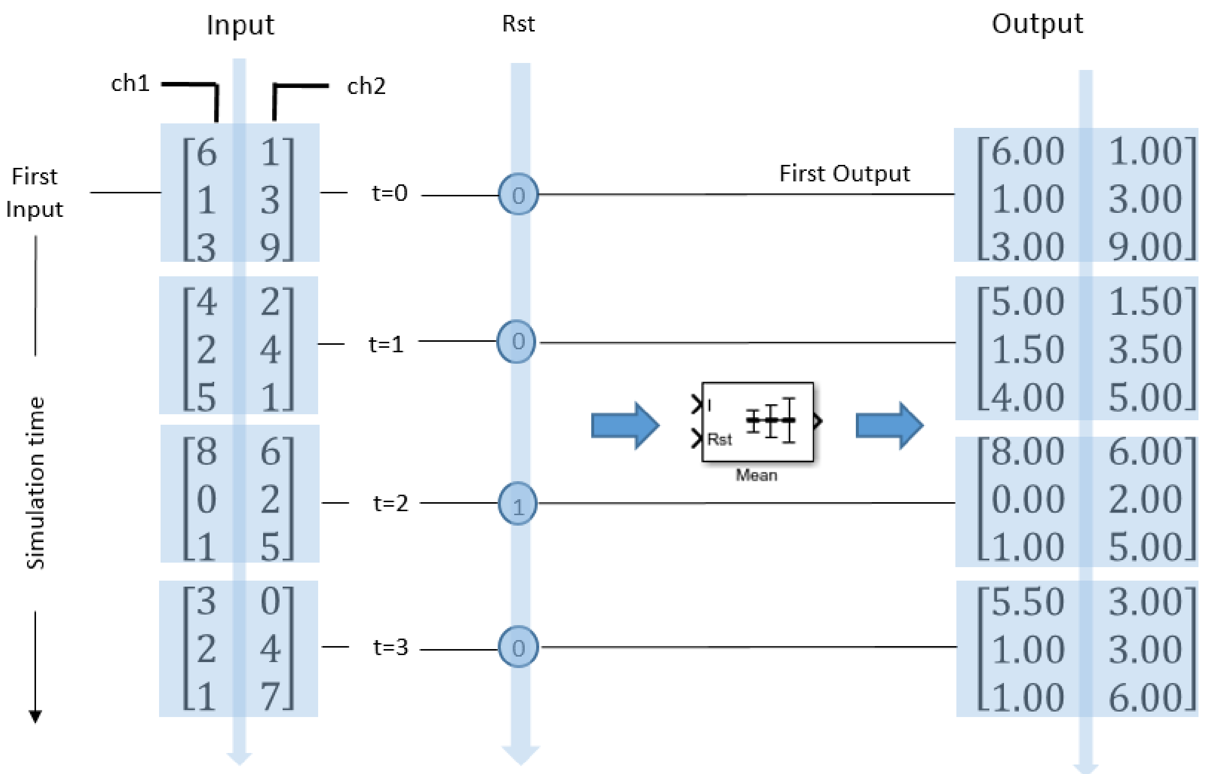
Running Mean

When you select the **Running mean** parameter, and set the **Input processing** parameter to Columns as channels (frame based), the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.



The block outputs the mean value over each channel since the last reset. At $t = 2$, the reset event occurs. The window of data in the second column now contains only 6.

When you select the **Running mean** parameter, and set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.



Each y_{ij} element of the output contains the mean value observed in element u_{ij} for all inputs since the last reset. The reset event occurs at $t = 2$. When a reset event occurs, the running mean, y_{ij}, in the current frame is reset to element u_{ij}.

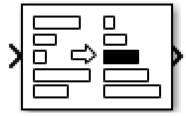
Blocks

`Maximum` | `Median` | `Median Filter` | `Minimum` | `Moving Average`

Introduced before R2006a

Median

Median value of input
Library: DSP System Toolbox / Statistics



Description

The Median block computes the median of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the median of the entire input. You can specify the dimension using the **Find the median value over** parameter. While computing the median, the block first sorts the input values. If the number of values is odd, the median is the middle value. If the number of values is even, the median is the average of the two middle values. To sort the data, you can specify the **Sort algorithm** parameter as either `Quick sort` or `Insertion sort`. The block sorts complex inputs according to their magnitude.

Ports

Input

`Port_1` — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

Output

`Port_1` — Median value along the specified dimension

vector | matrix | *N*-D array

The data type of the output matches the data type of the input.

The block computes the median value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the median of the entire input. Each element in the output array `y` is the median value of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the median value over** parameter. Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the median value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the median value of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the median value of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the median value of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.
- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an *M*-by-*N* matrix containing the median value of each vector over the third dimension of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

Parameters

Main Tab

`Sort algorithm` — Sort method
`Quick sort` (default) | `Insertion sort`

Specify the sorting algorithm as either `Quick sort` or `Insertion sort`.

`Find the median value over` — Dimension over which the block computes the median value
`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the median value over each column.
- `Each row` — The block outputs the median value over each row.
- `Entire input` — The block outputs the median value over the entire input.
- `Specified dimension` — The block outputs the median value over the dimension specified in the **Dimension** parameter.

`Dimension` — Custom dimension
`1` (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the median. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the median value over** to `Specified dimension`.

Data Types Tab

Note: To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

`Overflow mode` — Method of overflow action
`Wrap` (default) | `Saturate`

Select the overflow mode for fixed-point operations.

`Product output` — Product output data type

`Inherit: Same as input` (default) | `fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the Median block. For more information, see “Fixed Point” on page 2- and “Multiplication Data Types”.

- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Same as product output` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Median block. For more details, see “Fixed Point” on page 2- .

You can set this parameter to:

- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Output` — Output data type

`Inherit: Same as accumulator` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt([],16,0)`

Output specifies the data type of the output of the Median block. For more details, see “Fixed Point” on page 2- .

You can set this parameter to:

- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Output Minimum` — Minimum value the block can output

`[]` (default) | scalar

Specify the minimum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

`Output Maximum` — Maximum value the block can output

`[]` (default) | scalar

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Algorithms

Median

The median of a set of data is calculated using the following steps:

1. The values are sorted using the specified sorting algorithm.
2. If the number of values is odd, the median is the middle value.
3. If the number of values is even, the median is the average of the two middle values.

The block produces results identical to the MATLAB `median` function, when it is called as `y = median(u,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the median value.

The median value along the entire input is identical to calling the `median` function as `y = median(u(:))`.

When the input is complex, the block sorts the data according to the magnitude. The magnitude is computed by taking the sum of the squares of the real and imaginary components of the complex input.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

For fixed-point inputs, you can specify the **Accumulator**, **Product output**, and **Output** data types in the block dialog box. Not all these fixed-point parameters are applicable for all types of fixed-point inputs. The following table shows when each kind of data type and scaling is used.

M is the length of the sorted data along the specified dimension. X indicates that the particular data type is applicable.

	Output data type	Accumulator data type	Product output data type
Even *M*	X	X	Not Applicable
Odd *M*	X	Not Applicable	Not Applicable
Odd *M* and complex	X	X	X
Even *M* and complex	X	X	X

When *M* is even, the **Accumulator** and **Output** data types and scalings are used for fixed-point signals. While calculating the average of the two central rows of the input matrix, the result of the sum is stored in the **Accumulator** data type and scaling. The total result of the average which is the median of the data is stored in the **Output** data type and scaling.

When the fixed-point inputs are complex, both the **Accumulator** and the **Product output** data types are used in addition to the **Output** data type. Before sorting the data, the block computes the sum of the squares of the real and imaginary components of the complex input. The results of the squares are stored in the **Product output** data type and scaling. The result of the sum of the squares is stored in the **Accumulator** data type and scaling.

For fixed-point inputs that are both complex and have even M, **Accumulator** data type in addition stores the sum of the two central rows of the input matrix. The average of the two central rows which is the median of the data is stored in the **Output** data type.

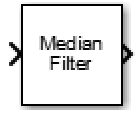
Median Filter

Median filter

Library: DSP System Toolbox / Filtering / Filter Designs
DSP System Toolbox / Statistics



Description

The Median Filter block computes the moving median of the input signal along each channel independently over time. The block uses the sliding window method to compute the moving median. In this method, a window of specified length moves over each channel sample by sample, and the block computes the median of the data in the window. This block performs median filtering on the input data over time. For more details, see “Algorithms” on page 2-1212.

Ports

Input

`Port_1` — Data input
column vector | row vector | matrix

Data over which the block computes moving median. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Moving median output
column vector | row vector | matrix

The size of the moving median output matches the size of the input. The block uses the sliding window method to compute the moving median. For more details, see “Algorithms” on page 2-1212.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

`Window length` — Length of the sliding window
5 (default) | positive scalar integer

Window length specifies the length of the sliding window.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

MIDI Controls

Output values from controls on MIDI control surface

Note: The MIDI Controls block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the MIDI Controls block from Audio System Toolbox instead.

Library

Sources

`dspsrcs4`

Description

The MIDI Controls block outputs values from controls on a MIDI control surface in real time.

Use the **MIDI device** parameter to specify the name of the MIDI control surface device from which to receive control values. You can choose:

- `Default`
- `Specify other`

If you choose `Default`, the block looks for a MATLAB preference with a group named `midi` and preference named `DefaultDevice`. You can set this preference using the MATLAB `setpref` function. For example, if the desired device is named `BCF2000`, you can type the following command at the MATLAB command line:

```
>> setpref('midi', 'DefaultDevice', 'BCF2000');
```

If the block does not find this preference, it then attempts to choose a device using an algorithm that is unspecified and platform dependent.

If you choose `Specify other`, then a **MIDI device name** edit box appears for you to enter a MATLAB expression for the device name. Enter any MATLAB expression that can evaluate to a string. Literal names must be enclosed in quotes, (for example, `'BCF2000'`).

You can determine the name of your MIDI device using the MATLAB function `midiid`, discussed in “Identifying MIDI Device Names and Control Numbers” on page 2-1217.

Use the **MIDI controls** parameter to specify the controls on the MIDI device to which the block should respond. This parameter also determines the size of the block output port. You can choose:

- `Respond to any control`
- `Respond to specified controls`

If you choose `Respond to any control`, then the block output will be a scalar. This scalar outputs the value from any and all controls that are manipulated on the MIDI device. Use this option in simple cases when you need only a single control value and the control to which it responds is unimportant.

If you choose `Respond to specified controls`, then a **MIDI control numbers** edit box opens. In this box, enter a MATLAB expression for the device control numbers. Enter any MATLAB expression that can evaluate to a row vector of real double-precision values. The block outputs a 1-D vector with one element corresponding to the output of each specified control.

Use the **Initial values** parameter to specify the value of the block output when simulation starts. The MIDI protocol transmits control values only when a control changes. This protocol provides no means for the block to query the current value of a control. Thus, the block must have some initial value to output until it receives a control change from the device.

Use the **Send initial values to device at start** check box to synchronize the device controls with the block outputs when simulation starts. Some MIDI control surfaces are bidirectional, meaning that they not only send control values but can also receive them. For example, some devices have motorized controls that move to the appropriate position when they receive a control value. If you have such a bidirectional device, select this check box. The block attempts to send the initial values to the device when the simulation starts. No diagnostic message appears if the attempt fails.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy. However you must account for these extra .dll files when doing so. The packNGo function creates a single .zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Output Port

The MIDI Controls block output is a vector whose width is determined by the **MIDI controls** and **MIDI control numbers** parameters previously described. The output data type can be either real double-precision floating point, or uint8 integer if the output mode is `'Raw MIDI'`. The output values range from 0.0 to 1.0, inclusively, and in the raw mode, they range from 0 to 127, inclusively. The output port back inherits its sample time.

Identifying MIDI Device Names and Control Numbers

To specify a particular control on a particular MIDI device, you must know the name assigned to the device by the operating system. In addition, a number is always associated with the control. You can interactively discover this information using the MATLAB function, `midiid`. Follow these steps to identify device names and control numbers:

1. Verify that MIDI control surface device is correctly connected to the host computer running MATLAB.

   Note: For the most consistent behavior, MathWorks recommends that you connect your MIDI control surface device to your computer before starting MATLAB. In some circumstances MATLAB may not be able to find your device if you connect it after starting your MATLAB session. Also, it may not find your device if you disconnect it and reconnect it during your MATLAB session.

   ---

2. Type the following command at the MATLAB command line.

   ```
   >> [ctlnum devname] = midiid
   ```

   You are prompted to move the control in which you are interested.

   ```
   >> [ctlnum devname] = midiid
   Move the control you wish to identify; type ^C to abort.
   Waiting for control message ...
   ```

3 Move the control. `midiid` detects the movement and returns the device name and control number.

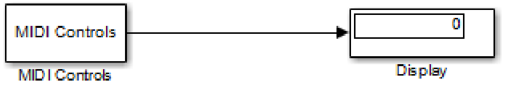
```
>> [ctlnum devname] = midiid
Move the control you wish to identify; type ^C to abort.
Waiting for control message ... done
ctlnum =
        1081
devname =
        BCF2000
>>
```

4 Use the device name in the block dialog, or set it as the default device using `setpref`. Then, enter the control number in the block dialog. Concatenate the number with other control numbers as needed.

Examples

How to Output Values from Controls

Use this example to familiarize yourself with how to set controls in the MIDI Controls block as it interacts with the MIDI control surface.



Open the ex_simplemidi model, and follow these steps:

Connect a MIDI device to the computer.

Use `midiid` to determine the name of the device, and set it on the MIDI Controls block.

Verify that any control changes the display value.

Use `midiid` to determine the number of a particular control, and set that on the MIDI Controls block.

Verify that a particular control changes the display value and that other controls do not.

Use `midiid` to determine the number of a few more controls, and set those on the MIDI Controls block.

Verify that the display block shows the correct number of values. Also verify that the controls you specified change the appropriate display values and that the other controls do not change the values.

Set each control to have a unique initial value.

Verify that the correct initial values appear on the display when the model starts.

If your MIDI device is bidirectional, on the MIDI Controls block, select the **Send initial values to device at start** check box.

Verify that the controls are set to the correct initial values when the model starts.

Parameters

MIDI device

Specify whether to use a default MIDI device, or specify a particular device by name.

MIDI device name

Specify the name of a particular MIDI control surface device from which to receive control values.

MIDI controls

Specify whether to respond to any control on the MIDI device or respond to particular specified controls.

MIDI control numbers

Specify particular controls to which the block should respond.

Initial values

Specify initial values to output when simulation starts.

Send initial values to device at start

Select this check box to attempt to synchronize a bidirectional MIDI device with block initial values when simulation starts.

Output mode

Specify the mode in which the control values are generated. When you set **Output mode** to `Normalized (0-1)`, the block generates control values in the range [`0`

1]. In this mode, control values are represented as a fraction of a full-scale. Hence, you can easily scale this range to your particular application. When you set **Output mode** to `RAW MIDI (0-127)`, the block generates byte-oriented MIDI control values in the range [`0 127`]. By default, this parameter is set to `Normalized (0-1)`.

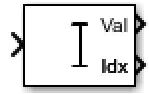
Supported Data Types

Port	Supported Data Types
Output	• Double-precision floating point, uint8 integer

Introduced in R2012a

Minimum

Minimum values of input or sequence of inputs
Library: DSP System Toolbox / Statistics



Description

The Minimum block identifies the value and position of the smallest element in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the minimum value of the entire input. The Minimum block can also track the minimum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to one of the following:

- `Value` — The block outputs the minimum values in the specified dimension.
- `Index` — The block outputs the index array of the minimum values in the specified dimension.
- `Value and Index` — The block outputs the minimum values and the corresponding index array in the specified dimension.
- `Running` — The block tracks the minimum values in a sequence of inputs over a period of time.

You can specify the dimension using the **Find the minimum value over** parameter.

Note: The **Running** mode in the Minimum block will be removed in a future release. To compute the running minimum in Simulink, use the `Moving Minimum` block instead.

Ports

Input

`In` — Data input
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be floating-point, fixed-point, or Boolean. Real fixed-point inputs can be either signed or unsigned. Complex fixed-point inputs must be signed.

This port is unnamed until you set the **Mode** parameter to `Running` and the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point`
Complex Number Support: Yes

`Rst` — Reset port
scalar

Specify the reset event that causes the block to reset the running minimum. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to `Running` and the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Val` — Minimum values along the specified dimension
scalar | vector | matrix | *N*-D array

The data type of the minimum value matches the data type of the input.

When the **Mode** parameter is set to either `Value and Index` or `Value`, the following applies:

- The size of the dimension for which the block computes the minimum value is 1. The sizes of all other dimensions match those of the input array. For example, when the input is an *M*-by-*N*-by-*P* array, with the dimension set to `1`, the block outputs a 1-by-*N*-by-*P* array. When the dimension is set to `3`, the block outputs a two-dimensional *M*-by-*N* matrix.

- When the input is an M-by-N matrix, with the dimension set to `1`, the block outputs a 1-by-N matrix.

If you specify the block to compute the minimum value over the entire input, the block outputs a scalar.

When the **Mode** parameter is set `Running`, the block tracks the minimum value of each channel in a time sequence of M-by-N inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each y_{ijk} element of the output contains the minimum value observed in element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running minimum y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the minimum value observed in the jth column of all inputs since the last reset, up to and including element u_{ij} of the current input.

  When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, set the **Mode** parameter to either `Value and Index` or `Value`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed_point`
Complex Number Support: Yes

`Idx` — Index of the minimum values along the specified dimension
scalar | vector | matrix | *N*-D array

When the input is `double`, the index values are also `double`. Otherwise, the index values are `uint32`.

Dependencies

To enable this port, set the **Mode** parameter to either `Value and Index` or `Index`.

Data Types: `double` | `uint32`

Parameters

Main Tab

`Mode` — Mode in which the block operates
`Value and Index` (default) | `Value` | `Index` | `Running`

When the **Mode** parameter is set to:

- `Value`— The block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each sample time, and outputs the array *y*. Each element in *y* is the minimum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the minimum value over** parameter. Consider a three dimensional input signal of size *M*-by-*N*-by-*P*. Set **Find the minimum value over** to:

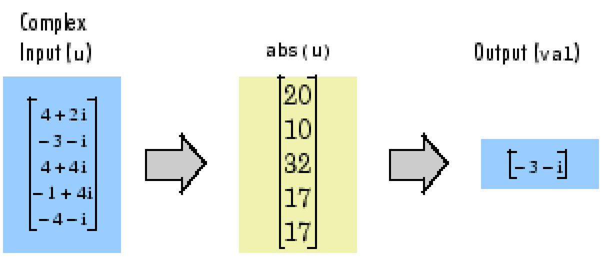
  - `Each row` — The output *y* at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the minimum value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.
  - `Each column` — The output *y* at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the minimum value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Entire input` — The output y at each sample time is a scalar that contains the minimum value in the M-by-N-by-P input matrix.
- `Specified dimension` — The output y at each sample time depends on **Dimension**. If **Dimension** is set to `1`, the output is the same as when you select `Each column`. If **Dimension** is set to `2`, the output is the same as when you select `Each row`. If **Dimension** is set to `3`, the output at each sample time is an M-by-N matrix containing the minimum value of each vector over the third dimension of the input.

Complex Inputs

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the minimum magnitude squared in the following figure. For complex value $u = a + bi$, the magnitude squared is $a^2 + b^2$.



- `Index` — The block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array I. Each element in I is an integer indexing the minimum value in the corresponding column, row, vector, or entire input. The output I depends on the setting of the **Find the minimum value over** parameter. Consider a three dimensional input signal of size M-by-N-by-P:

  - `Each row` — The output I at each sample time consists of an M-by-1-by-P array, where each element contains the index of the minimum value of each vector over the second dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is an M-by-1 column vector.

    - `Each column` — The output I at each sample time consists of a 1-by-N-by-P array, where each element contains the index of the minimum value of each vector over the first dimension of the input. For an input that is an M-by-N matrix, the output at each sample time is a 1-by-N row vector.

      In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.
    - `Entire input` — The output I at each sample time is a 1-by-3 vector that contains the location of the minimum value in the M-by-N-by-P input matrix. For an input that is an M-by-N matrix, the output is a 1-by-2 vector.
    - `Specified dimension` — The output I at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select `Each column`. If **Dimension** is set to 2, the output is the same as when you select `Each row`. If **Dimension** is set to 3, the output at each sample time is an M-by-N matrix containing the indices of the minimum values of each vector over the third dimension of the input.

  When a minimum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector `[3 2 1 2 3]'`, the computed one-based index of the minimum value is `1`, rather than `5` when `Each column` is selected.
- `Value and Index` — The block outputs the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and the corresponding index array I.
- `Running` — The block tracks the minimum value of each channel in a time sequence of M-by-N inputs. The block resets the running minimum whenever a reset event is detected at the optional `Rst` port. The reset sample time must be a positive integer multiple of the input sample time. In this mode, you must also specify the **Input processing** parameter as one of the following:

    - `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each y_{ijk} element of the output contains the minimum value observed in element u_{ijk} for all inputs since the last reset.

      When a reset event occurs, the running minimum y_{ijk} in the current frame is reset to the element u_{ijk}.

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the minimum value observed in the *j*th column of all inputs since the last reset, up to and including element u_{ij} of the current input.

  When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

Running Mode for Variable-Size Inputs

When the input is a variable-size signal, and you set the **Mode** to `Running`, then:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
  - When the input size difference is in the number of channels (columns), the state is reset.
  - When the input size difference is in the length of channels (rows), there is no reset and the running operation is carried out as usual.

`Index base` — Base of the minimum value index

`One` (default) | `Zero`

Specify whether the index of the minimum value is reported using one-based or zero-based numbering.

Dependencies

To enable this parameter, set **Mode** to either `Index` or `Value and Index`.

`Find the minimum value over` — Dimension over which the block computes the minimum value
`Each column` (default) | `Each row` | `Entire input` | `Specified dimension`

- `Each column` — The block outputs the minimum value over each column.
- `Each row` — The block outputs the minimum value over each row.
- `Entire input` — The block outputs the minimum value over the entire input.
- `Specified dimension` — The block outputs the minimum value over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, set **Mode** to `Value and Index`, `Value`, or `Index`.

`Dimension` — Custom dimension
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the minimum. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the minimum value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support an N-dimensional input signal, where N > 2. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the minimum value observed in the jth column of all inputs since the last reset, up to and including element u_{ij} of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each y_{ijk} element of the output contains the minimum value observed in element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running minimum y_{ijk} in the current frame is reset to the element u_{ijk}.

Dependencies

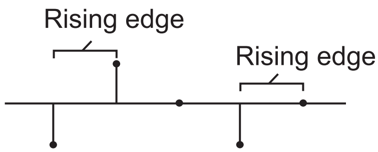
To enable this parameter, set **Mode** to `Running`.

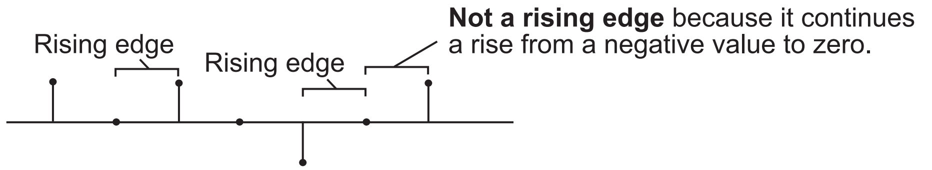
`Reset port` — Reset event

`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

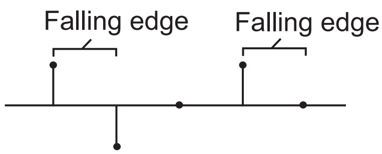
The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer which is a multiple of the input sample time.

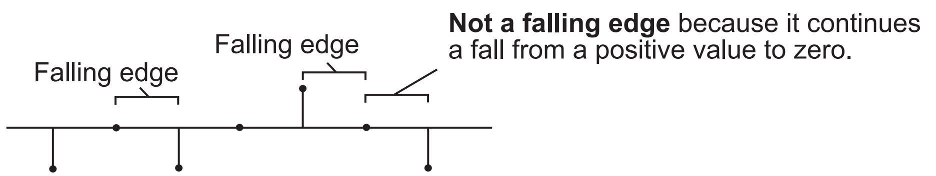
- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.





- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.





- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time that the **Rst** input is not zero.

Note: When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, set **Mode** to `Running`.

Data Types Tab

Note To use these parameters, the data input must be complex fixed-point.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

`Saturate on integer overflow` — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Note: The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

`Product output` — Product output data type

`Inherit: Same as input` (default) | `fixdt([],16,0)`

Product output specifies the data type of the output of a product operation in the Minimum block. For more information on the product output data type, see "Multiplication Data Types".

- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type

`Inherit: Same as product output` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

Accumulator specifies the data type of the output of an accumulation operation in the Minimum block.

- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

Model Examples

Algorithms

Minimum

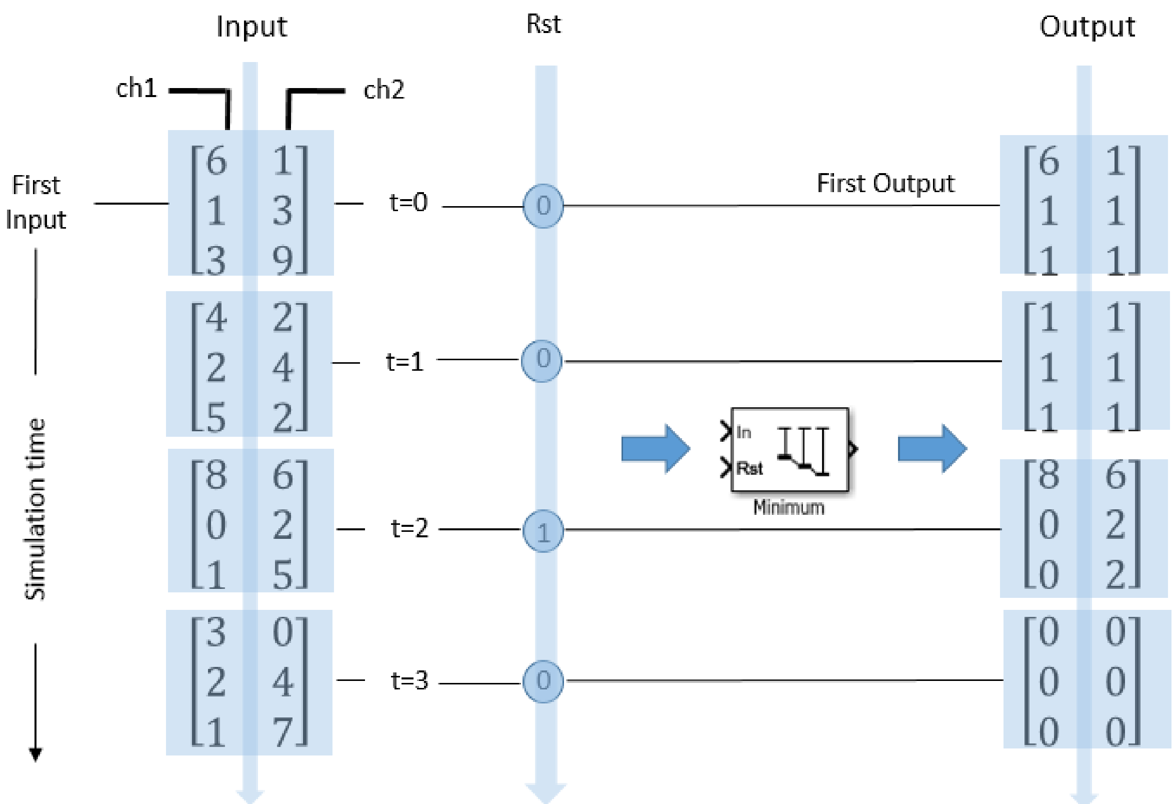
When you set **Mode** to one of `Value`, `Index`, or `Value and Index`, and specify a dimension, the block produces results identical to the MATLAB `min` function, when it is called as `[y,I] = min(u,[],D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the minimum value.
- `I` is the index of the minimum value.

The minimum value along the entire input is identical to calling the `min` function as `[y,I] = min(u(:))`.

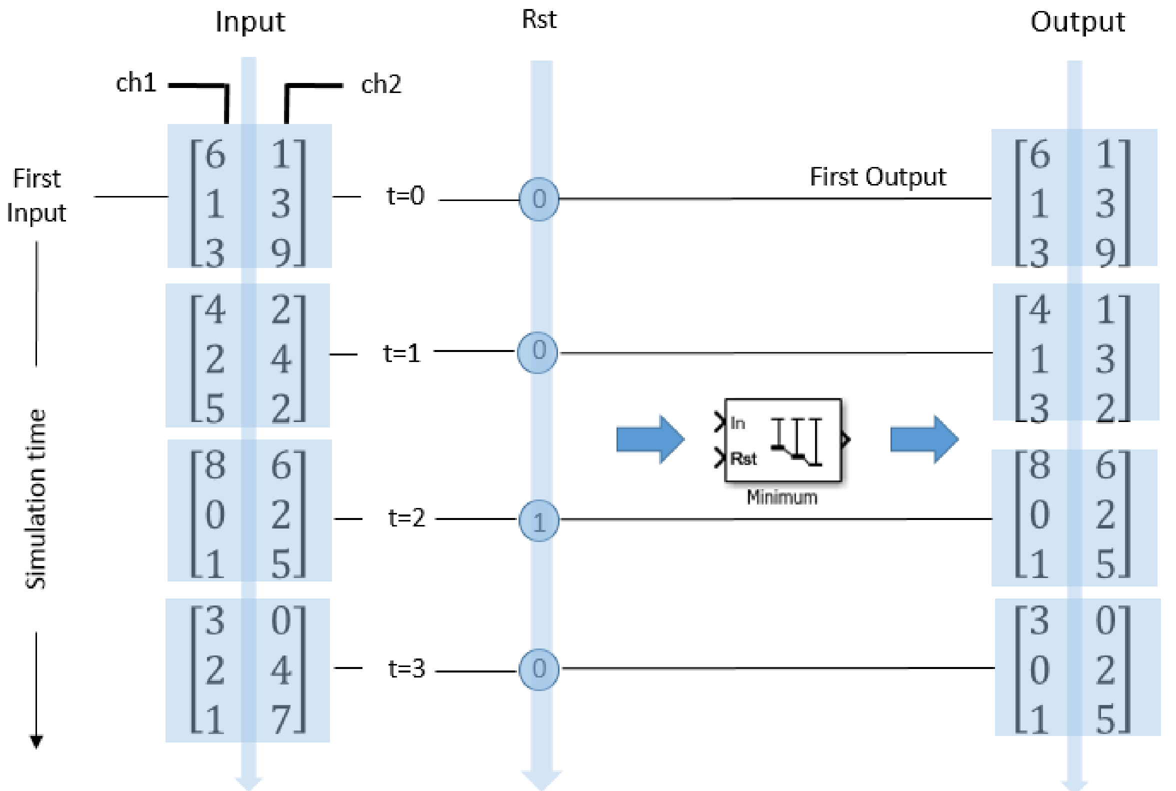
Running Minimum

When you set **Mode** to `Running`, and **Input processing** to `Columns as channels (frame based)`, the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.



The block outputs the minimum value over each channel since the last reset. At t = 2, the reset event occurs. The minimum value in the second column changes to 6, and then 2, even though these values are greater than 1, which was the minimum value since the previous reset event.

When you set **Mode** to `Running`, and **Input processing** to `Elements as channels (sample based)`, the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.



Each element y_{ij} of the output contains the minimum value observed in element u_{ij} for all inputs since the last reset. The reset event occurs at $t = 2$. When a reset event occurs, the running minimum, y_{ij}, in the current frame is reset to the element u_{ij}.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Minimum.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The parameters on the **Data Types Tab** of the block are used only for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described under the 'Mode' parameter in “Main Tab” on page 2-1224. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

Modified Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using modified covariance method

Library

Estimation / Parametric Estimation

`dspparest3`

Description

The Modified Covariance AR Estimator block uses the modified covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward and backward prediction errors in the least squares sense. The input is a frame of consecutive time samples, which is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters, *A(z)*, independently for each successive input.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

You specify the order, p, of the all-pole model in the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be less than or equal to two thirds the input vector length.

The output port labeled A outputs the normalized estimate of the AR model coefficients in descending powers of z.

```
[1 a(2) ... a(p+1)]
```

The scalar gain, G, is output from the output port labeled G.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Estimation order

Specify the order of the AR model, p.

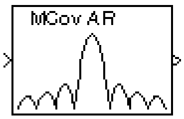
Modified Covariance Method

Power spectral density estimate using modified covariance method



Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Modified Covariance Method block estimates the power spectral density (PSD) of the input using the modified covariance method. This method fits an autoregressive (AR) model to the signal. It does so by minimizing the forward and backward prediction errors in the least squares sense. The **Estimation order** parameter value specifies the order of the all-pole model. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to two thirds of the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

Selecting **Inherit FFT length from estimation order**, specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the `Burg Method` block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker Method blocks.

Examples

The dspsacomp example compares the modified covariance method with several other spectral estimation methods.

Parameters

Estimation order

Specify the order of the AR model. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to two thirds of the input vector length.

Inherit FFT length from estimation order

When you select this check box, the option specifies that the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear this check box. You can then specify a power of two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points, N_{fft}, on which to perform the FFT. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from estimation order** check box.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Moving Average

Moving average
Library: DSP System Toolbox / Statistics

Description

The Moving Average block computes the moving average of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the average is over the data in the window. In the exponential weighting method, the block multiplies the data samples with a set of weighting factors and then sums the weighted data to compute the average. For more details on these methods, see “Algorithms” on page 2-1246.

Ports

Input

`Port_1` — Data input

column vector | row vector | matrix

Data over which the block computes the moving average. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Moving average output

column vector | row vector | matrix

The size of the moving average output matches the size of the input. The block uses either the sliding window method or the exponential weighting method to compute the moving average. For more details, see “Algorithms” on page 2-1246.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

`Method` — Averaging method

`Sliding window` (default) | `Exponential weighting`

- `Sliding window` — A window of length **Window length** moves over the input data along each channel. For every sample the window moves by, the block computes the average over the data in the window.
- `Exponential weighting` — The block multiplies the samples by a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the average, the algorithm sums the weighted data.

`Specify window length` — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the average of the current sample and all previous samples in the channel.

`Window length` — Length of the sliding window

4 (default) | positive scalar integer

Window length specifies the length of the sliding window. This parameter appears when you select the **Specify window length** check box.

`Forgetting factor` — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

This parameter applies when you set **Method** to `Exponential weighting`. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

This parameter is tunable. You can change its value even during the simulation.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the average when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1,$$
$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right)\bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right)x_N$$

- $\bar{x}_{N,\lambda}$ — Moving average at the current sample
- x_N — Current data input sample
- $\bar{x}_{N-1,\lambda}$ — Moving average at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right)\bar{x}_{N-1,\lambda}$ — Effect of the previous data on the average

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

Moving Maximum

Moving maximum
Library: DSP System Toolbox / Statistics

Description

The Moving Maximum block determines the moving maximum of the input signal along each channel independently over time. The block uses the sliding window method to determine the moving maximum. In this method, a window of specified length moves over each channel sample by sample, and the block determines the maximum over the data in the window. For more details, see "Algorithms" on page 2-1251.

Ports

Input

`Port_1` — Data input

column vector | row vector | matrix

Data over which the moving maximum is determined using the sliding window method. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Moving maximum output

column vector | row vector | matrix

Moving maximum output, determined using the sliding window method. The size of the output matches the size of the input. The window slides column-wise along each channel, and the block determines the maximum of the data in the window. For more details, see "Algorithms" on page 2-1251.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

`Specify window length` — Flag to specify window length
on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify through the **Window length** parameter. When you clear this check box, the length of the sliding window is infinite. In this mode, the block determines the maximum of the current sample and all previous samples in the channel.

`Window length` — Length of the sliding window
4 (default) | positive scalar integer

Window length specifies the length of the sliding window. This parameter appears when you select the **Specify window length** check box.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the maximum of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. When the algorithm computes the first *Len* - 1 outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the maximum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving maximum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Moving RMS

Moving RMS
Library: DSP System Toolbox / Statistics

Description

The Moving RMS block computes the moving root mean square (RMS) of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the RMS over the data in the window. In the exponential weighting method, the block squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The block then computes the RMS by taking the square root of the sum. For more details on these methods, see "Algorithms" on page 2-1261.

Ports

Input

`Port_1` — Data input

column vector | row vector | matrix

Data over which the block computes the moving RMS. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Moving RMS output

column vector | row vector | matrix

The size of the moving RMS output matches the size of the input. The block uses either the sliding window method or the exponential weighting method to compute the moving RMS. For more details, see “Algorithms” on page 2-1261.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

`Method` — Moving RMS method

`Sliding window` (default) | `Exponential weighting`

- `Sliding window` — A window of length **Window length** moves over the input data along each channel. For every sample the window moves by, the block computes the RMS over the data in the window.
- `Exponential weighting` — The block multiplies the squares of the samples by a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the RMS, the algorithm sums the weighted data and takes a square root of the sum.

`Specify window length` — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the RMS of the current sample and all the previous samples in the channel.

`Window length` — Length of the sliding window

4 (default) | positive scalar integer

Window length specifies the length of the sliding window. This parameter appears when you select the **Specify window length** check box.

`Forgetting factor` — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

This parameter applies when you set **Method** to `Exponential weighting`. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

This parameter is tunable. You can change its value even during the simulation.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the RMS when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1,$$

$$x\_rms_{N,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right) x\_rms_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x^2{}_N}$$

- $x\_rms_{N,\lambda}$ — Moving RMS at the current sample
- $x^2{}_N$ — Square of the current input data sample
- $x\_rms_{N-1,\lambda}$ — Moving RMS at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) x\_rms_{N-1,\lambda}$ — Effect of the previous data on the RMS

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda}$ = 1. For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

Moving Variance

Moving variance
Library: DSP System Toolbox / Statistics

Description

The Moving Variance block computes the moving variance of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the variance over the data in the window. In the exponential weighting method, the block subtracts each sample of the data from the average, squares the difference, and multiplies the squared result by a weighting factor. The object then computes the variance by adding all the weighted data. For more details on these methods, see “Algorithms” on page 2-1268.

Ports

Input

`Port_1` — Data input
column vector | row vector | matrix

Data over which the block computes the moving variance. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Moving variance output

column vector | row vector | matrix

The size of the moving variance output matches the size of the input. The block uses either the sliding window method or the exponential weighting method to compute the moving variance. For more details, see "Algorithms" on page 2-1268.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

`Method` — Moving variance method

`Sliding window` (default) | `Exponential weighting`

- `Sliding window` — A window of length **Window length** moves over the input data along each channel. For every sample the window moves by, the block computes the variance over the data in the window.
- `Exponential weighting` — The block subtracts each sample of the data from the average, squares the difference, and multiplies the squared result by a weighting factor. The block then computes the variance by adding all the weighted data. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero.

For more details on these methods, see "Algorithms" on page 2-1268.

`Specify window length` — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the variance of the current sample with respect to all the previous samples in the channel.

`Window length` — Length of the sliding window

4 (default) | positive scalar integer

Window length specifies the length of the sliding window. This parameter appears when you select the **Specify window length** check box.

`Forgetting factor` — Exponential weighting factor
0.9 (default) | positive real scalar in the range (0,1]

This parameter applies when you set **Method** to `Exponential weighting`. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

This parameter is tunable. You can change its value even during the simulation.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the variance when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. *Len* is the length of the window. The data vector, x, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Current sample at n = 5
2.000
var([3 2 5 2]')

Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s^2_{N,\lambda} = \frac{1}{v_{N,\lambda}} \sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2,$$

$$v_{N,\lambda} = \frac{2\lambda(1-\lambda^{N-1})}{(1-\lambda)(1+\lambda)}$$

To compute the moving variance, the algorithm implements these equations recursively.

- $s^2_{N,\lambda}$ — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$ — Moving average at the current sample. For details on computing the moving average, see dsp.MovingAverage.
- $\left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

Moving Standard Deviation

Moving standard deviation
Library: DSP System Toolbox / Statistics

Description

The Moving Standard Deviation block computes the moving standard deviation of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the standard deviation over the data in the window. In the exponential weighting method, the block computes the exponentially weighted moving variance and takes the square root. For more details on these methods, see “Algorithms” on page 2-1276.

Ports

Input

`Port_1` — Data input

column vector | row vector | matrix

Data over which the block computes the moving standard deviation. The block accepts real-valued or complex-valued multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$ and $n \geq 1$. The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`
Complex Number Support: Yes

Output

`Port_1` — Moving standard deviation output

column vector | row vector | matrix

The size of the moving standard deviation output matches the size of the input. The block uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. For more details, see “Algorithms” on page 2-1276.

Data Types: `single` | `double`
Complex Number Support: Yes

Parameters

`Method` — Moving standard deviation method

`Sliding window` (default) | `Exponential weighting`

- `Sliding window` — A window of length **Window length** moves over the input data along each channel. For every sample the window moves by, the block computes the standard deviation over the data in the window.
- `Exponential weighting` — The block computes the exponentially weighted moving standard deviation and takes the square root.

For more details on these methods, see “Algorithms” on page 2-1276.

`Specify window length` — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the standard deviation of the current sample with respect to all the previous samples in the channel.

`Window length` — Length of the sliding window

4 (default) | positive scalar integer

Window length specifies the length of the sliding window. This parameter appears when you select the **Specify window length** check box.

`Forgetting factor` — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

This parameter applies when you set **Method** to `Exponential weighting`. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

This parameter is tunable. You can change its value even during the simulation.

`Simulate using` — Type of simulation to run
`Code generation` (default) | `Interpreted execution`

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the standard deviation when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. *Len* is the length of the window. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2},$$

$$v_{N,\lambda} = \frac{2\lambda(1-\lambda^{N-1})}{(1-\lambda)(1+\lambda)}$$

- $s_{N,\lambda}$ — Moving standard deviation of the current data sample with respect to the rest of the data.
- $\left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

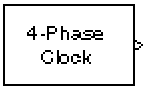
Multiphase Clock

Generate multiple binary clock signals



Library

- Sources

  `dspsrcs4`
- Signal Management / Switches and Counters

  `dspswit3`

Description

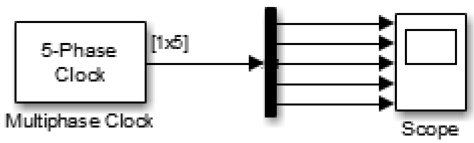
The Multiphase Clock block generates a 1-by-*N* vector of clock signals, where you specify the integer *N* in the **Number of phases** parameter. Each of the *N* phases has the same frequency, *f*, specified in hertz by the **Clock frequency** parameter.

The clock signal indexed by the **Starting phase** parameter is the first to become active, at *t*=0. The other signals in the output vector become active in turn, each one lagging the preceding signal's activation by 1/(*N**f*) seconds, the phase interval. The period of the output is therefore 1/(*N**f*) seconds.

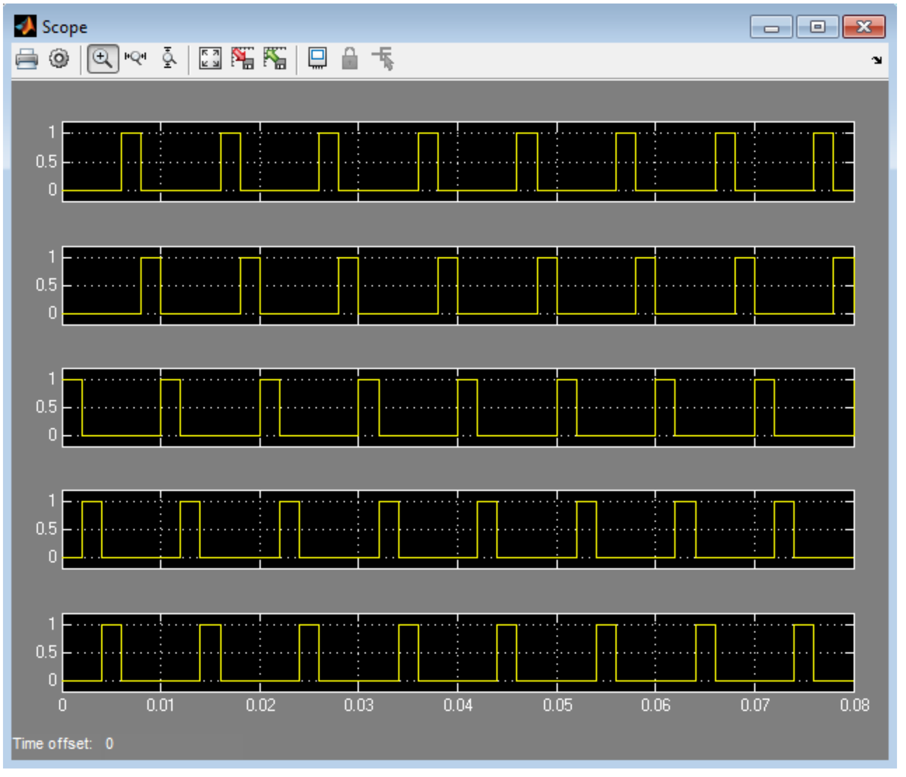
The active level can be either high (`1`) or low (`0`), as specified by the **Active level (polarity)** parameter. The duration of the active level, *D*, is set by the **Number of phase intervals over which the clock is active**. This value, which can be an integer value between 1 and *N*-1, specifies the number of phase intervals that each signal should remain in the active state after becoming active. The active duty cycle of the signal is *D*/*N*.

Examples

In the following ex_multiphaseclock_ref model, the Multiphase Clock block generates a 100 Hz five-phase output in which the third signal is first to become active. The block uses a high active level with a duration of one interval.



The Scope window below shows the Multiphase Clock block's output. Note that the first active level appears at *t*=0 on `y(3)`, the second active level appears at *t*=0.002 on `y(4)`, the third active level appears at *t*=0.004 on `y(5)`, the fourth active level appears at *t*=0.006 on `y(1)`, and the fifth active level appears at *t*=0.008 on `y(2)`. Each signal becomes active 1/(5*100) seconds after the previous signal.



To experiment further, try changing the **Number of phase intervals over which clock is active** setting to **3** so that the active-level duration is three phase intervals (60% duty cycle).

Parameters

Clock frequency

The frequency of all output clock signals.

Number of phases

The number of different phases, *N*, in the output vector.

Starting phase

The vector index of the output signal to first become active.

Number of phase intervals over which clock is active

The duration of the active level for every output signal.

Active level

The active level, `High (1)` or `Low (0)`.

Output data type

The output data type.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean

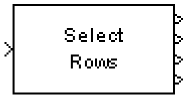
Multiport Selector

Distribute arbitrary subsets of input rows or columns to multiple output ports



Library

Signal Management / Indexing

`dspindex`

Description

The Multiport Selector block extracts multiple subsets of rows or columns from M-by-N input matrix u, and propagates each new submatrix to a distinct output port. The block treats an unoriented length-M vector input as an M-by-1 matrix.

The **Indices to output** parameter is a cell array whose kth cell contains a one-dimensional indexing expression specifying the subset of input rows or columns to be propagated to the kth output port. The total number of cells in the array determines the number of output ports on the block.

When you set the **Select** parameter to `Rows`, the block uses the one-dimensional indices you specify to select matrix rows, and all elements on the chosen rows are included. When you set the **Select** parameter to `Columns`, the block uses the one-dimensional indices you specify to select matrix columns, and all elements on the chosen columns are included. A given input row or column can appear any number of times in any of the outputs, or not at all.

When an index references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

Examples

Example 1

Consider the following **Indices to output** cell array:

```
{4,[1:2 5],[7;8],10:-1:6}
```

This is a four-cell array, which requires the block to generate four independent outputs (each at a distinct port). The table below shows the dimensions of these outputs when **Select** = `Rows` and the input dimension is M-by-N.

Cell	Expression	Description	Output Size
1	`4`	Row 4 of input	1-by-N
2	`[1:2 5]`	Rows 1, 2, and 5 of input	3-by-N
3	`[7;8]`	Rows 7 and 8 of input	2-by-N
4	`10:-1:6`	Rows 10, 9, 8, 7, and 6 of input	5-by-N

Parameters

Select

Specify the dimension of the input to select, `Rows` or `Columns`.

Indices to output

A cell array specifying the row- or column-subsets to propagate to each of the output ports. The number of cells in the array determines the number of output ports on the block.

Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- `Clip index` — Clip the index to the nearest valid value, and do not issue an alert.

  For example, if the block receives a `64`-by-`4` input and the **Select** parameter is set to `Rows`, the block clips an index of `72` to `64`. For the same input, if the **Select** parameter is set to `Columns`, the block clips an index of `72` to `4`. In both cases, the block clips an index of `-2` to `1`.

- `Clip and warn` — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- `Generate error` — Display an error dialog box and terminate the simulation.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Multiport Selector.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Outputs	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

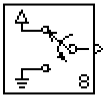
N-Sample Enable

Output ones or zeros for specified number of sample times



Library

- Sources

  `dspsrcs4`
- Signal Management / Switches and Counters

  `dspswit3`

Description

The N-Sample Enable block outputs the inactive value (`0` or `1`, whichever is not selected in the **Active level** parameter) during the first *N* sample times, where *N* is the **Trigger count** value. Beginning with output sample *N*+1, the block outputs the active value (`1` or `0`, whichever you select in the **Active level** parameter) until a reset event occurs or the simulation terminates.

The output of the block is always a scalar.

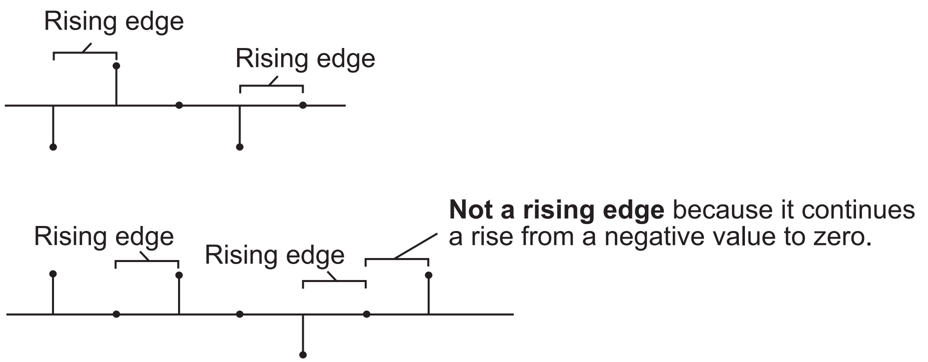
The **Reset input** check box enables the Rst input port. At any time during the count, a trigger event at the input port resets the counter to its initial state. This block supports triggered subsystems when you select the **Reset input** check box.

You specify the triggering event in the **Trigger type** pop-up menu:

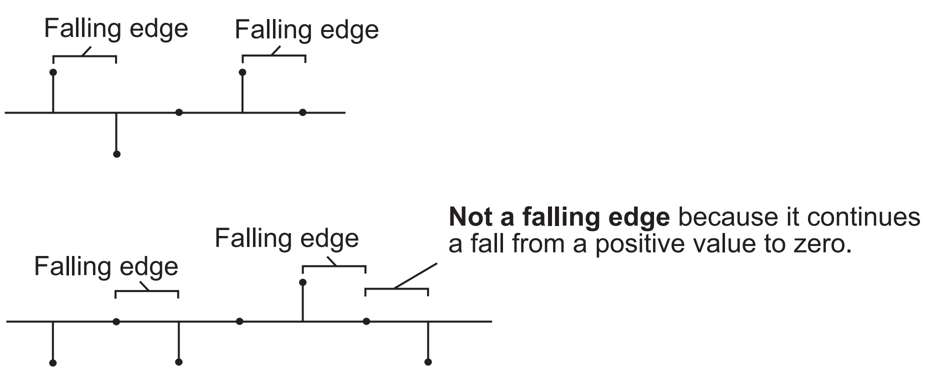
- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:

  - Rises from a negative value to a positive value or zero

- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero.

Parameters

Trigger count

Specify the number of samples for which the block outputs the active value. Tunable (Simulink).

Active level

Specify the value to output after the first *N* sample times, 0 or 1. Tunable (Simulink).

Reset input

Select to enable the Rst input port.

Trigger type

Select type of event that triggers a reset when the Rst port is enabled.

Sample time

Specify the sample period, T_s, for the block's counter. The block switches from the active value to the inactive value at $t=T_s*(N+1)$.

Output data type

Select the output data type.

Supported Data Types

- Double-precision floating point
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled when you select the **Reset input** parameter.

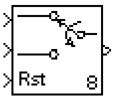
Counter	DSP System Toolbox
N-Sample Switch	DSP System Toolbox

Introduced before R2006a

N-Sample Switch

Switch between two inputs after specified number of sample periods



Library

Signal Management / Switches and Counters

`dspswit3`

Description

The N-Sample Switch block outputs the signal connected to the top input port during the first *N* sample times after the simulation begins or the block is reset, where you specify *N* in the **Switch count** parameter. Beginning with output sample *N*+1, the block outputs the signal connected to the bottom input until the next reset event or the end of the simulation.

You specify the sample period of the output in the **Sample time** parameter (that is, the output sample period is not inherited from the sample period of either input). The block applies a zero-order hold at the input ports, so the value the block reads from a given port between input sample times is the value of the most recent input to that port.

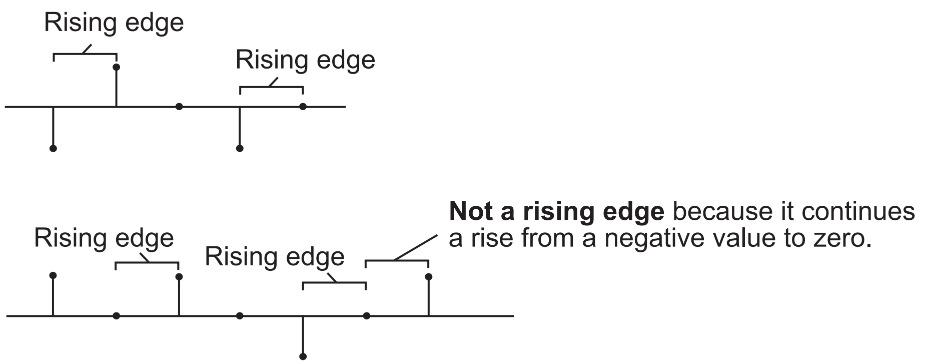
Both inputs must have the same dimension, except in the following two cases:

- When one input is a scalar, the block expands the scalar input to match the size of the other input.
- When one input is an unoriented vector and the other input is a row or column vector with the same number of elements, the block reshapes the unoriented vector to match the dimension of the other input.

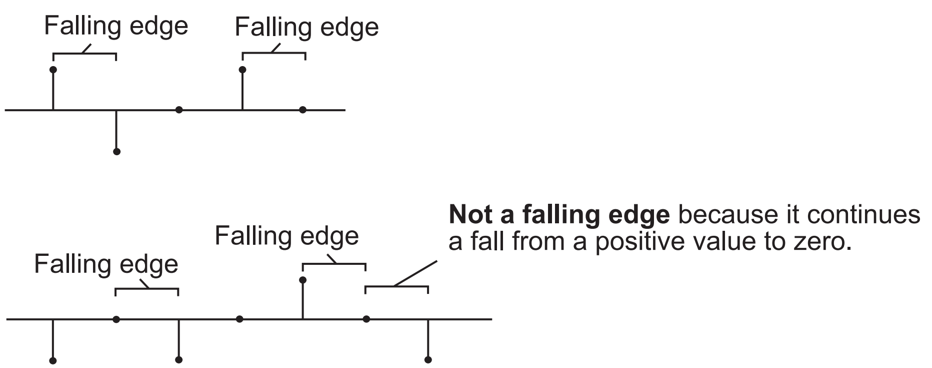
The **Reset input** check box enables the Rst input port. At any time during the count, a trigger event at the Rst port resets the counter to zero. The reset sample time must be a positive integer multiple of the input sample time. This block supports triggered subsystems when you select the **Reset input** check box.

You specify the triggering event in the **Trigger type** pop-up menu, and can be one of the following:

- `Rising edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)



- `Falling edge` — Triggers a reset operation when the `Rst` input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)



- `Either edge` — Triggers a reset operation when the `Rst` input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers a reset operation at each sample time that the `Rst` input is not zero.

Parameters

Switch count

The number of sample periods, N, for which the output is connected to the top input before switching to the bottom input. Tunable (Simulink).

Reset input

Enables the Rst input port when selected. The rate of the reset signal must be a positive integer multiple of the rate of the data signal input.

Trigger type

The type of event at the Rst port that resets the block's counter. This parameter is enabled when you select **Reset input**. Tunable (Simulink).

Sample time

The sample period, T_s, for the block's counter. The block switches inputs at $t=T_s*(N+1)$.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled when you set the **Reset input** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

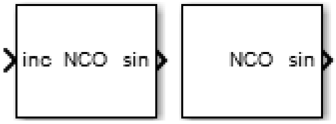
NCO

Generate real or complex sinusoidal signals



Library

Signal Operations

`dspsigops`

Sources

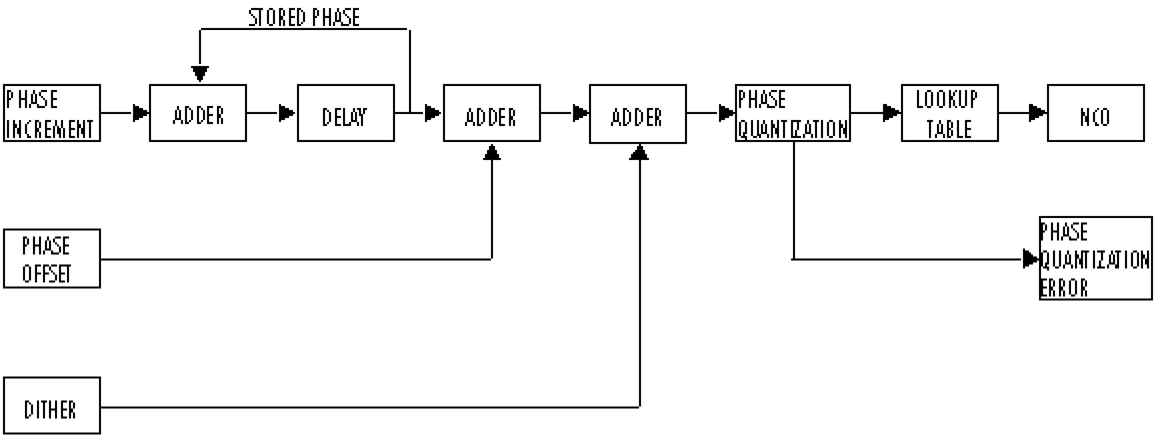
`dspsrcs4`

Description

The block appears in `dspsigops` with **Phase increment Source** parameter set to `Input port`.

In addition, the block also appears in `dspsrsc4` library with **Phase increment Source** parameter set to `Specify via dialog`.

The NCO block generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel. The amplitude of the created signal is always 1. The block implements the algorithm as shown in the following diagram:



The implementation of a numerically controlled oscillator (NCO) has two distinct parts. First, a phase accumulator accumulates the phase increment and adds in the phase offset. In this stage, an optional internal dither signal can also be added. The NCO output is then calculated by quantizing the results of the phase accumulator section and using them to select values from a lookup table. Since the lookup table contains a finite set of entries, in its normal mode of operation, the NCO block allows the adder's numeric values to overflow and wrap around. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

Given a desired output frequency F_0, calculate the value of the **Phase increment** block parameter with

$$phase\ increment = \left(\frac{F_0 \cdot 2^N}{F_s}\right)$$

where N is the accumulator word length and

$$F_s = \frac{1}{T_s} = \frac{1}{sample\ time}$$

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{Hz}$$

Given a desired phase offset (in radians), calculate the **Phase offset** block parameter with

$$phase\ offset = \frac{2^N \cdot desired\ phase\ offset}{2\pi}$$

The spurious free dynamic range (SFDR) is estimated as follows for a lookup table with 2^P entries, where P is the number of quantized accumulator bits:

$$\begin{aligned} SFDR &= (6P) \text{ dB} && \text{without dither} \\ SFDR &= (6P+12) \text{ dB} && \text{with dither} \end{aligned}$$

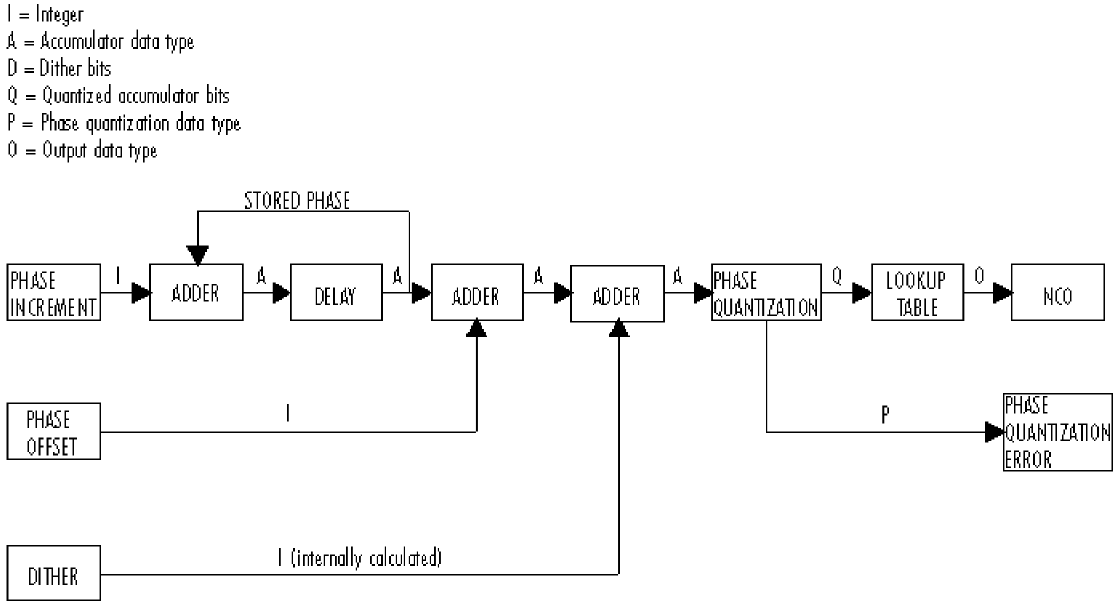
This block uses a quarter-wave lookup table technique that stores table values from 0 to π/2. The block calculates other values on demand using the accumulator data type, then casts them into the output data type. This can lead to quantization effects at the range limits of a given data type. For example, consider a case where you would expect the value of the sine wave to be –1 at π. Because the lookup table value at that point must be calculated, the block might not yield exactly –1, depending on the precision of the accumulator and output data types.

The NCO block supports real inputs only. All outputs are real except for the output signal in `Complex exponential` mode.

To produce a multichannel output, specify a vector quantity for the **Phase increment** and **Phase offset** parameters. Both parameters must have the same length, which defines the number of output channels. Each element of each vector is applied to a different output channel.

Fixed-Point Data Types

The following diagram shows the data types used within the NCO block.



- You can set the accumulator and output data types in the block dialog as discussed in "Dialog Box" on page 2-1303 below.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

- The phase increment and phase offset inputs must be integers or fixed-point data types with zero fraction length.
- You specify the number of quantized accumulator bits in the **Number of quantized accumulator bits** parameter.
- The phase quantization error word length is equal to the accumulator word length minus the number of quantized accumulator bits, and the fraction length is zero.

Examples

The NCO block is used in the GSM Digital Down Converter product example. Open this example by typing `dspddc` at the MATLAB command line.

You can also try the following example. Design an NCO source with the following specifications:

- Desired output frequency $F_0 = 510$ Hz
- Frequency resolution $\Delta f = 0.05$ Hz
- Spurious free dynamic range $SFDR \geq 90$ dB
- Sample period $T_s = 1/8000$ s
- Desired phase offset $\pi / 2$

1 Calculate the number of required accumulator bits from the equation for frequency resolution:

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{Hz}$$

$$0.05 = \frac{1}{\frac{1}{8000} \cdot 2^N} \text{Hz}$$

$$N = 18$$

Note that N must be an integer value. The value of N is rounded up to the nearest integer; 18 accumulator bits are needed to accommodate the value of the frequency resolution.

2 Using this best value of N, calculate the frequency resolution that will be achieved by the NCO block:

$$\Delta f = \frac{1}{T_s \cdot 2^N}\ \mathrm{Hz}$$

$$\Delta f = \frac{1}{\frac{1}{8000} \cdot 2^{18}}\ \mathrm{Hz}$$

$$\Delta f = 0.0305$$

3 Calculate the number of quantized accumulator bits from the equation for spurious free dynamic range and the fact that for a lookup table with 2^P entries, P is the number of quantized accumulator bits:

$$SFDR = (6P + 12)\,\mathrm{dB}$$

$$96\ \mathrm{dB} = (6P + 12)\ \mathrm{dB}$$

$$P = 14$$

4 Select the number of dither bits. In general, a good choice for the number of dither bits is the accumulator word length minus the number of quantized accumulator bits; in this case 4.

5 Calculate the phase increment:

$$phase\ increment = \mathrm{round}(\frac{F_0 \cdot 2^N}{F_s})$$

$$phase\ increment = \mathrm{round}(\frac{510 \cdot 2^{18}}{8000})$$

$$phase\ increment = 16712$$

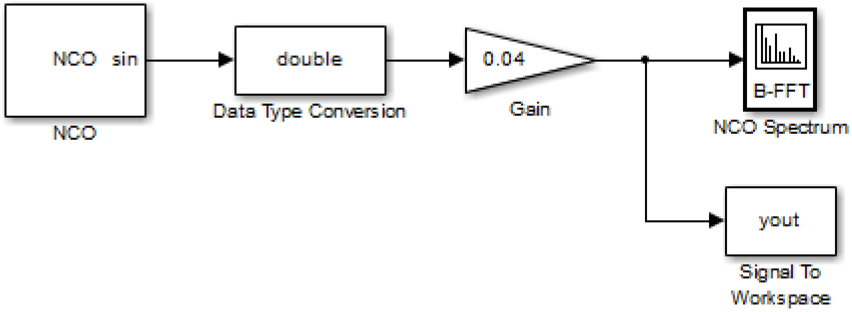
6 Calculate the phase offset:

$$phase\ offset = \frac{2^{accumulator\ word\ length} \cdot desired\ phase\ offset}{2\pi}$$

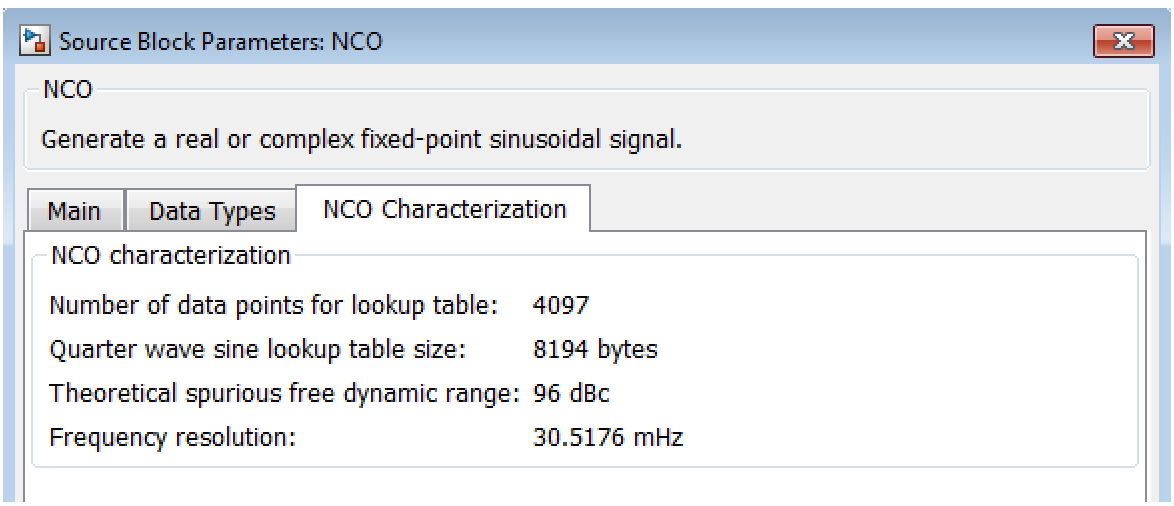
$$phase\ offset = \frac{2^{18} \cdot \frac{\pi}{2}}{2\pi}$$

$$phase\ offset = 65536$$

7 Type `ex_nco_example` at the MATLAB command line to open the following model:



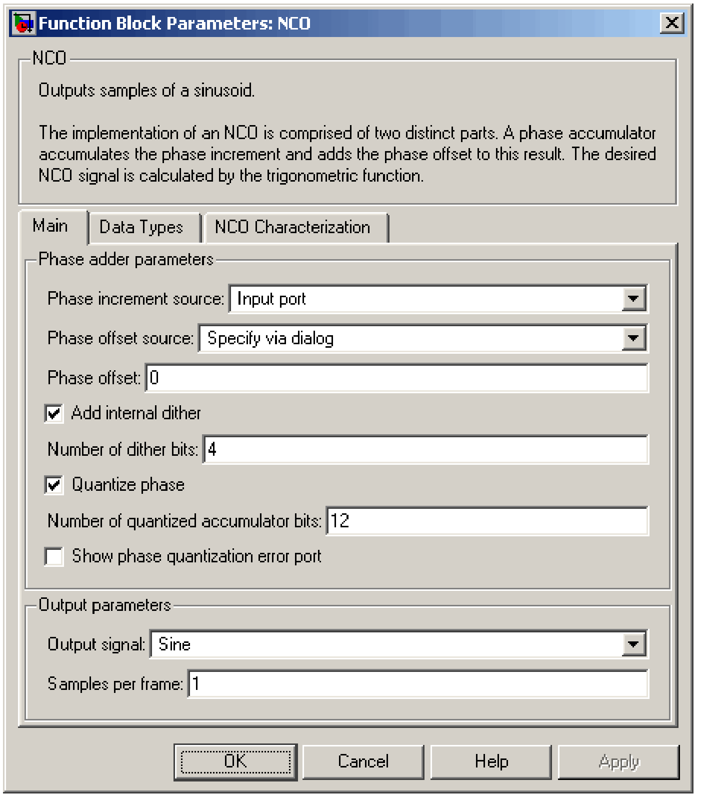
The NCO block in the model is populated with the specifications and quantities you just calculated. The output word length and fraction length depend on the constraints of your hardware; this example uses a word length of 16 and a fraction length of 14. You can verify that the specifications of this problem have been met by looking at the **NCO Characterization** pane of the NCO block.



8 Experiment with the model to observe the effects on the output shown on the Spectrum Analyzer. For example, try turning dithering on and off, and try changing the number of dither bits.

Dialog Box

The **Main** pane of the NCO dialog appears as follows.



Phase increment source

Choose how you specify the phase increment. The phase increment can come from an input port or from the dialog.

- If you select `Input port`, the inc port appears on the block icon.
- If you select `Specify via dialog`, the **Phase increment** parameter appears.

Phase increment

Specify the phase increment. Only integer data types, including fixed-point data types with zero fraction length, are allowed. The dimensions of the phase increment are dictated by those of the phase offset:

- When you specify the phase offset on the block dialog box, the phase increment must be a scalar or a vector with the same length as the phase offset. The block applies each element of the vector to a different channel, and therefore the vector length defines the number of output channels.
- When you specify the phase offset via an input port, the offset port treats each column of the input as an independent channel. The phase increment length must equal the number of columns in the input to the offset port.

This parameter is visible only if you set the **Phase increment source** parameter to `Specify via dialog`.

Phase offset source

Choose how you specify the phase offset. The phase offset can come from an input port or from the dialog.

- If you select `Input port`, the offset port appears on the block icon.
- If you select `Specify via dialog`, the **Phase offset** parameter appears.

When you specify the phase offset via an input port, it can be a scalar, vector, or a full matrix. The block treats each column of the input to the offset port as an independent channel. The number of channels in the phase offset must match the number of channels in the data input. For each frame of the input, the block can apply different phase offsets to each sample and channel. Only integer data types, including fixed-point data types with zero fraction length, are allowed.

Phase offset

Specify the phase offset. When you specify the phase offset using this parameter rather than via an input port, it must be a scalar or vector with the same length as the phase increment. Scalars are expanded to a vector with the same length as the phase increment. Each element of the phase offset vector is applied to a different channel of the input, and therefore the vector length defines the number of output channels. Only integer data types, including fixed-point data types with zero fraction length, are allowed.

This parameter is visible only if `Specify via dialog` is selected for the **Phase offset source** parameter.

Add internal dither

Select to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox™ product.

Number of dither bits

Specify the number of dither bits.

This parameter is visible only if **Add internal dither** is selected.

Quantize phase

Select to enable quantization of the accumulated phase.

Number of quantized accumulator bits

Specify the number of quantized accumulator bits. This determines the number of entries in the lookup table. The number of quantized accumulator bits must be less than the accumulator word length.

This parameter is visible only if **Quantize phase** is selected.

Show phase quantization error port

Select to output the phase quantization error. When you select this, the Qerr port appears on the block icon.

This parameter is visible only if **Quantize phase** is selected.

Output signal

Choose whether the block should output a `Sine`, `Cosine`, `Complex exponential`, or `Sine and cosine` signals. If you select `Sine and cosine`, the two signals output on different ports.

Sample time

Specify the sample time in seconds when the block is acting as a source. When either the phase increment or phase offset come in via block input ports, the sample time is inherited and this parameter is not visible.

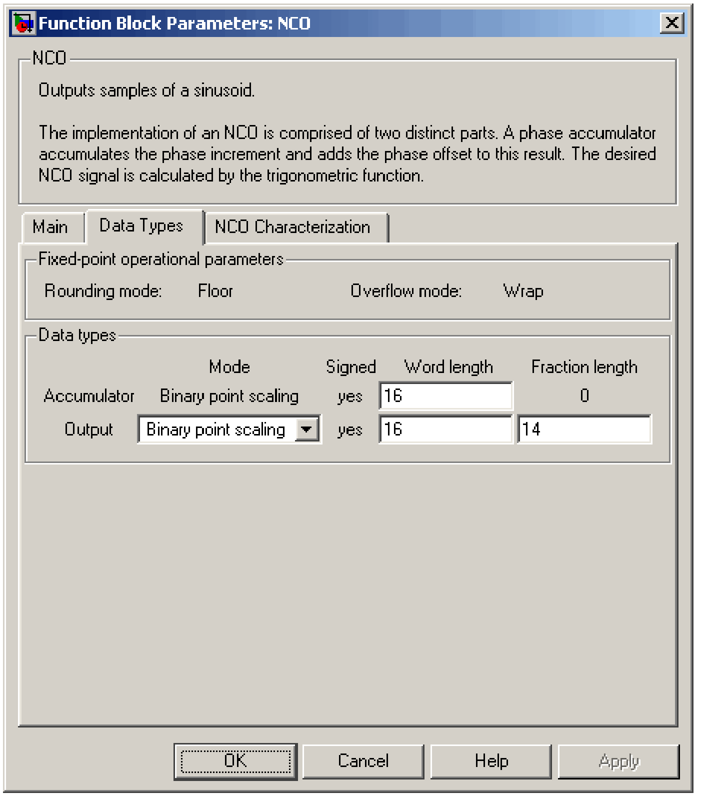
Samples per frame

Specify the number of samples per frame. When the value is greater than 1, the phase increment and phase offset can vary from channel to channel and from frame to frame, but they are constant along each channel in a given frame.

When the phase offset input port exists, it has the same frame status as any output port present. When the phase increment input port exists, it does not support frames.

This parameter is only visible if either **Phase increment source** or **Phase offset source** is set to `Specify via dialog`.

The **Data Types** pane of the NCO dialog appears as follows.



Rounding mode

The rounding mode used for this block when inputs are fixed point is always `Floor`.

Overflow mode

The overflow mode used for this block when inputs are fixed point is always `Wrap`.

Accumulator

Specify the word length of the accumulator data type. The fraction length is always zero; this is an integer data type.

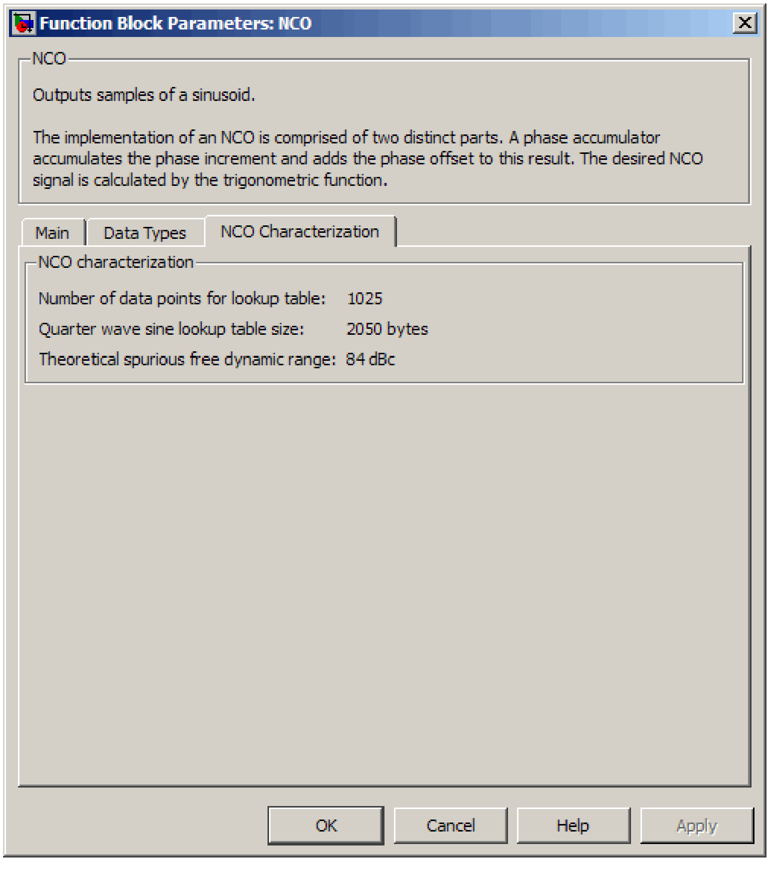
Output

Specify the output data type.

- Choose `double` or `single` for a floating-point implementation.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

The **NCO Characterization** pane of the NCO dialog appears as follows.



The **NCO Characterization** pane does not have any parameters. Instead, it provides you with details on the NCO signal currently being implemented by the block:

- `Number of data points for lookup table` — The lookup table is implemented as a quarter-wave sine table. The number of lookup table data points is defined by

  $$2^{\text{number of quantized accumulator bits}-2}+1$$

- `Quarter wave sine lookup table size` — The quarter wave sine lookup table size is defined by

  $$\frac{(\text{number of data points for lookup table})\cdot(\text{output word length})}{8}\ \text{bytes}$$

- `Theoretical spurious free dynamic range` — The spurious free dynamic range (SFDR) is calculated as follows for a lookup table with 2^P entries:

  $$SFDR=(6P)\ \text{dB} \qquad \text{without dither}$$
  $$SFDR=(6P+12)\ \text{dB} \qquad \text{with dither}$$

Supported Data Types

Port	Supported Data Types
inc	• Fixed point with zero fraction length • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
offset	• Fixed point with zero fraction length • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
sin	• Double-precision floating point • Single-precision floating point • Fixed point
Qerr	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

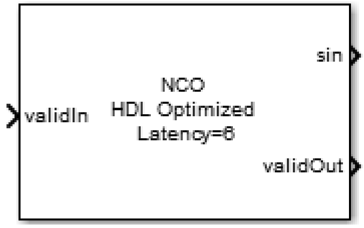
NCO HDL Optimized

Generate real or complex sinusoidal signals—optimized for HDL code generation



Library

Signal Operations

`dspsigops`

Sources

`dspsrcs4`

Description

Note:

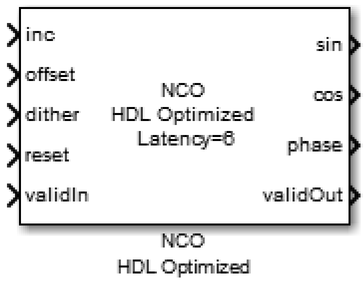
- This block appears in `dspsrsc4` library with **Phase increment source** parameter set to `Property`. The only input port is `validIn`.
- This block appears in `dspsigops` with **Phase increment source** parameter set to `Input port`. This configuration shows the optional input port `inc`.

The NCO HDL Optimized block generates real or complex sinusoidal signals, while providing hardware-friendly control signals. It uses the same phase accumulation and lookup table technology as implemented in the NCO block. It provides the following features:

- A lookup table compression option to reduce the lookup table size with less than one LSB loss in precision. See “Lookup Table Algorithm” on page 2-1315 for more detail.
- An option to synthesize the lookup table to a ROM when using HDL Coder with an FPGA target. To enable this feature, right-click the block, select **HDL Code > HDL Block Properties** and set **LUTRegisterResetType** to `none`.
- An optional input port for external dither.
- An optional reset port that triggers a reset of the phase to its initial value during the sinusoid output generation.
- An optional output port for the current NCO phase.

Signal Attributes

This icon shows all the possible ports of the NCO HDL Optimized block.



Port	Direction	Description	Data Type
`inc`	Input	Optional. Phase increment, specified as a scalar integer.	• `fixdt([],N,0)` • `int`, `uint` `double` and `single` are allowed for simulation but not for HDL code generation.
`offset`	Input	Optional. Phase offset, specified as a scalar integer.	• `fixdt([],N,0)` • `int`, `uint` `double` and `single` are allowed for simulation but not for HDL code generation.

Port	Direction	Description	Data Type
dither	Input	Optional. Dither, specified as a scalar integer.	• fixdt([],N,0) • int, uint double and single are allowed for simulation but not for HDL code generation.
reset	Input	Optional. Reset the accumulator to zero when reset is high.	boolean
validIn	Input	Optional. Increment the phase when validIn is true. When validIn is false, the phase is held.	boolean
sin, cos, exp	Output	Generated waveform, returned as a scalar value. By default, the output is a sine wave, sin. The port labels change based on your selection for **Type of output signal**.	• fixdt() double and single are allowed for simulation but not for HDL code generation.
phase	Output	Optional. Current phase of NCO, returned as a scalar value.	fixdt(1,M,-Z), where M is the number of quantized accumulator bits, and Z is the accumulator word length.
validOut	Output	Whether the data output is valid or not. When validOut is true, the data output is valid. When validOut is false, the data output is not valid.	boolean

Parameters

Main

Note: This block supports double input for simulation but not for HDL code generation. When a data input is fixed point, or when no data input ports are enabled, the block computes the output waveform based on the fixed-point mask settings. When a data input is floating-point, the block ignores **Number of dither bits**, **Quantize phase**, **Number of quantizer accumulator bits**, **Enable look up table compression method**, and the **Data Types** tab, and computes a double-precision output waveform.

Phase increment source

Defines how you specify the phase increment. You can set the phase increment with an input port or you can enter a value for the parameter. The default value is `Input port`. If you select `Property`, the **Phase increment** parameter appears.

Phase increment

Specify the phase increment. The default value is 100. This value is scalar.

This parameter is visible when you set **Phase increment source** to `Property`.

Phase offset source

Defines how you specify the phase offset. You can set the phase offset from an input port or from a parameter. The default value is `Property`. If you select `Input port`, the offset port appears on the block icon.

Phase offset

Specify the phase offset. The default value is 0. This value is scalar. You can use integer data types, including fixed-point data types with zero fraction length.

This parameter is visible when you set **Phase offset source** to `Property`.

Dither source

Defines how you specify the dither. The default value is `Property`. You can set the dither from an input port or from a parameter. If you select `Property`, the **Number of dither bits** parameter appears. If you select `Input port`, a port appears on the block. If you select `None`, the block does not add dither.

Number of dither bits

Specify the dither bits. The default value is 4. This value must be a positive integer.

This option is visible when you set **Dither source** to `Property`.

Quantize phase

Select to enable quantization of the accumulated phase. The default value is selected.

When you select **Quantize phase**, the **Number of quantizer accumulator bits** parameter appears.

Number of quantizer accumulator bits

Specify the number of quantized accumulator bits. The default value is 12. This parameter determines the number of entries needed in the lookup table of sine values. The number of quantized accumulator bits must be less than the accumulator word length.

This parameter is visible only if you select **Quantize phase**.

Enable look up table compression method

Compress the lookup table when selected. The default value is not selected.

Enable reset input port

When selected, the `reset` port is present on the block icon. When `reset` is high, the block resets the accumulator to zero. The default value is not selected.

Enable validIn input port

When selected, the `validIn` port is present on the block icon. When `validIn` is `true`, the block increments the phase. When `validIn` is `false`, the phase is held. The default value is selected.

Type of output signal

Choose whether the block output signal is `Sine`, `Cosine`, `Complex exponential`, or `Sine and cosine`. If you select `Complex exponential`, the output is of the form `sine + j*cosine` and the port is labeled `exp`. If you select `Sine and cosine`, the block shows two ports, `sin` and `cos`. The default is `Sine`.

Show phase port

Output the current phase when selected. The default is not selected.

Data Types

Rounding Mode

The rounding mode when inputs are fixed point is `Floor`.

Overflow Mode

The overflow mode when inputs are fixed point is `Wrap`.

(Accumulator) **Data Type**

The output data type is `Binary point scaling`.

(Accumulator) **Signed**

The accumulator data type is signed.

(Accumulator) **Word length**

Accumulator word length. Default value is 16.

(Accumulator) **Fraction length**

Accumulator fraction length. Value is 0.

(Output) **Data Type**

Select `double`, `single`, or `Binary point scaling`. The default is `Binary point scaling`.

If you select `Binary point scaling`, the parameters for output word length and fraction length appear. All output data types are signed.

(Output) **Signed**

All output data types are signed.

(Output) **Word length**

Output word length. Default value is 16.

(Output) **Fraction length**

Output fraction length. Default value is 14.

Algorithms

Lookup Table Algorithm

When you select lookup table (LUT) compression, the NCO HDL Optimized block applies the Sunderland compression method. Sunderland techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A+B+C) = \sin(A+B)\cos C + \cos A \cos B \cos C - \sin A \sin B \sin C$$

If the phase has 12 bits, the components are defined as:

- A, the four most significant bits

  $(0 \leq A \leq \frac{\pi}{2})$

- B, the following four bits

$$(0 \le B \le \frac{\pi}{2} \times 2^{-4})$$

- C, the four least significant bits

$$(0 \le C \le \frac{\pi}{2} \times 2^{-8})$$

Because C is small enough that sin(C)≅1 and cos(C)≅0, the equation is approximated by:

$$\sin(A+B+C) \approx \sin(A+B) + \cos A \sin C$$

The NCO HDL Optimized block implements this equation with one LUT for sin(A+B) and one LUT for cos(A)sin(C). The second term is a fine correction factor that you can truncate to fewer bits without losing precision. With the default accumulator size of 16 bits, and the example phase width of 12 bits, the LUTs use only $2^8 \times 16$ plus $2^8 \times 4$ bits (5kb). A quarter sine lookup table would use $2^{12} \times 16$ bits (65kb). This approximation is accurate within 1 LSB which gives an SNR of at least 60 dB on the output. See L. Cordesses, "Direct Digital Synthesis: A Tool for Periodic Wave Generation (Part 1)", IEEE Signal Processing Magazine, DSP Tips & Tricks column, pp. 50–54, Vol. 21, No. 4 July 2004.

Control Signals

There are two input control signals, `reset` and `validIn`, and one output control signal, `validOut`. When `reset` is high, the block sets the phase accumulator to zero. When `validIn` is high, the block increments the phase. When `validIn` is low, the block stops the phase accumulator and holds its state. When `validOut` is high, the output is valid.

Latency

The latency of the NCO HDL Optimized block is 6 cycles.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see NCO HDL Optimized in the HDL Coder documentation.

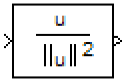
Normalization

Perform vector normalization along rows, columns, or specified dimension



Library

Math Functions / Math Operations

`dspmathops`

Description

The Normalization block independently normalizes each row, column, or vector of the specified dimension of the input. The block accepts both fixed- and floating-point signals in the squared 2-norm mode, but only floating-point signals in the 2-norm mode. The output always has the same dimensions as the input.

This block treats an arbitrarily dimensioned input *U* as a collection of vectors oriented along the specified dimension. The block normalizes these vectors by either their norm or the square of their norm.

For example, consider a 3-dimensional input *U(i,j,k)* and assume that you want to normalize along the second dimension. First, define the 2-dimensional intermediate quantity *V(i,k)* such that each element of *V* is the norm of one of the vectors in *U*:

$$V(i,k) = \left(\sum_{j=1}^{J} U^2(i,j,k) \right)^{1/2}$$

Given *V*, the output of the block *Y(i, j,k)* in 2-norm mode is

$$Y(i,j,k) = \frac{U(i,j,k)}{V(i,k)+b}$$

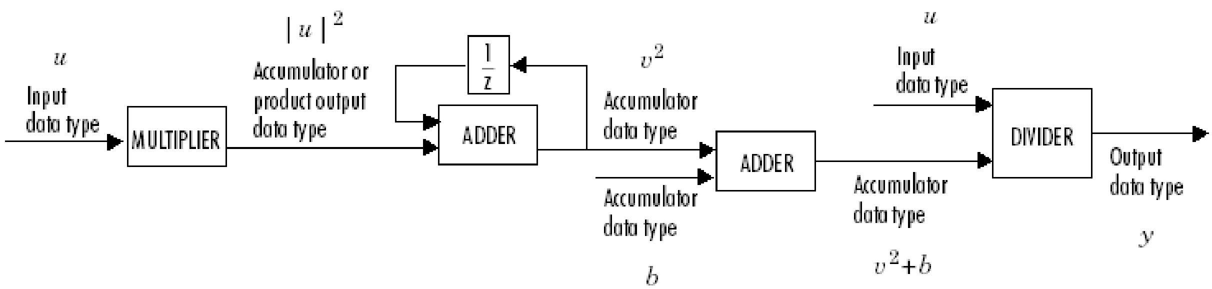
In squared 2-norm mode, the block output is

$$Y(i,j,k) = \frac{U(i,j,k)}{V(i,k)^2 + b}$$

The normalization bias, b, is typically chosen to be a small positive constant (for example, 1e-10) that prevents potential division by zero.

Fixed-Point Data Types

The following diagram shows the data types used within the Normalization block for fixed-point signals (squared 2-norm mode only).



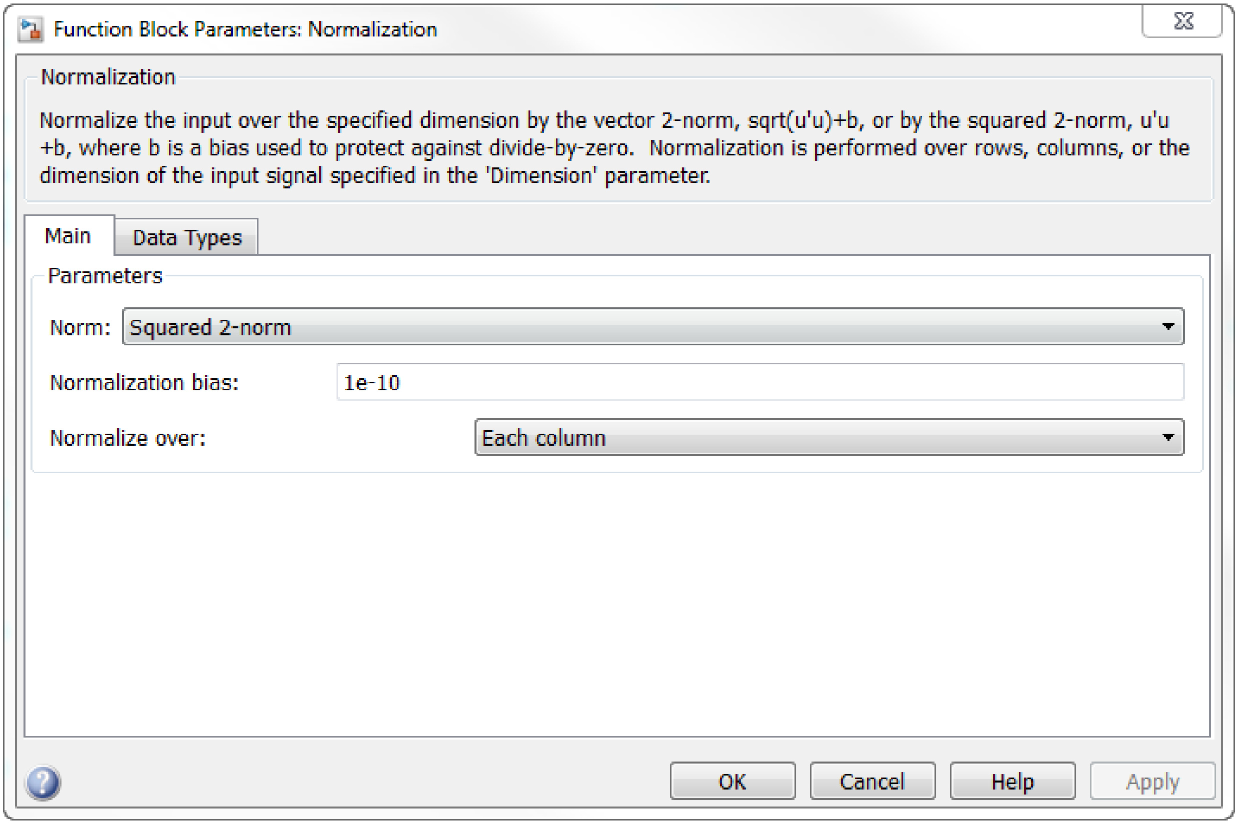
The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types". You can set the accumulator, product output, and output data types in the block dialog as discussed in "Dialog Box" on page 2-1319.

Examples

See "Zero Algorithmic Delay" in the *DSP System Toolbox User's Guide* for an example.

Dialog Box

The **Main** pane of the Normalization dialog appears as follows.



Norm

Specify the type of normalization to perform, `2-norm` or `Squared 2-norm`. `2-norm` mode supports floating-point signals only. `Squared 2-norm` supports both fixed-point and floating-point signals.

Normalization bias

Specify the real value *b* to be added in the denominator to avoid division by zero. Tunable (Simulink).

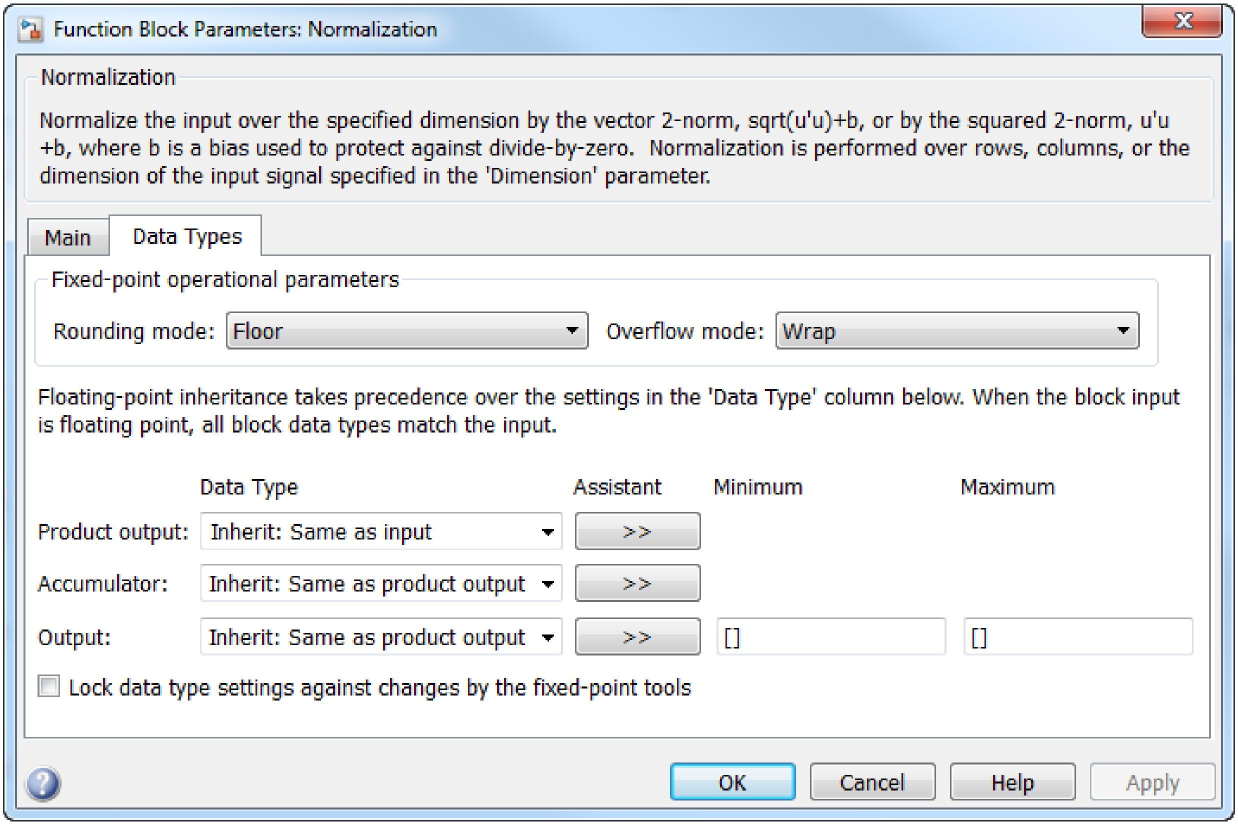
Normalize over

Specify whether to normalize along rows, columns, or the dimension specified in the **Dimension** parameter.

Dimension

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible if `Specified dimension` is selected for the **Normalize over** parameter.

The **Data Types** pane of the Normalization dialog appears as follows.



Note The parameters on this pane are only applicable to fixed-point signals when the block is in squared 2-norm mode. See "Fixed-Point Data Types" on page 2-1319 for a diagram of how the product output, accumulator, and output data types are used in this case.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1319 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1319 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1319 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`

- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

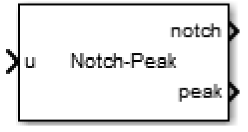
Notch-Peak Filter

Design second-order tunable notching and peaking IIR filter



Library

Filtering / Filter Designs

`dspfdesign`

Description

The Notch-Peak Filter block filters each channel of the input signal over time using a specified center frequency and 3 dB bandwidth. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the filter according to the filter parameters set in the block dialog box. The output port properties such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of the dsp.NotchPeakFilter System object to the Simulink environment.

The filter uses a coupled allpass structure to optimize joint computation of the peak and notch response. For information on the algorithms used by the Notch-Peak filter block, see the “Algorithms” on page 4-1385 section of `dsp.NotchPeakFilter`.

Parameters

Filter specification

Parameters or coefficients used to design the filter, specified as one of the following:

- `Bandwidth and center frequency` (default) — Design the filter using **3 dB bandwidth (Hz)** and **Notch/Peak center frequency (Hz)**.
- `Coefficients` — Design the filter using **Bandwidth coefficient** and **Center frequency coefficient**.
- `Quality factor and center frequency` — Design the filter using **Quality factor** and **Notch/Peak center frequency (Hz)**.

This parameter is nontunable.

3 dB bandwidth (Hz)

3 dB bandwidth of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to `Bandwidth and center frequency`. The default is `2205`. This parameter is tunable.

Notch/Peak center frequency (Hz)

Center frequency of the notch and peak of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to `Bandwidth and center frequency` or `Quality factor and center frequency`. The default is `11025`. This parameter is tunable.

Bandwidth coefficient

Coefficient that determines the 3 dB bandwidth of the filter, specified as a finite numeric scalar in the range `[-1 1]`.

- `-1` corresponds to the maximum 3 dB bandwidth (one-fourth the sample rate of the input signal).
- `1` corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This parameter applies when you set **Filter specification** to `Coefficients`. The default is `0.72654`. This parameter is tunable.

Center frequency coefficient

Coefficient that determines the center frequency of the filter, specified as a finite numeric scalar in the range `[-1 1]`.

- `-1` corresponds to the minimum center frequency (`0` Hz).
- `1` corresponds to the maximum center frequency (half the sample rate of the input signal).

This parameter applies when you set **Filter specification** to `Coefficients`. The default is `0`, which corresponds to quarter the sample rate of the input signal. This parameter is tunable.

Quality factor

Quality factor of the notch and peak filter, specified as a real positive scalar. The quality factor is defined as **Notch/Peak center frequency (Hz) / 3 dB bandwidth (Hz)**. A higher quality factor corresponds to a narrower peak or dip. This parameter applies when you set **Filter specification** to `Quality factor and center frequency`. The default is `5`. This parameter is tunable.

Output

Output of the filter block, specified as one of the following:

- `Notch and Peak` (default) — The block outputs the notch and peak responses of the filter.
- `Notch` — The block outputs the notch response of the filter.
- `Peak` — The block outputs the peak response of the filter.

This parameter is nontunable.

Inherit sample rate from input

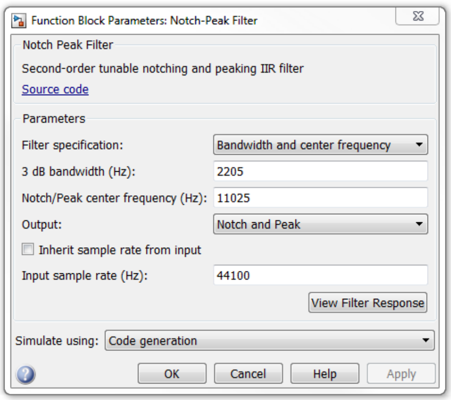
When you select this check box, the block sample rate is computed as *N*/*Ts*, where *N* is the frame size of the input signal, and *Ts* is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

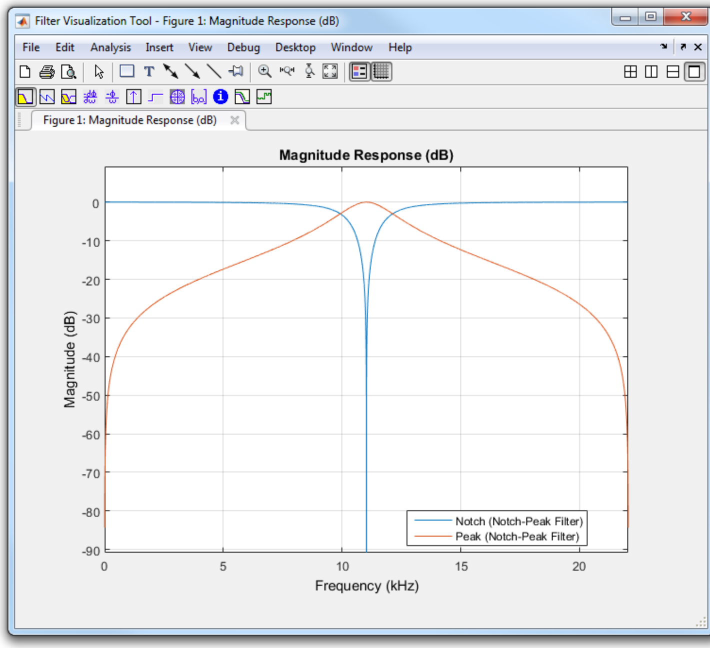
Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Notch-Peak Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, F_c, is calculated using the value for **Band**:

$F_c = F_s/(2 \cdot \mathbf{Band})$.

The default value, `2`, corresponds to a halfband filter.

Impulse response

Select either `FIR` or `IIR` from the drop-down list. `FIR` is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. These options are both available only when **Band** is `2`. For values of **Band** greater than `2`, only FIR designs are supported.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

Select the filter features that the block uses to define the frequency response characteristics.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is `Butterworth`, and the default FIR method is `Kaiser window`.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. The block applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Octave Filter

Design octave filter

Note: The Octave Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Octave Filter block from Audio System Toolbox instead.

Library

Filtering / Filter Designs

`dspfdesign`

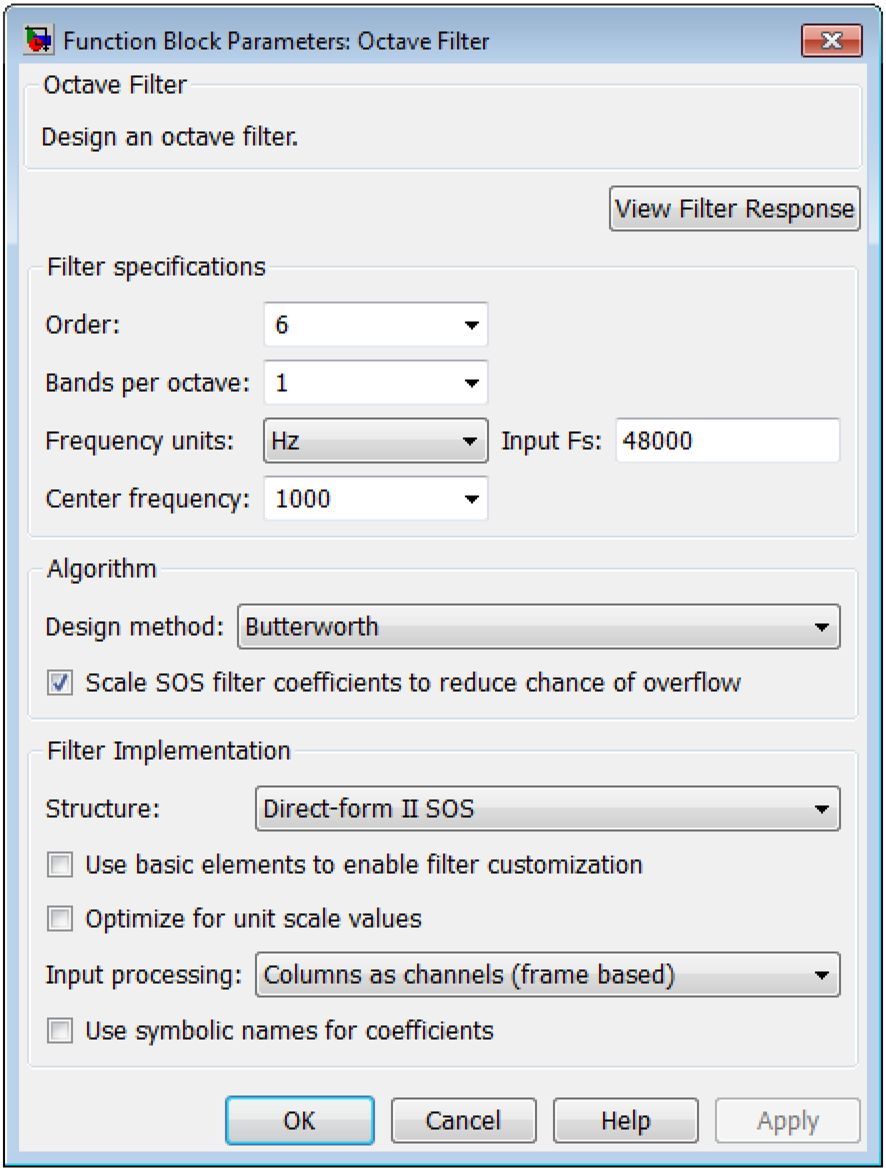
Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

See "Octave Filter Design — Main Pane" on page 5-786 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.



View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order

Specify filter order. Possible values are: `4, 6, 8, 10`.

Bands per octave

Specify the number of bands per octave. Possible values are: `1, 3, 6, 12, 24`.

Frequency units

Specify frequency units as `Hz` or `kHz`.

Input Fs

Specify the input sampling frequency in the frequency units specified previously.

Center Frequency

Select from the drop-down list of available center frequency values.

Algorithm

Design Method

Butterworth is the design method used for this type of filter.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

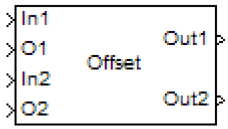
Offset

Truncate vectors by removing or keeping beginning or ending values



Library

Signal Operations

`dspsigops`

Description

The Offset block removes or keeps values from the beginning or end of the input vectors. You specify the length of the output vectors using the **Output port length** parameter. The inputs to the In ports (In1, In2, ...) can be scalars or vectors, but they must be the same size and data type. The offset values are the inputs to the O ports (O1, O2, ...); they must be scalar values with the same data type. These offset values should be integer values because they determine the number of values the block discards or retains from each input vector. The block rounds any offset value that is a noninteger value to the nearest integer value. There is one output port for each pair of In and O ports.

Use the **Mode** parameter to determine which values the block discards or retains from the input vector. To discard the initial values of the vector, select `Remove beginning samples`. To discard the final values of the vector, select `Remove ending samples`. To retain the initial values of the vector, select `Keep beginning samples`. To retain the final values of a vector, select `Keep ending` samples.

Use the **Number of input data-offset pairs** parameter to specify the number of inputs to the block. The number of input ports is twice the scalar value you enter. For example, if you enter `3`, ports In1, O1, In2, O2, In3, and O3 appear on the block.

The block uses the **Output port length** parameter to determine the length of the output vectors. If you select `Same as input`, the block outputs vectors that are the same length as the input to the In ports. If you select `User-defined`, the **Output length** parameter appears. Enter a scalar that represents the desired length of the output vectors. If your desired output length is greater than the number of values you extracted from your input vector, the block zero-pads the end of the vector to reach the length you specified.

Use the **Action for out of range offset value** parameter to determine how the block behaves when an offset value is not in the range 0 ≤ offset value ≤ N, where N is the input vector length. Select `Clip` if you want any offset values less than 0 to be set to 0 and any offset values greater than N to be set to N. Select `Clip and warn` if you want to be warned when any offset values less than 0 are set to 0 and any offset values greater than N are set to N. Select `Error` if you want the simulation to stop and display an error when the offset values are out of range.

Parameters

Mode

Use this parameter to determine which values the block discards or retains from the input vector. Your choices are `Remove beginning samples`, `Remove ending samples`, `Keep beginning samples`, and `Keep ending samples`.

Number of input data-offset pairs

Specify the number of inputs to the block. The number of input ports is twice the scalar value you enter.

Output port length

Use this parameter to specify the length of the output vectors. If you select `Same as input`, the output vectors are the same length as the input vectors. If you select `User-defined`, you can enter the desired length of the output vectors.

Output length

Enter a scalar that represents the desired length of the output vectors. This parameter is visible if, for the **Output port length** parameter, you select `User-defined`.

Action for out of range offset value

Use this parameter to determine how the block behaves when an offset value is not in the range such that 0 ≤ offset value ≤ N, where N is the input vector length. When you want any offset values less than 0 to be set to 0 and any offset values greater than N to be set to N, select `Clip`. When you want to be warned when any offset values less than 0 are set to 0 and any offset values greater than N are set to N, select `Clip and warn`. When you want the simulation to stop and display an error when the offset values are out of range, select `Error`.

Supported Data Types

Port	Supported Data Types

O	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Introduced before R2006a

Overlap-Add FFT Filter

Implement overlap-add method of frequency-domain filtering

Library

Filtering / Filter Implementations

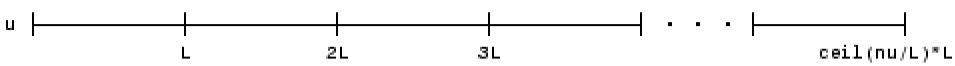
`dsparch4`

Description

The Overlap-Add FFT Filter block uses an FFT to implement the *overlap-add method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is M times faster than its data input rate, where M is the length of the columns in the input (frame-size).

The block breaks the scalar input sequence `u`, of length `nu`, into length-`L` nonoverlapping data sections,



which it linearly convolves with the filter's FIR coefficients,

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_{n+1} z^{-n}$$

The numerator coefficients for H(z) are specified as a vector by the **FIR coefficients** parameter. The coefficient vector, `b = [b(1) b(2) ... b(n+1)]`, can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

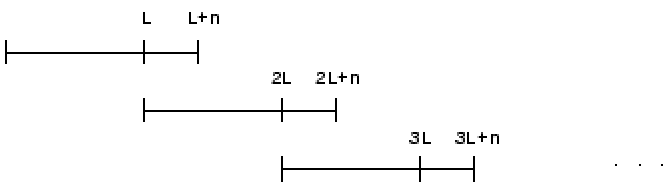
When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to `Complex`. Otherwise, the default **Output** setting, `Real`, instructs the block to take only the real part of the solution.

The block's overlap-add operation is equivalent to

```
y = ifft(fft(u(i:i+L-1),nfft) .* fft(b,nfft))
```

where you specify `nfft` in the **FFT size** parameter as a power-of-two value greater (typically *much* greater) than `n+1`. Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The block overlaps successive output sections by `n` points and sums them.



The first `L` samples of each summation are output in sequence. The block chooses the parameter `L` based on the filter order and the FFT size.

```
L = nfft - n
```

Latency

In *single-tasking* operation, the Overlap-Add FFT Filter block has a latency of `nfft-n+1` samples. The first `nfft-n+1` consecutive outputs from the block are zero; the first filtered input value appears at the output as sample `nfft-n+2`.

In *multitasking* operation, the Overlap-Add FFT Filter block has a latency of `2*(nfft-n)+1` samples. The first `2*(nfft-n)+1` consecutive outputs from the block are zero; the first filtered input value appears at the output as sample `2*(nfft-n)+3`.

Note: For more information on latency and the Simulink software tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

FFT size

The size of the FFT, which should be a power-of-two value greater than the length of the specified FIR filter.

FIR coefficients

The filter numerator coefficients.

Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based *M*-by-1 column vectors and unoriented sample-based vectors of length *M*. You can select one of the following options:

- `One channel` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a column vector (one channel).
- `M channels (this choice will be removed – see release notes)` — When you select this option, the block treats *M*-by-1 and unoriented sample-based inputs as a 1-by-*M* row vector.

Note: This parameter will be removed in a future release. At that time, the block will always treat *M*-by-1 and unoriented vectors as a single channel.

Supported Data Types

- Double-precision floating point

- Single-precision floating point

See Also

`Overlap-Save FFT Filter`	DSP System Toolbox product

Introduced before R2006a

Overlap-Save FFT Filter

Implement overlap-save method of frequency-domain filtering

Library

Filtering / Filter Implementations

`dsparch4`

Description

The Overlap-Save FFT Filter block uses an FFT to implement the *overlap-save method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is M times faster than its data input rate, where M is the length of the columns in the input (frame-size).

Overlapping sections of input `u` are circularly convolved with the FIR filter coefficients

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_{n+1} z^{-n}$$

The numerator coefficients for $H(z)$ are specified as a vector by the **FIR coefficients** parameter. The coefficient vector, `b = [b(1) b(2) ... b(n+1)]`, can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to `Complex`. Otherwise, the default **Output** setting, `Real`, instructs the block to take only the real part of the solution.

The circular convolution of each section is computed by multiplying the FFTs of the input section and filter coefficients, and computing the inverse FFT of the product.

```
y = ifft(fft(u(i:i+(L-1)),nfft) .* fft(b,nfft))
```

where you specify `nfft` in the **FFT size** parameter as a power of two value greater (typically *much* greater) than `n+1`. Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The first `n` points of the circular convolution are invalid and are discarded. The Overlap-Save FFT Filter block outputs the remaining `nfft-n` points, which are equivalent to the linear convolution.

Latency

In *single-tasking* operation, the Overlap-Save FFT Filter block has a latency of `nfft-n+1` samples. The first `nfft-n+1` consecutive outputs from the block are zero; the first filtered input value appears at the output as sample `nfft-n+2`.

In *multitasking* operation, the Overlap-Save FFT Filter block has a latency of `2*(nfft-n+1)` samples. The first `2*(nfft-n+1)` consecutive outputs from the block are zero; the first filtered input value appears at the output as sample `2*(nfft-n)+3`.

Note: For more information on latency and the Simulink environment tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

FFT size

The size of the FFT, which should be a power of two value greater than the length of the specified FIR filter.

FIR coefficients

The filter numerator coefficients.

Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based M-by-1 column vectors and unoriented sample-based vectors of length M. You can select one of the following options:

- `One channel` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a column vector (one channel).
- `M channels (this choice will be removed — see release notes)` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a 1-by-M row vector.

Note: This parameter will be removed in a future release. At that time, the block will always treat M-by-1 and unoriented vectors as a single channel.

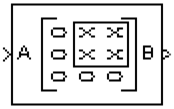
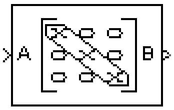
Overwrite Values

Overwrite submatrix or subdiagonal of input





Library

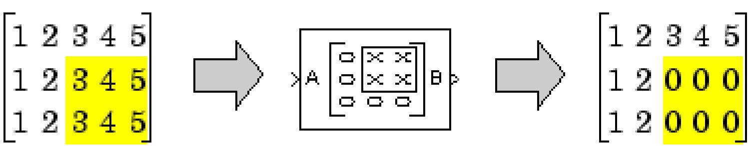
- Math Functions / Matrices and Linear Algebra / Matrix Operations

  `dspmtrx3`
- Signal Management / Indexing

  `dspindex`

Description

The Overwrite Values block overwrites a contiguous submatrix or subdiagonal of an input matrix. You can provide the overwriting values by typing them in a block parameter, or through an additional input port, which is useful for providing overwriting values that change at each time step.



The block accepts scalars, vectors and matrices. The output always has the same size as the original input signal, not necessarily the same size as the signal containing the overwriting values. The input(s) and output of this block must have the same data type.

Specifying the Overwriting Values

The **Source of overwriting value(s)** parameter determines how you must provide the overwriting values, and has the following settings.

- `Specify via dialog` — You must provide the overwriting value(s) in the **Overwrite with** parameter. The block uses the same overwriting values to overwrite the specified portion of the input at each time step. To learn how to specify valid overwriting values, see “Valid Overwriting Values” on page 2-1355.
- `Second input port` — You must provide overwriting values through a second block input port, `V`. Use this setting to provide different overwriting values at each time step. The output inherits its size and rate from the input signal, *not* the overwriting values.

  The rate at which you provide the overwriting values through input port `V` must match the rate at which the block receives each input matrix at input port `A`. In other words, the input signals must have the same Simulink sample time.

Valid Overwriting Values

The overwriting values can be a single constant, vector, or matrix, depending on the portion of the input you are overwriting, regardless of whether you provide the overwriting values through an input port or by providing them in the **Overwrite with** parameter.

Valid Overwriting Values

Portion of Input to Overwrite	Valid Overwriting Values	Example
A single element in the input $\begin{bmatrix} x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$	Any constant value, v	v `= 9` $\begin{bmatrix} x & x & x & x & x \\ x & x & x & 9 & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$

Portion of Input to Overwrite	Valid Overwriting Values	Example
A length-k portion of the diagonal $\begin{bmatrix} x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$	Any length-k column or row vector, v	$k = 3 \quad v = \begin{bmatrix} 2 & 4 & 6 \end{bmatrix}$ or $\begin{bmatrix} 2 \\ 4 \\ 6 \end{bmatrix}$ $\begin{bmatrix} 2 & x & x & x & x \\ x & 4 & x & x & x \\ x & x & 6 & x & x \\ x & x & x & x & x \end{bmatrix}$
A length-k portion of a row $\begin{bmatrix} x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$	Any length-k row vector, v	$k = 3 \quad v = \begin{bmatrix} 2 & 4 & 6 \end{bmatrix}$ $\begin{bmatrix} x & x & x & x & x \\ x & 2 & 4 & 6 & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$
A length-k portion of a column $\begin{bmatrix} x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$	Any length-k column vector, v	$k = 2 \quad v = \begin{bmatrix} 4 \\ 6 \end{bmatrix}$ $\begin{bmatrix} x & x & x & x & x \\ x & x & x & 4 & x \\ x & x & x & 6 & x \\ x & x & x & x & x \end{bmatrix}$
An m-by-n submatrix $\begin{bmatrix} x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \\ x & x & x & x & x \end{bmatrix}$	Any m-by-n matrix, v	$m = 2$ $n = 3$ $v = \begin{bmatrix} 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$ $\begin{bmatrix} x & x & x & x & x \\ x & x & 4 & 5 & 6 \\ x & x & 7 & 8 & 9 \\ x & x & x & x & x \end{bmatrix}$

This block supports Simulink virtual buses.

Parameters

Note Only some of the following parameters are visible in the dialog box at any one time.

Overwrite

Determines whether to overwrite a specified submatrix or a specified portion of the diagonal.

Source of overwriting value(s)

Determines where you must provide the overwriting values: either through an input port, or by providing them in the **Overwrite with** parameter. For more information, see "Specifying the Overwriting Values" on page 2-1355.

Overwrite with

The value(s) with which to overwrite the specified portion of the input matrix. Enabled only when **Source of overwriting value(s)** is set to `Specify via dialog`. To learn how to specify valid overwriting values, see "Valid Overwriting Values" on page 2-1355.

Row span

The range of input rows to be overwritten. Options are `All rows`, `One row`, or `Range of rows`. For descriptions of these options, see "Parameters" on page 2-1357.

Row/Starting row

The input row that is the first row of the submatrix that the block overwrites. For a description of the options for the **Row** and **Starting row** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row** is enabled when **Row span** is set to `One row`, and **Starting row** when **Row span** is set to `Range of rows`.

Row index/Starting row index

Index of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row index** is enabled when **Row** is set to `Index`, and **Starting row index** when **Starting row** is set to `Index`.

Row offset/Starting row offset

The offset of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row offset** is enabled when **Row** is set to `Offset from middle` or `Offset from last`, and **Starting row offset** is enabled when **Starting row** is set to `Offset from middle` or `Offset from last`.

Ending row

The input row that is the last row of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Row span** is set to `Range of rows`, and **Starting row** is set to any option but `Last`.

Ending row index

Index of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to `Index`.

Ending row offset

The offset of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to `Offset from middle` or `Offset from last`.

Column span

The range of input columns to be overwritten. Options are `All columns`, `One column`, or `Range of columns`. For descriptions of the analogous row options, see "Parameters" on page 2-1357.

Column/Starting column

The input column that is the first column of the submatrix that the block overwrites. For a description of the options for the **Column** and **Starting column** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column** is enabled when **Column span** is set to `One column`, and **Starting column** when **Column span** is set to `Range of columns`.

Column index/Starting column index

Index of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column index** is enabled when **Column** is set to `Index`, and **Starting column index** when **Starting column** is set to `Index`.

Column offset/Starting column offset

The offset of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column offset** is enabled when **Column** is set to `Offset from middle` or `Offset from last`, and **Starting column offset** is enabled when **Starting column** is set to `Offset from middle` or `Offset from last`.

Ending column

The input column that is the last column of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Column span** is set to `Range of columns`, and **Starting column** is set to any option but `Last`.

Ending column index

Index of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Index`.

Ending column offset

The offset of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Offset from middle` or `Offset from last`.

Diagonal span

The range of diagonal elements to be overwritten. Options are `All elements`, `One element`, or `Range of elements`. For descriptions of these options, see "Overwriting a Subdiagonal" on page 2-1364.

Element/Starting element

The input diagonal element that is the first element in the subdiagonal that the block overwrites. For a description of the options for the **Element** and **Starting element** parameters, see Element and Starting Element Parameters. **Element** is enabled when **Element span** is set to `One element`, and **Starting element** when **Element span** is set to `Range of elements`.

Element index/Starting element index

Index of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting

Element Parameters. **Element index** is enabled when **Element** is set to `Index`, and **Starting element index** when **Starting element** is set to `Index`.

Element offset/Starting element offset

The offset of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters. **Element offset** is enabled when **Element** is set to `Offset from middle` or `Offset from last`, and **Starting element offset** is enabled when **Starting element** is set to `Offset from middle` or `Offset from last`.

Ending element

The input diagonal element that is the last element of the subdiagonal that the block overwrites. For a description of this parameter's options, see Ending Element Parameters. This parameter is enabled when **Element span** is set to `Range of elements`, and **Starting element** is set to any option but `Last`.

Ending element index

Index of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to `Index`.

Ending element offset

The offset of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to `Offset from middle` or `Offset from last`.

Examples

Overwriting a Submatrix

To overwrite a submatrix, follow these steps:

1. Set the **Overwrite** parameter to `Submatrix`.
2. Specify the overwriting values as described in "Specifying the Overwriting Values" on page 2-1355.
3. Specify which rows and columns of the input matrix are contained in the submatrix that you want to overwrite by setting the **Row span** parameter to one of the following options and the **Column span** to the analogous column-related options:

- `All rows` — The submatrix contains all rows of the input matrix.
- `One row` — The submatrix contains only one row of the input matrix, which you must specify in the **Row** parameter, as described in the following table.
- `Range of rows` — The submatrix contains one or more rows of the input, which you must specify in the **Starting Row** and **Ending row** parameters, as described in the following tables.

4 When you set **Row span** to `One row` or `Range of rows`, you need to further specify the row(s) contained in the submatrix by setting the **Row** or **Starting row** and **Ending row** parameters. Likewise, when you set **Column span** to `One column` or `Range of columns`, you must further specify the column(s) contained in the submatrix by setting the **Column** or **Starting column** and **Ending column** parameters. For descriptions of the settings for these parameters, see the following tables.

Settings for Row, Column, Starting Row, and Starting Column Parameters

Settings for Specifying the Submatrix's First Row or Column	First Row of Submatrix (Only row for Row span = One row)	First Column of Submatrix (Only row for Row span = One row)
`First`	First row of the input	First column of the input
`Index`	Input row specified in the **Row index** parameter	Input column specified in the **Column index** parameter
`Offset from last`	Input row with the index `M - rowOffset` where `M` is the number of input rows, and `rowOffset` is the value of the **Row offset** or **Starting row offset** parameter	Input column with the index `N - colOffset` where `N` is the number of input columns, and `colOffset` is the value of the **Column offset** or **Starting column offset** parameter
`Last`	Last row of the input	Last column of the input
`Offset from middle`	Input row with the index `floor(M/2 + 1 - rowOffset)` where `M` is the number of input rows, and `rowOffset` is the value of the **Row offset** or **Starting row offset** parameter	Input column with the index `floor(N/2 + 1 - rowOffset)` where `N` is the number of input columns, and `colOffset` is the value of the or **Column offset** or **Starting column offset** parameter

Settings for Specifying the Submatrix's First Row or Column	First Row of Submatrix (Only row for Row span = One row)	First Column of Submatrix (Only row for Row span = One row)
`Middle`	Input row with the index `floor(M/2 + 1)` where `M` is the number of input rows	Input columns with the index `floor(N/2 + 1)` where `N` is the number of input columns

Settings for Ending Row and Ending Column Parameters

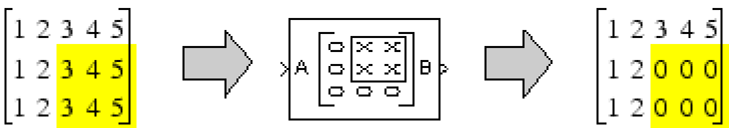
Settings for Specifying the Submatrix's Last Row or Column	Last Row of Submatrix	Last Column of Submatrix
`Index`	Input row specified in the **Ending row index** parameter	Input column specified in the **Ending column index** parameter
`Offset from last`	Input row with the index `M - rowOffset` where `M` is the number of input rows, and `rowOffset` is the value of the **Ending row offset** parameter	Input column with the index `N - colOffset` where `N` is the number of input columns, and `colOffset` is the value of the **Ending column offset** parameter
`Last`	Last row of the input	Last column of the input
`Offset from middle`	Input row with the index `floor(M/2 + 1 - rowOffset)` where `M` is the number of input rows, and `rowOffset` is the value of the **Ending row offset** parameter	Input column with the index `floor(N/2 + 1 - rowOffset)` where `N` is the number of input columns, and `colOffset` is the value of the **Ending column offset** parameter
`Middle`	Input row with the index `floor(M/2 + 1)` where `M` is the number of input rows	Input columns with the index `floor(N/2 + 1)` where `N` is the number of input columns

For example, to overwrite the lower-right 2-by-3 submatrix of a 3-by-5 input matrix with all zeros, enter the following set of parameters:

- **Overwrite** = `Submatrix`
- **Source of overwriting value(s)** = `Specify via dialog`

- **Overwrite with** = `0`
- **Row span** = `Range of rows`
- **Starting row** = `Index`
- **Starting row index** = `2`
- **Ending row** = `Last`
- **Column span** = `Range of columns`
- **Starting column** = `Offset from last`
- **Starting column offset** = `2`
- **Ending column** = `Last`

The following figure shows the block with the above settings overwriting a portion of a 3-by-5 input matrix.



There are often several possible parameter combinations that select the *same* submatrix from the input. For example, instead of specifying `Last` for **Ending column**, you could select the same submatrix by specifying

- **Ending column** = `Index`
- **Ending column index** = `5`

Overwriting a Subdiagonal

To overwrite a subdiagonal, follow these steps:

1. Set the **Overwrite** parameter to `Diagonal`.
2. Specify the overwriting values as described in "Specifying the Overwriting Values" on page 2-1355.
3. Specify the subdiagonal that you want to overwrite by setting the **Diagonal span** parameter to one of the following options:
   - `All elements` — Overwrite the entire input diagonal.
   - `One element` — Overwrite one element in the diagonal, which you must specify in the **Element** parameter (described below).
   - `Range of elements` — Overwrite a portion of the input diagonal, which you must specify in the **Starting element** and **Ending element** parameters, as described in the following table.
4. When you set **Diagonal span** to `One element` or `Range of elements`, you need to further specify which diagonal element(s) to overwrite by setting the **Element** or **Starting element** and **Ending element** parameters. See the following tables.

Element and Starting Element Parameters

Settings for Element and Starting Element Parameters	First Element in Subdiagonal (Only element when Diagonal span = One element)
`First`	Diagonal element in first row of the input
`Index`	kth diagonal element, where k is the value of the **Element index** or **Starting element index** parameter
`Offset from last`	Diagonal element in the row with the index `M - offset` where `M` is the number of input rows, and `offset` is the value of the **Element offset** or **Starting element offset** parameter
`Last`	Diagonal element in the last row of the input
`Offset from middle`	Diagonal element in the input row with the index `floor(M/2 + 1 - offset)` where `M` is the number of input rows, and `offset` is the value of the **Element offset** or **Starting element offset** parameter

Settings for Element and Starting Element Parameters	First Element in Subdiagonal (Only element when Diagonal span = One element)
`Middle`	Diagonal element in the input row with the index `floor(M/2 + 1)` where `M` is the number of input rows

Ending Element Parameters

Settings for Ending Element Parameter	Last Element in Subdiagonal
`Index`	*k*th diagonal element, where *k* is the value of the **Ending element index** parameter
`Offset from last`	Diagonal element in the row with the index `M - offset` where `M` is the number of input rows, and `offset` is the value of the **Ending element offset** parameter
`Last`	Diagonal element in the last row of the input
`Offset from middle`	Diagonal element in the input row with the index `floor(M/2 + 1 - offset)` where `M` is the number of input rows, and `offset` is the value of the **Ending element offset** parameter
`Middle`	Diagonal element in the input row with the index `floor(M/2 + 1)` where `M` is the number of input rows

Supported Data Types

The input(s) and output of this block must have the same data type.

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
V	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Pad

Pad or truncate specified dimension(s)

Library

Signal Operations

`dspsigops`

Description

The Pad block extends or crops the dimensions of the input by padding or truncating along its columns, rows, columns and rows, or any dimension(s) you specify. Truncation occurs when you specify output dimensions that are shorter than the corresponding input dimensions. If the input and output lengths are the same, the block is a pass-through.

You can enter the pad value in the block mask or via an input port. You can enter output sizes in the block mask, or have the block pad the specified dimensions until their length is the next highest power of two. The **Pad signal at** parameter controls whether the specified input dimensions are padded or truncated at their beginning, end, or both. For odd pad or truncation lengths, the extra pad value or truncation is applied to the end of the signal. When the block is in `Specified dimensions` mode, you can specify either the output size or the pad size.

You can have the block warn or error when an input signal is truncated using the **Action when truncation occurs** parameter.

Parameters

Pad over

Specify the dimensions over which to pad or truncate: `Columns`, `Rows`, `Columns and rows`, `None`, or `Specified dimensions`.

Dimensions to pad

Specify the one-based dimension(s) over which to pad or truncate. The value for this parameter can be a scalar or a vector. For example, specify `1` to pad columns. Specify `[1 2]` to pad columns and rows. Specify `[1 3 5]` to pad the first, third, and fifth dimensions.

This parameter is only visible when `Specified dimensions` is selected for the **Pad over** parameter.

Pad value source

Choose how you specify the pad value. The pad value can come from an input port or from the dialog:

- If you select `Input port`, the `PVal` port appears on the block icon.
- If you select `Specify via dialog`, the **Pad value** parameter appears.

Pad value

Specify the constant scalar value with which to pad the input. Tunable (Simulink).

This parameter is only visible when `Specify via dialog` is selected for the **Pad value source** parameter.

Output column mode

Choose how you specify the column length of the output:

- If you select `User-specified`, the **Column size** parameter appears.
- If you select `Next power of two`, the block pads the output columns until their length is the next highest power of two. If the column length is already a power of two, the columns are not padded.

This parameter is only visible when `Columns` or `Columns and rows` is selected for the **Pad over** parameter.

Column size

Specify the column length of the output. If the specified column length is longer than the input column length, the columns are padded. If the specified column length is shorter than the input column length, the columns are truncated. This parameter is only visible when `User-specified` is selected for the **Output column mode** parameter.

Output row mode

Choose how you specify the output row length of the output:

- If you select `User-specified`, the **Row size** parameter appears.
- If you select `Next power of two`, the block pads the output rows until their length is the next highest power of two. If the row length is already a power of two, the rows are not padded.

This parameter is only visible when `Rows` or `Columns and rows` is selected for the **Pad over** parameter.

Row size

Specify the row length of the output. If the specified row length is longer than the input row length, the rows are padded. If the specified row length is shorter than the input row length, the rows are truncated. This parameter is only visible when `User-specified` is selected for the **Output row mode** parameter.

Specify

Choose whether you want to control the output length of the specified dimensions by specifying the pad size or the output size.

This parameter is only visible when `Specified dimensions` is selected for the **Pad over** parameter.

Pad size at beginning

Specify how many values to add to the beginning of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at beginning** parameter gives the pad length for the beginning of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be zero or a positive integer.

This parameter is only visible if `Pad size` is selected for the **Specify** parameter.

Pad size at end

Specify how many values to add to the end of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at end** parameter gives the pad length for the end of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be zero or a positive integer.

This parameter is only visible if `Pad size` is selected for the **Specify** parameter.

Output size mode

Choose how you specify the output length of the specified dimensions:

- If you select `User-specified`, the **Output size** parameter appears.
- If you select `Next power of two`, the block pads the specified dimensions until their length is the next highest power of two. If the dimension length is already a power of two, no padding occurs in that dimension.

This parameter is only visible if `Output size` is selected for the **Specify** parameter.

Output size

Specify the output length of the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Output size** vector gives the output length for the corresponding dimension in the **Dimensions to pad** vector. If the specified length is longer than the input length for a given dimensions, that dimension is padded. If the specified length is shorter than the input length for a given dimension, that dimension is truncated.

This parameter is only visible if `Output size` is selected for the **Specify** parameter.

Pad signal at

Specify whether to pad or truncate the signal at the `Beginning`, `End`, or `Beginning and end` of the specified dimension(s). When you select `Beginning and end`, half the pad length is added to the beginning of the signal, and half is added to the end of the signal. For an odd pad length, the extra value is added to the end of the signal. This also applies to truncation. In this mode, an equal number of values are truncated from the beginning and the end of the signal. In the case of an odd truncation length, the extra value is removed from the end of the signal.

Action when truncation occurs

Choose `None` when you do not want to be notified that the input is truncated. Select `Warning` to display a warning when the input is truncated. Choose `Error` when to display an error and terminate the simulation when the input is truncated.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating-point

Port	Supported Data Types
	• Single-precision floating-point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating-point • Single-precision floating-point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

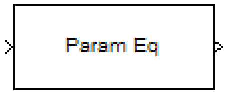
Parametric Equalizer

Design parametric equalizer



Note: The Parametric Equalizer block has been replaced by the `Parametric EQ Filter` block. Existing instances of the Parametric Equalizer block will continue to operate. For new models, use the Parametric EQ Filter block.

Library

Filtering / Filter Designs

`dspfdesign`

Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

See "Parametric Equalizer Filter Design — Main Pane" on page 5-788 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

Order mode

Select `Minimum` to design a minimum order filter that meets the design specifications, or `Specify` to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a `Minimum` order filter, the available frequency constraints are:

- `Center frequency, bandwidth, passband width`
- `Center frequency, bandwidth, stopband width`

If you select `Specify`, the available frequency constraints are:

- `Center frequency, bandwidth`
- `Center frequency, quality factor`
- `Shelf type, cutoff frequency, quality factor`
- `Shelf type, cutoff frequency, shelf slope parameter`
- `Low frequency, high frequency`

Order

Specify the filter order. This parameter is enabled only if the **Order mode** is set to `Specify`.

Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- `Center frequency, bandwidth, passband width` (available for minimum order only)
- `Center frequency, bandwidth, stopband width` (available for minimum order only)
- `Center frequency, bandwidth` (available for a specified order only)
- `Center frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, shelf slope parameter` (available for a specified order only)
- `Low frequency, high frequency` (available for a specified order only)

Frequency units

Select the frequency units from the available drop down list (`Normalized`, `Hz`, `kHz`, `MHz`, `GHz`). If `Normalized` is selected, then the **Input Fs** box is disabled for input.

Input Fs

Enter the input sampling frequency. This input box is disabled for input if `Normalized` is selected in the **Frequency units** input box.

Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to `db(sqrt(.5))`, or –3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: `Center frequency, bandwidth, passband width`, `Center frequency, bandwidth, stopband width`, or `Center frequency, bandwidth`.

Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, passband width`.

Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, stopband width`.

Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

Gain Specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- `Reference, center frequency, bandwidth, passband`
- `Reference, center frequency, bandwidth, stopband`
- `Reference, center frequency, bandwidth, passband, stopband`

- `Reference, center frequency, bandwidth`

Gain units

Specify the gain units either `dB` or `squared`. These units are used for all gain specifications in the dialog box.

Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a `bandwidth` parameter, or is `Low frequency, high frequency`.

Center frequency gain

Specify the center frequency in **Gain units**

Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are `Center frequency, bandwidth, stopband width`.

Boost/cut gain

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the `Shelf type` parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

Algorithm

Design method

Select the design method from the drop-down list. Different methods are available depending on the chosen filter constraints.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed — see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2007a

Parametric EQ Filter

Model second-order parametric equalizer filter

Note: The Parametric EQ Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Parametric EQ Filter block from Audio System Toolbox instead.

Library

Filtering / Filter Designs

`dspfdesign`

Description

The Parametric EQ Filter block filters each channel of the input signal over time using a specified center frequency, bandwidth, and peak (dip) gain. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of the dsp.ParametricEQFilter System object to the Simulink environment.

The filter uses a coupled allpass structure to optimize joint computation of the peak and notch response. For information on the algorithms used by the Parametric EQ Filter block, see the "Algorithm" on page 4-1401 section of `dsp.ParametricEQFilter`.

Parameters

Filter specification

Parameters or coefficients used to design the filter, specified as one of the following:

- `Bandwidth and center frequency` (default) — Design the filter using **Filter bandwidth (Hz)**, **Equalizer center frequency (Hz)**, and **Gain (dB)**.
- `Coefficients` — Design the filter using **Bandwidth coefficient**, **Center frequency coefficient**, and **Gain (Linear Units)**.
- `Quality factor and center frequency` — Design the filter using **Equalizer center frequency (Hz)**, **Gain (dB)**, and **Quality factor**.

This parameter is nontunable.

Filter bandwidth (Hz)

Bandwidth of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to `Bandwidth and center frequency`. The default is `2205`. This parameter is tunable.

Equalizer center frequency (Hz)

Center frequency of the filter, specified as a finite positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to `Bandwidth and center frequency` or `Quality factor and center frequency`. The default is `11025`. This parameter is tunable.

Gain (dB)

Peak or dip gain of the filter, specified as a real scalar in dB. A value greater than zero corresponds to a peak. A value less than zero corresponds to a dip. This parameter applies when you set **Filter specification** to `Bandwidth and center frequency` or `Quality factor and center frequency`. The default is `6.0206`. This parameter is tunable.

Bandwidth coefficient

Coefficient that determines the filter bandwidth, specified as a finite numeric scalar in the range `[-1 1]`.

- `-1` corresponds to the maximum bandwidth (one-fourth the sample rate of the input signal).
- `1` corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This parameter applies when you set **Filter specification** to `Coefficients`. The default is `0.72654`. This parameter is tunable.

Center frequency coefficient

Coefficient that determines the center frequency of the filter, specified as a finite numeric scalar in the range `[-1 1]`.

- `-1` corresponds to the minimum center frequency (`0` Hz).
- `1` corresponds to the maximum center frequency (half the sample rate of the input signal).

This parameter applies when you set **Filter specification** to `Coefficients`. The default is `0`, which corresponds to one-fourth the sample rate of the input signal. This parameter is tunable.

Gain (Linear Units)

Peak or dip gain of the filter, specified as a real positive scalar in linear units. A value greater than one boosts the input signal. A value less than one attenuates the input signal. This parameter applies when you set **Filter specification** to `Coefficients`. The default is `2`. This parameter is tunable.

Quality factor

Quality factor of the filter, specified as a real positive scalar. The quality factor is defined as **Equalizer center frequency (Hz) / Filter bandwidth (Hz)**. A higher quality factor corresponds to a narrower peak or dip. This parameter applies when you set **Filter specification** to `Quality factor and center frequency`. The default is `5`. This parameter is tunable.

Inherit sample rate from input

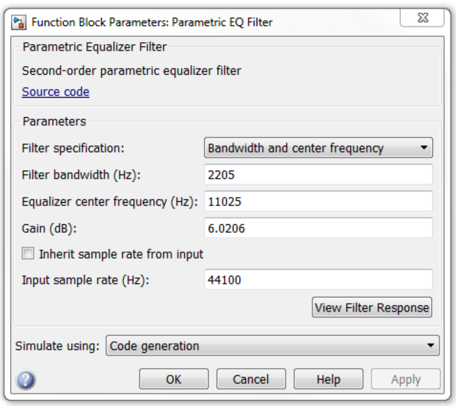
When you select this check box, the block's sample rate is computed as *N*/*Ts*, where *N* is the frame size of the input signal, and *Ts* is the sample time of the input signal. When you clear this check box, the block sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

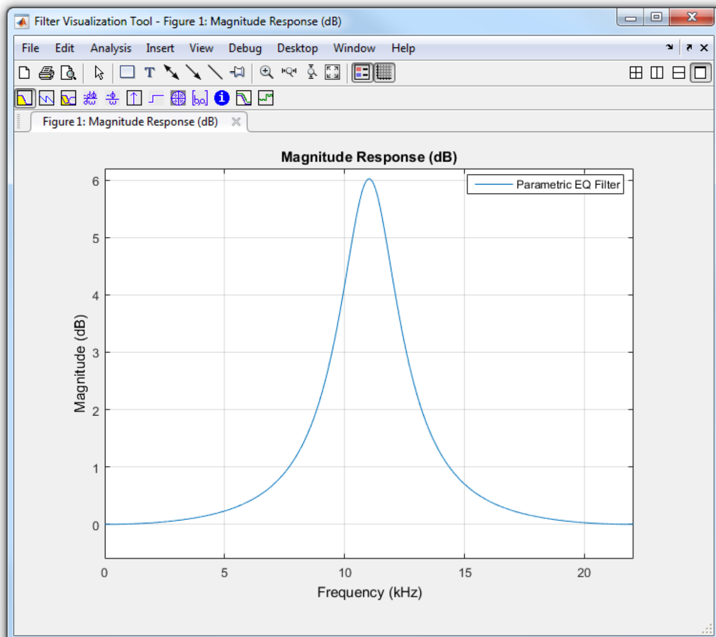
Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Parametric EQ Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

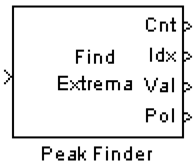
Peak Finder

Determine whether each value of input signal is local minimum or maximum



Library

Signal Operations

`dspsigops`

Description

The Peak Finder block counts the number of local extrema in each column of the real-valued input signal. The block outputs the number of local extrema at the Cnt port. You can also configure the block to output the extrema indices, the extrema values, and a binary indicator of whether or not the extrema are maxima or minima.

To qualify as an extrema, a point has to be larger (or smaller) than both of its neighboring points. Thus, end points are never considered extrema.

If you select the **Output peak indices** check box, the Idx port appears on the block. The block outputs the zero-based extrema indices at the Idx port. If you select the **Output peak values** check box, the Val port appears on the block. The block outputs the extrema values at the Val port. If you select either of these check boxes and set the **Peak type(s)** to `Maxima and Minima`, the Pol port also appears on the block. If the signal value is a maximum, the block outputs a 1 at the Pol ("Polarity") port. If the signal value is a minimum, the block outputs a 0 at the Pol port.

Use the **Maximum number of peaks to find** parameter to specify how many extrema to look for in each input signal. The block stops searching the input signal once this maximum number of extrema has been found.

If you select the **Ignore peaks within threshold of neighboring values** check box, the block no longer detects low-amplitude peaks. This feature allows the block to ignore noise within a threshold value that you define. Enter a threshold value for the **Threshold** parameter. Now, the current value is a maximum if (current – previous) > threshold and (current – next) > threshold. The current value is a minimum if (current – previous) < –threshold and (current – next) < –threshold.

Examples

Example 1

Consider the input vector

`[9 6 10 3 4 5 0 12]`

The table below shows the analysis made by the Peak Finder block. Note that the first and last input signal values are not considered:

Previous, current, and next values	9 6 10	6 10 3	10 3 4	3 4 5	4 5 0	5 0 12
Current value if it is an extremum	6	10	3	—	5	0
Index of current value if it is an extremum	1	2	3	—	5	6
Polarity of current value if it is an extremum	0	1	0	—	1	0

Therefore, for this example the outputs at the block ports are

Cnt: `5`

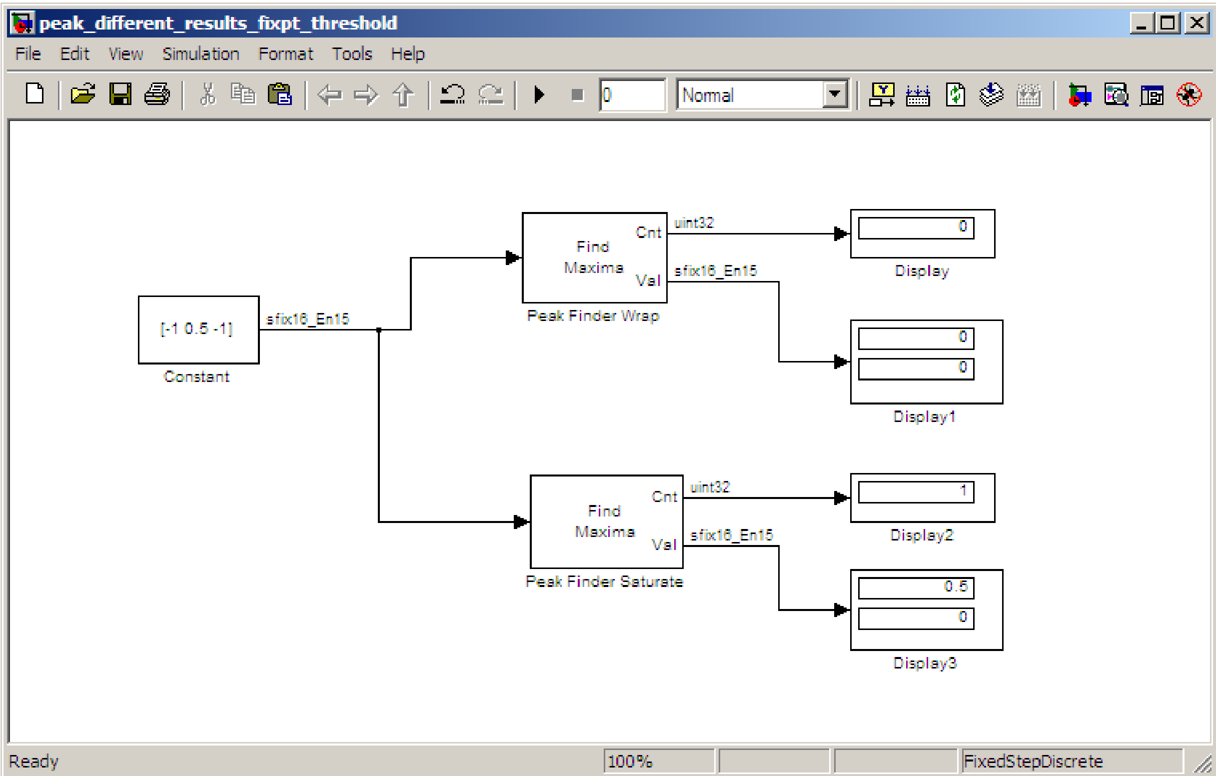
Idx: `[1 2 3 5 6]`

Val: `[6 10 3 5 0]`

Pol: `[0 1 0 1 0]`

Example 2

Note that the **Overflow mode** parameter can affect the output of the block when the input is fixed point. Consider the following model:



In this model, the settings in the Constant block are

- **Constant value** — `[-1 0.5 -1]`
- **Interpret vector parameters as 1-D** — not selected
- **Sampling mode** — `Sample based`
- **Sample time** — `1`
- **Output data type** — `<data type expression>`
- **Mode** — `Fixed point`
- **Sign** — `Signed`
- **Scaling** — `Binary point`
- **Word length** — `16`
- **Fraction length** — `15`

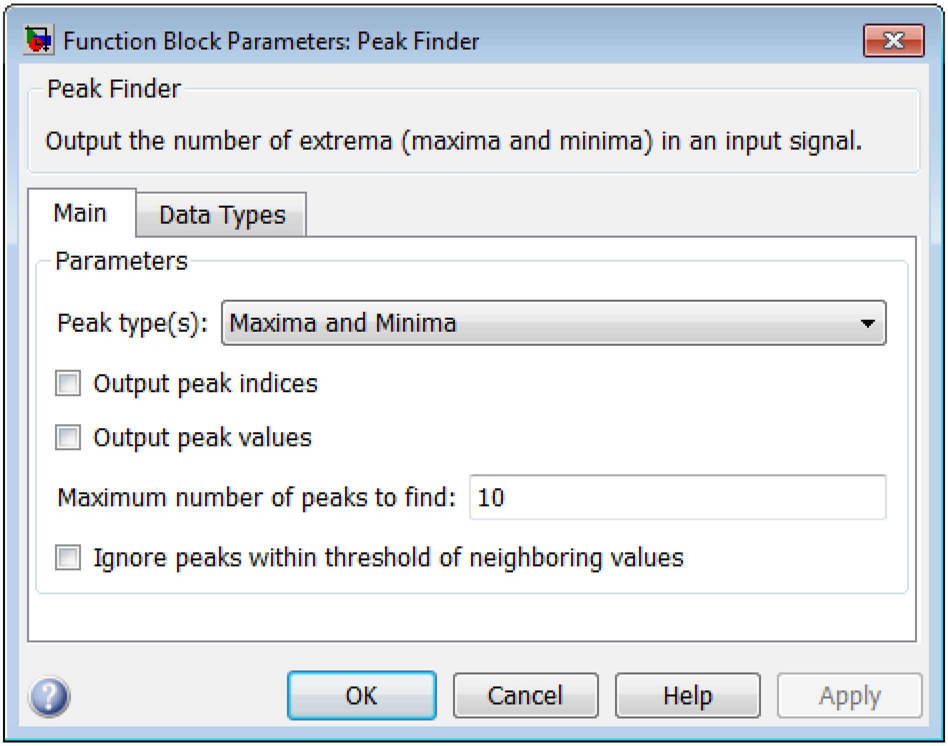
The settings in the Peak Finder blocks are

- **Peak type(s)** — `Maxima`
- **Output peak indices** — not selected
- **Output peak values** — selected
- **Maximum number of peaks to find** — `2`
- **Ignore peaks within threshold of neighboring values** — selected
- **Threshold** — `0.25`
- **Overflow mode** — `Wrap` for Peak Finder Wrap, `Saturate` for Peak Finder Saturate

Setting the **Overflow mode** parameter of the Peak Finder Wrap block to `Wrap` causes the calculations (current – previous) > threshold and (current – next) > threshold to wrap on overflow, thereby causing the maximum to be missed.

Dialog Box

The **Main** pane of the Peak Finder block dialog appears as follows.



Peak type(s)

Specify whether you are looking for maxima, minima, or both.

Output peak indices

Select this check box if you want the block to output the extrema indices at the Idx port.

Output peak values

Select this check box if you want the block to output the extrema values at the Val port.

Maximum number of peaks to find

Enter the number of extrema to look for in each input signal. The block stops searching the input signal for extrema once the maximum number of extrema has been found. The value of this parameter must be an integer greater than or equal to one.

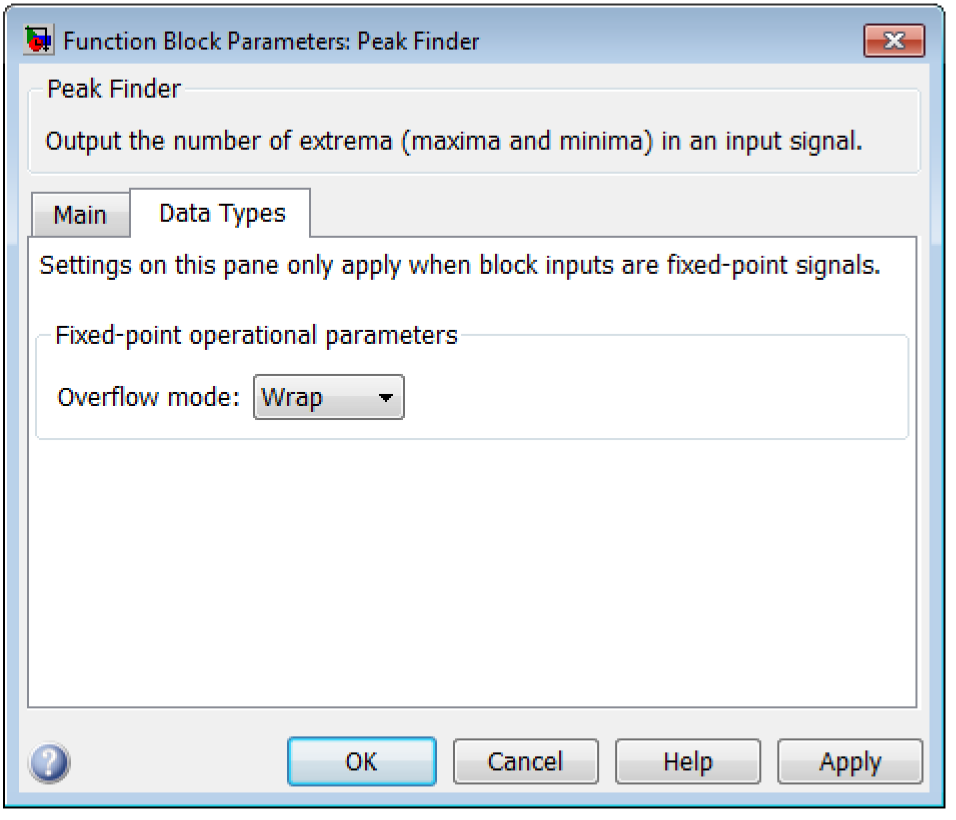
Ignore peaks within threshold of neighboring values

Select this check box if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values.

Threshold

Enter your threshold value. This parameter appears if you select the **Ignore peaks within threshold of neighboring values** check box.

When you select the **Ignore peaks within threshold of neighboring values** check box, the **Data Types** pane of the Peak Finder block appears as follows.



Overflow mode

Select the overflow mode to be used when block inputs are fixed point.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Cnt	• 32-bit unsigned integers
Idx	• 32-bit unsigned integers
Val	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Pol	• Boolean

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

Response

Select `Peak` or `Notch` from the drop-down list. The rest of the parameters that specify are equivalent for either filter type.

Order

Enter the filter order. The order must be even.

Frequency Specifications

This group of parameters allows you to specify frequency constraints and units.

Frequency Constraints

Select the frequency constraints for filter specification. There are two choices as follows:

- `Center frequency and quality factor`
- `Center frequency and bandwidth`

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1)`, `Hz`, `kHz`, `MHz`, `GHz`.

Input Fs

This input box is enabled if **Frequency units** other than `Normalized (0 to 1)` are specified. Enter the input sampling frequency.

Center frequency

Enter the center frequency in the units specified previously.

Quality Factor

This input box is enabled only when `Center frequency and quality factor` is chosen for the **Frequency Constraints**. Enter the quality factor.

Bandwidth

This input box is enabled only when `Center frequency and bandwidth` is chosen for the **Frequency Constraints**. Enter the bandwidth.

Magnitude Specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- `Unconstrained`
- `Passband ripple`
- `Stopband attenuation`
- `Passband ripple and stopband attenuation`

Magnitude units

Select the magnitude units: either `dB` or `squared`.

Apass

This input box is enabled if the magnitude constraints selected are `Passband ripple` or `Passband ripple and stopband attenuation`. Enter the passband ripple.

Astop

This input box is enabled if the magnitude constraints selected are `Stopband attenuation` or `Passband ripple and stopband attenuation`. Enter the stopband attenuation.

Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter Implementation

Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed – see release notes)` option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

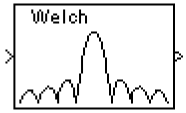
Supported Data Types

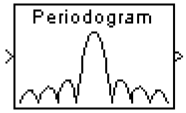
Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2007a

Periodogram

Power spectral density or mean-square spectrum estimate using periodogram method





Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Periodogram block estimates the power spectral density (PSD) or mean-square spectrum (MSS) of the input. It does so by using the periodogram method and Welch's averaged, modified periodogram method. The block averages the squared magnitude of the FFT computed over windowed sections of the input. It then normalizes the spectral average by the square of the sum of the window samples. See "Periodogram" (Signal Processing Toolbox) and "Welch's Method" (Signal Processing Toolbox) for more information.

The block treats M-by-N frame-based matrix input and M-by-N sample-based matrix input as M sequential time samples from N independent channels. The block computes a separate estimate for each of the N independent channels and generates an N_{fft}-by-N matrix output.

Each column of the output matrix contains the estimate of the power spectral density of the corresponding input column at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal. The block always outputs sample-based data.

Parameters

Measurement

Specify the type of measurement for the block to perform: `Power spectral density` or `Mean-square spectrum`. Tunable (Simulink).

Window

Select the type of window to apply. See the `Window Function` block reference page for more details. Tunable (Simulink).

Stopband attenuation in dB

Enter the level, in decibels (dB), of stopband attenuation, R_s, for the Chebyshev window. This parameter becomes visible if, for the **Window** parameter, you choose `Chebyshev`. Tunable (Simulink).

Beta

Enter the β parameter for the Kaiser window. This parameter becomes visible if, for the **Window** parameter, you chose `Kaiser`. Increasing **Beta** widens the mainlobe and decreases the amplitude of the sidelobes in the displayed frequency magnitude response. Tunable (Simulink). See the `Window Function` block reference page for more details.

Window sampling

From the list, choose `Symmetric` or `Periodic`. See the `Window Function` block reference page for more details.Tunable (Simulink).

FFT implementation

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using the Simulink Coder. The first dimension *M*, of the input matrix must be a power of two. To work with other input sizes, use the `Pad` block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

Set this parameter to `Auto` to let the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

Inherit FFT length from input dimensions

When you select this check box, the block uses the input frame size as the number of data points, N_{fft}, on which to perform the FFT. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power of two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

When you set the **FFT implementation** parameter to `Radix-2`, this value must be a power of two.

Number of spectral averages

Specify the number of spectra to average. When you set this value to `1`, the block computes the periodogram of the input. When you set this value greater `1`, the block implements "Welch's Method" (Signal Processing Toolbox) to compute a modified periodogram of the input.

Inherit sample time from input

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Example

The dspstfft example provides an illustration of using the Periodogram and Matrix Viewer blocks to create a spectrogram. The dspsacomp example compares the Periodogram block with several other spectral estimation methods.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:

  - **FFT implementation** is set to `FFTW`.
  - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

  Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".
- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

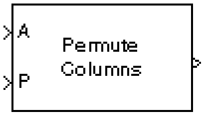
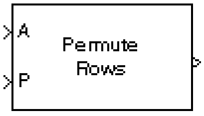
Permute Matrix

Reorder matrix rows or columns





Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Permute Matrix block reorders the rows or columns of M-by-N input matrix `A` as specified by indexing input `P`.

When the **Permute** parameter is set to `Rows`, the block uses the rows of `A` to create a new matrix with the same column dimension. Input `P` is a length-L vector whose elements determine where each row from `A` should be placed in the L-by-N output matrix.

```
% Equivalent MATLAB code
y = [A(P(1),:) ; A(P(2),:) ; A(P(3),:) ; ... ; A(P(end),:)]
```

For row permutation, the block treats length-M unoriented vector input at the `A` port as an M-by-1 matrix.

When the **Permute** parameter is set to `Columns`, the block uses the columns of `A` to create a new matrix with the same row dimension. Input `P` is a length-L vector whose elements determine where each column from `A` should be placed in the M-by-L output matrix.

```
% Equivalent MATLAB code
y = [A(:,P(1)) A(:,P(2)) A(:,P(3)) ... A(:,P(end))]
```

For column permutation, the block treats length-N unoriented vector input at the A port as a 1-by-N matrix.

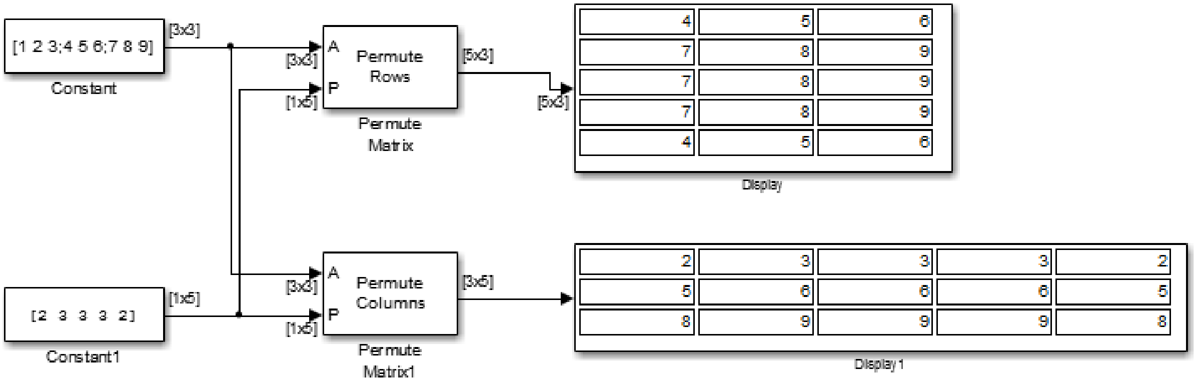
When an index value in input P references a nonexistent row or column of matrix A, the block reacts with the behavior specified by the **Invalid permutation index** parameter. The following options are available:

- `Clip index` — Clip the index to the nearest valid value (1 or M for row permutation, and 1 or N for column permutation), and *do not* issue an alert. Example: For a 3-by-7 input matrix, a column index of 9 is clipped to 7, and a row index of -2 is clipped to 1.
- `Clip and warn` — Display a warning message in the MATLAB command window, and clip the index as described above.
- `Generate error` — Display an error dialog box and terminate the simulation.

When length of the permutation vector P is not equal to the number of rows or columns of the input matrix A, you can choose to get an error dialog box and terminate the simulation by selecting **Error when length of P is not equal to Permute dimension size**.

Examples

In the model below, the top Permute Matrix block places the second row of the input matrix in both the first and fifth rows of the output matrix, and places the third row of the input matrix in the three middle rows of the output matrix. The bottom Permute Matrix block places the second column of the input matrix in both the first and fifth columns of the output matrix, and places the third column of the input matrix in the three middle columns of the output matrix.



As shown in the example above, rows and columns of A can appear any number of times in the output, or not at all.

Parameters

Permute

Method of constructing the output matrix; by permuting rows or columns of the input.

Index mode

When set to `One-based`, a value of 1 in the permutation vector P refers to the first row or column of the input matrix A. When set to `Zero-based`, a value of 0 in P refers to the first row or column of A.

Invalid permutation index

Response to an invalid index value. Tunable (Simulink).

Error when length of P is not equal to Permute dimension size

Option to display an error dialog box and terminate the simulation when the length of the permutation vector P is not equal to the number of rows or columns of the input matrix A.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
P	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

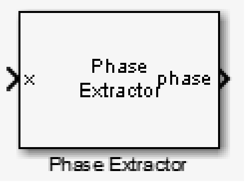
See “Reorder Channels in Multichannel Signals” for related information.

Introduced before R2006a

Phase Extractor

Extract the unwrapped phase of a complex input



Library

Signal Operations

`dspsigops`

Description

The Phase Extractor block extracts the unwrapped phase of a complex input. The input can be a vector or matrix. For 2D inputs, the block treats each column as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats 1D inputs as one channel.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

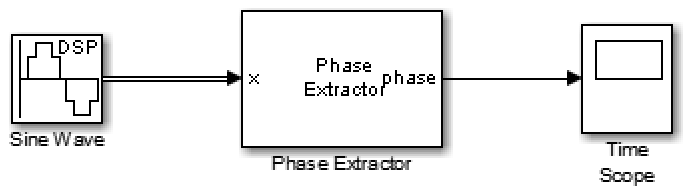
Examples

This example shows how to use the Phase Extractor block to extract the phase of a sign wave. The DSP Sine Wave block represents the system input signal. Set the DSP Sine Wave block parameters to the following:

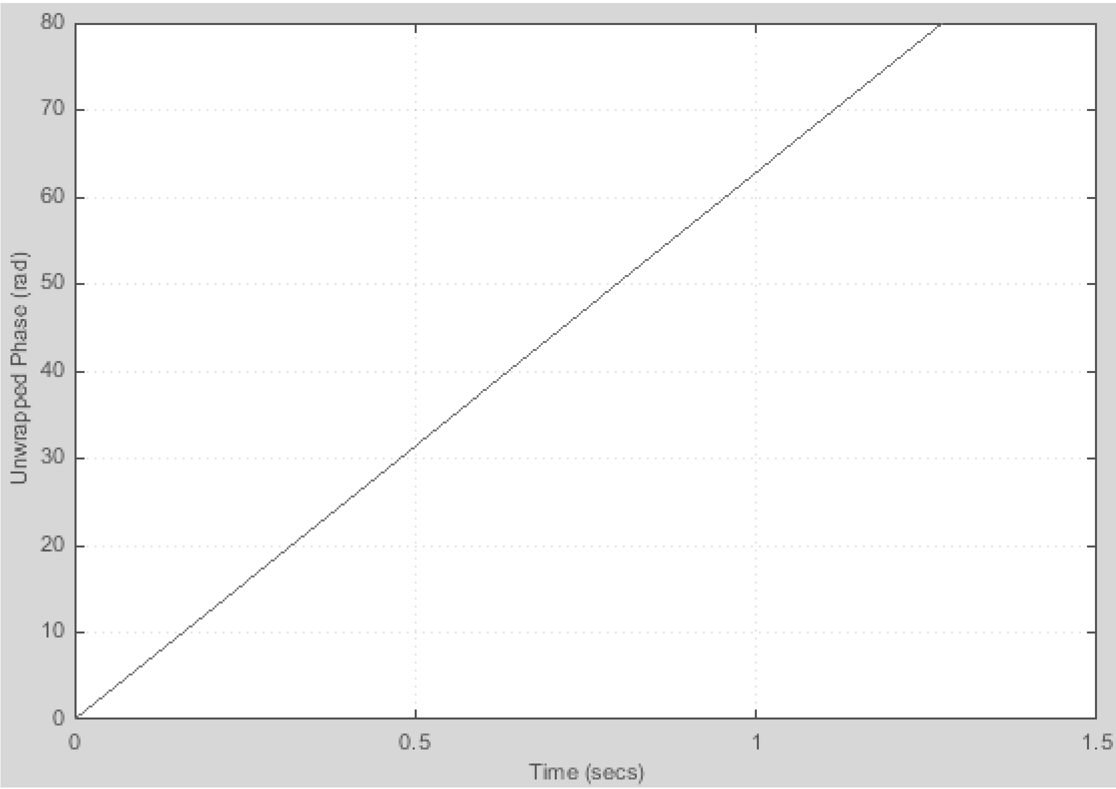
- **Frequency** set to `10` Hz
- **Sample mode** set to `Discrete`

- **Output complexity** set to `Complex`
- **Sample time** set to `1/1000`
- **Sample per frame** set to `128`

Do not select the Phase Extractor block parameter **Unwrap phase only within the frame**.



The Time Scope block displays the extracted phase.



Parameters

Unwrap phase only within the frame

When you clear this check box, the block ignores boundaries between the input frames. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame.

Simulate using

Select the simulation type from the following:

- `Code generation`
- `Interpreted execution`

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

See Also

dsp.PhaseExtractor	DSP System Toolbox

Algorithm

Consider an input frame of length N:

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The `step` method acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^{*} x_i)$$

Here, i runs from 1 to N. The `angle` function returns the phase angle in radians.

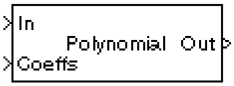
If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the `step` method treats each frame independently. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - Φ_0 is 0.
  - x_0 is 1.
- If you set `TreatFramesIndependently` to `false`, the `step` method ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - Φ_0 is the last unwrapped phase from the previous frame.
  - x_0 is the last sample from the previous frame.

Introduced in R2014b

Polynomial Evaluation

Evaluate polynomial expression



Library

Math Functions / Polynomial Functions

`dsppolyfun`

Description

The Polynomial Evaluation block applies a polynomial function to the real or complex input at the `In` port.

```
y = polyval(u)      % Equivalent MATLAB code
```

The Polynomial Evaluation block performs these types of operation more efficiently than the equivalent construction using Simulink Sum and Math Function blocks.

When you select the **Use constant coefficients** check box, you specify the polynomial expression in the **Constant coefficients** parameter. When you do not select **Use constant coefficients**, a variable polynomial expression is specified by the input to the `Coeffs` port. In both cases, the polynomial is specified as a vector of real or complex coefficients in order of descending exponents.

The table below shows some examples of the block's operation for various coefficient vectors.

Coefficient Vector	Equivalent Polynomial Expression
`[1 2 3 4 5]`	$y = u^4 + 2u^3 + 3u^2 + 4u + 5$
`[1 0 3 0 5]`	$y = u^4 + 3u^2 + 5$

Coefficient Vector	Equivalent Polynomial Expression
`[1 2+i 3 4-3i 5i]`	$y = u^4 + (2+i)u^3 + 3u^2 + (4-3i)u + 5i$

Each element of a vector or matrix input to the `In` port is processed independently, and the output size is the same as the input.

Parameters

Use constant coefficients

Select to enable the **Constant coefficients** parameter and disable the `Coeffs` input port.

Constant coefficients

Specify the vector of polynomial coefficients to apply to the input, in order of descending exponents. This parameter is enabled when you select the **Use constant coefficients** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

`polyval`	MATLAB

Introduced before R2006a

Polynomial Stability Test

Use Schur-Cohn algorithm to determine whether all roots of input polynomial are inside unit circle

Library

Math Functions / Polynomial Functions

`dsppolyfun`

Description

The Polynomial Stability Test block uses the Schur-Cohn algorithm to determine whether all roots of a polynomial are within the unit circle.

```
y = all(abs(roots(u)) < 1)        % Equivalent MATLAB code
```

Each column of the M-by-N input matrix u contains M coefficients from a distinct polynomial,

$$f(x) = u_1 x^{M-1} + u_2 x^{M-2} + \ldots + u_M$$

arranged in order of descending exponents, u_1, u_2, ..., u_M. The polynomial has order M-1 and positive integer exponents.

Inputs to the block represent the polynomial coefficients as shown in the previous equation. The block always treats length-M unoriented vector input as an M-by-1 matrix.

The output is a 1-by-N matrix with each column containing the value `1` or `0`. The value `1` indicates that the polynomial in the corresponding column of the input is stable; that is, the magnitudes of all solutions to $f(x) = 0$ are less than 1. The value `0` indicates that the polynomial in the corresponding column of the input might be unstable; that is, the magnitude of at least one solution to $f(x) = 0$ is greater than or equal to 1.

Applications

This block is most commonly used to check the pole locations of the denominator polynomial, $A(z)$, of a transfer function, $H(z)$.

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}}{a_1 + a_2 z^{-1} + \ldots + a_n z^{-(n-1)}}$$

The poles are the n-1 roots of the denominator polynomial, $A(z)$. When any poles are located outside the unit circle, the transfer function $H(z)$ is unstable. As is typical in DSP applications, the transfer function above is specified in descending powers of z^{-1} rather than z.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Block outputs are always Boolean.

Pseudoinverse

Compute Moore-Penrose pseudoinverse of matrix

Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

`dspinverses`

Description

The Pseudoinverse block computes the Moore-Penrose pseudoinverse of input matrix A.

```
[U,S,V] = svd(A,0)       % Equivalent MATLAB code
```

The pseudoinverse of A is the matrix $A^{\dagger}$ such that

$$A^{\dagger} = VS^{\dagger}U^{*}$$

where U and V are orthogonal matrices, and S is a diagonal matrix. The pseudoinverse has the following properties:

- $AA^{\dagger} = (AA^{\dagger})^{*}$
- $A^{\dagger}A = (A^{\dagger}A)^{*}$
- $AA^{\dagger}A = A$
- $A^{\dagger}AA^{\dagger} = A^{\dagger}$

Parameters

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- `0` — The pseudoinverse calculation converges.
- `1` — The pseudoinverse calculation does not converge.

If the pseudoinverse calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time. For this block, the simulation speed in this mode is faster than in `Code generation`.
- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but the simulation speed increases with subsequent simulations.

Pulse Shaping Filter

Design pulse shaping filter

Note: The Pulse Shaping Filter block has been removed from DSP System Toolbox block library. Existing instances of the Pulse Shaping Filter block will continue to operate. For new models, use the Raised Cosine Receive Filter and Raised Cosine Transmit Filter blocks from the Communications System Toolbox library. These blocks replace the functionality of Pulse Shaping Filter block, when **Filter Type** is set to `Decimator` and `Interpolator`, respectively.

Library

Filtering / Filter Designs

`dspfdesign`

Description

This block brings the filter design capabilities of the `filterBuilderfilterBuilder` function to the Simulink environment.

Dialog Box

See "Pulse-shaping Filter Design —Main Pane" on page 5-797 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

View filter response

This button opens the Filter Visualization Tool (`fvtool`) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

Filter Specifications

In this group, you specify the shape and length of the filter.

Pulse shape

Select the shape of the impulse response from the following options:

- `Raised Cosine`
- `Square Root Raised Cosine`
- `Gaussian`

Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- `Minimum`— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- `Specify order`—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be `Order+1` .
- `Specify symbols`—This option enables the user to specify the length of the impulse response in an alternative manner. If `Specify symbols` is chosen, the **Order** input box changes to the **Number of symbols** input box.

Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response.

If **Order** is specified in **Number of symbols**, the filter length will be **Number of symbols*Samples per symbol**+1. The product **Number of symbols*Samples per symbol** must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols*Samples per symbol** must be an even number. The filter length will be **Number of symbols*Samples per symbol**+1.

Frequency specifications

In this group, you specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

`Rolloff factor`

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

`Frequency units`

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`

For a Gaussian pulse shape, the available frequency specifications are:

`Bandwidth-time product`

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (`BT`) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

`Frequency units`

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`

Magnitude specifications

If the **Order mode** is specified as `minimum`, the magnitude units may be selected from:

- `dB` — Specify the magnitude in decibels (default).
- `Linear` — Specify the magnitude in linear units.

Algorithm

The only design method available for FIR pulse-shaping filters is the window method.

Filter Implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. FIR filters use direct-form structure.

Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of n unit delays with a single delay by n.
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for**

filter customization parameters. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed – see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the sample rate of the input.
- `Allow multirate processing` — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

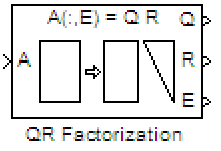
Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Introduced in R2009b

QR Factorization

Factor arbitrary matrix into unitary and upper triangular components



Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`

Description

The QR Factorization block uses a sequence of Householder transformations to triangularize the input matrix A. The block factors a column permutation of the M-by-N input matrix A as
$A_e = QR$

The column-pivoted matrix A_e contains the columns of A permuted as indicated by the contents of length-N permutation vector E.

```
Ae = A(:,E)     % Equivalent MATLAB code
```

The block selects a column permutation vector E, which ensures that the diagonal elements of matrix R are arranged in order of decreasing magnitude.

$$|r_{i+1,j+1}| < |r_{i,j}| \qquad i = j$$

The size of matrices Q and R depends on the setting of the **Output size** parameter:

- When you select `Economy` for the output size, Q is an M-by-min(M,N) unitary matrix, and R is a min(M,N)-by-N upper-triangular matrix.

```
[Q R E] = qr(A,0)   % Equivalent MATLAB code
```

- When you select `Full` for the output size, Q is an M-by-M unitary matrix, and R is a M-by-N upper-triangular matrix.

```
[Q R E] = qr(A)      % Equivalent MATLAB code
```

The block treats length-M unoriented vector input as an M-by-1 matrix.

QR factorization is an important tool for solving linear systems of equations because of good error propagation properties and the invertability of unitary matrices:
$Q^{-1} = Q'$

where Q' is the complex conjugate transpose of Q.

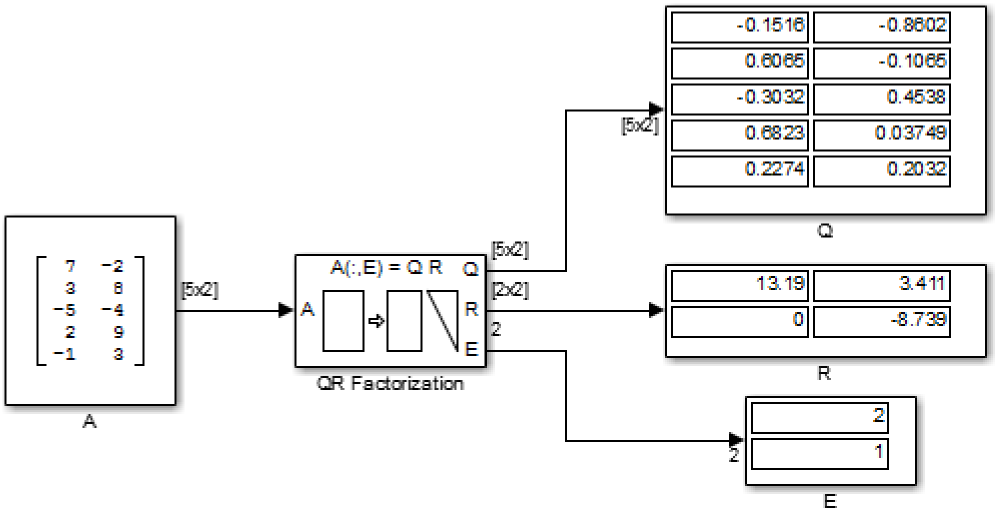
Unlike LU and Cholesky factorizations, the matrix A does not need to be square for QR factorization. However, QR factorization requires twice as many operations as LU Factorization (Gaussian elimination).

Examples

The **Output size** parameter of the QR factorization block has two settings: `Economy` and `Full`. When the M-by-N input matrix A has dimensions such that $M > N$, the dimensions of output matrices Q and R differ depending on the setting of the **Output size** parameter. If, however, the size of the input matrix A is such that $M \leq N$, output matrices Q and R have the same dimensions, regardless of whether the **Output size** is set to `Economy` or `Full`.

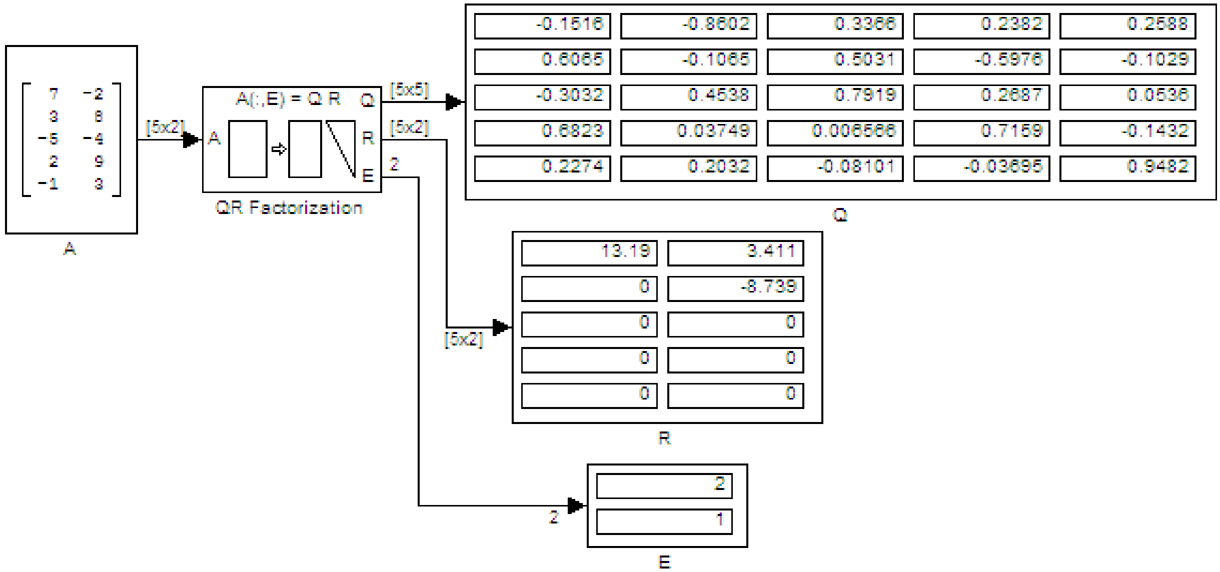
The input to the QR Factorization block in the following model is a `5`-by-`2` matrix A. When you change the setting of the **Output size** parameter from `Economy` to `Full`, the dimensions of the output given by the QR Factorization block also change.

1. Open the model by typing `ex_qrfactorization_ref` at the MATLAB command line.
2. Double-click the QR Factorization block, set the **Output size** parameter to `Economy`, and run the model.



The QR Factorization block outputs a 5-by-2 matrix Q and a 2-by-2 matrix R.

3 Change the **Output size** parameter of the QR Factorization block to `Full` and rerun the model.



The QR Factorization block outputs a 5-by-5 matrix Q and a 5-by-2 matrix R.

Parameters

Output size

Specify the size of output matrices Q and R:

- `Economy` — When this output size is selected, the block outputs an M-by-min(M,N) unitary matrix Q and a min(M,N)-by-N upper-triangular matrix R.
- `Full` — When this output size is selected, the block outputs an M-by-M unitary matrix Q and a M-by-N upper-triangular matrix R.

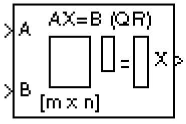
Introduced before R2006a

QR Solver

Find minimum-norm-residual solution to A*X*=B



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The QR Solver block solves the linear system A*X*=B, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying QR factorization to the M-by-N matrix, A, at the `A` port. The input to the `B` port is the right side M-by-L matrix, B. The block treats length-M unoriented vector input as an M-by-1 matrix.

The output at the `X` port is the N-by-L matrix, X. X is chosen to minimize the sum of the squares of the elements of B-AX. When B is a vector, this solution minimizes the vector 2-norm of the residual (B-AX is the residual). When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems $AX_k=B_k$, where B_k is the kth column of B, and X_k is the kth column of *X*.

X is known as the minimum-norm-residual solution to AX=B. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the QR Solver is applied to an underdetermined system, the output *X* is chosen such that the number of nonzero entries in X is minimized.

Algorithm

QR factorization factors a column-permuted variant (A_e) of the M-by-N input matrix A as
$A_e = QR$

where Q is a M-by-min(M,N) unitary matrix, and R is a min(M,N)-by-N upper-triangular matrix.

The factored matrix is substituted for A_e in
$A_e X = B_e$

and
$QRX = B_e$

is solved for X by noting that $Q^{-1} = Q^*$ and substituting $Y = Q^* B_e$. This requires computing a matrix multiplication for Y and solving a triangular system for X.
$RX = Y$

Supported Data Types

Quantizer

Discretize input at specified interval

Library

Quantizers

`dspquant2`

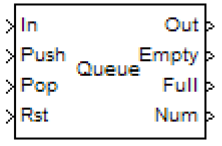
Description

The Quantizer block is an implementation of the Simulink Quantizer block. See Quantizer for more information.

Introduced in R2008a

Queue

Store inputs in FIFO register



Library

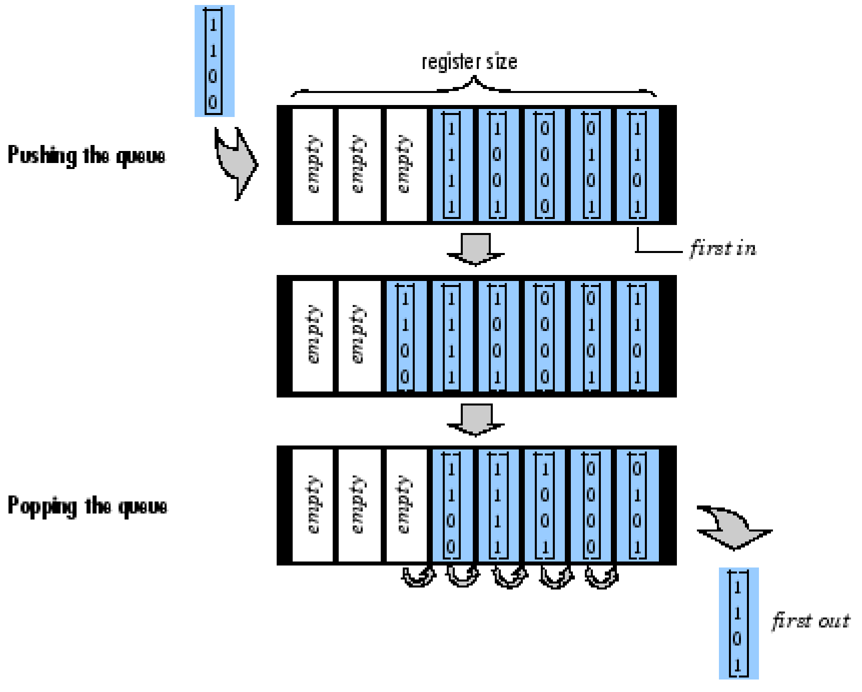
Signal Management / Buffers

`dspbuff3`

Description

The Queue block stores a sequence of input samples in a first in, first out (FIFO) register. The register capacity is set by the **Register size** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the `In` port onto the end of the queue when a trigger event is received at the `Push` port. When a trigger event is received at the `Pop` port, the block *pops* the first element off the queue and holds the `Out` port at that value. The first input to be pushed onto the queue is always the first to be popped off.



A trigger event at the optional `Rst` port empties the queue contents. When you select **Clear output port on reset**, then a trigger event at the `Rst` port empties the queue *and* sets the value at the `Out` port to zero. This setting also applies when a disabled subsystem containing the Queue block is reenabled; the `Out` port value is only reset to zero in this case when you select **Clear output port on reset**.

When you select the **Allow direct feedthrough** check box and two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

1. `Rst`
2. `Push`
3. `Pop`

When you clear the **Allow direct feedthrough** check box and two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

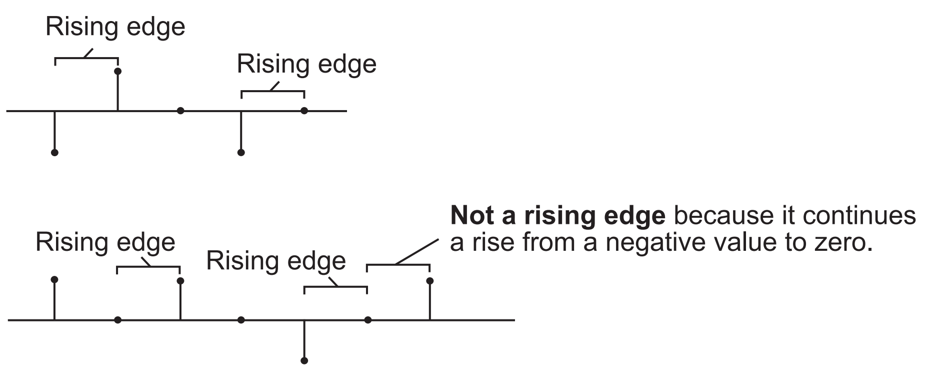
1 `Rst`

2 `Pop`

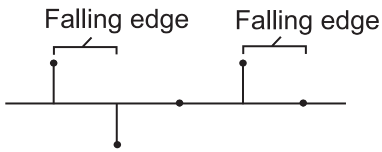
3 `Push`

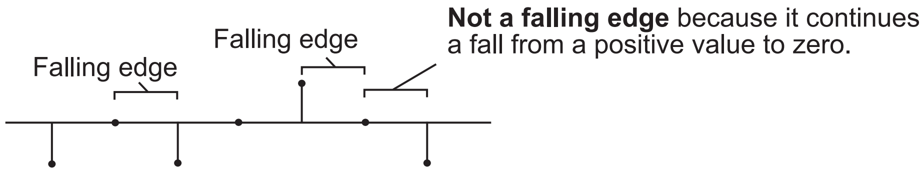
The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the `Push`, `Pop`, `and Rst` ports by the **Trigger type** pop-up menu:

- `Rising edge` — Triggers execution of the block when the trigger input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure



- `Falling edge` — Triggers execution of the block when the trigger input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure





- `Either edge` — Triggers execution of the block when the trigger input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers execution of the block at each sample time that the trigger input is not zero.

Note: If your model contains any referenced models that use a Queue block with the **Push onto full register** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push onto full register** parameter specifies the block's behavior when a trigger is received at the `Push` port but the register is full. The **Pop empty register** parameter specifies the block's behavior when a trigger is received at the `Pop` port but the register is empty. The following options are available for both cases:

- `Ignore` — Ignore the trigger event, and continue the simulation.
- `Warning` — Ignore the trigger event, but display a warning message in the MATLAB Command Window.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Push onto full register** and **Pop empty register** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push onto full register** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the queue at a given time, enable the `Num` output port by selecting the **Show number of register entries port** parameter.

Note: When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Examples

Example 1

The table below illustrates the Queue block's operation for a **Register size** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from `1` to `0` or `0` to `1` in the `Push`, `Pop`, and `Rst` columns below represents a distinct trigger event. A `1` in the `Empty` column indicates an empty queue, while a `1` in the `Full` column indicates a full queue.

In	Push	Pop	Rst	Queue	Out	Empty	Full	Num
1	0	0	0		0	1	0	0
2	1	0	0		0	0	0	1
3	0	0	0		0	0	0	2
4	1	0	0		0	0	0	3
5	0	0	0		0	0	1	4
6	0	1	0		2	0	0	3
7	0	0	0		3	0	0	2

In	Push	Pop	Rst	Queue	Out	Empty	Full	Num
8	0	1	0	top 5 bottom	4	0	0	1
9	0	0	0	top bottom	5	1	0	0
10	1	0	0	top 10 bottom	5	0	0	1
11	0	0	0	top 11 10 bottom	5	0	0	2
12	1	0	1	top 12 bottom	0	0	0	1

Note that at the last step shown, the `Push` and `Rst` ports are triggered simultaneously. The `Rst` trigger takes precedence, and the queue is first cleared and then pushed.

Example 2

The dspqdemo example provides another example of the operation of the Queue block.

Parameters

Register size

The number of entries that the FIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push onto full register

Response to a trigger received at the `Push` port when the register is full. Inputs to this port must have the same built-in data type as inputs to the `Pop` and `Rst` input ports.

When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Pop empty register

Response to a trigger received at the `Pop` port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Rst` input ports.

Show empty register indicator port

Enable the `Empty` output port, which is high (`1`) when the queue is empty, and low (`0`) otherwise.

Show full register indicator port

Enable the `Full` output port, which is high (`1`) when the queue is full, and low (`0`) otherwise. The `Full` port remains low when you select `Dynamic reallocation` from the **Push onto full register** parameter.

Show number of register entries port

Enable the `Num` output port, which tracks the number of entries currently on the queue. When inputs to the `In` port are double-precision values, the outputs from the `Num` port are double-precision values. Otherwise, the outputs from the `Num` port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the `Rst` input port, which empties the queue when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Pop` input ports.

Clear output port on reset

Reset the `Out` port to zero, in addition to clearing the queue, when a trigger is received at the `Rst` input port.

Allow direct feedthrough

When you select this check box, the input data is available immediately at the output port of the block. You can turn off direct feedthrough and delay the input data by an extra frame by clearing the **Allow direct feedthrough** check box.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Push	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports
Pop	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.
Rst	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

Port	Supported Data Types
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Empty	• Double-precision floating point • Boolean
Full	• Double-precision floating point • Boolean
Num	• Double-precision floating point The block outputs a double-precision floating-point value at this port when the data type of the In port is double-precision floating-point. • 32-bit unsigned integers The block outputs a 32-bit unsigned integer value at this port when the data type of the In port is anything other than double-precision floating-point.

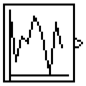
Random Source

Generate randomly distributed values



Library

Sources

`dspsrcs4`

Description

The Random Source block generates a frame of M values drawn from a uniform or Gaussian pseudorandom distribution, where you specify M in the **Samples per frame** parameter.

This reference page contains a detailed discussion of the following Random Source block topics:

- "Distribution Type" on page 2-1446
- "Output Complexity" on page 2-1447
- "Output Repeatability" on page 2-1448
- "Specifying the Initial Seed" on page 2-1449
- "Sample Period" on page 2-1450
- "Parameters" on page 2-1450
- "Supported Data Types" on page 2-1452
- "See Also" on page 2-1453

Distribution Type

When the **Source type** parameter is set to `Uniform`, the output samples are drawn from a uniform distribution whose minimum and maximum values are specified by the **Minimum** and **Maximum** parameters, respectively. All values in this range are equally likely to be selected. A length-N vector specified for one or both of these parameters generates an N-channel output (M-by-N matrix) containing a unique random distribution in each channel.

For example, specify

- **Minimum** = `[ 0 0 -3 -3]`
- **Maximum** = `[10 10 20 20]`

to generate a four-channel output whose first and second columns contain random values in the range [0, 10], and whose third and fourth columns contain random values in the range [-3, 20]. When you specify only one of the **Minimum** and **Maximum** parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

When the **Source type** parameter is set to `Gaussian`, you must also set the **Method** parameter, which determines the method by which the block computes the output, and has the following settings:

- `Ziggurat` — Produces Gaussian random values by using the Ziggurat method.
- `Sum of uniform values` — Produces Gaussian random values by adding and scaling uniformly distributed random signals based on the central limit theorem. This theorem states that the probability distribution of the sum of a sufficiently high number of random variables approaches the Gaussian distribution. You must set the **Number of uniform values to sum** parameter, which determines the number of uniformly distributed random numbers to sum to produce a single Gaussian random value.

For both settings of the **Method** parameter, the output samples are drawn from the normal distribution defined by the **Mean** and **Variance** parameters. A length-N vector specified for one or both of the **Mean** and **Variance** parameters generates an N-channel output (M-by-N frame matrix) containing a distinct random distribution in each column. When you specify only one of these parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

Output Complexity

The block's output can be either real or complex, as determined by the `Real` and `Complex` options in the **Complexity** parameter. These settings control all channels of the output, so real and complex data cannot be combined in the same output. For complex output with a `Uniform` distribution, the real and imaginary components in each channel are both drawn from the same uniform random distribution, defined by the **Minimum** and **Maximum** parameters for that channel.

For complex output with a `Gaussian` distribution, the real and imaginary components in each channel are drawn from normal distributions with different means. In this case, the **Mean** parameter for each channel should specify a complex value; the real component of the **Mean** parameter specifies the mean of the real components in the channel, while the imaginary component specifies the mean of the imaginary components in the channel. When either the real or imaginary component is omitted from the **Mean** parameter, a default value of 0 is used for the mean of that component.

For example, a **Mean** parameter setting of `[5+2i 0.5 3i]` generates a three-channel output with the following means.

Channel 1 mean	*real* = 5	*imaginary* = 2
Channel 2 mean	*real* = 0.5	*imaginary* = 0
Channel 3 mean	*real* = 0	*imaginary* = 3

For complex output, the **Variance** parameter, σ^2, specifies the *total variance* for each output channel. This is the sum of the variances of the real and imaginary components in that channel.

$$\sigma^2 = \sigma_{\mathrm{Re}}^2 + \sigma_{\mathrm{Im}}^2$$

The specified variance is equally divided between the real and imaginary components, so that

$$\sigma_{\mathrm{Re}}^2 = \frac{\sigma^2}{2}$$
$$\sigma_{\mathrm{Im}}^2 = \frac{\sigma^2}{2}$$

Output Repeatability

The **Repeatability** parameter determines whether or not the block outputs the same signal each time you run the simulation. You can set the parameter to one of the following options:

- `Repeatable` — Outputs the same signal each time you run the simulation. The first time you run the simulation, the block randomly selects an initial seed. The block reuses these same initial seeds every time you rerun the simulation.
- `Specify seed` — Outputs the same signal each time you run the simulation. Every time you run the simulation, the block uses the initial seed(s) specified in the **Initial seed** parameter. Also see "Specifying the Initial Seed" on page 2-1449.
- `Not repeatable` — Does not output the same signal each time you run the simulation. Every time you run the simulation, the block randomly selects an initial seed.

Specifying the Initial Seed

When you set the **Repeatability** parameter to `Specify seed`, you must set the **Initial seed** parameter. The **Initial seed** parameter specifies the initial seed for the pseudorandom number generator. The generator produces an identical sequence of pseudorandom numbers each time it is executed with a particular initial seed.

Specifying Initial Seeds for Real Outputs

To specify the N initial seeds for an N-channel real-valued output, **Complexity** parameter set to `Real`, provide one of the following in the **Initial seed** parameter:

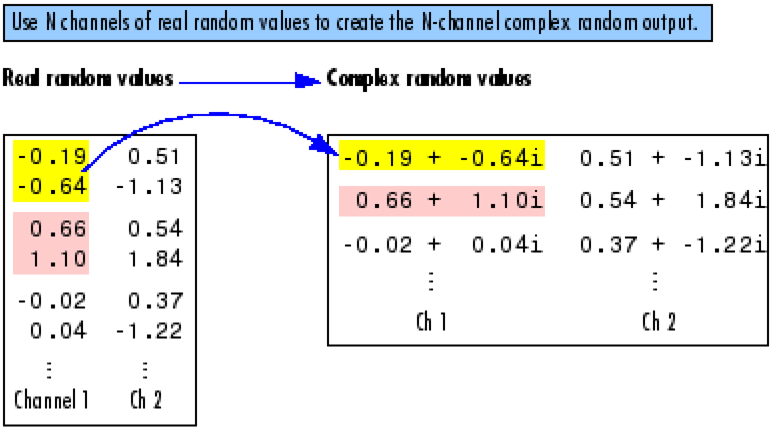
- Length-N vector of initial seeds — Uses each vector element as an initial seed for the corresponding channel in the N-channel output.
- Single scalar — Uses the scalar to generate N random values, which it uses as the seeds for the N-channel output.

Specifying Initial Seeds for Complex Outputs

To specify the initial seeds for an N-channel complex-valued output, **Complexity** parameter set to `Complex`, provide one of the following in the **Initial seed** parameter:

- Length-N vector of initial seeds — Uses each vector element as an initial seed for generating N channels of *real* random values. The block uses pairs of adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.
- Single scalar — Uses the scalar to generate N random values, which it uses as the seeds for generating N channels of *real* random values. The block uses pairs of

adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.



Sample Period

The **Sample time** parameter value, T_s, specifies the random sequence sample period when the **Sample mode** parameter is set to `Discrete`. In this mode, the block generates the number of samples specified by the **Samples per frame** parameter value, M, and outputs this frame with a period of $M*T_s$.

When **Sample mode** is set to `Continuous`, the block is configured for continuous-time operation, and the **Sample time** and **Samples per frame** parameters are disabled. Note that many DSP System Toolbox blocks do not accept continuous-time inputs.

Parameters

Source type

The distribution from which to draw the random values, `Uniform` or `Gaussian`. For more information, see "Distribution Type" on page 2-1446.

Method

The method by which the block computes the Gaussian random values, `Ziggurat` or `Sum of uniform values`. This parameter is enabled when **Source type** is set to `Gaussian`. For more information, see "Distribution Type" on page 2-1446.

Minimum

The minimum value in the uniform distribution. This parameter is enabled when you select `Uniform` from the **Source type** parameter. Tunable (Simulink) in Simulation mode only.

Maximum

The maximum value in the uniform distribution. This parameter is enabled when you select you select `Uniform` from the **Source type** parameter. Tunable (Simulink) in Simulation mode only.

Number of uniform values to sum

The number of uniformly distributed random values to sum to compute a single number in a Gaussian random distribution. This parameter is enabled when the **Source type** parameter is set to `Gaussian`, and the **Method** parameter is set to `Sum of uniform values`. For more information, see "Distribution Type" on page 2-1446.

Mean

The mean of the Gaussian (normal) distribution. This parameter is enabled when you select `Gaussian` from the **Source type** parameter. Tunable (Simulink) in Simulation mode only.

Variance

The variance of the Gaussian (normal) distribution. This parameter is enabled when you select `Gaussian` from the **Source type** parameter. Tunable (Simulink) in Simulation mode only.

Repeatability

The repeatability of the block output: `Not repeatable`, `Repeatable`, or `Specify seed`. In the `Repeatable` and `Specify seed` settings, the block outputs the same signal every time you run the simulation. For details, see "Output Repeatability" on page 2-1448.

Initial seed

The initial seed(s) to use for the random number generator when you set the **Repeatability** parameter to `Specify seed`. For details, see "Specifying the Initial Seed" on page 2-1449. Tunable (Simulink) in Simulation mode only.

Inherit output port attributes

When you select this check box, block inherits the sample mode, sample time, output data type, complexity, and signal dimensions of the signal from the downstream block. When you select this check box, the **Sample mode**, **Sample time**, **Samples per frame**, **Output data type**, and **Complexity** parameters are disabled.

Suppose you want to back propagate a 1-D vector. The output of the Random Source block is a 1-D vector of length M, where length M is inherited from the downstream block. When the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter specifies N channels, the 1-D vector output contains M/N samples from each channel. An error occurs in this case when M is not an integer multiple of N.

Suppose you want to back propagate a M-by-N signal. When N>1, your signal has N channels. When N = 1, your signal has M channels. The value of the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter can be a scalar or a vector of length equal to the number of channels. You can specify these parameters as either row or column vectors, except when the signal is a row vector. In this case, the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter must also be specified as a row vector.

Sample mode

The sample mode, `Continuous` or `Discrete`. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Sample time

The sample period, T_s, of the random output sequence. The output frame period is $M*T_s$. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Samples per frame

The number of samples, M, in each output frame.

This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Output data type

The data type of the output, single-precision or double-precision. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Complexity

The complexity of the output, `Real` or `Complex`. This parameter is enabled when the **Inherit output port attributes** check box is cleared.

Supported Data Types

- Double-precision floating-point
- Single-precision floating-point

Real Cepstrum

Compute real cepstrum of input

Library

Transforms

`dspxfrm3`

Description

The Real Cepstrum block computes the real cepstrum of each column in the real-valued M-by-N input matrix, `u`. The block treats each column of the input as an independent channel containing M consecutive samples. The block *always* processes unoriented vector inputs as a single channel, and returns the result as a length-M column vector. The block does not accept complex-valued inputs.

The output is a real M_o-by-N matrix, where you specify M_o in the **FFT length** parameter. Each output column contains the length-M_o real cepstrum of the corresponding input column.

```
y = real(ifft(log(abs(fft(u,Mo)))))
```

or, more compactly,

```
y = rceps(u,Mo)
```

When you select the **Inherit FFT length from input port dimensions** check box, the output frame size matches the input frame size (M_o=M).

The output port rate is the same as the input port rate.

Parameters

Inherit FFT length from input port dimensions

When you select this check box, the output frame size matches the input frame size.

FFT length

The number of frequency points at which to compute the FFT, which is also the output frame size, M_o. This parameter is visible only when you clear the **Inherit FFT length from input port dimensions** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

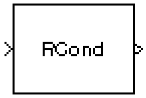
Reciprocal Condition

Compute reciprocal condition of square matrix in 1-norm



Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Reciprocal Condition block computes the reciprocal of the condition number for a square input matrix A.

```
y = rcond(A)     % Equivalent MATLAB code
```

or

$$y = \frac{1}{\kappa} = \frac{1}{\|A^{-1}\|_1 \|A\|_1}$$

where κ is the condition number ($\kappa \geq 1$), and y is the scalar output ($0 \leq y < 1$).

The matrix 1-norm, $\|A\|_1$, is the maximum column-sum in the M-by-M matrix A.

$$\|A\|_1 = \max_{1 \leq j \leq M} \sum_{i=1}^{M} |a_{ij}|$$

For a 3-by-3 matrix:

Repeat

Resample input at higher rate by repeating values

Library

Signal Operations

`dspsigops`

Description

The Repeat block upsamples each channel of the M_i-by-N input to a rate L times higher than the input sample rate. To do so, the block repeats each consecutive input sample L times at the output. You specify the integer L in the **Repetition count** parameter.

You can use the Repeat block inside of triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame *size* than the input. The block upsamples each channel independently by repeating each row of the input matrix L times at the output. For upsampling by a factor of L, the output frame size is L times larger than the input frame size ($M_o = M_i*L$), but the input and output frame rates are equal.

For an example of single-rate upsampling, see Example: Single-Rate Processing.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-N matrix input as N independent channels. The block generates the output at the faster (upsampled) rate by using a proportionally shorter frame *period* at the output port than at the input port. For L repetitions of the input, the output frame period is L times shorter than the input frame period ($T_{fo} = T_{fi}/L$). In this mode, the output always has the same frame size as the input.

  See Example: Multirate, Frame-Based Processing for an example that uses the Repeat block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M*N$ independent channels, and upsamples each channel over time. The block upsamples each channel over time such that the output sample rate is L times higher than the input sample rate ($T_{so} = T_{si}/L$). In this mode, the output is always the same size as the input.

Zero Latency

The Repeat block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Repetition count** parameter to `1` or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Repeat block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block repeats the first input (received at t=**0**) for the first L output samples, the second input for the next L output samples, and so on.

Nonzero Latency

The Repeat block has tasking latency for multirate, multitasking operation:

- In multirate, sample-based processing mode, the initial condition for each channel is repeated for the first L output samples. The channel's first input appears as output sample L+1. The **Initial conditions** parameter can be an M_i-by-N matrix containing one value for each channel, or a scalar to be applied to all signal channels.

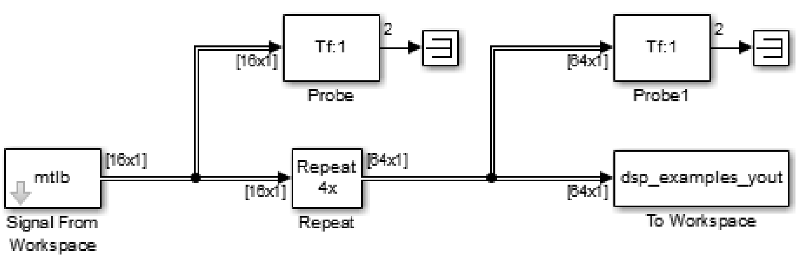
- In multirate, frame-based processing mode, the first row of the initial condition matrix is repeated for the first L output samples, the second row of the initial condition matrix is repeated for the next L output samples, and so on. The first row of the first input matrix appears in the output as sample M_iL+1. The **Initial conditions** parameter can be an M_i-by-N matrix, or a scalar to be repeated across all elements of the M_i-by-N matrix.

Note: For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Examples

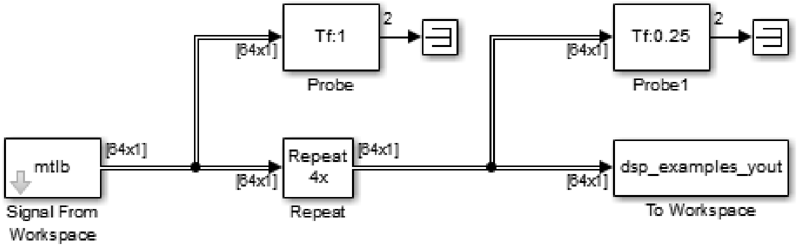
Example: Single-Rate Processing

In the ex_repeat_ref2 model, the Repeat block resamples a single-channel input with a frame size of 16. The block repeats input values to upsample the input by a factor of 4. Thus, the output of the block has a frame size of 64. The input and output frame rates are identical.



Example: Multirate, Frame-Based Processing

In the ex_repeat_ref1 model, the Repeat block resamples a single-channel input with a frame period of 1 second. The block repeats input values to upsample the input by a factor of 4. Thus, the output of the block has a frame period of 0.25 seconds. The input and output frame sizes are identical.



Parameters

Repetition count

The integer number of times, L, that the input value is repeated at the output. This is the factor by which the block increases the output frame size or sample rate.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of L. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is L times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency; a scalar or matrix. This parameter appears only when you configure the block to perform multirate processing.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Repeat.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

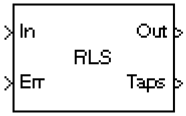
`Upsample`	DSP System Toolbox

Introduced before R2006a

RLS Adaptive Filter (Obsolete)

Compute filter estimates for input using RLS adaptive filter algorithm



Library

`dspobslib`

Description

Note The RLS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `RLS Filter` block.

The RLS Adaptive Filter block recursively computes the recursive least squares (RLS) estimate of the FIR filter coefficients.

The corresponding RLS filter is expressed in matrix form as

$$
\begin{aligned}
k(n) &= \frac{\lambda^{-1}P(n-1)u(n)}{1+\lambda^{-1}u^{H}(n)P(n-1)u(n)} \\
y(n) &= \hat{w}^{H}(n-1)u(n) \\
e(n) &= d(n)-y(n) \\
\hat{w}(n) &= \hat{w}(n-1)+k(n)e^{*}(n) \\
P(n) &= \lambda^{-1}P(n-1)-\lambda^{-1}k(n)u^{H}(n)P(n-1)
\end{aligned}
$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows

Variable	Description
n	The current algorithm iteration
$u(n)$	The buffered input samples at step n
$P(n)$	The inverse correlation matrix at step n
$k(n)$	The gain vector at step n
$\hat{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The exponential memory weighting factor

The block icon has port labels corresponding to the inputs and outputs of the RLS algorithm. Note that inputs to the `In` and `Err` ports must be sample-based scalars. The signal at the `Out` port is a scalar, while the signal at the `Taps` port is a sample-based vector.

Block Ports	Corresponding Variables
`In`	u, the scalar input, which is internally buffered into the vector $u(n)$
`Out`	$y(n)$, the filtered scalar output
`Err`	$e(n)$, the scalar estimation error
`Taps`	$\hat{w}(0)$, the vector of filter-tap estimates

An optional `Adapt` input port is added when you select the **Adapt input** check box in the dialog box. When this port is enabled, the block continuously adapts the filter coefficients while the `Adapt` input is nonzero. A zero-valued input to the `Adapt` port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero `Adapt` input.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse correlation matrix $P(n)$. This decreases the total number of computations by a factor of two.

The **FIR filter length** parameter specifies the length of the filter that the RLS algorithm estimates. The **Memory weighting factor** corresponds to λ in the equations, and specifies how quickly the filter "forgets" past sample information. Setting λ=1 specifies an infinite memory; typically, $0.95 \le \lambda \le 1$.

The **Initial value of filter taps** specifies the initial value $\hat{w}(0)$ as a vector, or as a scalar to be repeated for all vector elements. The initial value of $P(n)$ is

$$I\frac{1}{\hat{\sigma}^2}$$

where you specify $\hat{\sigma}^2$ in the **Initial input variance estimate** parameter.

Examples

The rlsdemo example illustrates a noise cancellation system built around the RLS Adaptive Filter block.

Parameters

FIR filter length

The length of the FIR filter.

Memory weighting factor

The exponential weighting factor, in the range `[0,1]`. A value of `1` specifies an infinite memory. Tunable (Simulink).

Initial value of filter taps

The initial FIR filter coefficients.

Initial input variance estimate

The initial value of 1/P(n).

Adapt input

Enables the `Adapt` port.

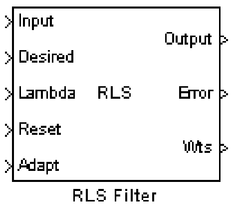
RLS Filter

Compute filtered output, filter error, and filter weights for given input and desired signal using RLS adaptive filter algorithm



Library

Filtering / Adaptive Filters

`dspadpt3`

Description

The RLS Filter block recursively computes the least squares estimate (RLS) of the FIR filter weights. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The corresponding RLS filter is expressed in matrix form as

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1+\lambda^{-1}\mathbf{u}^{H}(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$
$$y(n) = \mathbf{w}(n-1)\mathbf{u}(n)$$
$$e(n) = d(n) - y(n)$$
$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}^{H}(n)e(n)$$
$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^{H}(n)\mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{P}(n)$	The inverse covariance matrix at step n
$\mathbf{k}(n)$	The gain vector at step n
$\mathbf{w}(n)$	The vector of filter-tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse covariance matrix $P(n)$. This decreases the total number of computations by a factor of two.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Forgetting factor (0 to 1)** parameter corresponds to λ in the equations. It specifies how quickly the filter "forgets" past sample information. Setting λ=1 specifies an infinite memory. Typically, $1-\frac{1}{2L}<\lambda<1$, where L is the filter length. You can specify a forgetting factor using the input port, Lambda, or enter a value in the **Forgetting factor (0 to 1)** parameter in the Block Parameters: RLS Filter dialog box.

Enter the initial filter weights, $\widehat{w}(0)$, as a vector or a scalar for the **Initial value of filter weights** parameter. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

The initial value of $P(n)$ is

$$\frac{1}{\sigma^2} I$$

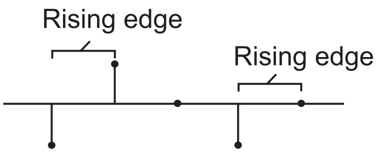
where you specify σ^2 in the **Initial input variance estimate** parameter.

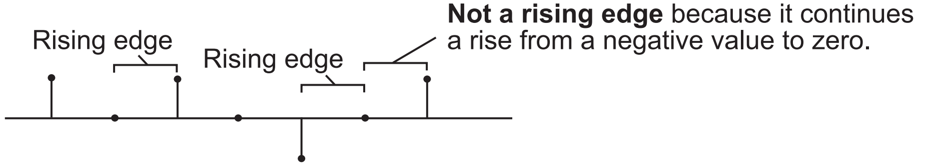
When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

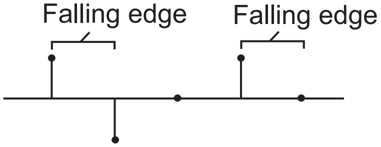
From the **Reset input** list, select `None` to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

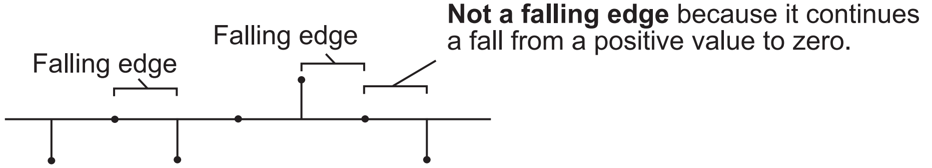
- `Rising edge` — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure





- `Falling edge` — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure





- `Either edge` — Triggers a reset operation when the Reset input is a `Rising edge` or `Falling edge`, as described above
- `Non-zero sample` — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

Examples

The rlsdemo example illustrates a noise cancellation system built around the RLS Filter block.

Parameters

Filter length

Enter the length of the FIR filter weights vector.

Specify forgetting factor via

Select `Dialog` to enter a value for the forgetting factor in the Block parameters: RLS Filter dialog box. Select `Input port` to specify the forgetting factor using the Lambda input port.

Forgetting factor (0 to 1)

Enter the exponential weighting factor in the range $0 \leq \lambda \leq 1$. A value of `1` specifies an infinite memory. Tunable (Simulink).

Initial value of filter weights

Specify the initial values of the FIR filter weights.

Initial input variance estimate

The initial value of $1/P(n)$.

Adapt port

Select this check box to enable the Adapt input port.

Reset input

Select this check box to enable the Reset input port.

Output filter weights

Select this check box to export the filter weights from the Wts port.

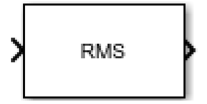
RMS

Root mean square value of input or sequence of inputs
Library: DSP System Toolbox / Statistics



Description

The RMS block computes the root mean square (RMS) value of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the RMS value of the entire input. You can specify the dimension using the **Find the RMS value over** parameter. The RMS block can also track the RMS value in a sequence of inputs over a period of time. To track the RMS value in a sequence of inputs, select the **Running RMS** parameter.

Note: The **Running** mode in the RMS block will be removed in a future release. To compute the running RMS in Simulink, use the `Moving RMS` block instead.

Ports

Input

`In` — Data input
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running RMS** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double`
Complex Number Support: Yes

`Rst` — Reset port
scalar

Specify the reset event that causes the block to reset the running RMS. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running RMS** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — RMS value along the specified dimension

scalar | vector | matrix | *N*-D array

The data type of the output matches the data type of the input.

When you do not select the **Running RMS** parameter, the block computes the RMS value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the RMS value of the entire input at each individual sample time. Each element in the output array `y` is the RMS value of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the RMS value over** parameter. Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the RMS value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the RMS value of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the RMS value of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the RMS value of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

  In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an M-by-N matrix containing the RMS value of each vector over the third dimension of the input.

When you select **Running RMS**, the block tracks the RMS value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each element y_{ijk} of the output contains the RMS value of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running RMS y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the RMS value of the elements in the jth column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double`

Parameters

Main Tab

`Running RMS` — Option to select running RMS

off (default) | on

When you select the **Running RMS** parameter, the block tracks the RMS value of each channel in a time sequence of inputs.

`Find the RMS value over` — Dimension over which the block computes the RMS value
`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the RMS value over each column.
- `Each row` — The block outputs the RMS value over each row.
- `Entire input` — The block outputs the RMS value over the entire input.
- `Specified dimension` — The block outputs the RMS value over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running RMS** parameter.

`Dimension` — Custom dimension
`1` (default) | scalar

Specify the dimension (one-based value) of the input signal over which the RMS value is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the RMS value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the RMS value of the elements in the jth column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the RMS value of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running RMS y_{ijk} in the current frame is reset to the element u_{ijk}.

  Variable-Size Inputs

  When your inputs are of variable size, and you select the **Running RMS** parameter, then:

  - If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
  - If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
    - When the input size difference is in the number of channels (number of columns), the state is reset.
    - When the input size difference is in the length of channels (number of rows), there is no reset and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running RMS** parameter.

`Reset port` — Reset event

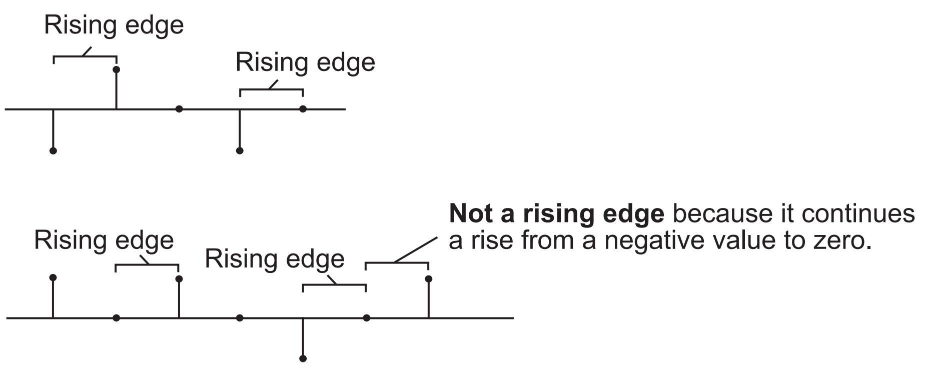
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

The block resets the running RMS whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

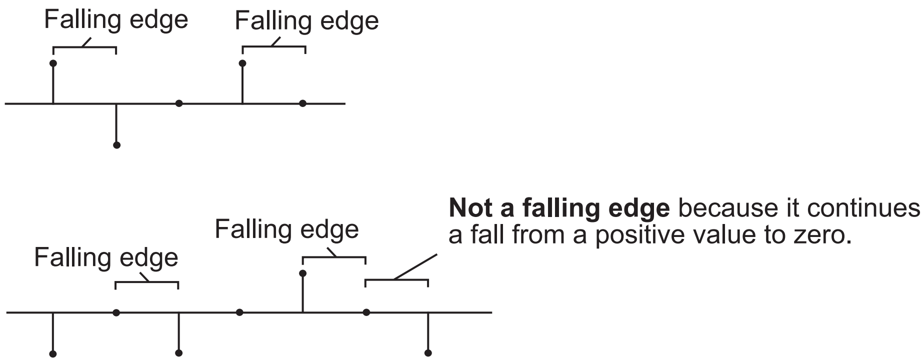
When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running RMS for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note: When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Dependencies

To enable this parameter, select the **Running RMS** parameter.

Definitions

Root Mean Square (RMS)

The RMS value of a discrete-time signal is the square root of the arithmetic mean of the squares of the signal sample values.

For an M-by-N input matrix u, the RMS value of the jth column of the input is given by:

$$y_j = \sqrt{\frac{\sum_{i=1}^{M} |u_{ij}|^2}{M}} \qquad 1 \le j \le N$$

Algorithms

Root Mean Square (RMS)

When you clear the **Running RMS** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `rms` function, when it is called as `y = rms(u,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the RMS value.

The RMS value along the entire input is identical to calling the `rms` function as `y = rms(u(:))`.

When inputs are complex, the block computes the RMS value of the magnitude of the complex input.

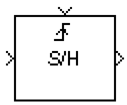
Sample and Hold

Sample and hold input signal



Library

Signal Operations

`dspsigops`

Description

The Sample and Hold block acquires the input at the signal port whenever it receives a trigger event at the trigger port (marked by). The block then holds the output at the acquired input value until the next triggering event occurs.

The trigger input must be a sample-based scalar with sample rate equal to the input frame rate at the signal port. You specify the trigger event using the **Trigger type** parameter:

- `Rising edge` triggers the block to acquire the signal input when the trigger input rises from a negative value or zero to a positive value.
- `Falling edge` triggers the block to acquire the signal input when the trigger input falls from a positive value or zero to a negative value.
- `Either edge` triggers the block to acquire the signal input when the trigger input either rises from a negative value or zero to a positive value or falls from a positive value or zero to a negative value.

You specify the block's output prior to the first trigger event using the **Initial condition** parameter. When the acquired input is an M-by-N matrix, the **Initial condition** can be an M-by-N matrix, or a scalar to be repeated across all elements of the matrix. When the input is a length-M unoriented vector, the **Initial condition** can be a length-M row or column vector, or a scalar to be repeated across all elements of the vector.

If you select the **Latch (buffer) input** check box, the block outputs the value of the input from the previous time step until the next triggering event occurs. To use this block in a loop, select this check box.

Parameters

Trigger type

The type of event that triggers the block to acquire the input signal.

Initial condition

The block's output prior to the first trigger event.

Latch (buffer) input

If you select this check box, the block outputs the value of the input from the previous time step until the next triggering event occurs.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Trigger	• Any data type supported by the Trigger block
Outputs	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

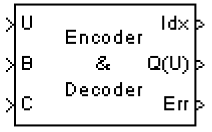
Scalar Quantizer (Obsolete)

Convert input signal into set of quantized output values or index values, or convert set of index values into quantized output signal



Library

dspobslib

Description

Note The Scalar Quantizer block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `Scalar Quantizer Encoder` block or the `Scalar Quantizer Decoder` block.

The Scalar Quantizer block has three modes of operation. In `Encoder` mode, the block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the index of the associated region. In `Decoder` mode, the block transforms the input index values into quantized output values, defined in the **Codebook** parameter. In the `Encoder and Decoder` mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

You can select how you want to enter the **Boundary points** and/or **Codebook** values using the **Source of quantizer** parameters. When you select `Specify via dialog`, type the parameters into the block parameters dialog box. Select `Input ports`, and port B and/or C appears on the block. In `Encoder` and `Encoder and decoder` mode, the input to port B is used as the **Boundary points**. In `Decoder` and `Encoder and decoder` mode, the input to port C is used as the **Codebook**.

In `Encoder` and `Encoder and decoder` mode, the **Boundary points** are the values used to break up the input signal into regions. Each region is specified by an index number. When your first boundary point is `-inf` and your last boundary point is `inf`, your quantizer is unbounded. When your first and last boundary point is finite, your quantizer is bounded. When only your first or last boundary point is `-inf` or `inf`, your quantizer is semi-bounded.

For instance, when your input signal ranges from 0 to 11, you can create a bounded quantizer using the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The boundary points can have equal or varied spacing. Any input values between 0 and 0.5 would correspond to index 0. Input values between 0.5 and 3.7 would correspond to index 1, and so on.

Suppose you wanted to create an unbounded quantizer with the following boundary points:

```
[-inf 0 2 5.5 7.1 10 inf]
```

When your input signal has values less than 0, these values would be assigned to index 0. When your input signal has values greater than 10, these values would be assigned to index 6.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter defines the index to which the value is assigned. When you want the input value to be assigned to the lower index value, select `Choose the lower index`. To assign the input value with the higher index, select `Choose the higher index`.

In `Decoder` and `Encoder and decoder` mode, the **Codebook** is a vector of quantized output values that correspond to each index value.

In `Encoder` and `Encoder and decoder` mode, the **Searching method** determines how the appropriate quantizer index is found. Select `Linear` and the Scalar Quantizer block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P, where P is the number of boundary points.

Select Binary for the **Searching method** and the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the Binary option is faster than the Linear option.

In Decoder mode, the input to this block is a vector of index values, where $0 \leq$ index $< N$ and N is the length of the codebook vector. Use the **Action for out of range input** parameter to determine what happens when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N -1, select Clip. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to N -1, select Clip and warn. When you want the simulation to stop and display an error when the index values are out of range, select Error.

In Encoder and decoder mode, you can select the **Output the quantization error** check box. The quantization error is the difference between the input value and the quantized output value. Select this check box to output the quantization error for each input value from the Err port on this block.

Data Type Support

In Encoder mode, the input data values and the boundary points can be the input to the block at ports U and B. Similarly, in Encoder and decoder mode, the codebook values can also be the input to the block at port C. The data type of the input data values, boundary points, and codebook values can be double, single, uint8, uint16, uint32, int8, int16, or int32. In Decoder mode, the input to the block can be the index values and the codebook values. The data type of the index input to the block at port Idx can be uint8, uint16, uint32, int8, int16, or int32. The data type of the codebook values can be double, single, uint8, uint16, uint32, int8, int16, or int32.

In Encoder mode, the output of the block is the index values. In Encoder and decoder mode, the output can also include the quantized output values and the quantization error. In Encoder and Encoder and decoder mode, use the **Output index data type** parameter to specify the data type of the index output from the block at port Idx. The data type of the index output can be uint8, uint16, uint32, int8, int16, or int32. The data type of the quantized output and the quantization error can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In `Decoder` mode, the output of the block is the quantized output values. Use the **Output data type** parameter to specify the data type of the quantized output values. The data type can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`.

Note The input data, codebook values, boundary points, quantization error, and the quantized output values must have the same data type whenever they are present in any of the quantizer modes.

Parameters

Quantizer mode

Specify `Encoder`, `Decoder`, or `Encoder and decoder` as a mode of operation.

Source of quantizer parameters

Choose `Specify via dialog` to type the parameters into the block parameters dialog box. Select `Input ports` to specify the parameters using the block's input ports. In `Encoder` and `Encoder and decoder` mode, input the **Boundary points** using port B. In `Decoder` and `Encoder and decoder` mode, input the **Codebook** values using port C.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. Tunable (Simulink).

Codebook

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

Searching method

Select `Linear` and the block finds the region in which the input value is located using a linear search. Select `Binary` and the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower index value. When you select `Choose the higher index`, the value is assigned to the higher index.

Action for out of range input

Choose the block's behavior when an input index value is out of range, where 0 ≤ index <*N* and *N* is the length of the codebook vector. Select `Clip`, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to *N* to be set to *N* -1. Select `Clip and warn`, when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to *N* are set to *N* -1. Select `Error`, when you want the simulation to stop and display an error when the index values are out of range.

Output the quantization error

In `Encoder and decoder` mode, select this check box to output the quantization error from the Err port on this block.

Output index data type

In `Encoder` and `Encoder and decoder` mode, specify the data type of the index output from the block at port Idx. The data type can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. This parameter becomes visible when you select the **Show additional parameters** check box.

Output data type

In `Decoder` mode, specify the data type of the quantized output. The data type can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`, `single`, or `double`. This parameter becomes visible when you select `Specify via dialog` for the **Source of quantizer parameters** and you select the **Show additional parameters** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers

- 8-, 16-, and 32-bit unsigned integers

For more information on what data types are supported for each quantizer mode, see "Data Type Support" on page 2-1488.

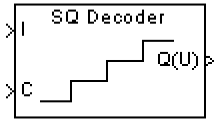
Introduced in R2008b

Scalar Quantizer Decoder

Convert each index value into quantized output value



Scalar Quantizer Decoder

Library

Quantizers

`dspquant2`

Description

The Scalar Quantizer Decoder block transforms the zero-based input index values into quantized output values. The set of all possible quantized output values is defined by the **Codebook values** parameter.

Use the **Codebook values** parameter to specify a matrix containing all possible quantized output values. You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, type the codebook values into the block parameters dialog box. When you select `Input port`, port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The input to this block is a vector of integer index values, where $0 \leq \text{index} < N$ and N is the number of distinct codeword vectors in the codebook matrix. Use the **Action for out of range index value** parameter to determine what happens when an input index value is outside this range. When you want any index value less than 0 to be set to 0 and any index value greater than or equal to N to be set to N -1, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

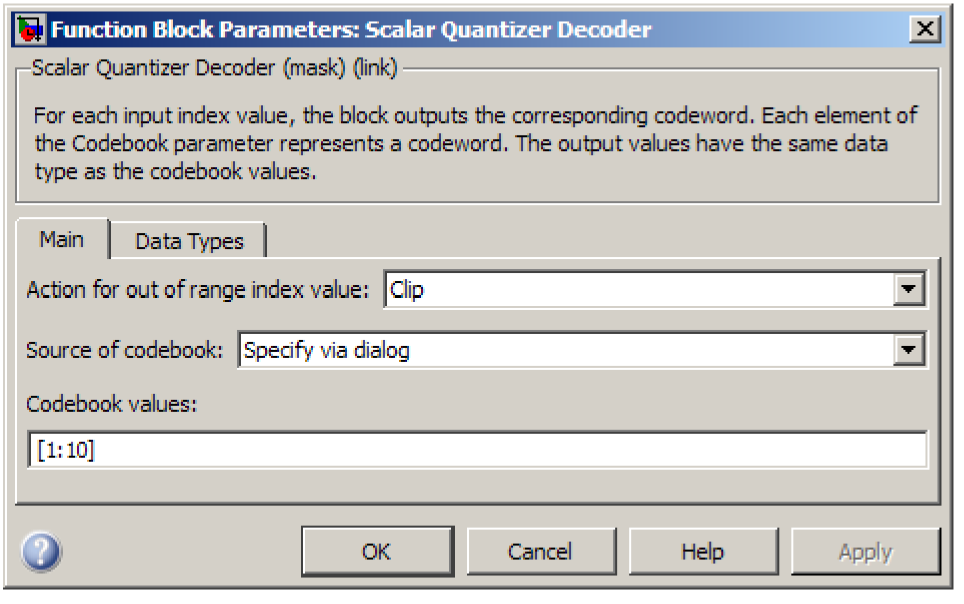
Data Type Support

The data type of the index values input at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values input at port C can be `double`, `single`, or Fixed-point.

The output of the block is the quantized output values. If, for the **Source of codebook** parameter, you select `Specify via dialog`, the **Codebook and output data type** parameter appears. You can use this parameter to specify the data type of the codebook and quantized output values. In this case, the data type of the output values can be `Same as input`, `double`, `single`, `Fixed-point`, or `User-defined`. If, for the **Source of codebook** parameter you select `Input port`, the quantized output values have the same data type as the codebook values input at port C.

Dialog Box

The **Main** pane of the Scalar Quantizer Decoder block dialog appears as follows.



Action for out of range index value

Use this parameter to determine the block's behavior when an input index value is out of range, where $0 \leq$ index $< N$ and N is the length of the codebook vector. Select `Clip`, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N -1. Select `Clip and warn`, when you want to be warned when clipping occurs. Select `Error`, when you want the simulation to stop and the block to display an error when the index values are outside the range.

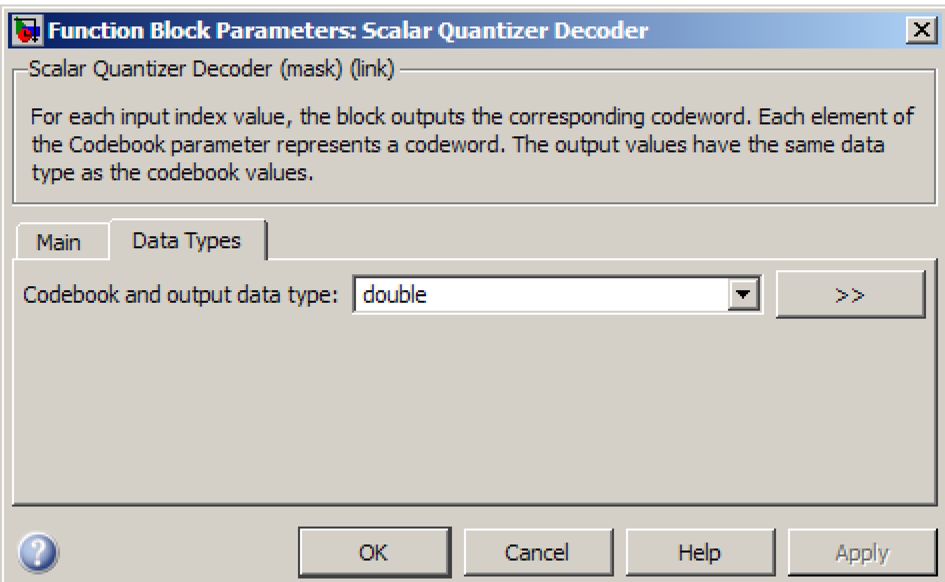
Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook using input port C.

Codebook values

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

The **Data Types** pane of the Scalar Quantizer Decoder block dialog appears as follows.



Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.

- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

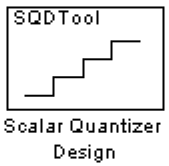
Scalar Quantizer Design

Start Scalar Quantizer Design Tool (SQDTool) to design scalar quantizer using Lloyd algorithm



Library

Quantizers

`dspquant2`

Description

Double-click on the Scalar Quantizer Design block to start SQDTool, a GUI that allows you to design and implement a scalar quantizer. Based on your input values, SQDTool iteratively calculates the codebook values that minimize the mean squared error until the stopping criteria for the design process is satisfied. The block uses the resulting quantizer codebook values and boundary points to implement your scalar quantizer encoder and/or decoder.

For the **Training Set** parameter, enter a set of observations, or samples, of the signal you want to quantize. This data can be any variable defined in the MATLAB workspace including a variable created using a MATLAB function, such as the default value `randn(10000,1)`.

You have two choices for the **Source of initial codebook** parameter. Select `Auto-generate` to have the block choose the values of the initial codebook vector. In this case, the minimum training set value becomes the first codeword, and the maximum training set value becomes the last codeword. Then, the remaining initial codewords are equally spaced between these two values to form a codebook vector of length N, where N is the **Number of levels** parameter. When you select `User defined`, enter the initial codebook values in the **Initial codebook** field. Then, set the **Source**

of initial boundary points parameter. You can select `Mid-points` to locate the boundary points at the midpoint between the codewords. To calculate the mid-points, the block internally arranges the initial codebook values in ascending order. You can also choose `User defined` and enter your own boundary points in the **Initial boundary points (unbounded)** field. Only one boundary point can be located between two codewords. When you select `User defined` for the **Source of initial boundary points** parameter, the values you enter in the **Initial codebook** and **Initial boundary points (unbounded)** fields must be arranged in ascending order.

Note This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary points are always `-inf` and `inf` regardless of any other boundary point values you might enter.

After you have specified the quantization parameters, the block performs an iterative process to design the optimal scalar quantizer. Each step of the design process involves using the Lloyd algorithm to calculate codebook values and quantizer boundary points. Then, the block calculates the squared quantization error and checks whether the stopping criteria has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared quantization error is below a certain value, select `Relative threshold`. Then, for **Relative threshold**, type the maximum acceptable fractional drop. When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter a **Relative threshold** and **Maximum iteration** value. The block stops iterating as soon as one of these conditions is satisfied.

With each iteration, the block quantizes the training set values based on the newly calculated codebook values and boundary points. When the training point lies on a boundary point, the algorithm uses the **Tie-breaking rules** parameter to determine which region the value is associated with. When you want the training point to be assigned to the lower indexed region, select `Lower indexed codeword`. To assign the training point with the higher indexed region, select `Higher indexed codeword`.

The **Searching methods** parameter determines how the block compares the training points to the boundary points. Select `Linear search` and SQDTool compares each training point to each quantization region sequentially. This process continues until all the training points are associated with the appropriate regions.

Select `Binary search` for the **Searching methods** parameter and the block compares the training point to the middle value of the boundary points vector. When the training point is larger than this boundary point, the block discards the lower boundary points. The block then compares the training point to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the training point is associated with the appropriate region.

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the staircase character of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool dialog box.

SQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file. The **Error** values represent the mean squared error for each iteration.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Scalar Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Scalar Quantizer Decoder block. When you have a Scalar Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block(s)** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Scalar Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is `1e6`.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Select `User defined` to enter your own initial codebook values.

Number of levels

Enter the length of the codebook vector. For a b-bit quantizer, the length should be $N = 2^b$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Source of initial boundary points

Select `Mid-points` to locate the boundary points at the midpoint between the codebook values. Choose `User defined` to enter your own boundary points. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Initial boundary points (unbounded)

Enter your initial boundary points. This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary point are `-inf` and `inf`, regardless of any other boundary point values you might enter. From the **Source of initial boundary points** list, select `User defined` in order to activate this parameter.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

Type the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

Enter the maximum number of iterations you want the block to perform. From the **Stopping criteria** list, select `Maximum iteration` in order to activate this parameter.

Searching methods

Choose `Linear search` to use a linear search method when comparing the training points to the boundary points. Choose `Binary search` to use a binary search method when comparing the training points to the boundary points.

Tie-breaking rules

When a training point lies on a boundary point, choose `Lower indexed codeword` to assign the training point to the lower indexed quantization region. Choose `Higher indexed codeword` to assign the training point to the higher indexed region.

Design and Plot

Click this button to display the performance curve and the staircase character of the quantizer in the figures on the right side of the GUI. These plots are based on the current parameter settings.

You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file.

Destination

Choose `Current model` to create a Scalar Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

Encoder block name

Enter a name for the Scalar Quantizer Encoder block.

Decoder block name

Enter a name for the Scalar Quantizer Decoder block.

Overwrite target block(s)

When you do not select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Scalar Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

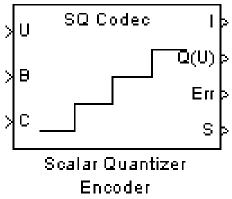
Scalar Quantizer Encoder

Encode each input value by associating it with index value of quantization region



Library

Quantizers

dspquant2

Description

The Scalar Quantizer Encoder block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the zero-based index of the associated region.

You can select how you want to enter the **Boundary points** using the **Source of quantizer parameters**. When you select `Specify via dialog`, type the boundary points into the block parameters dialog box. When you select `Input port`, port B appears on the block. The block uses the input to port B as the **Boundary points** parameter.

Use the **Boundary points** parameter to specify the boundary points for your quantizer. These values are used to break up the set of input numbers into regions. Each region is specified by an index number.

Let `N` be the number of quantization regions. When the codebook is defined as `[c1 c2 c3 ... cN]`, and the **Boundary points** parameter is defined as `[p0 p1 p2 p3 ... pN]`, then `p0<c1<p1<c2 ... p(N-1)<cN<pN` for a regular quantizer. When your

quantizer is bounded, from the **Partitioning** list, select `Bounded`. You need to specify N +1 boundary points, or `[p0 p1 p2 p3 ... pN]`. When your quantizer is unbounded, from the **Partitioning** list, select `Unbounded`. You need to specify N-1 boundary points, or`[p1 p2 p3 ... p(N-1)]`; the block sets `p0` equal to `-inf` and `pN` equal to `inf`.

The block uses the **Partitioning** parameter to interpret the boundary points you enter. For instance, to create a bounded quantizer, from the **Partitioning** list, select `Bounded` and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 0, input values between 0.5 and 3.7 to index 1, and so on. The block assigns any values that are less than 0 to index 0, the lowest index value. The block assigns any values that are greater than 11 to index 4, the highest index value.

To create an unbounded quantizer, from the **Partitioning** list, select `Unbounded` and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 1, input values between 0.5 and 3.7 to index 2, and so on. The block assigns any input values less than 0 to index 0 and any values greater than 11 to index 6.

The **Searching method** parameter determines how the appropriate quantizer index is found. When you select `Linear`, the Scalar Quantizer Encoder block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P, where P is the number of boundary points.

When you select `Binary` for the **Searching method**, the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the `Binary` option is faster than the `Linear` option.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter determines the region to which the value is assigned. When you want the input value to be assigned to the lower indexed region, select `Choose the lower index`. To assign the input value with the higher indexed region, select `Choose the higher index`.

Select the **Output codeword** check box to output the codeword values that correspond to each index value at port Q(U).

Select the **Output the quantization error** check box to output the quantization error for each input value from the Err port on this block. The quantization error is the difference between the input value and the quantized output value.

When you select either the **Output codeword** check box or the **Output quantization error** check box, you must also enter your codebook values. If, from the **Source of quantizer parameters** list, you choose `Specify via dialog`, use the **Codebook** parameter to enter a vector of quantized output values that correspond to each region. If, from the **Source of quantizer parameters** list, you choose `Input port`, use input port C to specify your codebook values.

If, for the **Partitioning** parameter, you select `Bounded`, the **Output clipping status** check box and the **Action for out of range input** parameter appear. When you select the **Output clipping status** check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at the S port. When the value is inside the range, the blocks outputs a 0.

You can use the **Action for out of range input** parameter to determine the block's behavior when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points for a bounded quantizer are defined as `[p0 p1 p2 p3 ... pN]` and the possible index values are defined as `[i0 i1 i2 ... i(N-1)]`, where `i0=0` and `i0<i1<i2<...<i(N-1)`. When you want any input value less than `p0` to be assigned to index value `i0` and any input values greater than `pN` to be assigned to index value `i(N-1)`, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

The Scalar Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see "Data Type Support" on page 2-1506 or "Supported Data Types" on page 2-1511.

Data Type Support

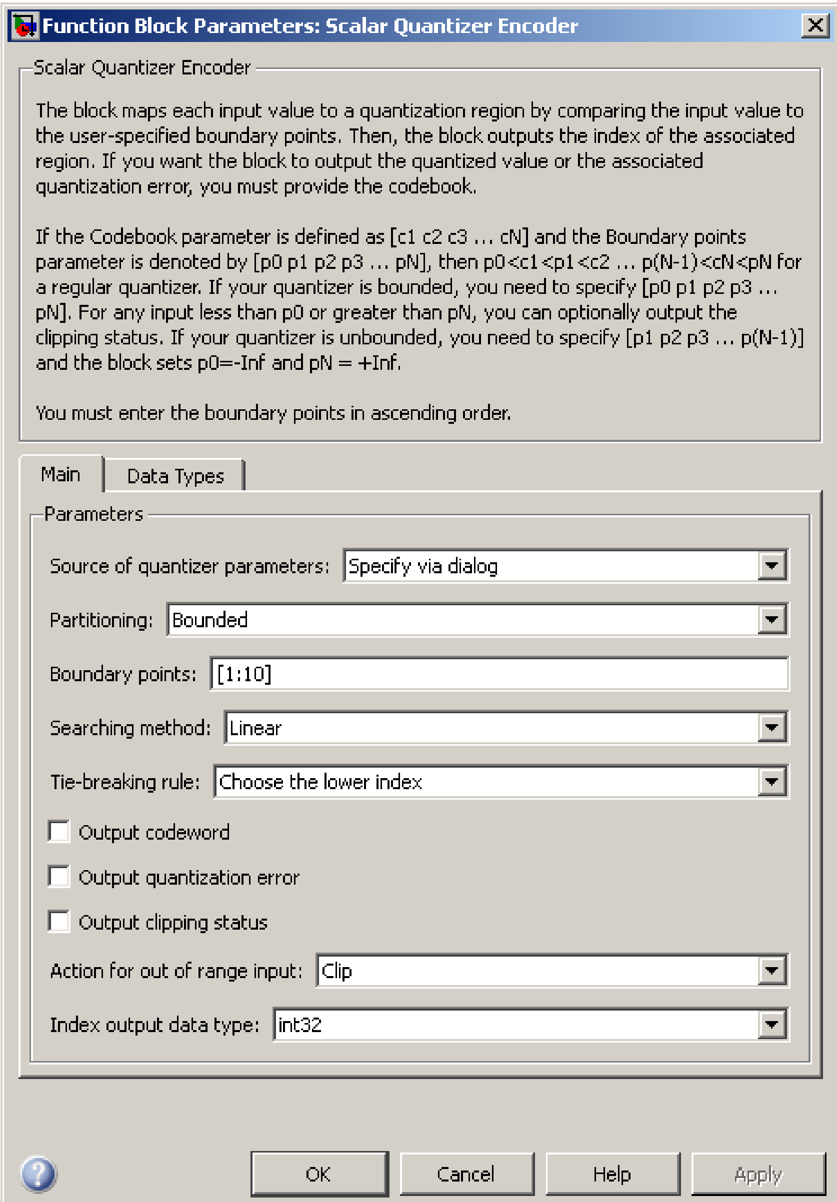
The input data values, boundary points, and codebook values can be input to the block at ports U, B, and C, respectively. The data type of the inputs can be `double`, `single`, or Fixed-point.

The outputs of the block can be the index values, the quantized output values, the quantization error, and the clipping status. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the quantized output and the quantization error can be `double`, `single`, or Fixed-point. The clipping status values output at port S are Boolean values.

Note The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

Dialog Box

The **Main** pane of the Scalar Quantizer Encoder block dialog appears as follows.



Source of quantizer parameters

Choose `Specify via dialog` to enter the boundary points and codebook values using the block parameters dialog box. Select `Input port` to specify the parameters using the block's input ports. Input the boundary points and codebook values using ports B and C, respectively.

Partitioning

When your quantizer is bounded, select `Bounded`. When your quantizer is unbounded, select `Unbounded`.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list. Tunable (Simulink).

Searching method

When you select `Linear`, the block finds the region in which the input value is located using a linear search. When you select `Binary`, the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower indexed region. When you select `Choose the higher index`, the value is assigned to the higher indexed region.

Output codeword

Select this check box to output the codeword values that correspond to each index value at port Q(U).

Output quantization error

Select this check box to output the quantization error for each input value at port Err.

Codebook

Enter a vector of quantized output values that correspond to each index value. If, for the **Partitioning** parameter, you select `Bounded` and your boundary points vector has length N, then you must specify a codebook of length N-1. If, for the **Partitioning** parameter, you select `Unbounded` and your boundary points vector has length N, then you must specify a codebook of length N+1.

This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list and you select either the **Output codeword** or **Output quantization error** check box. Tunable (Simulink).

Output clipping status

When you select this check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at this port. When the value is inside the range, the block outputs a 0. This parameter is visible when you select `Bounded` from the **Partitioning** list.

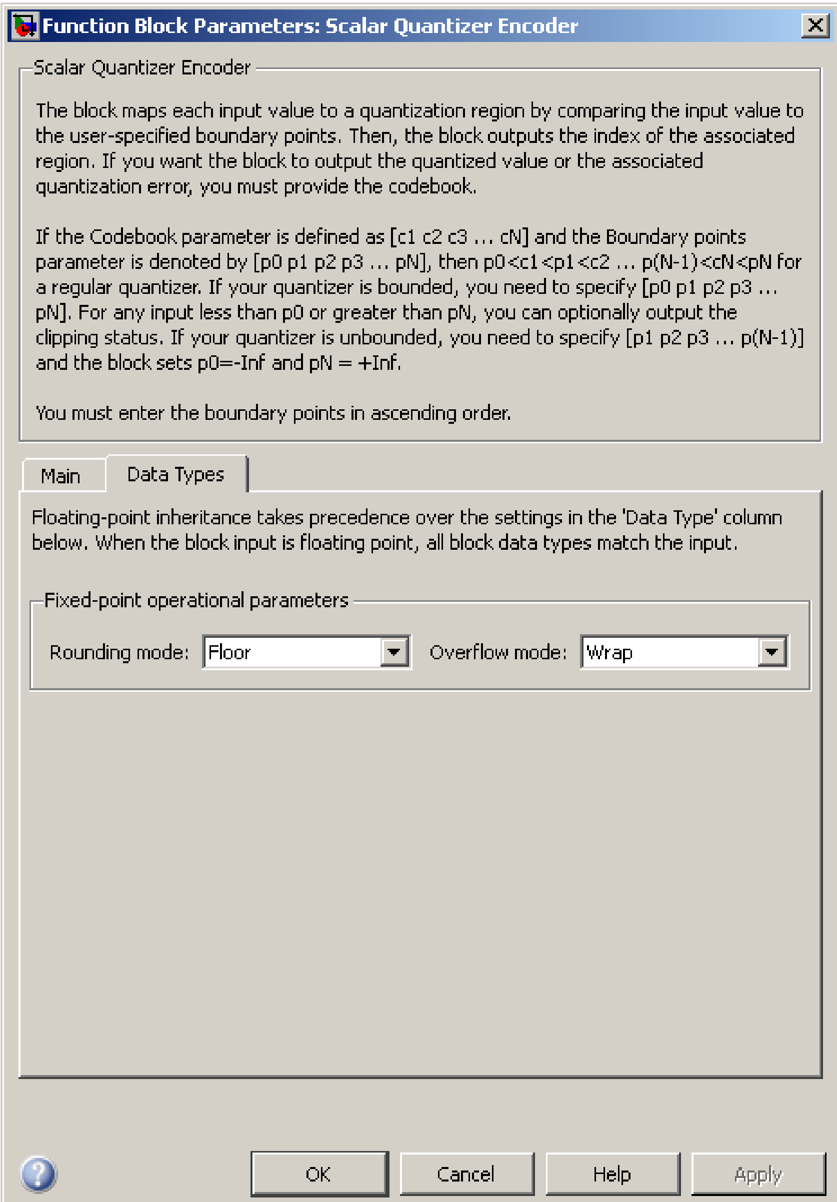
Action for out of range input

Use this parameter to determine the behavior of the block when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points are defined as `[p0 p1 p2 p3 ... pN]` and the index values are defined as `[i0 i1 i2 ... i(N-1)]`. When you want any input value less than `p0` to be assigned to index value `i0` and any input values greater than `pN` to be assigned to index value `i(N-1)`, select `Clip`. When you want to be warned when clipping occurs, select `Clip and warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`. This parameter is visible when you select `Bounded` from the **Partitioning** list.

Index output data type

Specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

The **Data Types** pane of the Scalar Quantizer Encoder block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode to be used when block inputs are fixed point.

Supported Data Types

Port	Supported Data Types
U	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
B	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
C	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
I	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Q(U)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
Err	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
S	• Boolean

For more information on what data types are supported for each quantizer mode, see "Data Type Support" on page 2-1506.

Selector

Select input elements from vector, matrix, or multidimensional signal

Library

Signal Management / Indexing

`dspindex`

Description

The Selector block is an implementation of the Simulink Selector block. See Selector for more information.

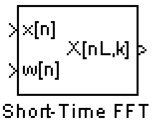
HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Selector.

Introduced in R2008a

Short-Time FFT

Nonparametric estimate of spectrum using short-time, fast Fourier transform (FFT) method



Library

Transforms

`dspxfrm3`

Description

The Short-Time FFT block computes a nonparametric estimate of the spectrum. The block buffers, applies a window, and zero pads the input signal. The block then takes the FFT of the signal, transforming it into the frequency domain.

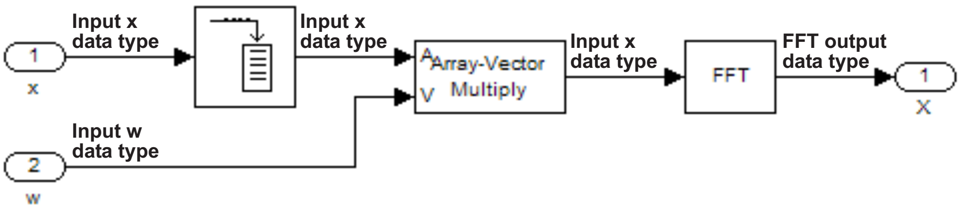
Connect your single-channel analysis window to the w(n) port. For the **Analysis window length** parameter, enter the length of the analysis window, *W*. The block buffers the input signal such that it has a frame length of *W*

Connect your single-channel or multichannel input signal to the x(n) port. After the block buffers and windows this signal, it zero-pads the signal before computing the FFT. For the **FFT length** parameter, enter the length to which the block pads the input signal. For the **Overlap between consecutive windows (in samples)** parameter, enter the number of samples to overlap each frame of the input signal.

The block outputs the complex-valued, single-channel or multichannel short-time FFT at port X(n,k).

Fixed-Point Data Types

The following diagram shows the data types used within the Short-Time FFT subsystem block for fixed-point signals.



The settings for the fixed-point parameters of the Array-Vector Multiply block in the diagram above are as follows:

- **Rounding Mode** — `Floor`
- **Overflow Mode** — `Wrap`
- **Product output** — `Inherit via internal rule`
- **Accumulator** — `Inherit via internal rule`
- **Output** — `Same as first input`

The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- **Rounding Mode** — `Floor`
- **Overflow Mode** — `Wrap`
- **Sine table** — `Same word length as input`
- **Product output** — `Inherit via internal rule`
- **Accumulator** — `Inherit via internal rule`
- **Output** — `Inherit via internal rule`

See the `FFT` and `Array-Vector Multiply` block reference pages for more information.

Examples

The dspstsa example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal. To open the `dspstsa` model, type `dspstsa` in the MATLAB command prompt.

Parameters

Analysis window length

Specify the frame length of the analysis window. The **Analysis window length** must be a positive integer value greater than one.

Overlap between consecutive windows (in samples)

Enter the number of samples of overlap for each frame of the input signal.

FFT length

Enter the length to which the block pads the input signal.

Treat Mx1 and unoriented sample-based signals as

Specify how the block treats sample-based M-by-1 column vectors and unoriented sample-based vectors of length M. You can select one of the following options:

- `One channel` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a column vector (one channel).
- `M channels (this choice will be removed — see release notes)` — When you select this option, the block treats M-by-1 and unoriented sample-based inputs as a 1-by-M row vector.

Note: This parameter will be removed in a future release. See the *DSP System Toolbox Release Notes* for more information.

Supported Data Types

Port	Supported Data Types
x(n)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
w(n)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
X(n,k)	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Signal From Workspace

Import signal from MATLAB workspace

Library

Sources

`dspsrcs4`

Description

The Signal From Workspace block imports a signal from the MATLAB workspace into the Simulink model. The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

When the **Signal** parameter specifies an M-by-N matrix (M≠1), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o, and the output is an M_o-by-N matrix containing M_o consecutive samples from each signal channel. You specify the output sample period in the **Sample time** parameter, T_s, and the output frame period is M_o*T_s. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, each of the P pages (an M-by-N matrix) is output in sequence with period T_s. The **Samples per frame** parameter must be set to `1`.

Initial and Final Conditions

Unlike the Simulink From Workspace block, the Signal From Workspace block holds the output value constant between successive output frames (that is, no linear interpolation takes place). Additionally, the initial signal values are always produced immediately at t=0.

When the block has output all of the available signal samples, it can start again at the beginning of the signal, or simply repeat the final value or generate zeros until the end of the simulation. (The block does not extrapolate the imported signal beyond the last sample.) The **Form output after final data value by** parameter controls this behavior:

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after it reaches the last sample in the signal. If the frame size you specify in the **Samples per frame** parameter does not evenly divide the input length, a buffer block is inserted into the Signal From Workspace subsystem, and the model becomes multirate. If you do not want your model to become multirate, make sure the frame size evenly divides the input signal length.

  Select the **Warn when frame size does not evenly divide input length** parameter to be alerted when the input length is not an integer multiple of the frame size and your model will become multirate. Use the Model Explorer to turn these warnings on or off model-wide:

  a Select **Model Explorer** from the **View** menu in your model.

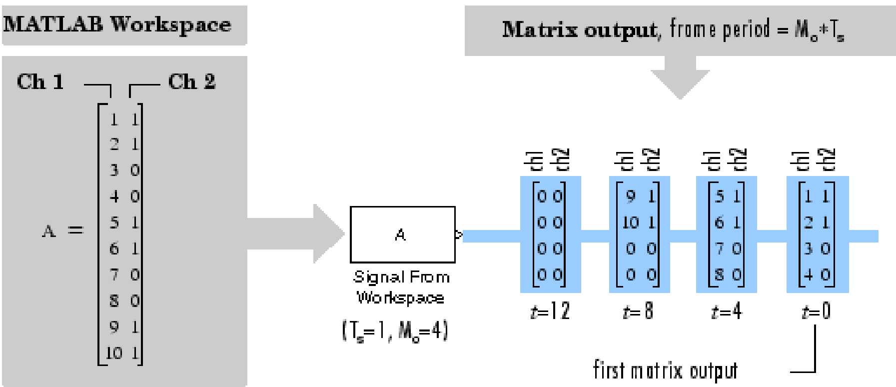
  b In the **Search** bar of the Model Explorer, search `by Property Name` for the `ignoreOrWarnInputAndFrameLengths` property. Each block with the **Warn when frame size does not evenly divide input length** check box appears in the list in the **Contents** pane.

  c Select each of the blocks for which you wish to toggle the warning parameter, and select or deselect the check box in the `ignoreOrWarnInputAndFrameLengths` column.

Examples

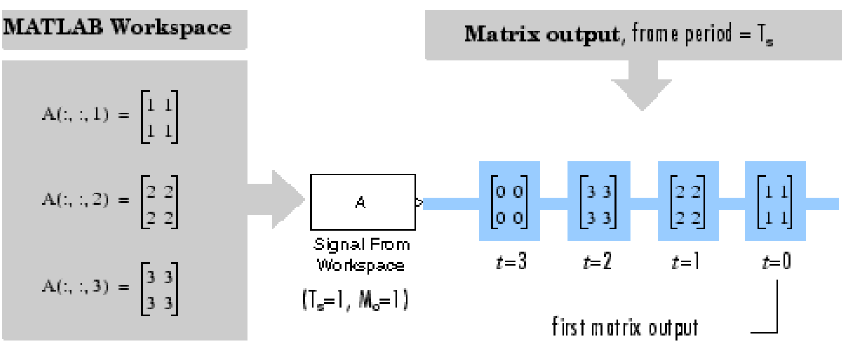
Example 1

In the first model, ex_signal_from_workspace_fb, the Signal From Workspace imports a two-channel signal from the workspace matrix,`A`. The **Sample time** is set to `1` and the **Samples per frame** is set to `4`. The output has a frame size of 4 and a frame period of 4 seconds. The **Form output after final data value by** parameter specifies `Setting To Zero`, so all outputs after the third frame (at *t*=8) are zero.



Example 2

In the second model, ex_signal_from_workspace_sb, the Signal From Workspace block imports a matrix signal from the 3-D workspace array, `A`. Again, the **Form output after final data value by** parameter specifies `Setting To Zero`, so all outputs after the third (at *t*=2) are zero.



The **Samples per frame** parameter is set to `1` for 3-D input.

Parameters

Signal

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Sample time

The sample period, T_s, of the output. The output frame period is M_o*T_s.

Samples per frame

The number of samples, M_o, to buffer into each output frame. This value must be `1` when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by

Specifies the output after all of the specified signal samples have been generated. The block can output zeros for the duration of the simulation (`Setting to zero`), repeat the final data sample (`Holding Final Value`) or repeat the entire signal from the beginning (`Cyclic Repetition`).

Warn when frame size does not evenly divide input length

Select this parameter to be alerted when the input length is not an integer multiple of the frame size and your model will become multirate. For more information, see "Initial and Final Conditions" on page 2-1519.

This parameter is only visible when `Cyclic Repetition` is selected for the **Form output after final data value by** parameter.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

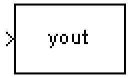
Signal To Workspace

Write data to MATLAB workspace



Note: The Signal To Workspace block has been replaced by the To Workspace block in Simulink. Existing instances of the Signal To Workspace block will continue to operate. For new models, use the To Workspace block.

Library

Sinks

`dspsnks4`

Description

The Signal To Workspace block writes data from your simulation into an array or structure in the main MATLAB workspace. You can specify a name for the workspace variable as well as whether the data is saved as an array, structure, or structure with time.

When the **Save format** is set to `Array` or `Structure`, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table, K represents the value of the **Limit data points to last** parameter.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M-by-N matrix	`2-D array (concatenate along first dimension)`	K-by-N matrix.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
		If you set the **Limit data points to last** parameter to `inf`, *K* represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size (*M*) by the total number of *M*-by-*N* inputs acquired by the block.
M-by-*N* matrix	`3-D array (concatenate along third dimension)`	*M*-by-*N*-by-*K* array. If you set the **Limit data points to last** parameter to `inf`, *K* represents the total number of *M*-by-*N* inputs acquired by the end of the simulation.
Length-*N* unoriented vector	Any setting	*K*-by-*N* matrix
N-dimensional array where $N > 2$	Any setting	Array with *N+1* dimensions, where the size of the last dimension is equal to *K*. If you set the **Limit data points to last** parameter to `inf`, *K* represents the total number of *M*-by-*N* inputs acquired by the end of simulation

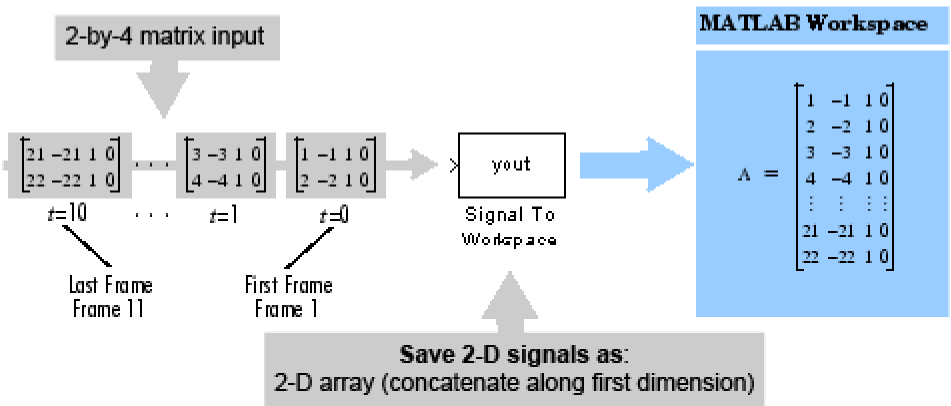
Examples

Example 1: Save 2-D Signals as a 2-D Array

In the ex_signaltoworkspace_ref2 model, the Signal To Workspace block receives a 2-by-4 matrix input and logs 11 frames (two samples per frame) by the end of the simulation.

Because the **Save 2-D signals as** parameter is set to `2-D array (concatenate along first dimension)`, the block concatenates the input along the first dimension to create a 22-by-4 matrix, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

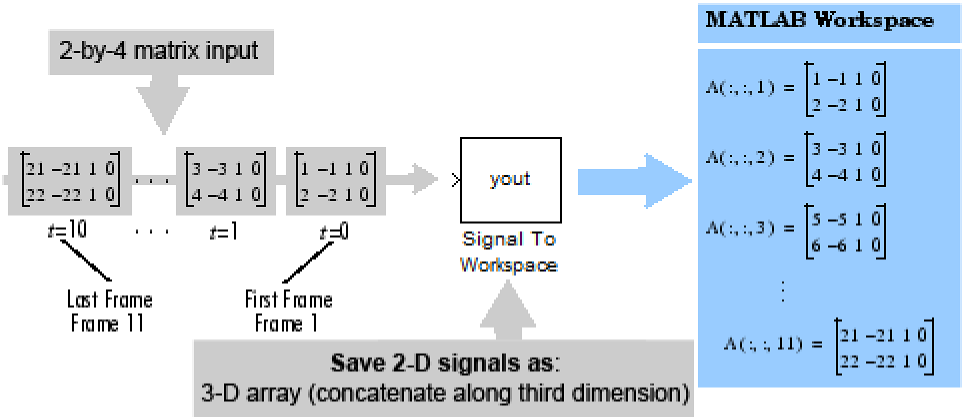


In the 2-D output mode, there is no indication of where one frame ends and another begins. To log input frames separately, set the **Save 2-D signals as** parameter to `3-D array (concatenate along third dimension)`, as shown in Example 2.

Example 2: Save 2-D Signals as a 3-D Array

In the ex_signaltoworkspace_ref1 model, the input to the Signal To Workspace block is a 2-by-4 matrix. The **Save 2-D signals as** parameter is set to `3-D array (concatenate along third dimension)`, so by the end of the simulation the Signal To Workspace block logs 11 frames of data as a 2-by-4-by-11 array, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.



Parameters

Variable name

Specify the name of the array or structure into which the block logs the simulation data. The block creates this variable in the MATLAB workspace only after the simulation stops running. When you enter the name of an existing workspace variable, the block overwrites that variable with the simulation data.

Limit data points to last

Specify the maximum number of samples or frames the block will save. When the simulation generates more than the specified maximum number of samples or frames, the simulation saves only the most recently generated data. To capture all data, set this parameter to `inf`. See the table in the Description section for more information on how this parameter affects the dimensions of the logged data.

Decimation

Specify a positive integer *d* to determine how often the block writes data to the workspace array or structure. The block writes data to the array or structure every *d*th sample. With the default decimation value of `1`, the block writes data at every time step.

Save format

Specify the format in which to save simulation output to the workspace. You can select one of the following options:

- `Array` — Select this option to save the data as an N-dimensional array. If the input signal is an unoriented vector, the resulting workspace array is 2-D. Each input vector is saved in a row of the output matrix, vertically concatenated onto the previous vector. If the input signal is 2-dimensional, the dimensions of the resulting workspace array depend on the setting of the **Save 2-D signals as** parameter.
- `Structure` — Select this option to save the data as a structure consisting of three fields: `time`, `signals` and `blockName`. In this mode, the `time` field is empty, and the `blockName` field contains the name of the Signal To Workspace block. The `signals` field contains a structure with three additional fields: `values`, `dimensions`, and `label`. The `values` field contains the array of signal values, the `dimensions` field specifies the dimensions of the values array, and the `label` field contains the label of the input line.
- `Structure with time` — This option is the same as `Structure`, except that the `time` field contains a vector of simulation time steps. This is the only output format that can be read directly by a From Workspace block. When you select this option, the **Save 2-D signals as** parameter is not available. In this mode, the block always saves 2-D input arrays as a 3-D array.

The default setting of this parameter is `Array`.

Save 2-D signals as

Specify whether the block outputs 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- `2-D array (concatenate along first dimension)` — When you select this option, the block saves an M-by-N input signal as a (K*M)-by-N matrix, where K*M is the total number of samples acquired by the end of the simulation. The block vertically concatenates each M-by-N matrix input with the previous input to produce the 2-D output array. See "Example 1: Save 2-D Signals as a 2-D Array" on page 2-1525 for more information about this mode.
- `3-D array (concatenate along third dimension)` — When you select this option, the block saves an M-by-N input signal as an M-by-N-by-K array, where K is the number of M-by-N inputs logged by the end of the simulation. K has an upper bound equal to the value of the **Limit data points to last** parameter. See "Example 2: Save 2-D Signals as a 3-D Array" on page 2-1526 for more information about this mode.

This parameter is visible only when you set the **Save format** parameter to `Array` or `Structure`. When you set the **Save format** parameter to `Structure with time`, the block outputs the 2-D input signal as a 3-D array.

Note: The `Inherit from input (this choice will be removed - see release notes)` option will be removed in a future release. See "Signal To Workspace Block Changes" in the *DSP System Toolbox Release Notes* for more information.

Log fixed-point data as a fi object

Select this check box to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

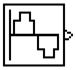
Sine Wave

Generate continuous or discrete sine wave



Library

Sources

`dspsrcs4`

Description

The Sine Wave block generates a multichannel real or complex sinusoidal signal, with independent amplitude, frequency, and phase in each output channel. A real sinusoidal signal is generated when the **Output complexity** parameter is set to `Real`, and is defined by an expression of the type

$$y = A\sin(2\pi ft + \phi)$$

where you specify A in the **Amplitude** parameter, f in hertz in the **Frequency** parameter, and ϕ in radians in the **Phase offset** parameter. A complex exponential signal is generated when the **Output complexity** parameter is set to `Complex`, and is defined by an expression of the type

$$y = Ae^{j(2\pi ft+\phi)} = A\left\{\cos(2\pi ft + \phi) + j\sin(2\pi ft + \phi)\right\}$$

Generating Multichannel Outputs

For both real and complex sinusoids, the **Amplitude**, **Frequency**, and **Phase offset** parameter values (A, f, and ϕ) can be scalars or length-N vectors, where N is the desired number of channels in the output. When you specify at least one of these parameters as a length-N vector, scalar values specified for the other parameters are applied to every channel.

For example, to generate the three-channel output containing the real sinusoids below, set **Output complexity** to `Real` and the other parameters as follows:

- **Amplitude** = `[1 2 3]`
- **Frequency** = `[1000 500 250]`
- **Phase offset** = `[0 0 pi/2]`

$$y = \begin{cases} \sin(2000\pi t) & \text{(channel 1)} \\ 2\sin(1000\pi t) & \text{(channel 2)} \\ 3\sin\left(500\pi t + \dfrac{\pi}{2}\right) & \text{(channel 3)} \end{cases}$$

Output Sample Time and Samples Per Frame

In all discrete modes, the block buffers the sampled sinusoids into frames of size M, where you specify M in the **Samples per frame** parameter. The output is an M-by-N matrix with frame period M*T_s, where you specify T_s in the **Sample time** parameter.

Sample Mode

The **Sample mode** parameter specifies the block's sampling property, which can be `Continuous` or `Discrete`:

- `Continuous`

In continuous mode, the sinusoid in the ith channel, y_i, is computed as a continuous function,

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad \text{(real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \qquad \text{(complex)}$$

and the block's output is continuous. In this mode, the block's operation is the same as that of a Simulink Sine Wave block with **Sample time** set to `0`. This mode offers high accuracy, but requires trigonometric function evaluations at each simulation step, which is computationally expensive. Additionally, because this method tracks absolute simulation time, a discontinuity will eventually occur when the time value reaches its maximum limit.

Note also that many DSP System Toolbox blocks do not accept continuous-time inputs.

- `Discrete`

  In discrete mode, the block's discrete-time output can be generated by directly evaluating the trigonometric function, by table lookup, or by a differential method. The three options are explained below.

Discrete Computational Methods

When you select `Discrete` from the **Sample mode** parameter, the secondary **Computation method** parameter provides three options for generating the discrete sinusoid:

- `Trigonometric Fcn`
- `Table Lookup`

- `Differential`

Note: To generate fixed-point sinusoids, you must select `Table Lookup`.

Trigonometric Fcn

The trigonometric function method computes the sinusoid in the *i*th channel, y_i, by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad \text{(real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \qquad \text{(complex)}$$

with a period of T_s, where you specify T_s in the **Sample time** parameter. This mode of operation shares the same benefits and liabilities as the `Continuous` sample mode described above.

At each sample time, the block evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the block avoids the imprecision of computing the sine of very large numbers, and eliminates the possibility of discontinuity during extended operations (when an absolute time variable might overflow). This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, ..., N$.

When the **Optimize table for** parameter is set to `Speed`, the table constructed for each channel contains k_i elements. When the **Optimize table for** parameter is set to `Memory`, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods, but can demand considerably more memory, especially for high sample rates (long tables). This is the recommended method for models that are intended to emulate or generate code for DSP hardware, and that therefore need to be optimized for execution speed.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the `Table lookup` computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by making use of the following identities.

$$\sin(t+T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$
$$\cos(t+T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the ith channel, y_i, can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i (t+T_s)+\phi_i\} \\ \cos\{2\pi f_i (t+T_s)+\phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t+\phi_i) \\ \cos(2\pi f_i t+\phi_i) \end{bmatrix}$$

where you specify T_s in the **Sample time** parameter. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of $A_i\sin[2\pi f_i(t+T_s)+\phi_i]$ is then computed from the values of $\sin(2\pi f_i t+\phi_i)$ and $\cos(2\pi f_i t+\phi_i)$ by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations (when an absolute time variable might overflow).

Examples

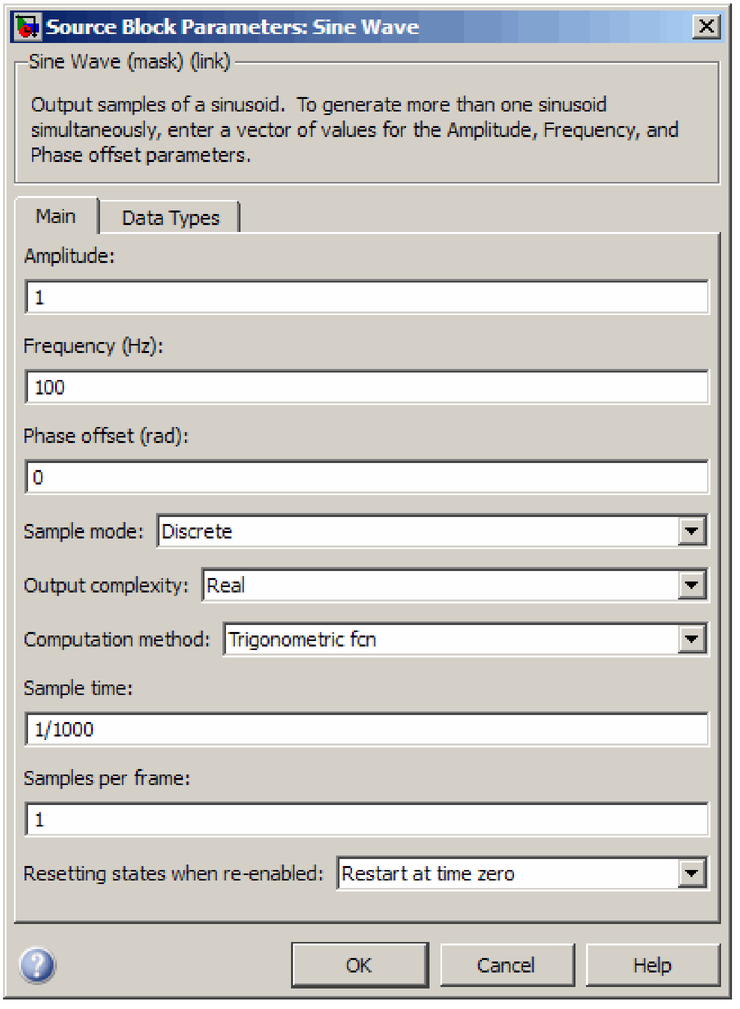
Dialog Box

The **Main** pane of the Sine Wave block dialog appears as follows.



Amplitude

A length-N vector containing the amplitudes of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Frequency** and **Phase offset** parameters. Tunable (Simulink) when **Computation method** is to `Trigonometric fcn` or `Differential`.

Frequency

A length-*N* vector containing frequencies, in Hertz, of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Amplitude** and **Phase offset** parameters. You can specify positive, zero, or negative frequencies. Tunable (Simulink) when **Sample mode** is `Continuous` or **Computation method** is `Trigonometric fcn`.

Phase offset

A length-*N* vector containing the phase offsets, in radians, of the sine waves in each of *N* output channels, or a scalar to be applied to all *N* channels. The vector length must be the same as that specified for the **Amplitude** and **Frequency** parameters. Tunable (Simulink) when **Sample mode** is `Continuous` or **Computation method** is `Trigonometric fcn`.

Sample mode

The block's sampling behavior, `Continuous` or `Discrete`. This parameter is not tunable.

Output complexity

The type of waveform to generate: `Real` specifies a real sine wave, `Complex` specifies a complex exponential. This parameter is not tunable.

Computation method

The method by which discrete-time sinusoids are generated: `Trigonometric fcn`, `Table lookup`, or `Differential`. This parameter is not tunable. For more information on each of the available options, see “Discrete Computational Methods” on page 2-1532 in the Description section.

This parameter is only visible when you set the **Sample mode** to `Discrete`.

Note: To generate fixed-point sinusoids, you must set the **Computation method** to `Table lookup`.

Optimize table for

Optimizes the table of sine values for `Speed` or `Memory` (this parameter is only visible when the **Computation method** parameter is set to `Table lookup`). When optimized for speed, the table contains *k* elements, and when optimized for memory, the table contains *k*/4 elements, where *k* is the number of input samples in one full period of the sine wave.

Sample time

The period with which the sine wave is sampled, T_s. The block's output frame period is $M*T_s$, where you specify M in the **Samples per frame** parameter. This parameter is disabled when you select `Continuous` from the **Sample mode** parameter. This parameter is not tunable.

Samples per frame

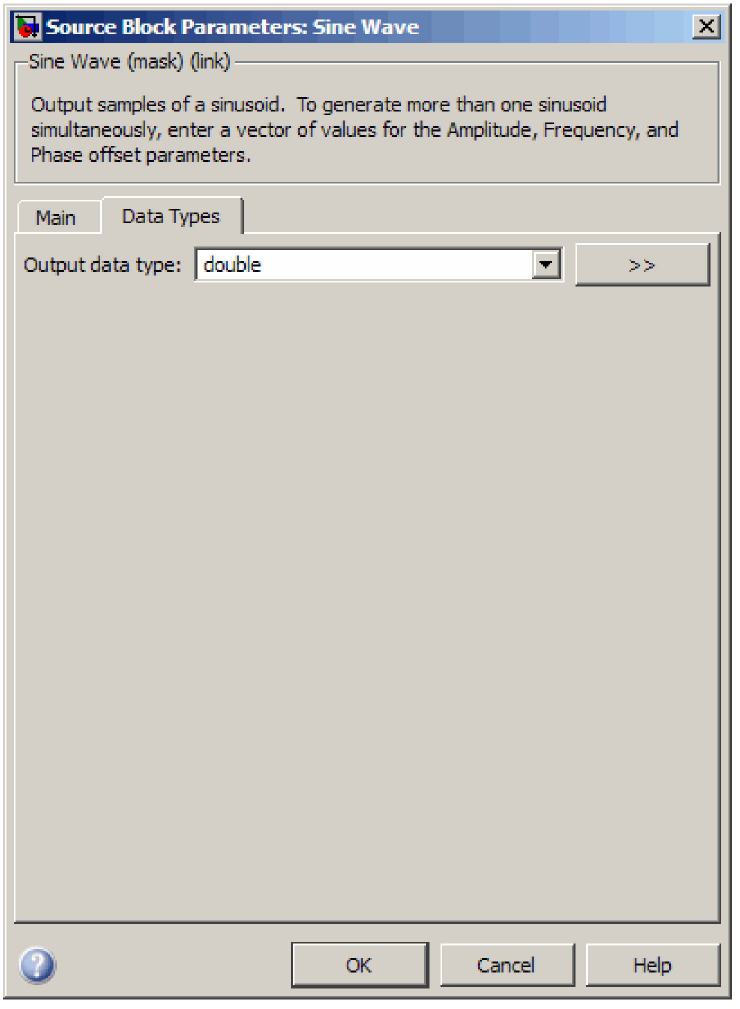
The number of consecutive samples from each sinusoid to buffer into the output frame, M.

This parameter is disabled when you select `Continuous` from the **Sample mode** parameter.

Resetting states when re-enabled

This parameter only applies when the Sine Wave block is located inside an enabled subsystem and the **States when enabling** parameter of the Enable block is set to `reset`. This parameter determines the behavior of the Sine Wave block when the subsystem is re-enabled. The block can either reset itself to its starting state (`Restart at time zero`), or resume generating the sinusoid based on the current simulation time (`Catch up to simulation time`). This parameter is disabled when you select `Continuous` from the **Sample mode** parameter.

The **Data Types** pane of the Sine Wave block dialog appears as follows.



Output data type

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built in data type, such as `double`

- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Note: The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the `Table lookup` computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Sine Wave.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

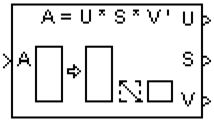
Singular Value Decomposition

Factor matrix using singular value decomposition



Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

`dspfactors`

Description

The Singular Value Decomposition block factors the M-by-N input matrix A such that

$$A = U \cdot diag(S) \cdot V^*$$

where

- U is an M-by-P matrix
- V is an N-by-P matrix
- S is a length-P vector
- P is defined as min(M,N)

When

- $M = N$, U and V are both M-by-M unitary matrices
- $M > N$, V is an N-by-N unitary matrix, and U is an M-by-N matrix whose columns are the first N columns of a unitary matrix
- $N > M$, U is an M-by-M unitary matrix, and V is an N-by-M matrix whose columns are the first M columns of a unitary matrix

In all cases, S is an unoriented vector of positive singular values having length P.

Length-N row inputs are treated as length-N columns.

Note that the first (maximum) element of output S is equal to the 2-norm of the matrix A.

Parameters

Show singular vector ports

Select to enable the `U` and `V` output ports.

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- `0` — The singular value decomposition calculation converges.
- `1` — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at ports U, S, and V are undefined matrices of the correct size.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option shortens startup time.

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time.

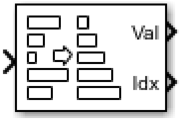
Sort

Sort input elements by value

Library: DSP System Toolbox / Statistics



Description

The Sort block ranks the values of the input elements along each channel (column) in an `Ascending` or a `Descending` order, based on the **Sort order** you specify. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. You can choose the **Sort algorithm** to be either `Quick sort` or `Insertion sort`. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, to avoid recursive function calls, use the insertion sort algorithm.

The **Mode** parameter specifies the block's mode of operation, which you can set to `Value`, `Index`, or `Value and Index`.

Ports

Input

`Port_1` — Data input

vector | matrix

The block accepts real-valued or complex-valued multichannel inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

Complex Number Support: Yes

Output

`Val` — Sorted data
vector | matrix

The block sorts the data along each channel, and outputs the sorted data through this port. The size, data type, and complexity of the sorted data matches that of the input data. The block sorts complex inputs according to their magnitude.

Dependencies

To enable this port, set the **Mode** parameter to `Value and index` or `Value`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

`Idx` — Index of the sorted data
vector | matrix

The output at this port contains the indices of the sorted data.

Dependencies

To enable this port, set the **Mode** parameter to `Value and index` or `Index`.

Data Types: `uint32`

Parameters

Main Tab

`Mode` — Mode in which the block operates
`Value and Index` (default) | `Value` | `Index`

When the **Mode** parameter is set to:

- `Value` — The block sorts the elements in each channel of the M-by-N input matrix in an ascending or descending order, based on what you specify in the **Sort order** parameter. The output at each sample time, Val, is an M-by-N matrix that contains the sorted columns of the input.

  The block sorts complex inputs according to their magnitude.
- `Index` — The block sorts the elements in each channel of the M-by-N input matrix, and outputs the index array, I. Each element in I is an integer of type `uint32` that indexes the sorted value in the corresponding column of the input.
- `Value and index` — The block outputs the sorted values of the input data, Val, and the corresponding indices in the index array, I.

`Sort order` — Order to sort the data in
`Ascending` (default) | `Descending`

Specify to sort the input data in either ascending or descending order.

`Sort algorithm` — Sort method
`Quick sort` (default) | `Insertion sort`

The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, to avoid recursive function calls, use the insertion sort algorithm.

Data Types Tab

Note: To use these parameters, the data input must be complex and fixedpoint. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

`Overflow mode` — Method of overflow action
`Wrap` (default) | `Saturate`

Select the overflow mode for fixed-point operations.

`Product output` — Product output data type
`Inherit: Same as input` (default) | `fixdt([],16,0)`

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

`Accumulator` — Accumulator data type
`Inherit: Same as product output` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button >>.

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink).

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Algorithms

Sort

The block produces results identical to the MATLAB `sort` function.

The output of the block is equivalent to the following MATLAB code, when **Sort order** is set to:

- `Ascending` — `[Val,I] = sort(u,'ascend')`
- `Descending` — `[Val,I] = sort(u,'descend')`

where:

- `u` is the data input.
- `Val` is the sorted output.
- `I` is the index of the sorted output.

When the input is complex, the block sorts the data according to the magnitude. The block computes the magnitude by taking the sum of the squares of the real and imaginary components of the complex input. This is identical to calling the `sort` function as `[Val,I] = sort(u,...,'ComparisonMethod','abs')`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

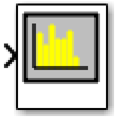
Spectrum Analyzer

Display frequency spectrum of time-domain signals



Library

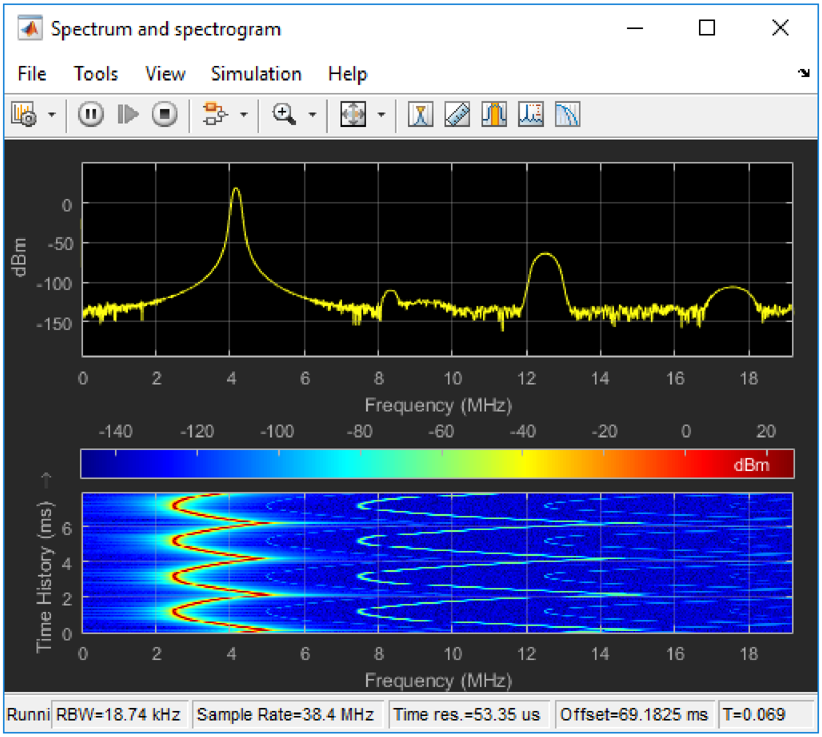
Sinks

`dspsnks4`

Description

The Spectrum Analyzer block, referred to here as the scope, displays frequency spectra of signals. The Spectrum Analyzer block accepts input signals, through one or more input ports, with the following characteristics:

- Discrete sample time
- Real- or complex-valued
- Fixed number of channels of variable length
- Floating- or fixed-point data type



You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations. See the "Supported Simulation Modes" on page 2-1605 section for more information.

You can use the Spectrum Analyzer block inside of all subsystems and conditional subsystems. *Conditional subsystems* include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See "Conditional Subsystems" (Simulink) for more information.

You can configure and display Spectrum Analyzer settings from the command line with spbscopes.SpectrumAnalyzerConfiguration.

For an example that uses the Spectrum Analyzer, see the "Display Frequency-Domain Data in Spectrum Analyzer".

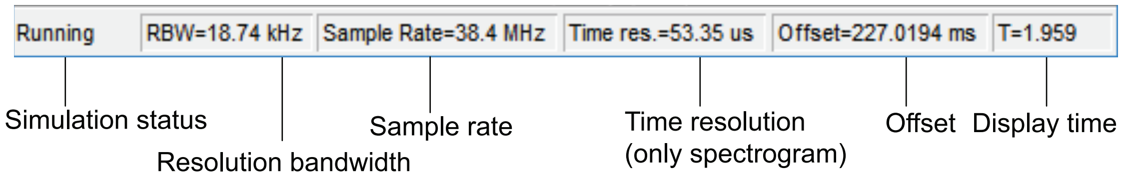
See the following sections for more information on the Spectrum Analyzer:

- “Signal Display” on page 2-1555
- “Spectrum Settings” on page 2-1562
- “Measurements Panels” on page 2-1570
- “Visuals — Spectrum Properties” on page 2-1584
- “Style Dialog Box” on page 2-1587
- “Tools — Axes Scaling Properties” on page 2-1588
- “Algorithms” on page 2-1592
- “Differences from Spectrum Scope Block” on page 2-1600
- “Supported Data Types” on page 2-1605
- “Supported Simulation Modes” on page 2-1605

Note: For information about the Spectrum Analyzer System object, see dsp.SpectrumAnalyzer.

Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the **Resolution Bandwidth**, **Time Resolution**, and **Offset** indicators on the status bar in the scope window for this information. These indicators relate to the Minimum Frequency-Axis limit and Maximum Frequency-Axis limit values on the *frequency*-axis of the scope window. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the Simulation Status and Simulation time indicators on the status bar in the scope window for this information. The following figure highlights these aspects of the Spectrum Analyzer window.



Note: To prevent the scope from opening when you run your model, right-click the scope icon and select `Comment Out`. If the scope is already open, and you comment it out in the model, the scope displays, "No data can be shown because this scope is commented out." Select `Uncomment` to turn the scope back on.

- *Frequency Span* — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

  Details

  Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

  - `Span (Hz)` and `CF (Hz)` visible — The *Frequency Span* value equals the **Span** parameter in the **Main options** pane.
  - `FStart (Hz)` and `FStop (Hz)` — The frequency span value equals the difference of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the formula: $f_{span} = f_{stop} - f_{start}$.

  By default, the **Full Span** check box in the **Main options** pane is enabled. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

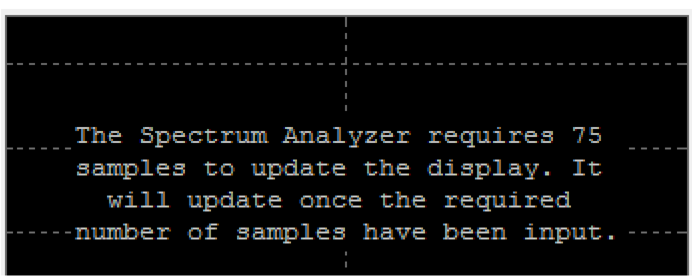
- *Resolution Bandwidth* — The smallest positive frequency or frequency interval that can be resolved.

Details

Spectrum Analyzer sets the resolution bandwidth using the value of the frequency resolution parameter on the **Main options** pane of the **Spectrum Settings** panel. By default, this parameter is set to `RBW (Hz)` and `'Auto'`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified *Frequency Span*.

You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to *RBW* by the following equation:

$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.



Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

If the frequency resolution setting on the **Main options** pane of the **Spectrum Settings** is `Window length`, you specify the window length and the resulting RBW is $\frac{NENBW * Fs}{N_{window}}$. The **Samples/update** in this case is directly related to *RBW* by the following equation: $N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$

- *Time Resolution* — The time resolution for a spectrogram line.

  Details

  Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of data time it takes to compute a single spectral estimate. *Time Resolution* is displayed only when the spectrum **Type** is `Spectrogram`.

- *Offset* — The constant frequency offset to apply to the entire spectrum or a vector of frequency offsets to apply to each spectrum for multiple inputs.

  Details

  Spectrum Analyzer adds this constant offset or the vector of offsets to the values on the *frequency*-axis using the value of **Offset** on the **Trace options** pane of the **Spectrum Settings** panel. The offset is the current time value at the middle of the interval of the line displayed at 0 seconds. The actual time of a particular spectrogram line is the offset minus the *y*-axis time listing. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters on the **Main options** pane of the **Spectrum Settings** panel to ensure that the frequency span is within Nyquist limits. The offset is displayed on the plot only when the spectrum **Type** is `Spectrogram`.

- *Simulation Status* — Provides the current status of the model simulation.

  Details

  The status can be one of the following conditions:

  - Processing — Occurs after you construct the `SpectrumAnalyzer` object.
  - Stopped — Occurs after you run the release method.

The *Simulation Status* is part of the *Status Bar* in the Spectrum Analyzer window. You can choose to hide or display the entire *Status Bar*. From the Spectrum Analyzer menu, select **View > Status Bar**.

- *Display time* — The amount of time that has progressed since the last update to the Spectrum Analyzer display.

  Details

  Every time data is processed by the block, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula: $t_{sim} = t_{sim} + \frac{\text{length(0:length(xsine))-1}}{\text{SampleRate}}$. When **Reduce Plot Rate to Improve Performance** is checked, the simulation time and display time might differ. At the beginning of a simulation, you can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel.

  The *Display time* indicator is a component of the *Status Bar* in the Spectrum Analyzer window. You can choose to hide or display the entire *Status Bar*. From the Spectrum Analyzer menu, select **View > Status Bar** .

For more information, see "Spectrum Settings" on page 2-1562.

Reduce Plot Rate to Improve Performance

By default, Spectrum Analyzer updates the display at fixed intervals of time at a rate not exceeding 20 hertz. If you want Spectrum Analyzer to plot a spectrum on every simulation time step, you can disable the **Reduce Plot Rate to Improve Performance** option. In the Spectrum Analyzer menu, select **Simulation > Reduce Plot Rate to Improve Performance** to clear the check box. Tunable (Simulink).

Note: When this check box is selected, Spectrum Analyzer may display a misleading spectrum in some situations. For example, if the input signal is wide-band with non-stationary behavior, such as a chirp signal, Spectrum Analyzer might display a stationary spectrum. The reason for this behavior is that Spectrum Analyzer buffers the input signal data and only updates the display periodically at approximately 20 times per second. Therefore, Spectrum Analyzer does not render changes to the spectrum that occur and elapse between updates, which gives the impression of an incorrect spectrum. To ensure that spectral estimates are as accurate as possible, clear the **Reduce Plot**

Rate to Improve Performance check box. When you clear this box, Spectrum Analyzer calculates spectra whenever there is enough data, rendering results correctly.

Spectral Masks

You can add upper and lower spectral mask lines to spectrum plots. You use spectral masks to enhance visualizing spectrum limits. Spectral masks also are useful for comparing spectrum values to specification values.

You must use commands at the MATLAB command line to setup or configure spectral masks for a Spectrum Analyzer block. You use `get_param` to create a Spectrum Analyzer configuration object to control the block. The configuration object has a `SpectralMask` property. The `SpectralMask` property uses `SpectralMaskSpecfication` properties to enable and configure the spectral masks. The `SpectralMaskSpecfication` properties, which are described in spbscopes.SpectrumAnalyzerConfiguration, are

- `EnabledMasks` — Turn on spectral mask.
- `UpperMask` — Set upper mask values.
- `LowerMask` — Set lower mask values.
- `ReferenceLevel` — Select the mask reference level to use a specific value or the spectrum peak value.
- `CustomReferenceLevel` — Set mask reference level value.
- `SelectedChannel` — Set channel to use for mask reference.
- `MaskFrequencyOffset` — Set frequency offset for mask.

You can check the status of the spectral mask using a method or an event listener.

- To get the status of the spectral masks, call getSpectralMaskStatus.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

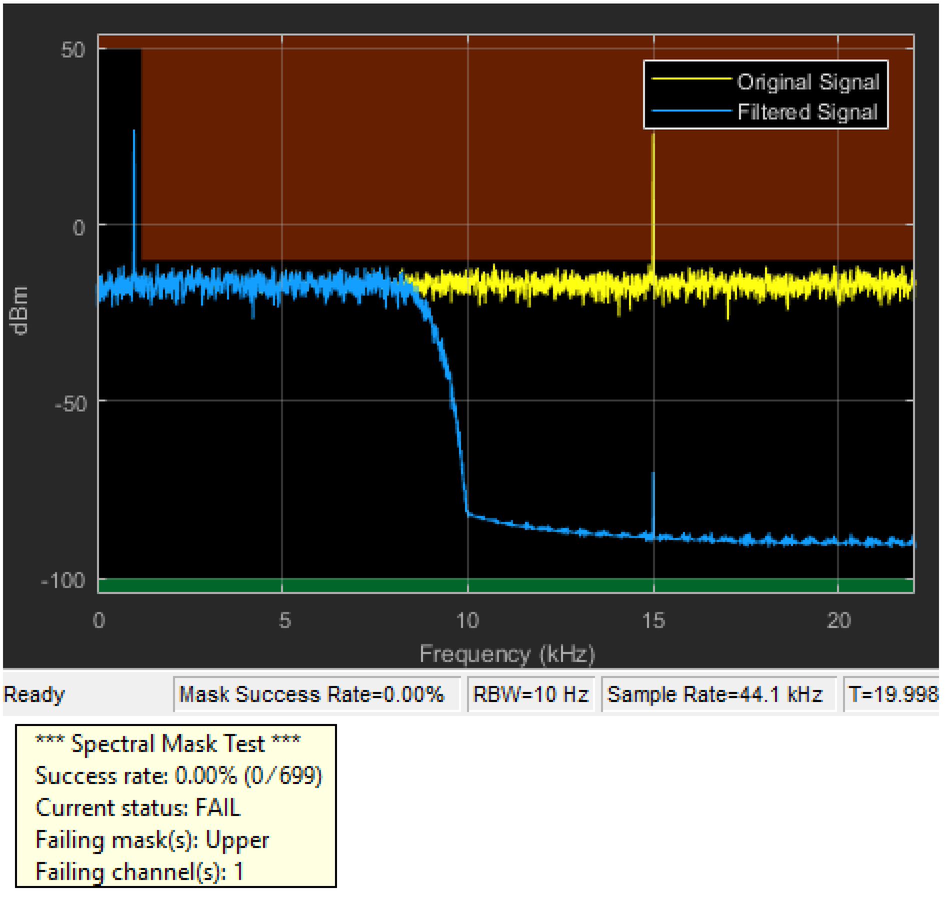
Example of Spectral Mask

This example shows how to create a new model based on the `dsp_basic_filter` template, add a spectral mask to its Spectrum Analyzer block, and run the model.

```
[~,mdl] = fileparts(tempname);
open_system(new_system(mdl,'FromTemplate','dsp_basic_filter'));
saBlock = find_system(mdl,'BlockType','SpectrumAnalyzer');

scopeConfig = get_param(saBlock{1},'ScopeConfiguration');
upperMask = [0 50; 1200 50; 1200 -10; 24000 -10];
scopeConfig.SpectralMask.UpperMask = upperMask;
scopeConfig.SpectralMask.LowerMask = -100;
scopeConfig.SpectralMask.EnabledMasks = 'Upper and lower';

sim(mdl,'StopTime','20');
```

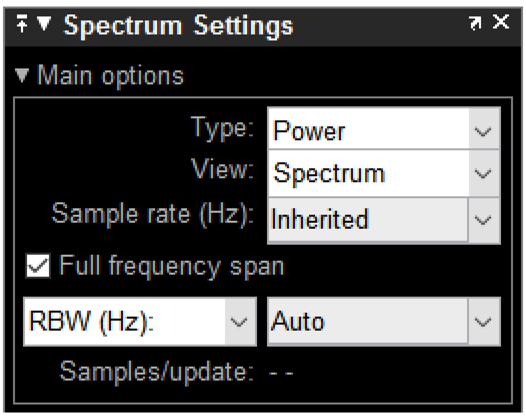


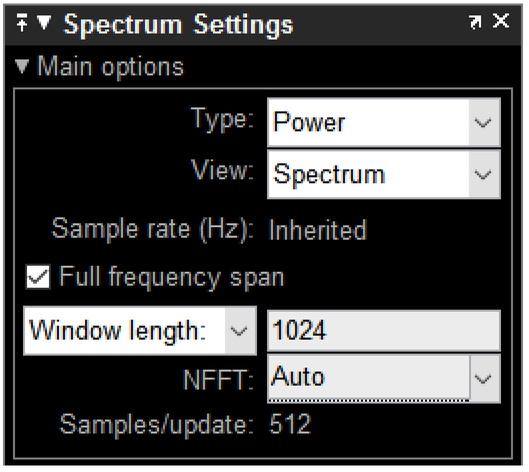
Masks are overlaid on the spectrum. If the mask is green, the signal is passing. If the mask is red, the signal is failing.

At the bottom of the window, the **Mask success rate** shows what percentage of the time the mask is succeeding. A tooltip gives you details about which mask is failing, how many times the mask(s) failed, and which channels are causing the failure.

Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View** > **Spectrum Settings**. Alternatively, in the Spectrum Analyzer toolbar, select the Spectrum Settings  button.





The **Spectrum Settings** panel is separated into three panes, labeled **Main Options**, **Window Options**, and **Trace Options**. You can expand each pane to see the available options.

Main Options Pane

The **Main Options** pane enables you to modify the main options.

- **Type** — The type of spectrum to display. Available options are `Power`, `Power density`, and `RMS`. When you set this parameter to `Power`, the Spectrum Analyzer shows the power spectrum. When you set this parameter to `Power density`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz. When you set this parameter to `RMS`, the Spectrum Analyzer shows the root mean squared spectrum. Tunable (Simulink)
- **View** — The spectrum view to display. Available options are `Spectrum`, `Spectrogram`, and `Spectrum and spectrogram`. When you set this parameter to `Spectrum`, the Spectrum Analyzer shows the spectrum. When you set this parameter to `Spectrogram`, the Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display and time scrolls from the bottom to the top of the display. When you set this parameter to `Spectrum and spectrogram`, the Spectrum Analyzer shows both the spectrum and spectrogram. Tunable (Simulink).

- **Sample rate (Hz)** — The sample rate, in hertz, of the input signals. Select `Inherited` to use the same sample rate as the input signal. To specify a sample rate, enter its value.
- **Full frequency span** — Enable this check box to have Spectrum Analyzer compute and plot the spectrum over the entire *Nyquist* frequency interval. By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. Tunable (Simulink).
- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency*-axis values using start frequency and stop frequency instead.
  - **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency*-axis on the Spectrum Analyzer window. Tunable (Simulink).
  - **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer window. Tunable (Simulink).
  - **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency*-axis on the Spectrum Analyzer window. Tunable (Simulink).
  - **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency*-axis on the Spectrum Analyzer window. Tunable (Simulink).
- **RBW (Hz) / Window length** — The frequency resolution method.

  If set to **RBW (Hz)**, the resolution bandwidth, in hertz. This property defines the smallest positive frequency that can be resolved. By default, this property is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified frequency span.

If you set this property to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall frequency span to *RBW* must be at least two: $\frac{span}{RBW} > 2$.

Tunable (Simulink).

If set to **Window length**, the length of the window, in samples, used to control the frequency resolution and compute the spectral estimates. The window length must be an integer scalar greater than 2.

Tunable (Simulink).

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
RBW (Hz)	`Auto`	`Auto`	1/RBW s
RBW (Hz)	`Auto`	Manually entered	Time Resolution s
RBW (Hz)	Manually entered	`Auto`	1/RBW s
RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW s. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
Window length	—	`Auto`	1/RBW s RBW = *(NENBW**Fs)/Window Length, where *NENBW* is the normalized effective noise bandwidth of the specified window.
Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, *(NENBW**Fs)/Window Length. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

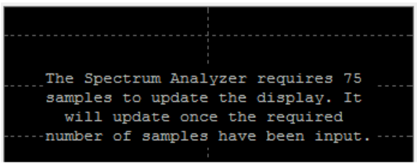
- **NFFT** — The number of Fast Fourier Transform (FFT) points. You can set the **NFFT** only when in Window length mode. This property defines the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive, scalar integer. The **NFFT** value must be greater than or equal to the **Window length**. By default, when **NFFT** is set to `Auto`, Spectrum Analyzer sets the number of FFT points to the window length. When in RBW mode, an FFT length is used that equals the window length required to achieve the specified RBW value.

  When this property is set to a positive integer, this property is equivalent to the `n` parameter that you can set when you run the MATLAB `fft` function. Tunable (Simulink).

- **Samples/update** — The number of input samples required to compute one spectral update. You cannot modify this property; it is shown here for display purposes only. This property is directly related to *RBW* by the following equation:

  $N_{samples} = \dfrac{\left(1 - \dfrac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$ or to the window length by this equation:

$N_{samples} = \left(1-\frac{O_p}{100}\right) x\ WindowLength$. $NENBW$ is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. If the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.

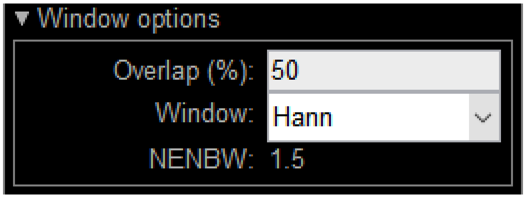


Spectrogram Options Pane

- **Channel** — Select the signal channel for which the spectrogram settings apply. This option displays only when the **Type** is `Spectrogram` and only if there is more than one signal channel input.
- **Time res. (s)** — The time resolution, in seconds. Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of data time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings. This property applies only to spectrograms. Tunable (Simulink)
- **Time span (s)** — The time span over which the Spectrum Analyzer displays the spectrogram, in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to `Auto`, 100 spectral lines are used. This property applies only to spectrograms.Tunable (Simulink)

Window Options Pane

The **Window Options** pane enables you to modify the window options.



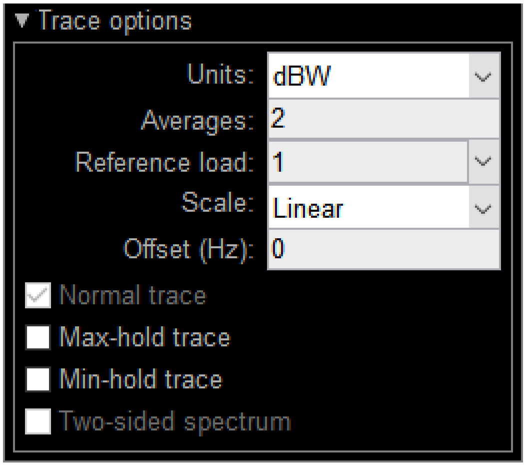
- **Overlap (%)** — The segment overlap percentage. This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. Tunable (Simulink).
- **Window** — The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see "Windows" (Signal Processing Toolbox). Tunable (Simulink).
- **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to `Chebyshev` or `Kaiser`. You must specify a value greater than or equal to `45`. Tunable (Simulink).
- **NENBW** — Normalized Effective Noise Bandwidth of the window. You cannot modify this parameter; it is a readout shown here for display purposes only. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same noise power with the same peak power gain. NENBW can be calculated from the windowing function using the following equation:

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.



- **Units** — The units of the spectrum. The available values depends on the value of **Type**. Available options include `dBm`, `dBW`, `Watts`, `Vrms`, and `dBV`. Tunable (Simulink).
- **Averages** — Specify as a positive, scalar integer the number of spectral averages. This property applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*. Tunable (Simulink).
- **Reference load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. Tunable (Simulink).
- **Scale** — Linear or logarithmic scale. When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. Tunable (Simulink).
- **Offset** — The constant frequency offset to apply to the entire spectrum or a vector of frequencies to apply to each spectrum for multiple inputs. The offset parameter is added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. You must take the parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within Nyquist limits. The Nyquist interval is

$\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz if **Two-sided spectrum** is selected, and $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz otherwise. Tunable (Simulink)

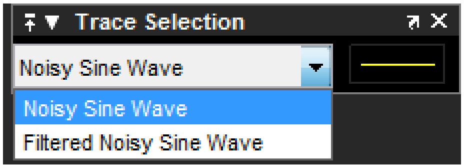
- **Normal trace** — Normal trace view. This property applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. Tunable (Simulink).
- **Max hold trace** — Maximum hold trace view. This property applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. Tunable (Simulink).
- **Min hold trace** — Minimum hold trace view. This property applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. Tunable (Simulink)
- **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued.

Measurements Panels

The Measurements panels are the other four panels that appear to the right side of the Spectrum Analyzer figure.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

Cursor Measurements Panel

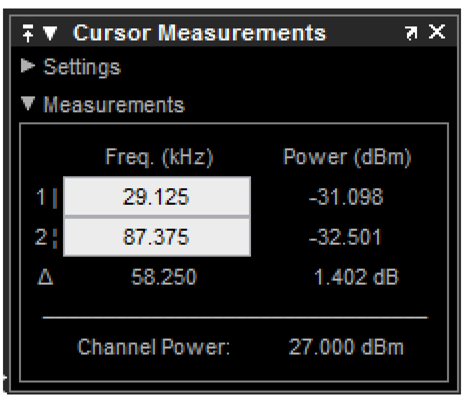
The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note: If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

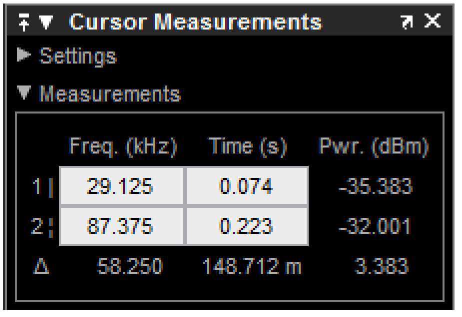
In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel appears as follows for the spectrum and dual view.



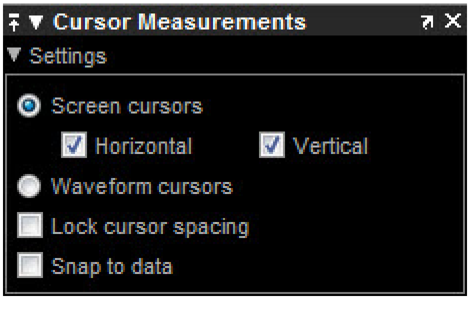
The **Cursor Measurements** panel appears as follows for the spectrogram view. You must pause the spectrogram display before you can use cursors.



The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.



- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

Measurements Pane

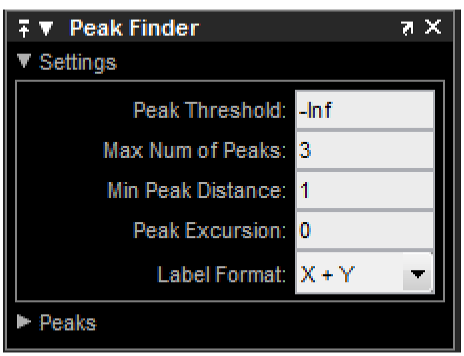
The **Measurements** pane displays the frequency (Hz) , time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.



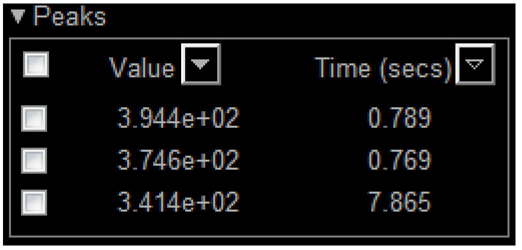
The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button ( ) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button ( ). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled ( ), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Channel Measurements Panel

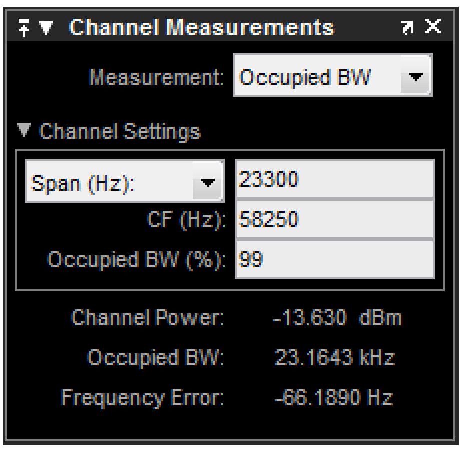
The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements. You can choose to hide or display this pane in the Scope menu by selecting **Tools** > **Measurements** > **Channel Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are `Occupied BW` or `ACPR`. See "Algorithms" on page 2-1592 for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select `Occupied BW` as the **Measurement**, the following fields appear.



- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

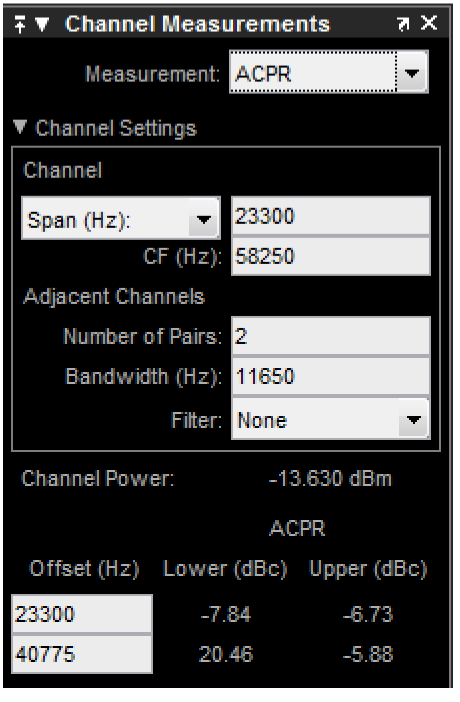
  #### Channel Settings for Occupied BW

  - Select the frequency span of the channel, `Span(Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, FStart(Hz), and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.

- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.

- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select Occupied BW as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select Occupied BW as the **Measurement** type.

When you select ACPR as the **Measurement**, the following fields appear.



- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

  Channel Settings for ACPR

  - Select the frequency span of the channel, `Span (Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
  - **CF (Hz)** — The center frequency of the channel.
  - **Number of Pairs** — The number of pairs of adjacent channels.
  - **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
  - **Filter** — The filter to use for both main and adjacent channels. Available filters are `None`, `Gaussian`, and `RRC` (root-raised cosine).
- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.

Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements. You can choose to hide or display this panel in the Scope menu by selecting **Tools** > **Measurements** > **Distortion Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements  button.

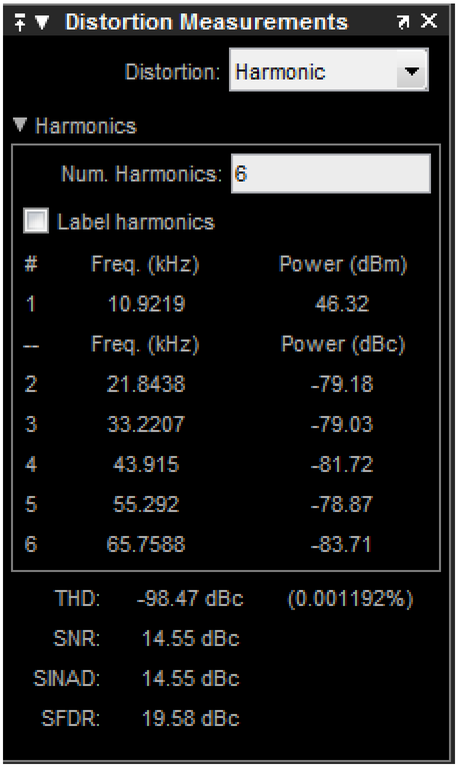
The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note: For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are `Harmonic` or `Intermodulation`. Select `Harmonic` if your system input is a single sinusoid. Select `Intermodulation` if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

  See “Algorithms” on page 2-1592 for information on how distortion measurements are calculated.

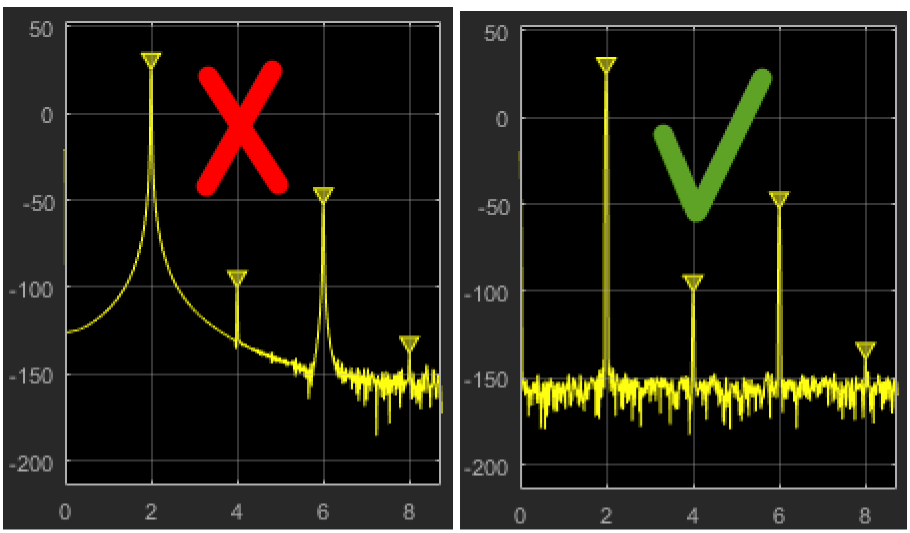
When you select `Harmonic` as the **Distortion**, the following fields appear.



The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note: To best view the harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Additionally, the noise floor should be visible.

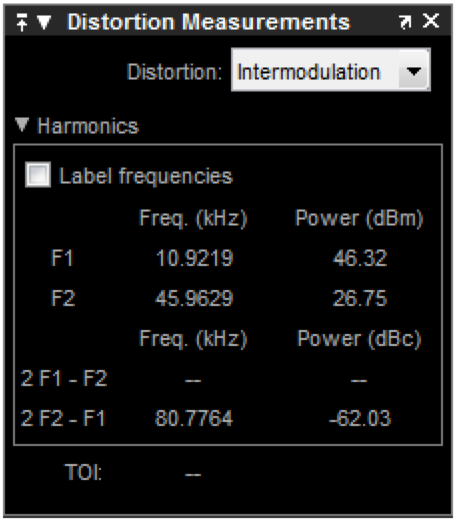
For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).



- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from 2 to 99. The default value is 6.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to one milliwatt (dBm).

- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, *D*, to the power in the fundamental frequency, *S*. If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window. $THD = 10\log_{10}(D/S)$.
- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, *S*, to the power of all nonharmonic content, *N*, including spurious signals, in decibels relative to the carrier (dBc). $SNR = 10\log_{10}(S/N)$. If you see – – as the reported SNR, your signal's total non-harmonic content is less than 30% of the total signal.
- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, *S* to all other content (including noise, *N*, and harmonic distortion, *D*), in decibels relative to the carrier (dBc). $SINAD = 10\log_{10}(S/(N+D)$.
- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, *S*, to power of the largest spurious signal, *R*, regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics. $SFDR = 10\log_{10}(S/R)$.

When you select `Intermodulation` as the **Distortion**, the following fields appear.



The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products (2*F1-F2 and 2*F2-F1).

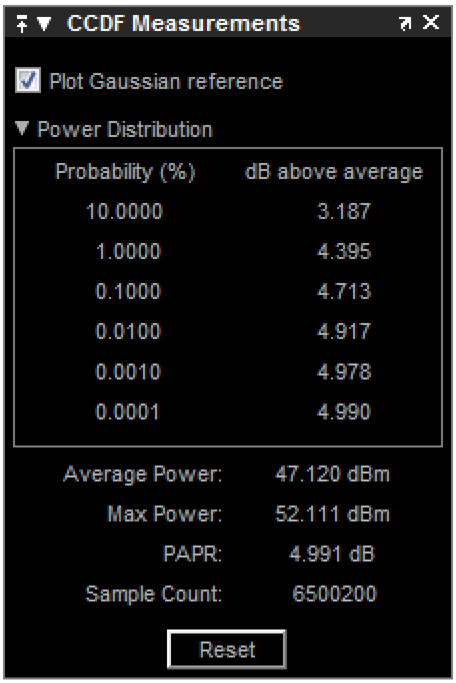
- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal's instantaneous power being a specified level above the signal's average power. These measurements are useful indicators of a signal's dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

You can choose to hide or display this panel in the Scope menu by selecting **Tools** > **Measurements** > **CCDF Measurements**. Alternatively, in the Scope toolbar, click the CCDF Measurements button.



- **Plot Gaussian reference** — Select **Plot Gaussian reference** to show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.

- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.

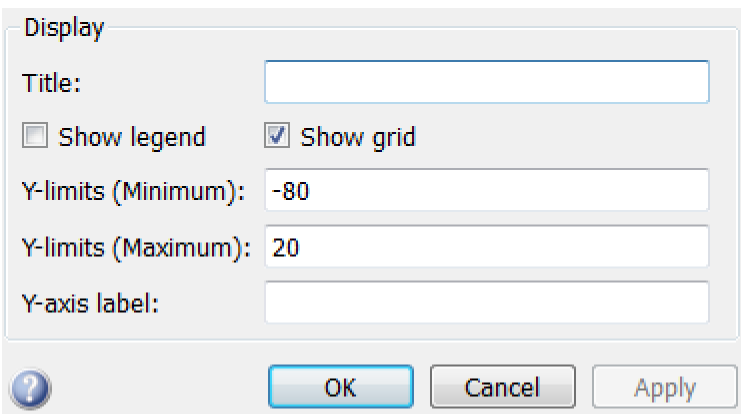
  Max Power — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less that 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — The total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

Visuals — Spectrum Properties

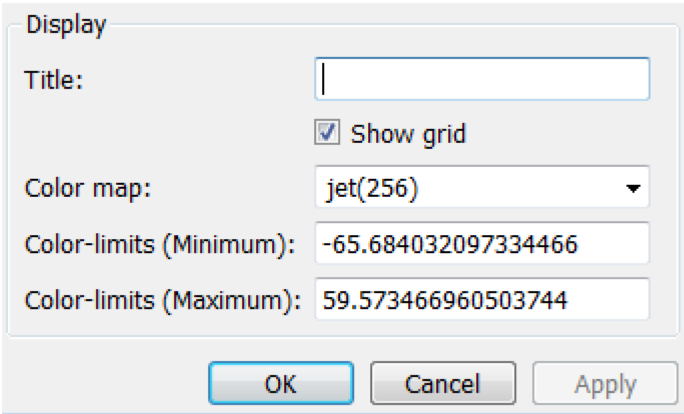
The Visuals—Spectrum Properties dialog box controls the visual configuration settings of the Spectrum Analyzer display. From the Spectrum Analyzer menu, select **View** > **Configuration Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the Configuration Properties  button.

Display Pane

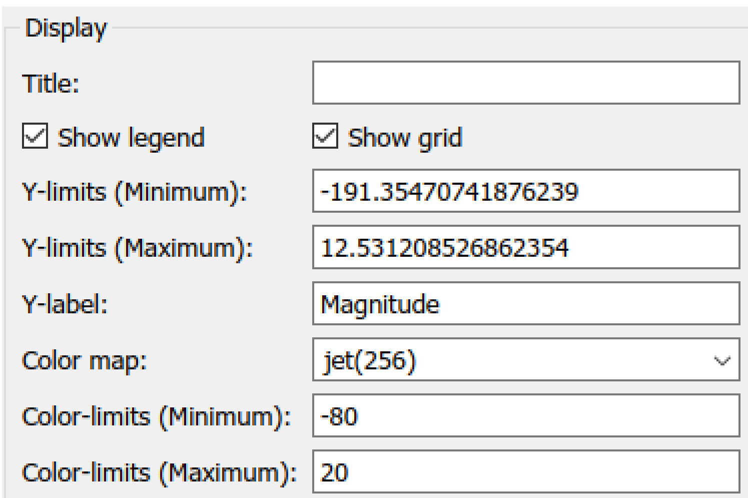
When the Spectrum **View** is `Spectrum`, the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



When the Spectrum **View** is Spectrogram the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



When the Spectrum **View** is Spectrum or spectroogram the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



Title

Specify the display title as a character vector. Enter %<SignalLabel> to use the signal labels in the Simulink Model as the axes titles. This property is Tunable (Simulink).

By default, the display has no title.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn off the legend, clear the **Show legend** check box.

You can edit the name of any channel in the legend by double-clicking the current name and entering a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View** > **Style**.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

This parameter applies only when the **View Type** is `Spectrum` or `Spectrum and spectrogram`. Tunable (Simulink)

Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable (Simulink)

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. Tunable (Simulink)

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable (Simulink)

Y-axis label

Specify the text for the scope to display to the left of the *y*-axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`, `Vrms`, or `dBV`Tunable (Simulink).

Color map

Select the color map for the spectrogram, or enter a 3-column matrix expression for the color map. See `colormap` for information. Tunable (Simulink).

Color-limits (Minimum)

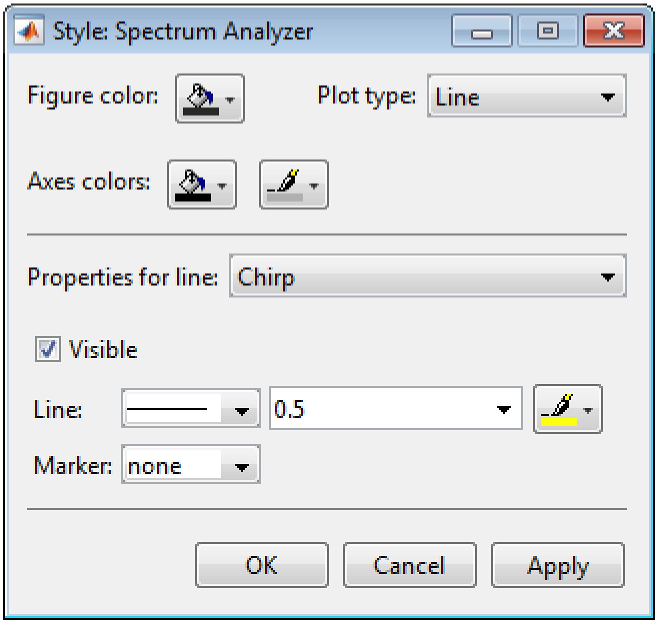
Set the signal power for the minimum color value of the spectrogram. Tunable (Simulink).

Color-limits (Maximum)

Set the signal power for the maximum color value of the spectrogram. Tunable (Simulink).

Style Dialog Box

In the **Style** dialog box, you can customize the style of spectrum display. This dialog box is not available for the spectrogram view. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View** > **Style** to open this dialog box.



Properties

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify whether to display a `Line` or `Stem` plot.

Axes colors

Specify the color that you want to apply to the background of the axes.

Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected channel.

Marker

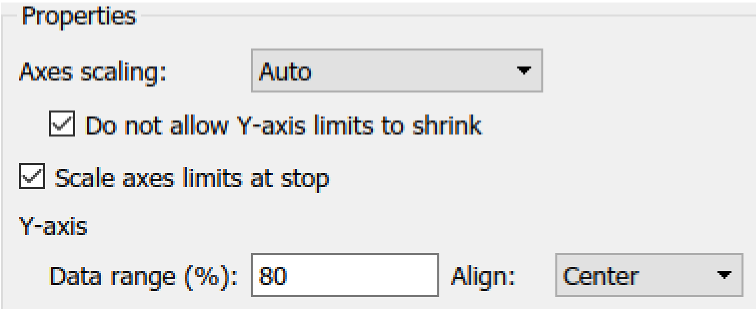
Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for plot objects. You can choose any of the marker symbols from the dropdown.

Tools — Axes Scaling Properties

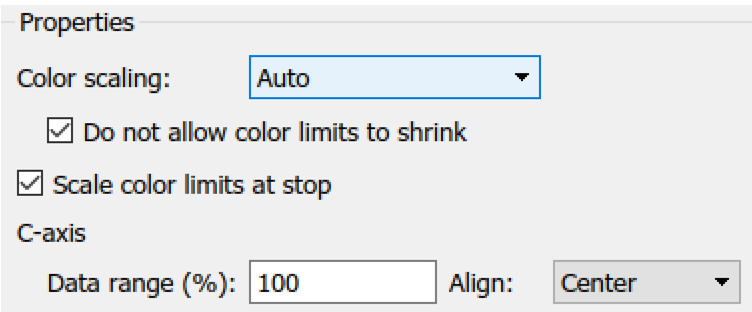
The Tools — Axes Scaling Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes and color of the Spectrum Analyzer. In the Spectrum Analyzer menu, select **Tools** > **Scaling Properties** to open this dialog box.

Properties

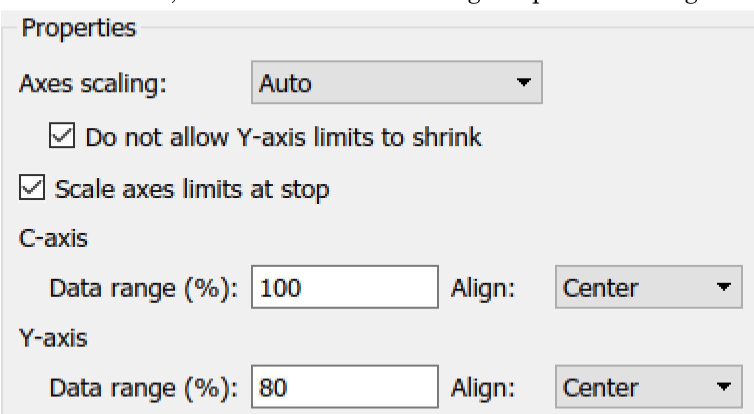
For the spectrum view, the Tools—Axes Scaling Properties dialog box appears as:



For spectrogram view, the Tools—Axes Scaling Properties dialog box appears as:



For dual view, the Tools—Axes Scaling Properties dialog box appears as:



Note: The X-axis scaling options only apply when using CCDF measurements.

Axes scaling/Color scaling

Specify when the scope automatically scales the axes. If the spectrogram is displayed, specify when the scope automatically scales the color. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
  - Select **Tools** > **Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink** .
- `After N Updates` — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this parameter is set to `Auto`, and the scope does not shrink the *y*-axis limits when scaling the axes or color. Tunable (Simulink).

Do not allow Y-axis limits to shrink / Do not allow color limits to shrink

When you select this property, the *y*-axis are allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this property allows the color limits to grow during axis scaling. If you clear this check box, the *y*-axis or color limits can shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** or **Color scaling** property. When you set the **Axes scaling** or **Color scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits can shrink. Tunable (Simulink).

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. If the spectrogram is displayed, this property specifies the number of updates after which to scale the color. This property appears only when you select `After N Updates` for the **Axes scaling** or **Color scaling** property. Tunable (Simulink).

Scale axes limits at stop/Scale color limits at stop

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%) / Color-limits Data range

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range or color such that your data uses only 30% of the *y*-axis range or color. Tunable (Simulink).

Y-axis Align / Color-limits Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the *y*-axis when it scales the color. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable (Simulink).

X-axis Data range (%)

Set the percentage of the *x*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement along the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

X-axis Align

Specify how the scope aligns your data along the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

Algorithms

Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** panel to determine the data window length. The value of the `FrequencyResolutionMethod` property determines whether RBW or window length is used. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

1 Spectrum Analyzer requires that a minimum number of samples have been provided before it computes a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation or to the window length, by the equation shown in step 1b.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, *NENBW*, is a factor that depends on the windowing method. Spectrum Analyzer shows NENBW in the **Window Options** pane of the **Spectrum Settings** panel. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** panel.

a When in RBW mode, the window length required to compute one spectral update, N_{window}, is directly related to the resolution bandwidth and normalized effective noise bandwidth by the following equation.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in WindowLength mode, the window length is used as specified.

b The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

c The normalized effective noise bandwidth, *NENBW*, is a window parameter determined by the window length, N_{window}, and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then *NENBW* is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

d When in RBW mode, you can set the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two, as given in the following equation.

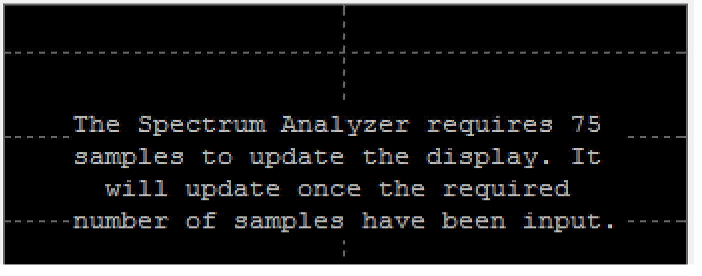
$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to `Auto`, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

e When in window length mode, you specify N_{window} and the resulting RBW is

$$\frac{NENBW * Fs}{N_{window}}$$

In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.



Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input. Notice that this behavior differs from the Spectrum Scope block in versions R2012b and earlier. If the **Buffer input** check box was selected, the Spectrum Scope block computed a spectral update using the number of samples given by the **Buffer size** parameter. Otherwise, the Spectrum Scope block computed a spectral update using the number of samples in each frame.

2 Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified *Periodogram* estimator. For more information about the Periodogram method, see `periodogram` in the Signal Processing Toolbox documentation.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^2}{\left[\sum_{n=1}^{N_{window}} w[n]\right]^2}$$

Spectrogram — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is 1/RBW, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms may be combined. You then use interpolation to calculate noninteger values of 1/RBW. In the spectrogram display, time scrolls from bottom to top, so the most recent data is shown at the bottom of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Note: The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values provided that N_{fft} is greater than or equal to N_{window}.

The *Occupied BW* is calculated as follows.

- Calculate the total power in the measured frequency range.
- Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this sum is $\frac{100 - Occupied\ BW\ \%}{2}$ of the total power.
- Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until it reaches $\frac{100 - Occupied\ BW\ \%}{2}$ of the total power.
- The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- The frequency halfway between the lower and upper frequency values is the center frequency.

The *Distortion Measurements* are computed as follows.

1. Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it clears all monotonically decreasing values (that is, it treats all of these values as if they belong to the peak). Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
2. The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power associated from the fundamental is removed as in step 1.
3. The power and width of the second, and higher order harmonics (P_2, W_2, P_3, W_3, etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases in a monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.

4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$) peak value ($P_{maxspur}$), and its median value ($P_{estnoise}$).

5 The sum of all the removed bandwidth is computed as $W_{sum} = W_0+W_1+W_2+...+W_n$.

The sum of powers of the second and higher order harmonics are computed as $P_{harmonic} = P_2+P_3+P_4+...+P_n$.

6 The sum of the noise power is then estimated as $P_{noise} = (P_{remaining}$*dF + $P_{estnoise}*W_{sum})/RBW$, where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10}\left(\frac{P_{harmonic}}{P_1}\right)$$

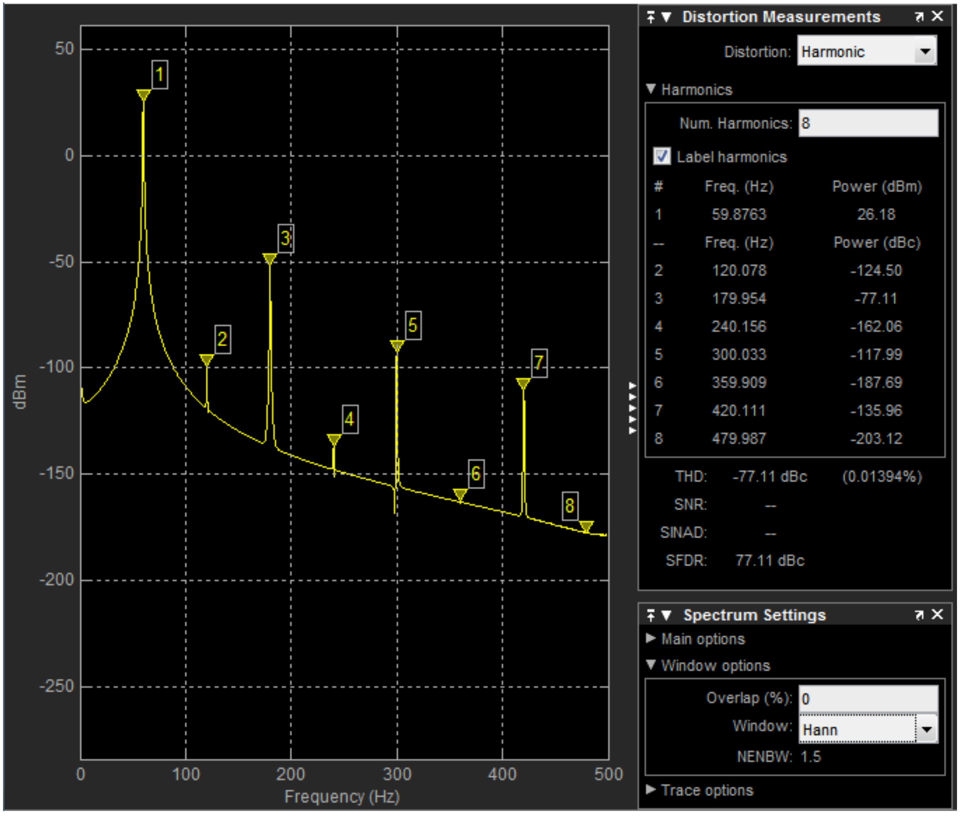
$$SINAD = 10 \cdot \log_{10}\left(\frac{P_1}{P_{harmonic} + P_{noise}}\right)$$

$$SNR = 10 \cdot \log_{10}\left(\frac{P_1}{P_{noise}}\right)$$

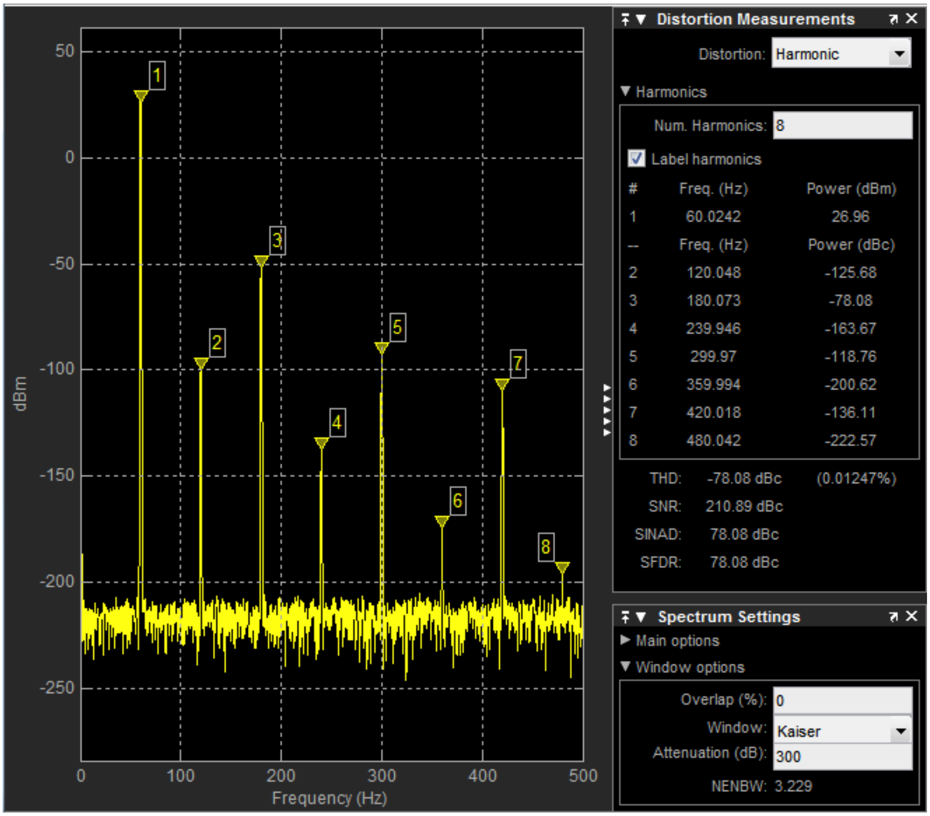
$$SFDR = 10 \cdot \log_{10}\left(\frac{P_1}{\max\left(P_{maxspur}, \max\left(P_2, P_3, ..., P_n\right)\right)}\right)$$

The following considerations apply to *Distortion Measurements*.

- The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default `Hann` window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.



The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. Consider using a Kaiser window with a high attenuation (up to 330dB) to minimize spectral leakage if your application can tolerate the increased equivalent noise bandwidth (ENBW) of the Kaiser window.



- The DC component is ignored.
- After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- *N*th order intermodulation products occur at

  $A*F1 + B*F2$

  where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

- For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to one milliwatt (dBm).:
  - $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
  - $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
  - $TOI = + (TOI_{lower} + TOI_{upper})/2$

Differences from Spectrum Scope Block

All Simulink models containing Spectrum Scope blocks load with Spectrum Analyzer blocks in R2013a or later. Several options that were available on the Parameters dialog box of the Spectrum Scope block are no longer available or have changed. The parameters of Spectrum Scope map to Spectrum Analyzer parameters in the following manner.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	**Buffer input** check box	R2013a Spectrum Analyzer does not require that input signals are buffered. Spectrum Analyzer determines the number of samples needed using the value of the **RBW** parameter. Regardless of whether the input is a frame-based or sample-based signal, Spectrum Analyzer calculates the spectrum once it has acquired the requisite number of samples.	For Spectrum Scope blocks in R2012b or earlier models, the equivalent R2013a Spectrum Analyzer **RBW** value is given by the equation: $$RBW = \frac{NENBW \times F_s}{N_{window}}$$ In the preceding equation, $NENBW$ is the window constant calculated for a window length of 1000, F_s is the sample rate of the block,

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
			and N_{window} is the buffer length. If the input signal to the R2012b Spectrum Scope block was frame-based and the **Buffer input** check box was cleared, then the R2013a Spectrum Analyzer computes the **RBW** value with N_{window} set to the frame size of the input signal.
Scope Properties	**Buffer size** parameter	R2013a Spectrum Analyzer uses the **RBW** parameter to determine the requisite number of samples to calculate the spectrum, instead of using the buffer size or frame length.	For Spectrum Scope blocks in R2012b or earlier models, if the input signal was frame-based and the **Buffer input** check box was selected, then the R2013a Spectrum Analyzer computes the **RBW** value with N_{window} set to the value of the **Buffer size** parameter.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	**Buffer Overlap** parameter	R2013a Spectrum Analyzer has an **Overlap %** parameter that is directly related to buffer overlap.	R2013a Spectrum Analyzer will compute its **Overlap %** using the equation: $$O_p = {O_l}/{N_{window}} \times 100$$ In the preceding equation, O_p is **Overlap %** parameter value, O_l is the R2012b Spectrum Scope **Buffer overlap** parameter value, and N_{window} is the buffer length.
Scope Properties	**Treat Mx1 and unoriented sample-based signals as**	R2013a Spectrum Analyzer defaults to treating Mx1 and unoriented sample-based signals as one channel.	Spectrum Scope blocks in R2012b or earlier models with **Treat Mx1 and unoriented sample-based signals as** set to `M Channels` will have the Spectrum Analyzer property `TreatMby1SignalAsOneChannel` set to `false`. This property is available only via the Scope Configuration object.
Scope Properties	**Window** parameter	R2013a Spectrum Analyzer does not have the `Bartlett`, `Blackman`, `Triang`, or `Hanning` settings.	Spectrum Scope blocks in R2012b or earlier models with a window parameter set to any of these values will have their **Window** parameter set to `Hann` in the R2013a Spectrum Analyzer.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Scope Properties	**Window Sampling** parameter	R2013a Spectrum Analyzer does not have a `Periodic` option. All window sampling is now symmetric in the R2013a Spectrum Analyzer.	n/a
Display Properties	**Persistence** check box — this setting would execute the equivalent of the MATLAB `hold on` command, adding another line for each spectrum computation on the display.	This option is not available in the R2013a Spectrum Analyzer, which has replaced this feature with the trace options, **Normal Trace**, **Max Hold Trace**, and **Min Hold Trace**.	Spectrum Scope blocks in R2012b or earlier models with persistence enabled will have their **Max Hold Trace** check box selected in the R2013a Spectrum Analyzer.
Display Properties	**Compact Display** check box	There is no equivalent capability in the R2013a Spectrum Analyzer.	n/a
Axis Properties	**Inherit Sample time from input** check box	R2013a Spectrum Analyzer always uses the sample time of the input signal.	n/a

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Axis Properties	**Frequency display limits** parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the **Full Span**, **FStart (Hz)**, and **FStop (Hz)** parameters.	If this parameter was set to: • `Auto` — R2013a Spectrum Analyzer selects the **Full Span** check box on the Spectrum Settings panel, Main options pane. • `User-defined` — R2013a Spectrum Analyzer clears the **Full Span** check box on the Spectrum Settings panel Main options pane.
Axis Properties	**Minimum frequency (Hz)** parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the **Full Span**, **FStart (Hz)**, and **FStop (Hz)** parameters.	If the `User-defined` parameter was chosen, then this parameter maps to the R2013a Spectrum Analyzer **FStart (Hz)** parameter.
Axis Properties	**Maximum frequency (Hz)** parameter	R2013a Spectrum Analyzer determines the range of frequencies calculated based on the **Full Span**, **FStart (Hz)**, and **FStop (Hz)** parameters.	If the `User-defined` parameter was chosen, then this parameter maps to the R2013a Spectrum Analyzer **FStop (Hz)** parameter.

R2012b Spectrum Scope Block Parameters dialog box Tab name	R2012b Spectrum Scope Parameter	R2013a Spectrum Analyzer Change	R2013a Spectrum Analyzer Equivalent Parameter
Line Properties	**Line visibilities**, **Line styles**, **Line markers**, and **Line colors** parameters	There are no equivalent capabilities in the R2013a Spectrum Analyzer.	Once the simulation has started, you can modify the line styles, markers, and colors using the Style dialog box.

The R2012b Spectrum Scope allowed you to retain the axes limits over multiple simulations by selecting **Axes** > **Save Axes Settings**. There is no equivalent capability in the R2013a Spectrum Analyzer. However, you can automatically scale the axes to a specified range using the Tools — Axes Scaling Properties dialog box.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned)

Supported Simulation Modes

You can use the scope block in models running the following supported simulation modes.

Mode	Supported	Notes and Limitations
Normal	Yes	

Mode	Supported	Notes and Limitations
Accelerator	Yes	
Rapid Accelerator	Yes	You can use Rapid Accelerator mode as a method to increase the execution speed of your Simulink model. Rapid Accelerator mode creates an executable that includes the solver and model methods. This executable resides outside MATLAB and Simulink. Rapid Accelerator mode uses External mode to communicate with Simulink. For more information about Rapid Accelerator mode, see "Acceleration" (Simulink).
PIL	No	
SIL	No	
External	Yes	You can use External mode to tune block parameters in real time and view block outputs in many types of blocks and subsystems. External mode establishes communication between a host system, where the Simulink environment resides, and a target system, where the executable runs after code generation and the build process. For more information about External mode, see "Set Up and Use Host/Target Communication Channel" (Simulink Coder). The scope does not support data archiving. See "Set External Mode Data Archiving Parameters" (Simulink Desktop Real-Time).

For more information about these modes, see "How Acceleration Modes Work" (Simulink).

Spectrum Analyzer Measurements

Introduced in R2014b

Spectrum Estimator

Estimate power spectrum or power-density spectrum

Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Spectrum Estimator block outputs the power spectrum or power-density spectrum of a real or complex input signal, using the Welch method of averaged modified periodograms and the filter bank approach.

When you choose the filter bank approach, the block uses an analysis filter bank to estimate the power spectrum. The filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and more precise peaks than the Welch method, with low or no spectral leakage. They come at the expense of increased computation and slower tracking.

When you choose the Welch method, the block computes the averaged modified periodograms to compute the spectral estimate. The block buffers the input data into overlapping segments. Use the block parameters to set the length of the data segments, the amount of data overlap between consecutive segments, and other features of the power spectrum.

For more information on the Welch method and the filter bank method, see “Algorithms” on page 2-1617.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

Parameters

Main Tab

Method

Specify the spectral estimation method.

- `Filter bank` (default) — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The block computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band.
- `Welch` — The block uses the Welch averaged modified periodograms method to compute the power spectrum over the narrow subbands.

Number of taps per band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to **Number of taps per band** times the FFT length.

This parameter applies when you set **Method** to `Filter bank`. The default is 12.

Spectrum type

Type of spectrum to compute. You can set this parameter to:

- `Power` (default) — Compute the power spectrum.
- `Power density` — Compute the power spectral density.

This parameter is nontunable.

Frequency resolution method

Frequency resolution method. You can set this parameter to:

- `Auto` (default) — The Spectrum Estimator block computes the resolution bandwidth (RBW) so that the frequency span fits 1024 RBW intervals.

  - Welch method — The window length, *winLen*, is calculated using $winLen = NENBW \times Fs / RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate.
  - Filter bank method — The FFT length is the ceiling of the ratio of **Sample rate (Hz)** to the computed resolution bandwidth.
- `RBW` — Specify the resolution bandwidth, which is used to determine the window length (Welch method) or the FFT length (filter bank method). When the block uses the Welch method, the behavior is equivalent to that of the `Spectrum Analyzer` block. The window length is calculated using $winLen = NENBW \times Fs / RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate. The FFT length is equal to the ceiling of the ratio of **Sample rate (Hz)** to **RBW (Hz)**.
- `Window length` — Specify the window or segment length to use in the Welch algorithm. This option appears when you set **Method** to `Welch`.
- `Number of frequency bands` — Specify the number of polyphase branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. This option appears when you set **Method** to `Filter bank`.

This parameter is nontunable.

RBW (Hz)

Resolution bandwidth, specified as a positive scalar in Hz. The default is `5`. This parameter applies when you set **Frequency resolution method** to `RBW`. The ceiling of the ratio of the frequency span to RBW must be greater than `2`.

This parameter is nontunable.

Number of bands source

Source of the number of frequency bands. This parameter applies when you set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`. You can set this parameter to:

- `Same as input frame length` (default) — The FFT length is set to the frame size of the input.
- `Specify on dialog` — The FFT length is the value you specify in **Number of bands**.

This parameter is nontunable.

Number of bands

Number of frequency bands, or the FFT length the filter bank uses to compute the power spectral estimate, specified as a positive scalar. The default is `1024`. This parameter applies when you set **Method** to `Filter bank`, **Frequency resolution method** to `Number of frequency bands`, and **Number of bands source** to `Specify on dialog`. This parameter is nontunable.

Window length source

Source of the window length value. This parameter applies when you set **Method** to `Welch` and **Frequency resolution method** to `Window length`. You can set this parameter to:

- `Same as input frame length` (default) — Window length is set to the frame size of the input. Specify this option to obtain behavior equivalent to that of the `Periodogram` block.
- `Specify on dialog` — Window length is the value you specify in the **Window length** parameter.

This parameter is nontunable.

Window length

Length of the window used to compute the spectrum estimate, specified as a positive integer scalar greater than `2`. The default is `1024`. This parameter applies when you set **Method** to `Welch`, **Frequency resolution method** to `Window length`, and **Window length source** to `Specify on dialog`. This parameter is nontunable.

FFT length source

Source of the FFT length value. This parameter applies when you set **Method** to `Welch` and **Frequency resolution method** to `Window length`. You can set this parameter to:

- `Auto` (default) — The block sets the FFT length to the frame size of the input.
- `Property` — The block sets the FFT length to the value you specify in **FFT length**.

This parameter is nontunable.

FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **Method** to `Welch`, **Frequency resolution method** to `Window length`, and **FFT length source** to `Property`. The default is `1024`. This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block sample rate is computed as N/T_s, where N is the frame size of the input signal and T_s is the sample time of the input signal.

This check box applies when you do one of the following:

- Set **Method** to `Welch` and **Frequency resolution method** to `Window length`.
- Set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`.

When you clear this check box, the block sample rate is the value you specify in **Sample rate (Hz)**. By default, this check box is selected. This parameter is nontunable.

Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is `44100`. This parameter applies when you do one of the following:

- Set **Frequency resolution method** to `Auto` or `RBW`.
- Set **Method** to `Welch`, **Frequency resolution method** to `Window length`, and clear the **Inherit sample rate from input** check box.
- Set **Method** to `Filter bank`, **Frequency resolution method** to `Number of frequency bands`, and clear the **Inherit sample rate from input** check box.

This parameter is nontunable.

Window function

Window function the Welch algorithm uses, specified as one of `Chebyshev | Flat Top | Hamming | Hann | Kaiser | Rectangular`. This parameter appears when you set **Method** to `Welch`. The default is `Hann`. This parameter is nontunable.

Sidelobe attenuation of window (dB)

Sidelobe attenuation of the window, specified as a real positive scalar greater than or equal to `45`, in dB. The default is `60`. This parameter appears when you set **Method** to `Welch` and **Window function** to `Chebyshev` or `Kaiser`. This parameter is nontunable.

Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The default is `1`. The spectrum estimator computes the current power spectrum estimate by averaging the last *N* power spectrum estimates, where *N* is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

Advanced Tab

Window overlap (%)

Percentage of overlap between successive data windows, specified as a scalar from `0` and `100`. The default value is `0`. To enable this parameter, on the **Main Tab**, set **Method** to `Welch`. This parameter is nontunable.

Reference load (ohms)

Load used as a reference to compute the power values, specified as a real positive scalar expressed in ohms. The default value is `1`. This parameter is nontunable.

Frequency range

Frequency range of the spectrum estimator. You can set this parameter to:

- `One-sided` — The spectrum estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length (`NFFT`/2) + `1` and is computed over the frequency range `[0 SampleRate/2]`. `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length (`NFFT` + 1)/2 and is computed over the frequency range [`0 SampleRate/2`).
- `Two-sided` — The spectrum estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range [`0 SampleRate`), where `SampleRate` is the sample rate of the input signal.
- `Centered` (default) — The spectrum estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range (`-SampleRate/2 SampleRate/2`] when the FFT length is even and `(-SampleRate/2 SampleRate/2)` when the FFT length is odd.

This parameter is nontunable.

Power units

Units used to measure power. You can set this parameter to:

- `'Watts'` (default) — The spectrum estimator measures power in watts.
- `'dBw'` — The spectrum estimator measures power in decibel-watts.

- 'dBm' — The spectrum estimator measures power in decibel-milliwatts.

This parameter is nontunable.

Output max-hold spectrum

When you select this check box, the block computes the max-hold spectrum of the input signal by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output min-hold spectrum

When you select this check box, the block computes the min-hold spectrum of the input signal by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output frequency vector

When you select this check box, the block outputs the frequency vector. By default, this check box is not selected. This parameter is nontunable.

Output effective RBW

When you select this check box, the block computes the effective resolution bandwidth. By default, this check box is not selected. This parameter is nontunable.

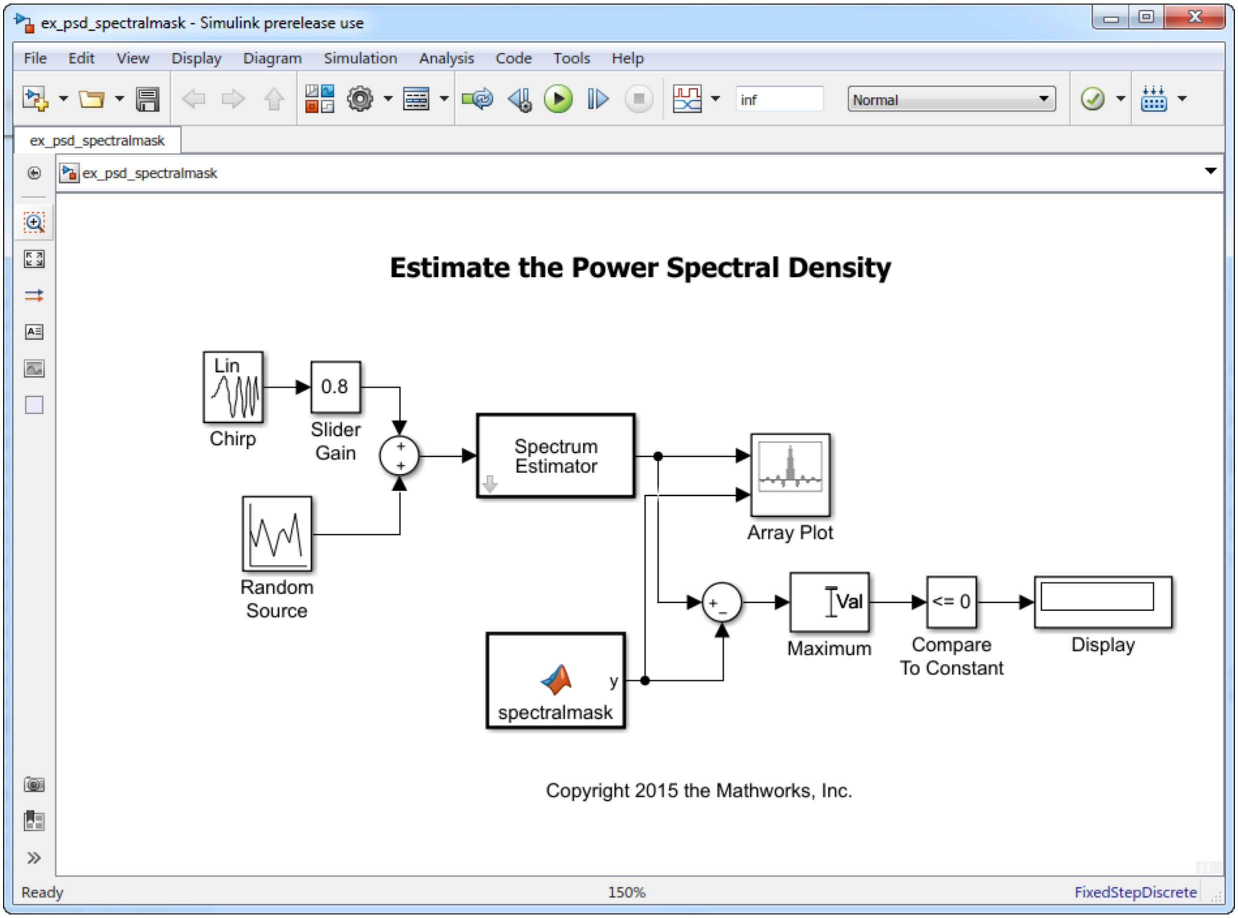
Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Example

Estimate the Power Spectral Density (PSD) of a chirp signal using the Spectrum Estimator block. Compare the PSD data with a Bluetooth® spectral mask and determine if the PSD data complies with the mask.



To view the complete model, enter `ex_psd_spectralmask` in the MATLAB command prompt.

Input Signal

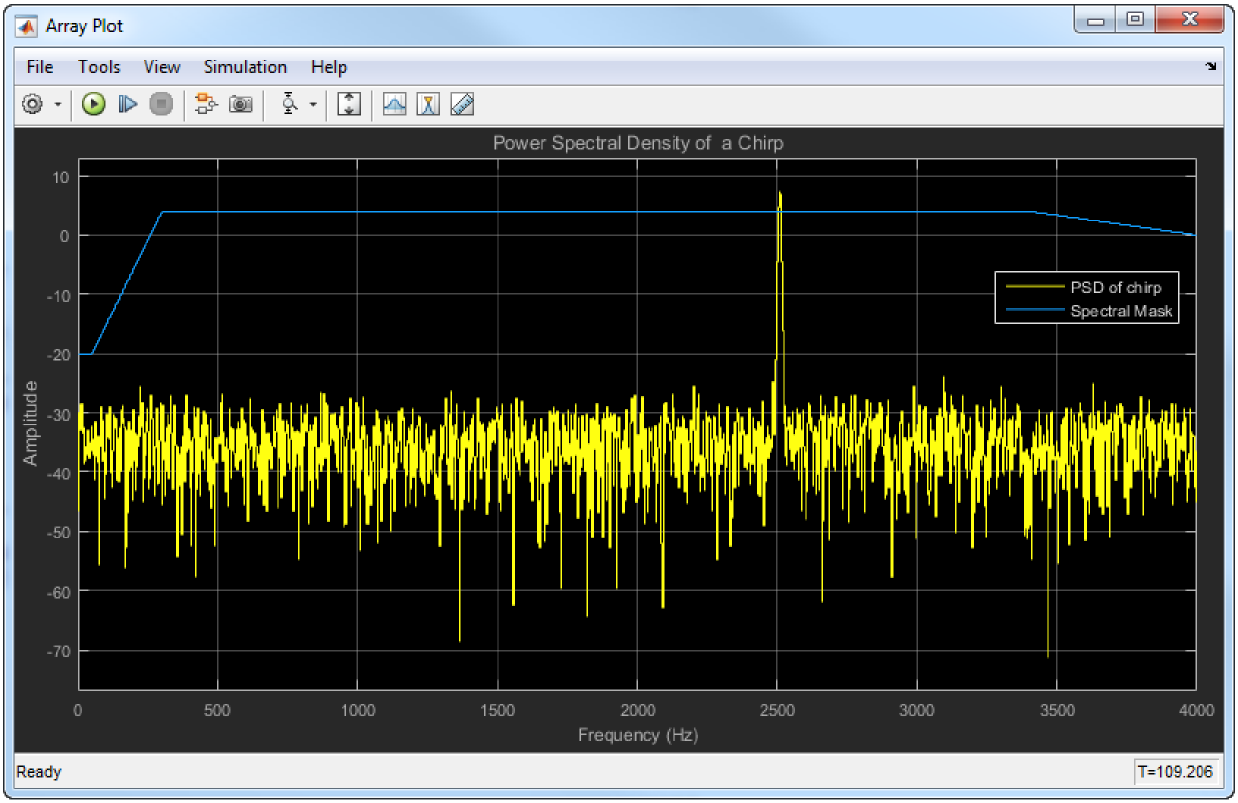
The input to the Spectrum Estimator block is a chirp signal embedded in Gaussian noise with zero mean and a variance of `0.01`. The chirp signal is amplified with a gain factor in the range [`0 1`].

Spectral Mask

The Spectral mask is created using the MATLAB Function block. The mask is based on the Bluetooth standard described in [5].

Live Processing

The Spectrum Estimator block estimates the PSD of the chirp. In this example, the PSD data is compared with the spectral mask. The Display block shows a 1 or 0, depending on whether the spectral data is within the mask or not. During simulation, you can change the power in the input signal by moving the slider in the Slider Gain block. Simultaneously, you can view this change in the Array Plot block.



Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

Algorithms

Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

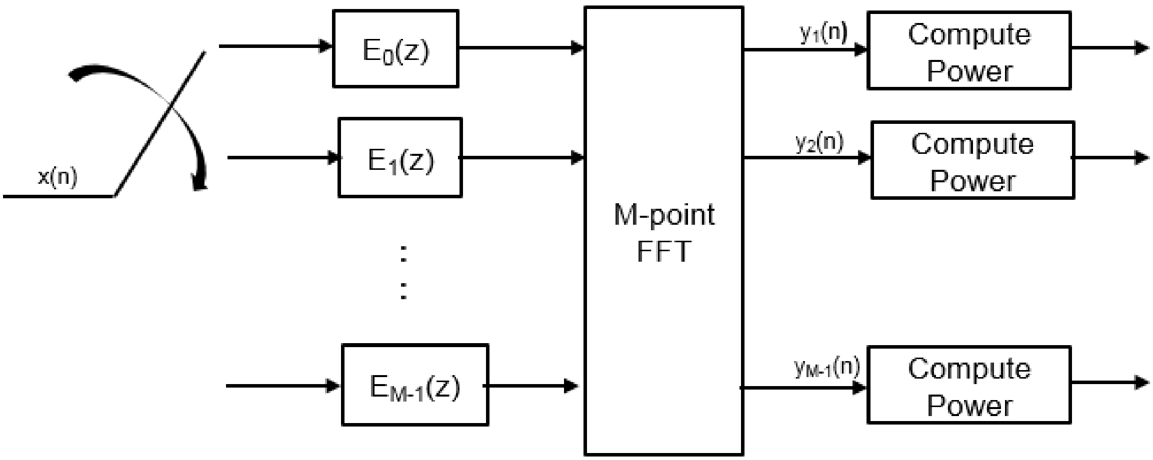
Let `x` be the input frame. Multiply `x` by the window and scale the result by the window power. Take the FFT of the signal, `Y`, and take the square magnitude using `Z = Y*conj(Y)`. Compute the current power spectrum estimate by averaging the last *N* `Z`s and scaling the answer by the sample rate. *N* is the number of spectral averages.

For further information refer to the "Algorithms" on page 2-1592 section in Spectrum Analyzer, which uses the same algorithm.

Filter Bank

The spectrum estimator uses an analysis filter bank to estimate the power spectrum. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the FFT length.

The filter-bank-based spectrum estimator splits the broadband input signal, *x(n)*, into multiple narrow bands and computes the power in each band. Each value becomes the estimate of the power over that narrow frequency band. The power in all the narrow bands forms the spectral estimate vector.



For more details on the implementation, see the “Algorithm” on page 2-214 section in `dsp.Channelizer`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

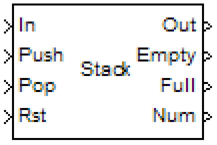
Stack

Store inputs into LIFO register



Library

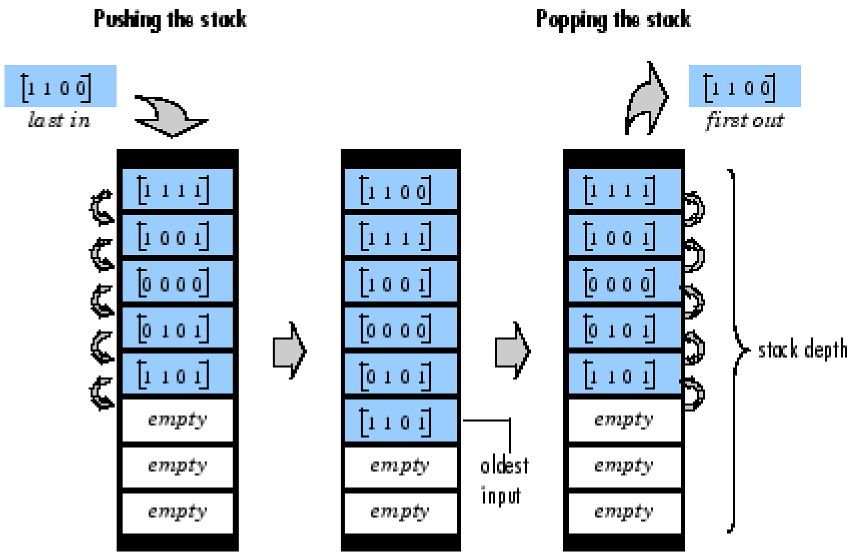
Signal Management / Buffers

`dspbuff3`

Description

The Stack block stores a sequence of input samples in a last in, first out (LIFO) register. The register capacity is set by the **Stack depth** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the `In` port onto the top of the stack when a trigger event is received at the `Push` port. When a trigger event is received at the `Pop` port, the block *pops* the top element off the stack and holds the `Out` port at that value. The last input to be pushed onto the stack is always the first to be popped off.



A trigger event at the optional `Rst` port empties the stack contents. When you select **Clear output port on reset**, then a trigger event at the `Rst` port empties the stack *and* sets the value at the `Out` port to zero. This setting also applies when a disabled subsystem containing the Stack block is reenabled; the `Out` port value is only reset to zero in this case when you select **Clear output port on reset**.

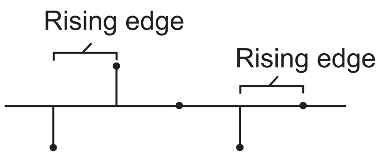
When two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

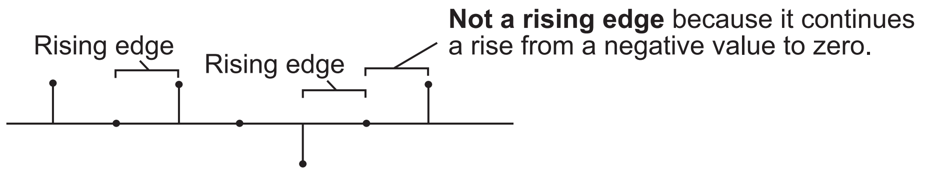
1. `Rst`
2. `Push`
3. `Pop`

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the `Push`, `Pop`, and `Rst` ports in the **Trigger type** pop-up menu:

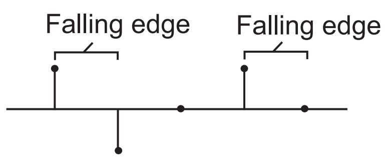
- `Rising edge` — Triggers execution of the block when the trigger input does one of the following:
  - Rises from a negative value to a positive value or zero

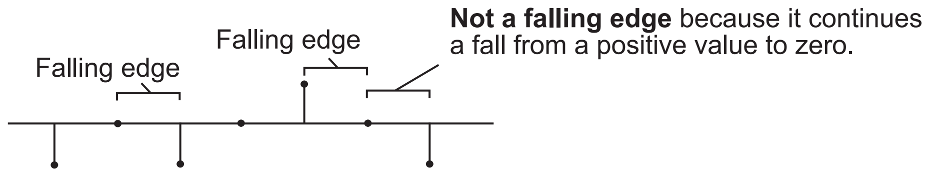
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)





- `Falling edge` — Triggers execution of the block when the trigger input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)





- `Either edge` — Triggers execution of the block when the trigger input is a `Rising edge` or `Falling edge` (as described above).
- `Non-zero sample` — Triggers execution of the block at each sample time that the trigger input is not zero.

Note: If your model contains any referenced models that use a Stack block with the **Push full stack** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push full stack** parameter specifies the block's behavior when a trigger is received at the `Push` port but the register is full. The **Pop empty stack** parameter specifies the block's behavior when a trigger is received at the `Pop` port but the register is empty. The following options are available for both cases:

- `Ignore` — Ignore the trigger event, and continue the simulation.
- `Warning` — Ignore the trigger event, but display a warning message in the MATLAB command window.
- `Error` — Display an error dialog box and terminate the simulation.

Note The **Push full stack** and **Pop empty stack** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push full stack** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the stack at a given time, enable the `Num` output port by selecting the **Show number of stack entries port** parameter.

Note: When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Examples

Example 1

The table below illustrates the Stack block's operation for a **Stack depth** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from `1` to `0` or `0` to `1` in the `Push`, `Pop`, and `Rst` columns below represents a distinct trigger event. A `1` in the `Empty` column indicates an empty buffer, while a `1` in the `Full` column indicates a full buffer.

In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
1	0	0	0	top bottom	0	1	0	0
2	1	0	0	top 2 bottom	0	0	0	1
3	0	0	0	top 3 2 bottom	0	0	0	2
4	1	0	0	top 4 3 2 bottom	0	0	0	3
5	0	0	0	top 5 4 3 2 bottom	0	0	1	4
6	0	1	0	top 4 3 2 bottom	5	0	0	3
7	0	0	0	top 3 2 bottom	4	0	0	2
8	0	1	0	top 2 bottom	3	0	0	1
9	0	0	0	top bottom	2	1	0	0
10	1	0	0	top 10 bottom	2	0	0	1
11	0	0	0	top 11 10 bottom	2	0	0	2
12	1	0	1	top 12 bottom	0	0	0	1

Note that at the last step shown, the `Push` and `Rst` ports are triggered simultaneously. The `Rst` trigger takes precedence, and the stack is first cleared and then pushed.

Example 2

The dspqdemo example provides an example of the related Queue block.

Parameters

Stack depth

The number of entries that the LIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push full stack

Response to a trigger received at the `Push` port when the register is full. Inputs to this port must have the same built-in data type as inputs to the `Pop` and `Rst` input ports.

When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc — Generic Real-Time Target with dynamic memory allocation`.

Pop empty stack

Response to a trigger received at the `Pop` port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Rst` input ports.

Show empty stack indicator port

Enable the `Empty` output port, which is high (`1`) when the stack is empty, and low (`0`) otherwise.

Show full stack indicator port

Enable the `Full` output port, which is high (`1`) when the stack is full, and low (`0`) otherwise. The `Full` port remains low when you select **Dynamic reallocation** from the **Push full stack** parameter.

Show number of stack entries port

Enable the `Num` output port, which tracks the number of entries currently on the stack. When inputs to the `In` port are double-precision values, the outputs from the `Num` port are double-precision values. Otherwise, the outputs from the `Num` port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the `Rst` input port, which empties the stack when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the `Push` and `Pop` input ports.

Clear output port on reset

Reset the `Out` port to zero (in addition to clearing the stack) when a trigger is received at the `Rst` input port.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Push	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports
Pop	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.
Rst	• Double-precision floating point • Single-precision floating point • Boolean

Port	Supported Data Types
	• 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Empty	• Double-precision floating point • Boolean
Full	• Double-precision floating point • Boolean
Num	• Double-precision floating point The block outputs a double-precision floating-point value at this port when the data type of the In port is double-precision floating-point. • 32-bit unsigned integers The block outputs a 32-bit unsigned integer value at this port when the data type of the In port is anything other than double-precision floating-point.

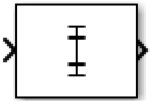
Standard Deviation

Standard deviation of input or sequence of inputs
Library: DSP System Toolbox / Statistics



Description

The Standard Deviation block computes the standard deviation of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input. You can specify the dimension using the **Find the standard deviation value over** parameter. The Standard Deviation block can also track the standard deviation in a sequence of inputs over a period of time. To track the standard deviation in a sequence of inputs, select the **Running standard deviation** parameter.

Note: The **Running** mode in the Standard Deviation block will be removed in a future release. To compute the running standard deviation in Simulink, use the `Moving Standard Deviation` block instead.

Ports

Input

`In` — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double`

Complex Number Support: Yes

`Rst` — Reset port
scalar

Specify the reset event that causes the block to reset the running standard deviation. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — Standard deviation along the specified dimension
scalar | vector | matrix | *N*-D array

The data type of the output matches the data type of the input.

When you do not select the **Running standard deviation** parameter, the block computes the standard deviation in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input at each individual sample time. Each element in the output array `y` is the standard deviation of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the standard deviation value over** parameter. Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the standard deviation value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the standard deviation of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the standard deviation of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.

- `Each column` — The output at each sample time consists of a 1-by-N-by-P array, where each element contains the standard deviation of each vector over the first dimension of the input. For an M-by-N matrix input, the output at each sample time is a 1-by-N row vector.

  In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.
- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an M-by-N matrix containing the standard deviation of each vector over the third dimension of the input.

When you select **Running standard deviation**, the block tracks the standard deviation of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the jth column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double`

Parameters

Main Tab

`Running standard deviation` — Option to select running standard deviation

off (default) | on

When you select the **Running standard deviation** parameter, the block tracks the standard deviation value of each channel in a time sequence of inputs.

`Find the standard deviation value over` — Dimension over which the block computes the standard deviation

`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the standard deviation over each column.
- `Each row` — The block outputs the standard deviation over each row.
- `Entire input` — The block outputs the standard deviation over the entire input.
- `Specified dimension` — The block outputs the standard deviation over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running standard deviation** parameter.

`Dimension` — Custom dimension

`1` (default) | scalar

Specify the dimension (one-based value) of the input signal over which the standard deviation is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the standard deviation value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the *j*th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.
- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk}.

  Variable-Size Inputs

  When your inputs are of variable size, and you select the **Running standard deviation** parameter, then:

  - If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
  - If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:

    - When the input size difference is in the number of channels (number of columns), the state is reset.
    - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

`Reset port` — Reset event

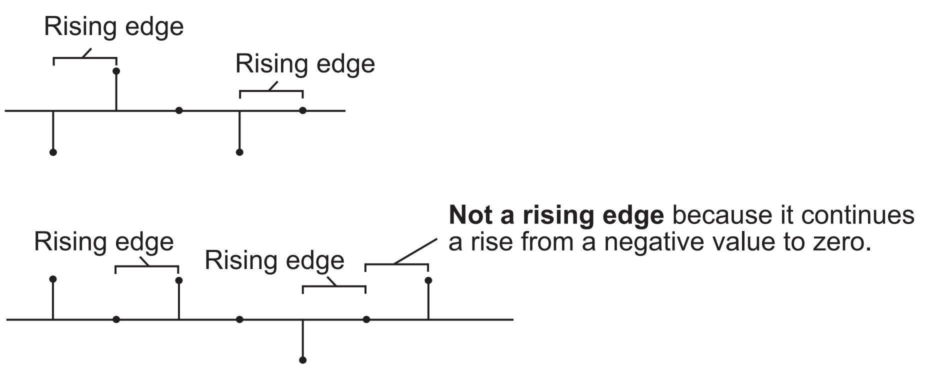
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

The block resets the running standard deviation whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

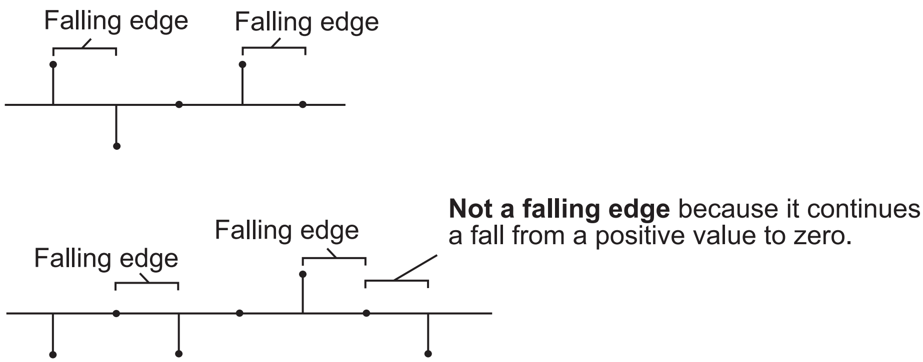
When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running standard deviation for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.



- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note: When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

Definitions

Standard Deviation

The standard deviation of a discrete-time signal is the square root of the variance of the signal.

Standard deviation gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u, of size M-by-N, the standard deviation is given by the following equation:

$$y = \sigma = \sqrt{\frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1}}$$

- u_{ij} is the input data element at indices i, j.
- M is the length of the jth column.
- N is the number of columns.

For complex inputs, the standard deviation is given by the following equation:

$$\sigma = \sqrt{\sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2}$$

- $\sigma_{Re}{}^2$ is the variance of the real part of the complex input.
- $\sigma_{Im}{}^2$ is the variance of the imaginary part of the complex input.

Algorithms

Standard Deviation

When you clear the **Running standard deviation** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `std` function, when it is called as `y = std(u,0,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the standard deviation along the specified dimension.

The standard deviation along the entire input is identical to calling the `std` function as `y = std(u(:))`.

For a complex input signal, the standard deviation is the square root of the sum of the variances of the real and imaginary parts.

$$\sigma = \sqrt{\sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2}$$

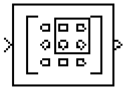
Submatrix

Select subset of elements (submatrix) from matrix input



Library

- Math Functions / Matrices and Linear Algebra / Matrix Operations

  `dspmtrx3`
- Signal Management / Indexing

  `dspindex`

Description

The Submatrix block extracts a contiguous submatrix from the *M*-by-*N* input matrix `u`. The block treats length-*M* unoriented vector input as an *M*-by-`1` matrix. The **Row span** parameter provides three options for specifying the range of rows in `u` to be retained in submatrix output `y`:

- `All rows`

  Specifies that `y` contains all *M* rows of `u`.
- `One row`

  Specifies that `y` contains only one row from `u`. The **Row** parameter (described below) is enabled to allow selection of the desired row.
- `Range of rows`

  Specifies that `y` contains one or more rows from `u`. The **Starting row** and **Ending row** parameters (described below) are enabled to allow selection of the desired range of rows.

The **Column span** parameter contains a corresponding set of three options for specifying the range of columns in `u` to be retained in submatrix `y`: `All columns`, `One column`, or `Range of columns`. The `One column` option enables the **Column** parameter, and `Range of columns` options enable the **Starting column** and **Ending column** parameters.

Range Specification Options

When you select `One row` or `Range of rows` from the **Row span** parameter, you specify the desired row or range of rows in the **Row** parameter, or the **Starting row** and **Ending row** parameters. Similarly, when you select `One column` or `Range of columns` from the **Column span** parameter, you specify the desired column or range of columns in the **Column** parameter, or the **Starting column** and **Ending column** parameters.

The **Row**, **Column**, **Starting row** or **Starting column** can be specified in six ways:

- `First`

  For rows, this specifies that the first row of `u` should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(1,:)`.

  For columns, this specifies that the first column of `u` should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,1)`.
- `Index`

  For rows, this specifies that the row of `u`, `firstrow`, forward-indexed by the **Row index** parameter or the **Starting row index** parameter, should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(firstrow,:)`.

  For columns, this specifies that the column of `u`, forward-indexed by the **Column index** parameter or the **Starting column index** parameter, `firstcol`, should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,firstcol)`.
- `Offset from last`

  For rows, this specifies that the row of `u` offset from row *M* by the **Row offset** or **Starting row offset** parameter, `firstrow`, should be used as the first row of `y`. When all columns are to be included, this is equivalent to `y(1,:) = u(M-firstrow,:)`.

For columns, this specifies that the column of `u` offset from column *N* by the **Column offset** or **Starting column offset** parameter, `firstcol`, should be used as the first column of `y`. When all rows are to be included, this is equivalent to `y(:,1) = u(:,N-firstcol)`.

- `Last`

  For rows, this specifies that the last row of `u` should be used as the only row of `y`. When all columns are to be included, this is equivalent to `y = u(M,:)`.

  For columns, this specifies that the last column of `u` should be used as the only column of `y`. When all rows are to be included, this is equivalent to `y = u(:,N)`.

- `Offset from middle`

  When you select this option, the block selects the first row or column of the output `y` by adding the specified offset to the middle row or column of the input `u`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

  When all columns are to be included, the following code defines the starting row: `y(1,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Row offset** or **Starting row offset** parameter. When all rows are to be included, the following code defines the starting column: `y(1,:) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Column offset** or **Starting column offset** parameter.

- `Middle`

  When you select this option, the block uses the middle row or column of the input `u` as the first row or column of the output `y`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

  When all columns are to be included, the following code defines the starting row: `y = u(MiddleRow,:)`. When all rows are to be included, the following code defines the starting column: `y = u(:,MiddleColumn)`.

The **Ending row** or **Ending column** can similarly be specified in five ways:

- `Index`

For rows, this specifies that the row of `u` forward-indexed by the **Ending row index** parameter, `lastrow`, should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(lastrow,:)`.

For columns, this specifies that the column of `u` forward-indexed by the **Ending column index** parameter, `lastcol`, should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,lastcol)`.

- `Offset from last`

  For rows, this specifies that the row of `u` offset from row *M* by the **Ending row offset** parameter, `lastrow`, should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(M-lastrow,:)`.

  For columns, this specifies that the column of `u` offset from column *N* by the **Ending column offset** parameter, `lastcol`, should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,N-lastcol)`.

- `Last`

  For rows, this specifies that the last row of `u` should be used as the last row of `y`. When all columns are to be included, this is equivalent to `y(end,:) = u(M,:)`.

  For columns, this specifies that the last column of `u` should be used as the last column of `y`. When all rows are to be included, this is equivalent to `y(:,end) = u(:,N)`.

- `Offset from middle`

  When you select this option, the block selects the last row or column of the output `y` by adding the specified offset to the middle row or column of the input `u`. When the number, *X*, of input rows or columns is even, the block defines the middle one as *X*/2 +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**(*X*/2).

  When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Ending row offset** parameter. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Ending column offset** parameter.

- `Middle`

When you select this option, the block uses the middle row or column of the input `u` as the last row or column of the output `y`. When the number, X, of input rows or columns is even, the block defines the middle one as $X/2$ +1. When the number of input rows or columns is odd, the block defines the middle one as **`ceil`**($X/2$).

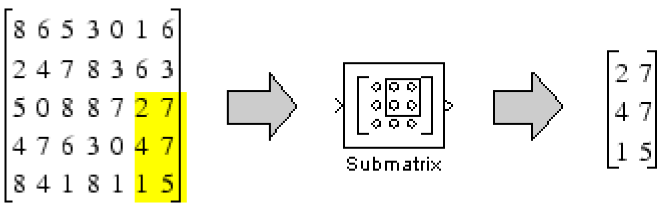
When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow,:)`. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn)`.

This block supports Simulink virtual buses.

Examples

The ex_submatrix_ref model uses a Submatrix block to extract a 3-by-2 submatrix from the lower-right corner of a 5-by-7 input matrix.

The following figure shows the operation of the Submatrix block with a 5-by-7 input matrix of random integer elements, `randi([0 9],5,7)`.



There are often several possible parameter combinations that you can use to select the *same* submatrix from the input. For example, in the case of a 5-by-7 input matrix, instead of specifying `Last` for **Ending column**, you could select the same submatrix by specifying

- **Ending column** = `Index`
- **Ending column index** = `7`

Parameters

Row span

The range of input rows to be retained in the output. Options are `All rows`, `One row`, or `Range of rows`.

Row/Starting row

The input row to be used as the first row of the output. **Row** is enabled when you select `One row` from **Row span**, and **Starting row** when you select `Range of rows` from **Row span**.

Row index/Starting row index

The index of the input row to be used as the first row of the output. **Row index** is enabled when you select `Index` from Row, and **Starting row index** when you select `Index` from **Starting row**.

Row offset/Starting row offset

The offset of the input row to be used as the first row of the output. **Row offset** is enabled when you select `Offset from middle` or `Offset from last` from **Row**, and Starting row offset is enabled when you select `Offset from middle` or `Offset from last` from **Starting row**.

Ending row

The input row to be used as the last row of the output. This parameter is enabled when you select `Range of rows` from **Row span** and you select any option but `Last` from **Starting row**.

Ending row index

The index of the input row to be used as the last row of the output. This parameter is enabled when you select `Index` from **Ending row**.

Ending row offset

The offset of the input row to be used as the last row of the output. This parameter is enabled when you select `Offset from middle` or `Offset from last` from **Ending row**.

Column span

The range of input columns to be retained in the output. Options are `All columns`, `One column`, or `Range of columns`.

Column/Starting column

The input column to be used as the first column of the output. **Column** is enabled when you select `One column` from **Column span**, and **Starting column** is enabled when you select `Range of columns` from **Column span**.

Column index/Starting column index

The index of the input column to be used as the first column of the output. **Column index** is enabled when you select `Index` from Column, and **Starting column index** is enabled when you select `Index` from **Starting column**.

Column offset/Starting column offset

The offset of the input column to be used as the first column of the output. **Column offset** is enabled when you select `Offset from middle` or `Offset from last` from Column. **Starting column offset** is enabled when you select `Offset from middle` or `Offset from last` from **Starting column**.

Ending column

The input column to be used as the last column of the output. This parameter is enabled when you select `Range of columns` from **Column span** and you select any option but `Last` from **Starting column**.

Ending column index

The index of the input column to be used as the last column of the output. This parameter is enabled when you select `Index` from **Ending column**.

Ending column offset

The offset of the input column to be used as the last column of the output. This parameter is enabled when you select `Offset from middle` or `Offset from last` from **Ending column**.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned)

Port	Supported Data Types
	• Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

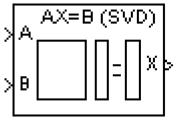
SVD Solver

Solve $AX=B$ using singular value decomposition



Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

`dspsolvers`

Description

The SVD Solver block solves the linear system $AX=B$, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying singular value decomposition (SVD) factorization to the M-by-N matrix A, at the A port. The input to the B port is the right side M-by-L matrix, B. The block treats length-M unoriented vector input as an M-by-1 matrix.

The output at the X port is the N-by-L matrix, X. X is chosen to minimize the sum of the squares of the elements of B-AX (the residual). When B is a vector, this solution minimizes the vector 2-norm of the residual. When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems $AX_k=B_k$, where B_k is the kth column of B, and X_k is the kth column of X.

X is known as the minimum-norm-residual solution to $AX=B$. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the SVD Solver block is applied to an underdetermined system, the output X is chosen such that the number of nonzero entries in X is minimized.

Parameters

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- `0` — The singular value decomposition calculation converges.
- `1` — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Supported Data Types

Port	Supported Data Types
A	• Double-precision floating point • Single-precision floating point
B	• Double-precision floating point • Single-precision floating point
X	• Double-precision floating point • Single-precision floating point
E	• Boolean

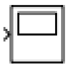
Time Scope

Display time-domain signals



Library

Sinks

Description

The Time Scope block displays signals in the time domain. The Time Scope block accepts input signals with the following characteristics:

- Continuous or discrete sample time
- Real- or complex-valued
- Fixed or variable size dimensions

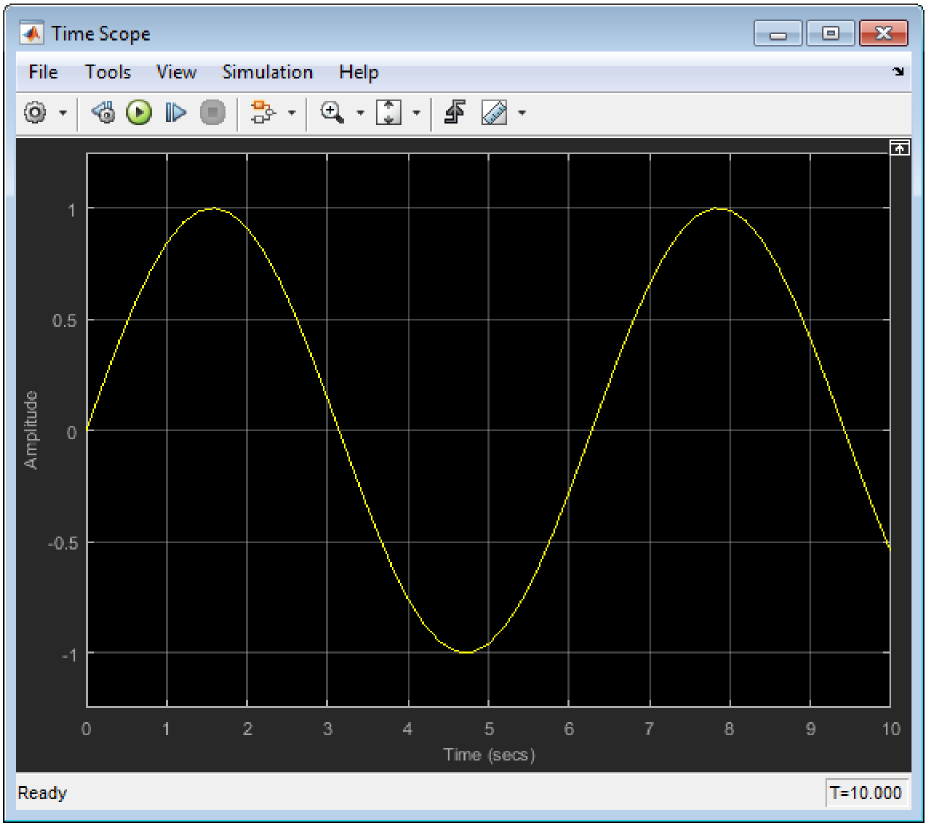
- Simulink enumerations

To determine whether to use the DSP System Toolbox Time Scope or the Simulink Scope, see “Simulink Scope Versus DSP System Toolbox Time Scope” (Simulink).

For information on the simulation modes supported by the scope and limitations on these modes, see “Supported Simulation Modes” on page 2-1718. You can use the Time Scope block inside any subsystem or conditional subsystem. See “Conditional Subsystems” (Simulink) for more information.

To improve the performance of models that contain scopes, select **Analysis** > **Performance Tools** > **Performance Advisor** in the Simulink Editor or type `performanceadvisor('your_model_name')` at the command line. See “Automated Performance Optimization” (Simulink) for more information. A quick change you can make to improve performance is to close and comment out scope blocks using the right-click menu. Another performance improvement is to use **Scope Simulation** > **Reduce Updates to Improve Performance**.



The following sections describe the features of the Time Scope:

- "Signal Display" on page 2-1650
- "Measurements Panels" on page 2-1652
- "Configuration Properties Dialog Box" on page 2-1683
- "Style Dialog Box" on page 2-1698
- "Stepping Options" on page 2-1701
- "Tools—Axes Scaling Properties" on page 2-1702
- "Examples" on page 2-1705
- "Supported Data Types" on page 2-1718
- "Supported Simulation Modes" on page 2-1718

Note: For information about the Time Scope System object, see dsp.TimeScope.

For information on controlling the Time Scope from the command line, see “Control Scopes Programmatically” (Simulink).

Signal Display

Time Scope uses the simulation start time and stop time to determine the default time range. To define the length of simulation time for which the Time Scope displays data. see **Time span** and **Time display offset** parameters in the “Configuration Properties Dialog Box” on page 2-1683.

By default, the scope updates the displays periodically at a rate not exceeding 20 hertz. If you would like the scope to update on every simulation time step, you can disable the **Reduce Updates to Improve Performance** option. However, as a recommended practice, leave this option enabled because doing so can significantly improve the speed of the simulation.

In the Time Scope menu, clear the **Simulation** > **Reduce Updates to Improve Performance** check box. You can also use **Ctrl+R** to toggle this setting.

The scope shows the following status information.

Note: To prevent the scope from opening when you run your model, right-click the scope icon and select `Comment Out`. If the scope is already open, and you comment it out in the model, the scope displays, “No data can be shown because this scope is commented out.” Select `Uncomment` to turn the scope back on.

The scope shows the following plot labels and status information.

- *Minimum time-axis limit* — The Time Scope sets the minimum time-axis limit using the value of the **Time display offset** parameter on the **Time** tab of the Visuals—Time Domain Properties dialog box. If you specify a vector of values for the **Time display offset** parameter, the scope uses the smallest of those values to set the minimum time-axis limit.
- *Maximum time-axis limit* — The Time Scope sets the maximum time-axis limit by summing the value of **Time display offset** parameter with the value of the

Time span parameter. If you specify a vector of values for the **Time display offset** parameter, the scope sets the maximum time-axis limit by summing the largest of those values with the value of the **Time span** parameter.

You can choose to hide or display both the scope menus and the toolbar using the or button in the upper right corner of the scope. To hide or display the toolbar separately, use **View** > **Toolbar** in the scope menu.

You can choose to hide or display the entire *Status Bar* with **View** > **Status Bar** in the scope menu. The following items are in the Status Bar:

- *Simulation status* — Provides the status of the model simulation. The status can be one of the following conditions:

  - `Initializing`
  - `Ready`
  - `Running`
  - `Paused`

  The *Simulation status* is part of the *Status Bar* in the Time Scope window. You can choose to hide or display the entire *Status Bar*. From the Time Scope menu, select **View** > **Status Bar**.
- *Time offset* — The `Offset` value helps you determine the simulation times for which the scope is displaying data. The value is always in the range `0`≤ `Offset`≤ *Simulation time*. If the time offset is 0, the Scope does not display the `Offset` status field. Add the Time offset to the fixed time span values on the time-axis to get the overall simulation time.

  For example, if you set the **Time span** to `20` seconds, and you see an `Offset` of `0 (secs)` on the scope window. This value indicates that the scope is displaying data for the first `0` to `20` seconds of simulation time. If the **Offset** changes to `20 (secs)`, the scope displays data for simulation times from `20` seconds to `40` seconds. The scope continues to update the `Offset` value until the simulation is complete.
- *Simulation time* — When the model is running or simulation has been paused, the scope displays the current simulation time. This time is the amount of time that the Time Scope has spent processing the input. If the model simulation completes or is stopped, the scope displays the time at which the simulation stopped. You can choose to hide or display the entire *Status Bar*. From the Time Scope menu, select **View** > **Status Bar**.

Note: In some situations, the Time Scope block simulation time can be different from the Simulink simulation time. For multirate input signals, which have different sample times, and input signals originating from conditionally executed subsystems, such as Triggered and Enabled subsystems, separate Time Scope blocks can report different simulation times. The Time Scope block reports the simulation time as the time corresponding to the last point in the display.

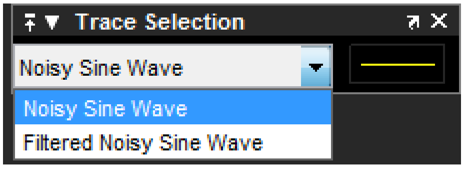
To show and adjust multiple displays in your scope, see "Display Multiple Signals in the Time Scope".

Measurements Panels

The Measurements panels are the panels that appear to the right side of the Time Scope GUI. Select the desired panels using **Tools** > **Measurements** in the scope toolbar or click the icons in the measurements dropdown.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



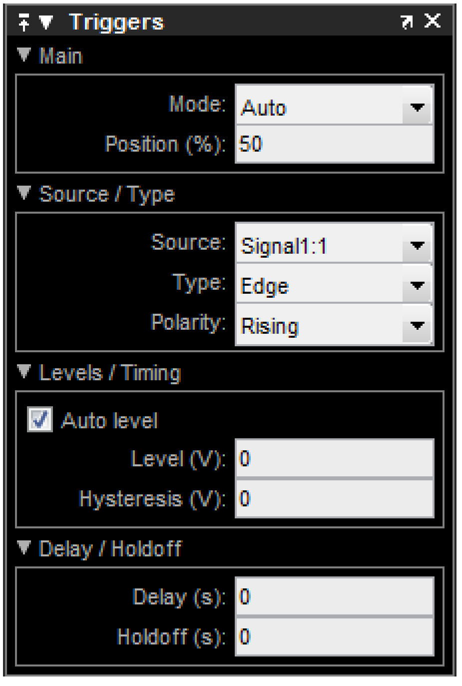
You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

Triggers Panel

The **Triggers** panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. You can configure triggers to both select and align specific regions of interest in the display area of the scope. Triggers work across multiple displays.

Note: If triggers are on and your model is running, you cannot pan the signal display. Panning, when triggers are on, is enabled only when your model is paused or stopped.

To open the Triggers panel, click the Triggers button ( ) or select **Tools** > **Triggers** in the scope menu.



When the **Triggers** panel is displayed, triangle pointers appear at the top and right side of the axes on each display. These markers indicate the time position ( ) and level ( ) at the event. The color of the markers corresponds to the color of the source signal.

Note: Triggers are governed by the **Time Span** setting of the scope. The time span is used for autoleveling and determines how much data to show in the display. The scope does not display an event until an entire time span is viewable in the display. To prevent data from being shown twice, the scope suppresses the alignment of recurring events until an entire time span has elapsed since the previous update.

The **Main** pane lets you choose how often the display updates and in what position the trigger indicator appears.

- `Mode` — Define how often the display updates.
  - `Auto` — The scope aligns and displays data from the latest trigger event. Data between trigger events is displayed. If no trigger event is found after an entire time span has elapsed, the scope displays that time span of data. Use this mode to see your data and have it align whenever a trigger event occurs.
  - `Normal` — The scope aligns and displays data only from the last trigger event in the time span and freezes the display. Data between trigger events is not displayed. Use this mode to search for infrequently occurring events in your data.
  - `Once` — The scope aligns and displays data on the first encountered trigger event and freezes the display. The scope ignores subsequent data until you press the **Rearm** button. If no trigger event is found, no data is shown in the display.
  - `Off` — Triggering is disabled. This setting is equivalent to hiding the **Triggers** panel.

  If mode is set to either `Normal` or `Once` and no trigger event occurs, the display remains blank. Set **Mode** to `Auto` to display all signal data, in addition to trigger events.
- **Position (%)** — Specify, as a percentage of the total time span within the active display, the horizontal position in which the trigger indicator appears. A position value of `0` corresponds to the minimum time-axis value at the far-left side of the display. A position value of `100` corresponds to the maximum time-axis value at the far-right side of the display. Drag the trigger position indicator to the left or right to adjust its position.

The **Source/Type** pane lets you choose the source of the trigger and the type of events on which to stop.

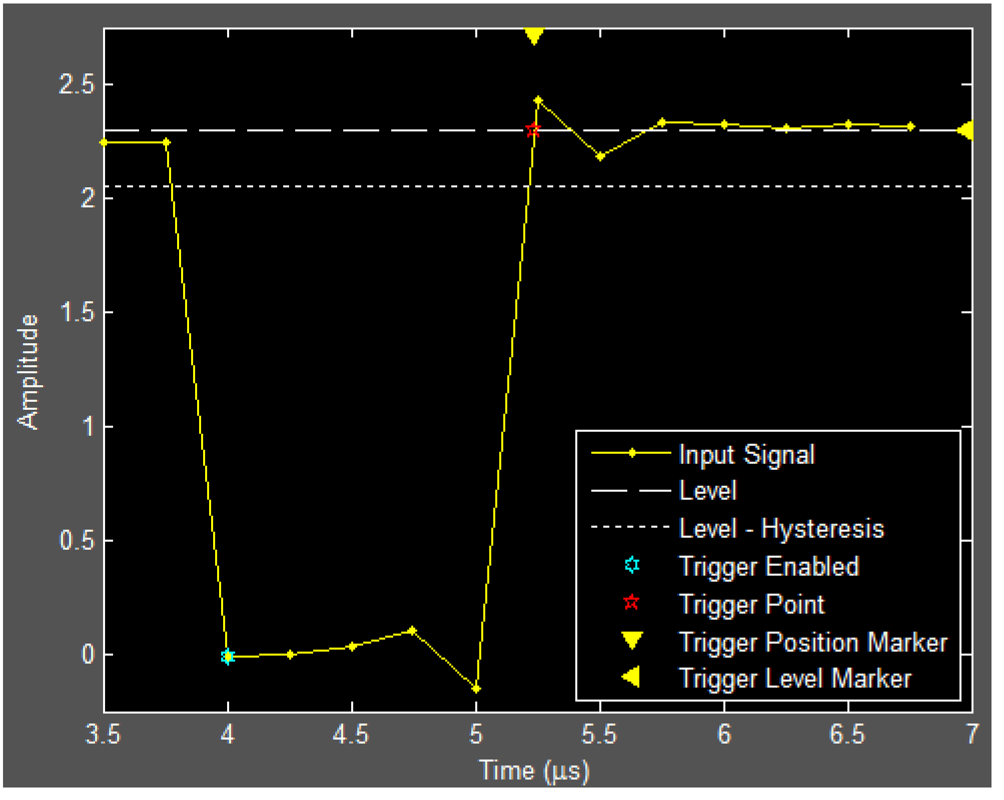
- **Source** — Assign the trigger source to a particular channel. If you are viewing a magnitude/phase plot, you can trigger off the magnitude or the phase. If you are not viewing the magnitude/phase plot, you can trigger off the real or imaginary data. If the input signal has multiple channels, the scope assigns an index number to identify each channel of that signal. For more information, see “Display Multiple Signals in the Time Scope”.

- **Type** — Select the type of trigger to use.

  - `Edge` — Trigger when the scope crosses a level threshold.

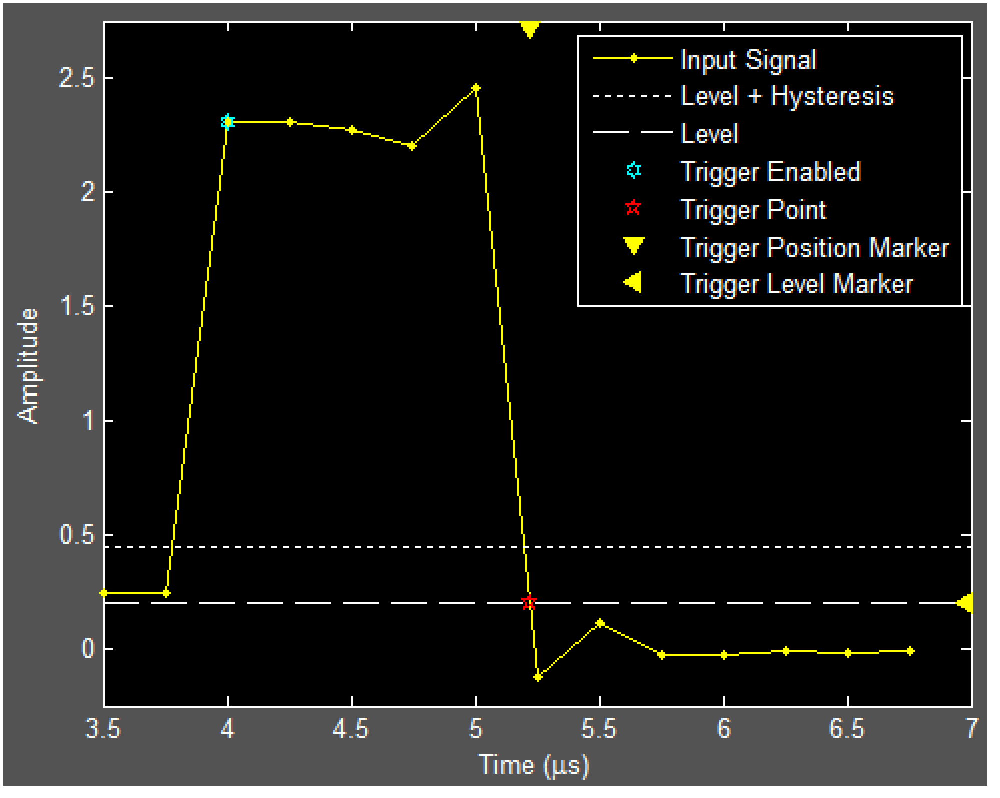
    For a rising edge, the scope enables the trigger event when the signal value becomes less than the level threshold minus hysteresis. The scope disables the trigger event when the signal becomes greater than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold.

Rising Edge Trigger Plot



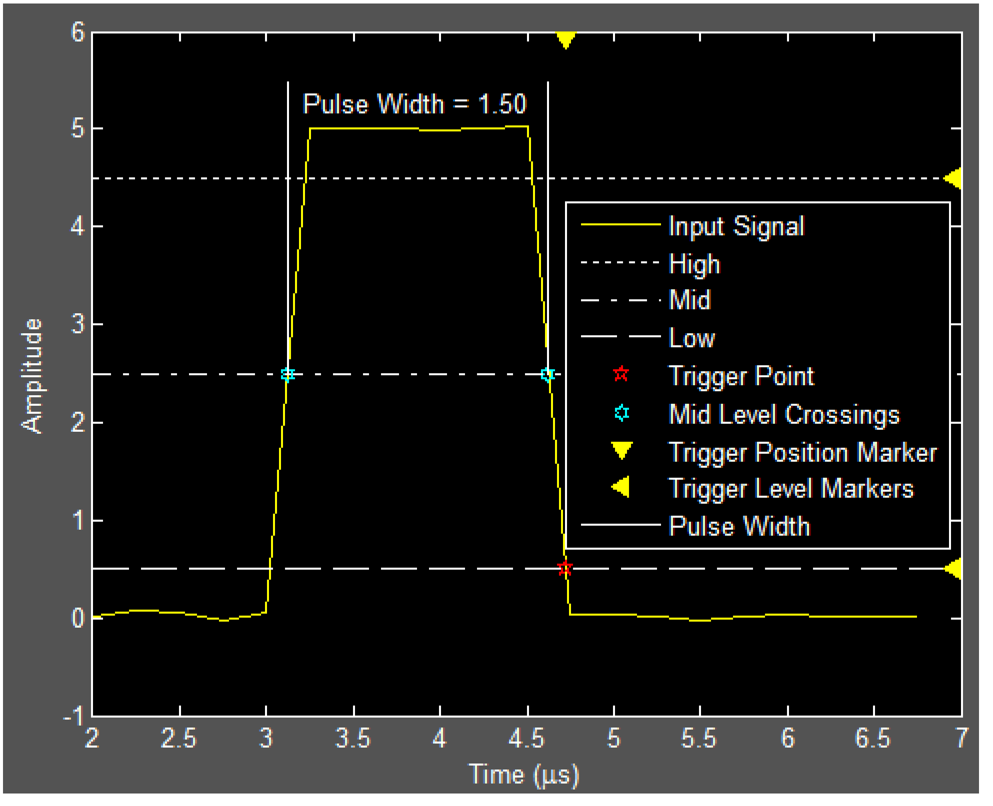
For a falling edge, the scope enables the trigger event when the signal value becomes greater than the level threshold plus hysteresis. The scope disables the trigger event when the signal becomes less than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold.

Falling Edge Trigger Plot



- `Pulse Width` — Trigger when the scope encounters a pulse whose width falls inside or outside specified time limits. You specify the range of valid time limits in the **Levels / Timing** pane. For a positive-polarity pulse, the scope encounters a trigger event when the signal crosses the low threshold for the second time. The scope measures the pulse width as the time between the first and second crossings of the middle threshold, located halfway between the high and low thresholds.

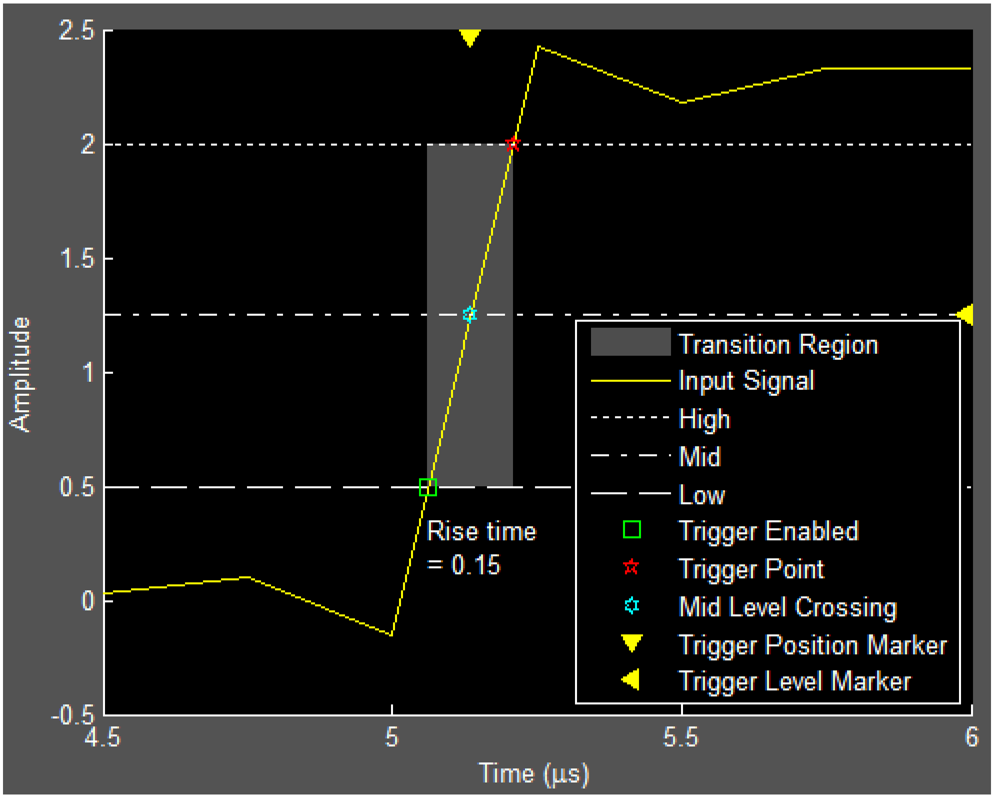
Pulse Width Trigger Plot



Note: A *Glitch*-type trigger looks for a pulse or spike with a duration less than a specified amount. You can implement a *Glitch* type trigger by using a `Pulse Width` type trigger and manually setting the **Max Width** parameter.

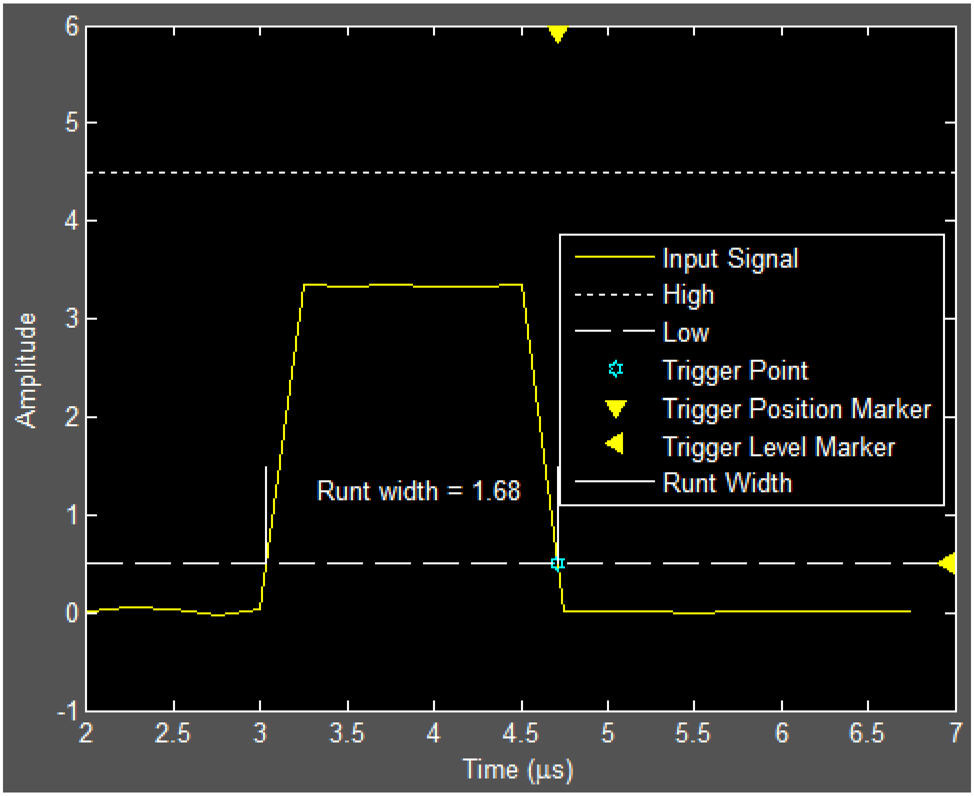
- `Transition` — Trigger on a rising or falling edge that crosses two levels, high and low, inside or outside a specified time interval. You specify the range of valid transition times in the **Levels / Timing** pane. For a rising transition, the scope encounters the trigger event when the signal crosses the high threshold. The transition time is when the signal crosses the middle threshold, located halfway between the high and low thresholds.

Transition Trigger Plot



- `Runt` — Trigger on a runt pulse, which crosses one threshold, high or low, but not both. For a positive-polarity runt pulse, the scope encounters a trigger event when the signal crosses the low threshold the second time, without ever crossing the high threshold. The scope measures the runt width as the time between the first and second crossings of the low threshold, as shown in the following figure. The runt width is the **Max Width** – **Min Width**. Any runt pulse width that is less than the minimum width or greater than the maximum width does not generate a trigger event.

Runt Trigger Plot

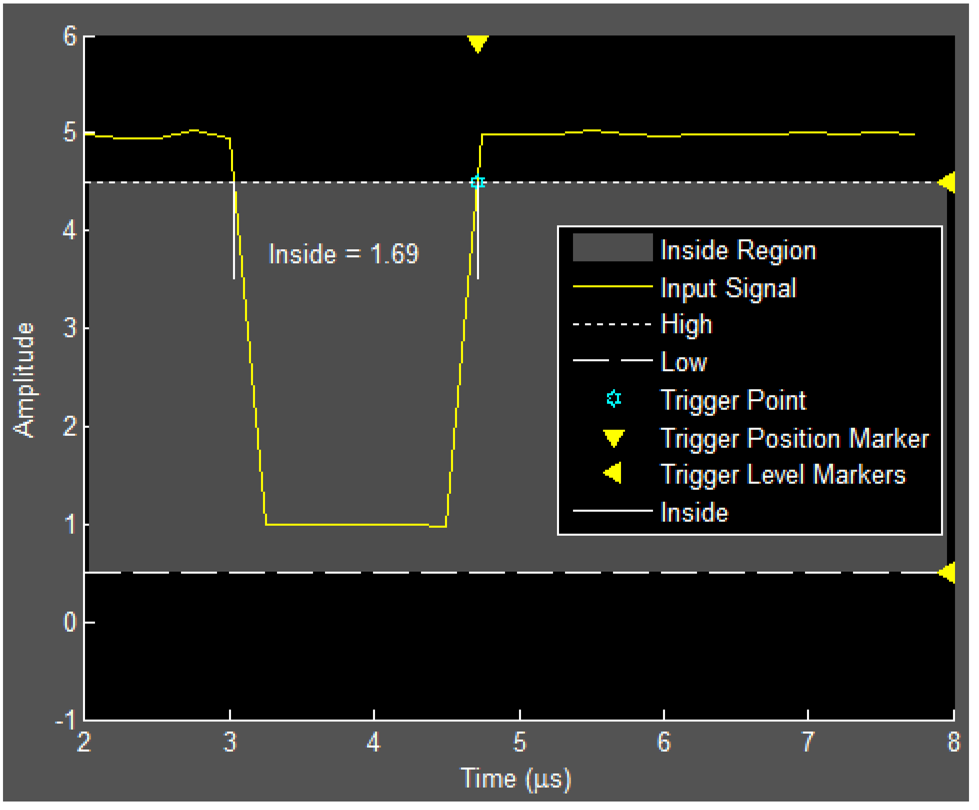


Note: You can also replicate a runt-type trigger by using a window-type trigger and setting **Polarity** to `Inside`.

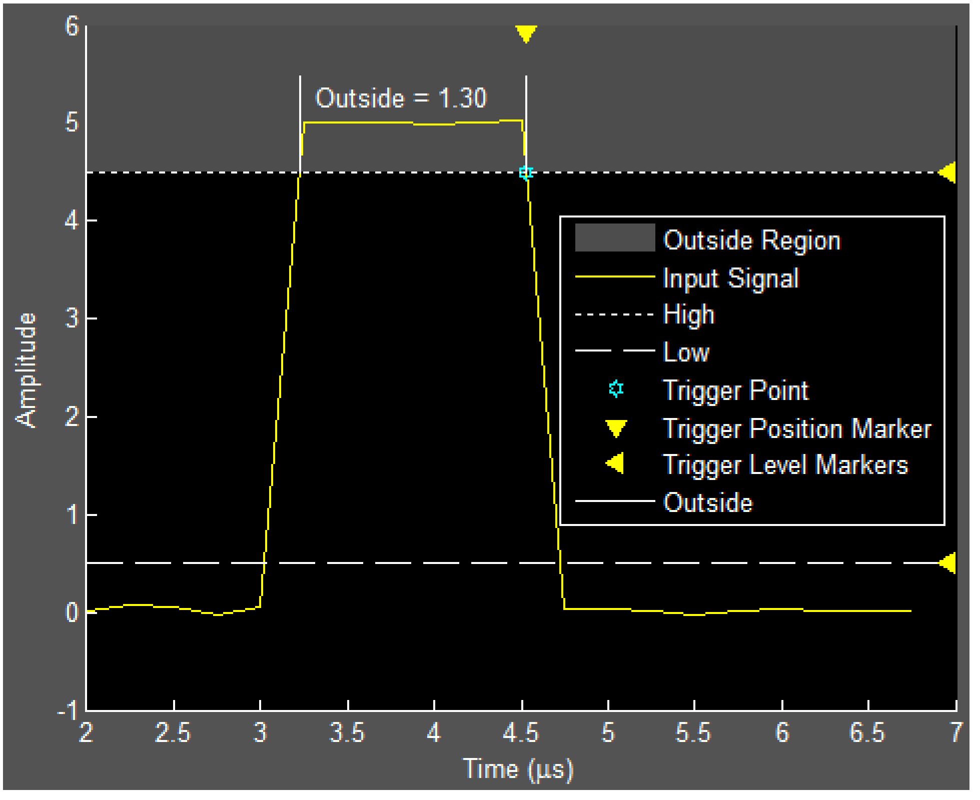
- `Window` — Trigger when the input signal stays within or outside the region defined by the high and low thresholds for a time.

  For an inside window, the scope encounters a trigger event when the signal enters and exits the inside region. For an outside window, the scope encounters a trigger event when the signal enters and exits the outside region.

Inside Window Trigger Plot



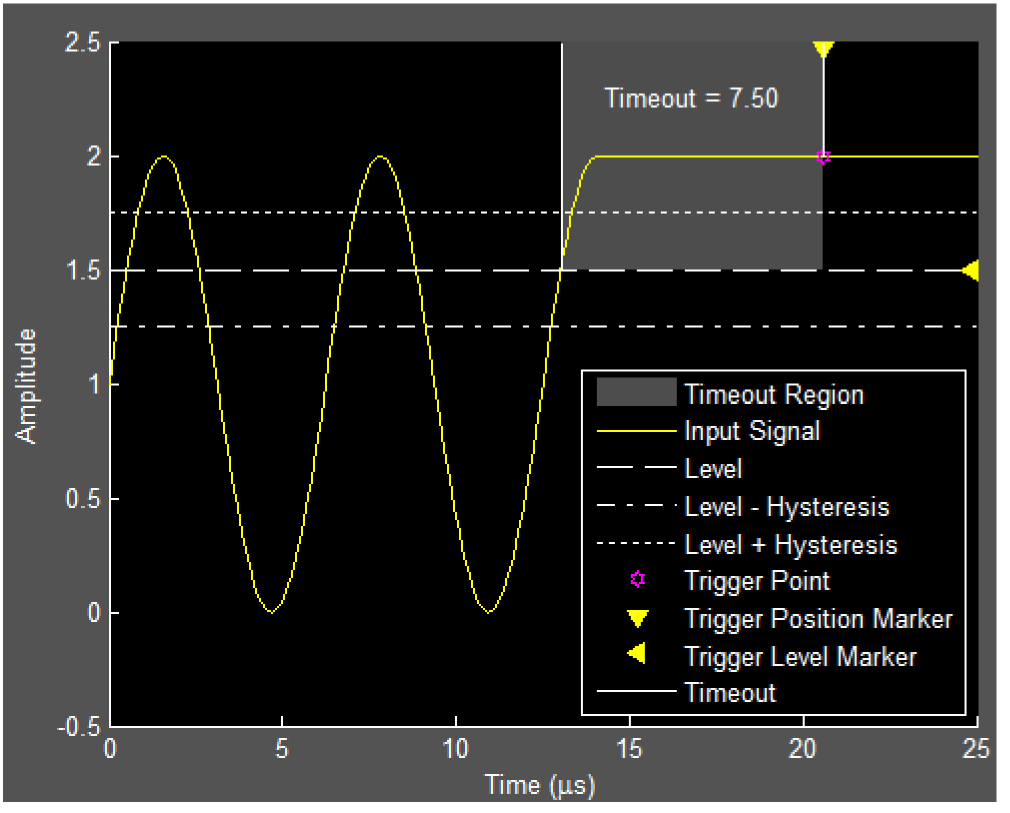
Outside Window Trigger Plot

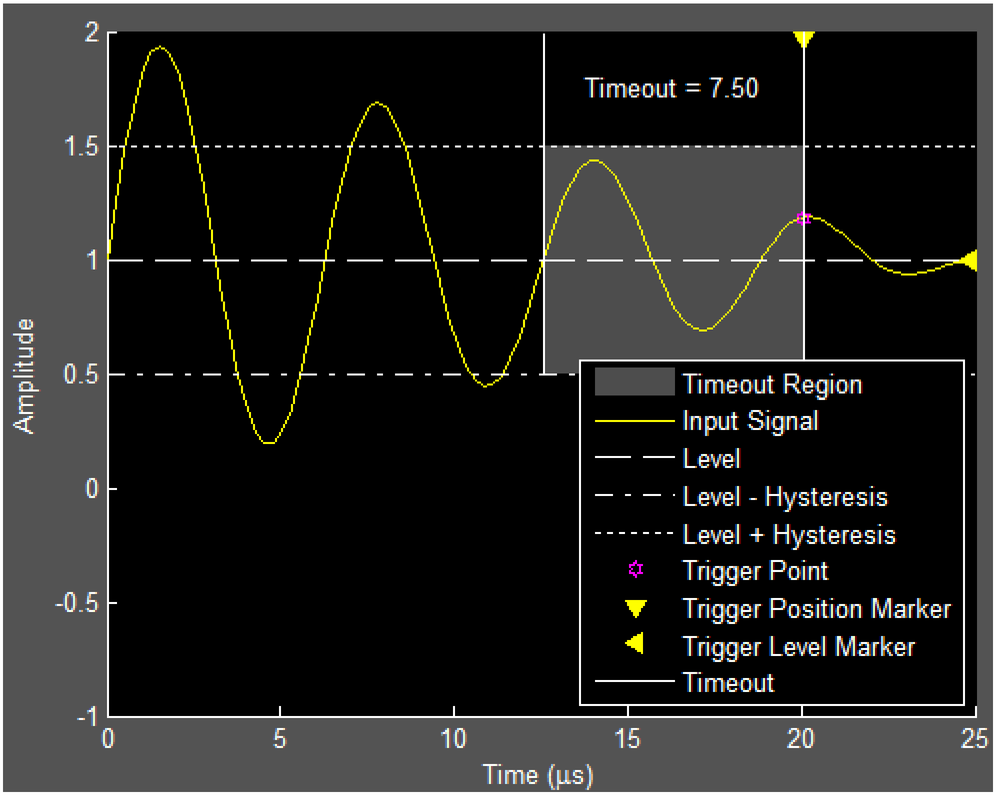


The scope encounters a trigger event when the signal crosses either the high or low threshold the second time.

- `Timeout` — Trigger when the input signal stays above or below a voltage threshold longer than a specified time. For a timeout trigger with polarity set to `Either` and a timeout duration of 7.50 seconds, the scope can encounter the trigger event 7.50 seconds after the signal crosses the level threshold the last time. Alternatively, the scope can encounter the trigger event when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the level threshold.

Timeout Trigger Plots





- **Polarity** — Select the polarity of the trigger type. The option you choose for **Type** determines the options available for polarity.

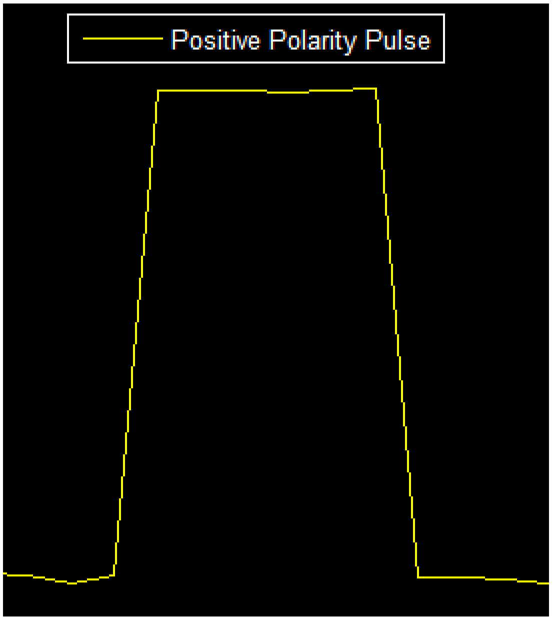
  For **Type** `Edge`:

  - `Rising` — Trigger on a *rising edge*, a transition from a low-state level to a high-state level.
  - `Falling` — Trigger on a *falling edge*, transition from a high-state level to a low-state level.
  - `Either` — Trigger on both rising edges and falling edges.

  For **Type** `Pulse Width`

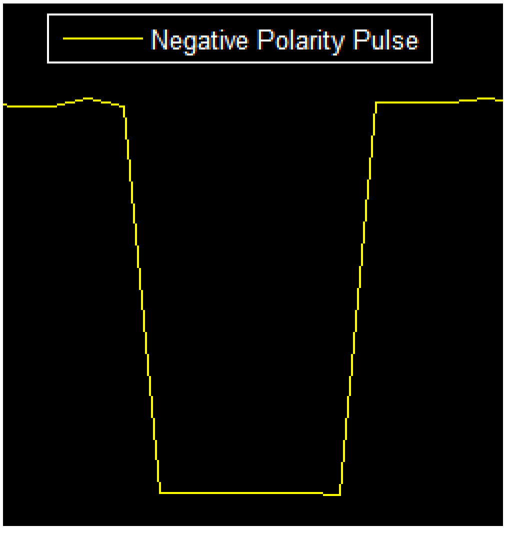
  - `Positive` — Trigger on a positive-polarity pulse.

Positive Polarity Plot



- `Negative` — Trigger on a negative-polarity pulse.

Negative Polarity Plot



For **Type** `Transition`

- `Rise Time` — Trigger based on how long the signal takes to transition from the low threshold to the high threshold.
- `Fall Time` — Trigger based on how long the signal takes to transition from the high threshold to the low threshold.
- `Either` — Trigger based on how long it takes to make either a rising or falling transition.

Type `Window`

- `Inside` — Trigger when the signal stays within the low and high levels for a specified time duration.
- `Outside` — Trigger when the signal stays outside of the low and high levels for a specified time duration.
- `Either` — Trigger on both inside and outside windows.

For **Type** `Timeout`

- `Rising` — Trigger when the signal does not cross the reference level from below.
- `Falling` — Trigger when the signal does not cross the reference level from above.
- `Either` — Trigger when the signal does not cross the reference level from either direction.

The **Levels / Timing** pane enables you to set the trigger level and hysteresis value. The option you choose for **Type** directly affects which level and timing parameters are available, as shown in the following table.

Trigger Type	Level Parameters	Auto-Level Setting	Timing Parameters
`Edge`	Level, Hysteresis	Level = 50%	n/a
`Pulse Width`, `Runt`	High, Low	High = 90%, Low = 10%	Min Width, Max Width
`Transition`, `Window`	High, Low	High = 90%, Low = 10%	Min Time, Max Time
`Timeout`	Level, Hysteresis	n/a	Timeout
