When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable (Simulink).

Default: `false`

`ShowLegend`

Show or hide legend

When you set this property to `true`, the scope displays a legend with the input channels labels specified in the `ChannelNames` on page 4-1570 property. When you set this property to `false`, the scope does not display a legend.

This property applies only when you set the `ViewType` property to `'Spectrum'` or `'Spectrum and spectrogram'`. This property is Tunable (Simulink).

Default: `false`

SidelobeAttenuation

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the Window property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to `45`.

This property is Tunable (Simulink).

Default: `60`

Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to `'Span and center frequency'`. The overall span, defined by this property and the CenterFrequency property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `10e3`

SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. This property applies only when you set the ViewType property to `'Spectrum'`. The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*.

This property is Tunable (Simulink).

Default: 1

SpectralMask

Spectral mask lines for a spectrum plot.

Specify whether to display upper and lower spectral masks lines on a spectrum plot. This property uses SpectralMaskSpecfication properties to enable and configure the spectral masks. The SpectralMaskSpecfication properties are:

- EnabledMasks — Masks to enable, specified as a character vector. Valid values are 'None', 'Upper', 'Lower', or 'Upper and lower'.

  Default: 'None'
- UpperMask — Upper limit spectral mask, specified as a scalar or two-column matrix. If UpperMask is a scalar, the upper limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If UpperMask is a matrix, the first column contains the frequency values (Hz), which correspond to the *x*-axis values. The second column contains the power values, which correspond to the associated *y*-axis values. To apply offsets to the power and frequency values, use ReferenceLevel and MaskFrequencyOffset property values, respectively.

  Default: Inf
- LowerMask — Lower limit spectral mask, specified as a scalar or two-column matrix. If LowerMask is a scalar, the lower limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If LowerMask is a matrix, the first column contains the frequency values (Hz), which correspond to the *x*-axis values. The second column contains the power values, which correspond to the associated *y*-axis values. To apply offsets to the power and frequency values, use ReferenceLevel and MaskFrequencyOffset property values, respectively.

  Default: Inf
- ReferenceLevel — Reference level for mask power values, specified as either 'Custom' or 'Spectrum peak'. When ReferenceLevel is 'Custom', the CustomReferenceLevel property value is used as the reference to the power values, in dBr, in the UpperMask and LowerMask properties. When ReferenceLevel is 'Spectrum peak', the peak value of the current spectrum of the SelectedChannel is used.

  Default: 'Custom'

- `CustomReferenceLevel` — Custom reference level, specified as a real value, in the same units as the power units. The reference level is the value to which to reference the power values in the `UpperMask` and `LowerMask` properties. This property applies when `ReferenceLevel` is set to `'Custom'`. This property uses the same units as the `PowerUnits` property of the Spectrum Analyzer.

  Default: `0`
- `SelectedChannel` — Input channel with peak spectrum to use as the mask reference level, specified as an integer. This property applies when `ReferenceLevel` is set to `'Spectrum peak'`.

  Default: `1`
- `MaskFrequencyOffset` — Frequency offset, specified as a finite, numeric scalar. Frequency offset is the amount of offset to apply to frequency values in the `UpperMask` and `LowerMask` properties.

  Default: `0`

All `SpectralMaskSpecfication` properties are Tunable (Simulink).

You can check the status of the spectral mask using a method or an event listener.

- To get the status of the spectral masks, call getSpectralMaskStatus.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

This example shows how to add a spectral mask to an existing `dsp.SpectrumAnalyzer` System object scope and get the status with getSpectralMaskStatus.

```
sine = dsp.SineWave('Frequency',[98 100],'SampleRate',1000);
sine.SamplesPerFrame = 1024;
scope = dsp.SpectrumAnalyzer('SampleRate',sine.SampleRate, ...
       'PlotAsTwoSidedSpectrum',false,'ShowLegend',true);
for i=1:100
    scope(sine() + 0.05*randn(1024,2));
end

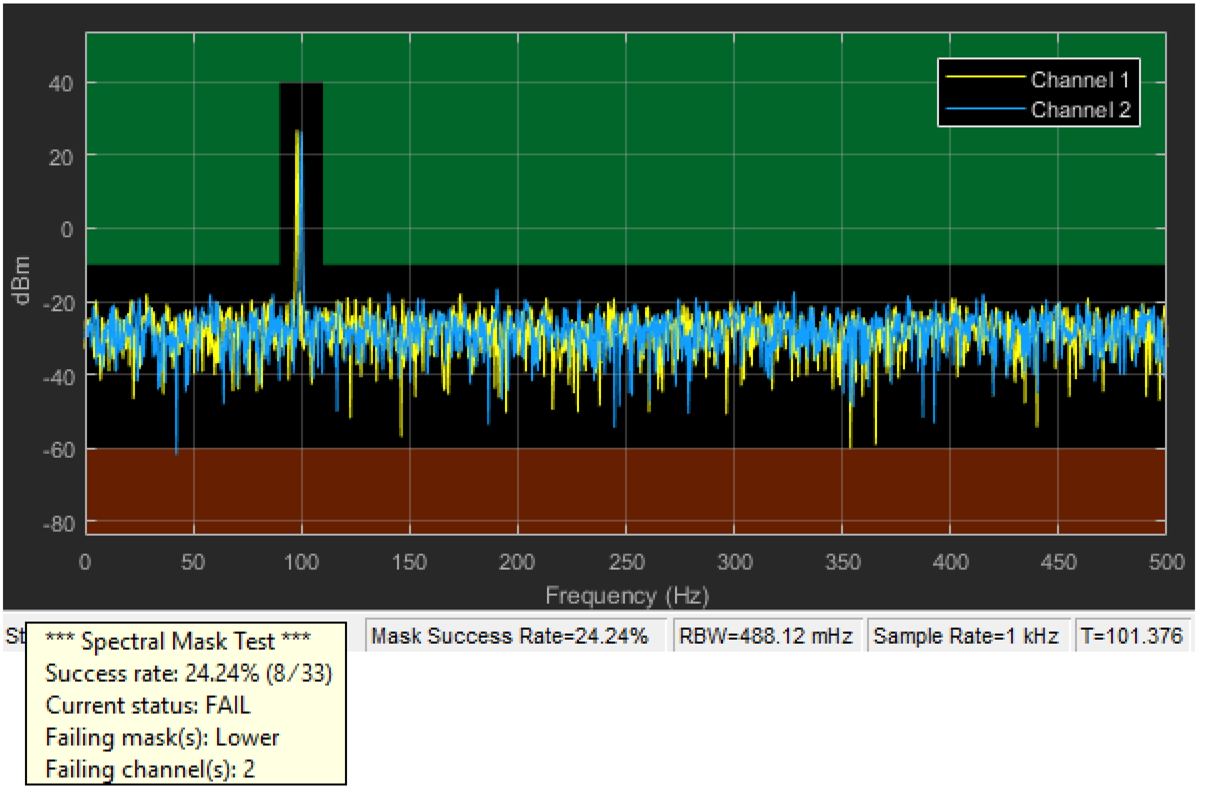
scope.SpectralMask.EnabledMasks = 'Upper and lower';
upperMask = [0 -10; 90 -10; 90 40; 110 40; 110 -10; 500 -10];
```

```
set(scope.SpectralMask,'UpperMask',upperMask,'LowerMask',-60);

res = getSpectralMaskStatus(scope)
release(scope);

res =
  struct with fields:

    IsCurrentlyPassing: 0
        NumPassedTests: 8
         NumTotalTests: 33
           SuccessRate: 24.2424
          FailingMasks: 'Lower'
       FailingChannels: 2
        SimulationTime: 101.3760
```



Masks are overlaid on the spectrum. If the mask is green, the signal is passing. If the mask is red, the signal is failing.

At the bottom of the window, the **Mask success rate** shows what percentage of the time the mask is succeeding. A tooltip gives you details about which mask is failing, how many times the mask failed, and which channels are causing the failure.

SpectrumType

Type of spectrum to show

Specify the spectrum type as one of `'Power'`, `'Power density'`, or `'RMS'`.

- `'Power'`, the Spectrum Analyzer shows the power spectrum.
- `'Power density'`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.
- `'RMS'`, the Spectrum Analyzer shows the root mean squared. The root mean squared shows the square root of the sum of the squared means. This option is useful when viewing the frequency of voltage or current signals.

This property is Tunable (Simulink).

Default: `'Power'`

SpectrumUnits

Units of the spectrum

Specify the units in which the Spectrum Analyzer displays power values as either `'dBm'`, `'dBW'`, `'Watts'`, `'Vrms'`, or `'dBV'`.

The available spectrum units depends on the value of `SpectrumType`.

SpectrumType	**Allowed SpectrumUnits**
`Power` or `Power density`	`'dBm'`, `'dBW'`, `'Watts'`
`RMS`	`'Vrms'`, `'dBV'`

This property is Tunable (Simulink).

Default: `'dBm'`

`StartFrequency`

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to `'Start and stop frequencies'`. The overall span, which is defined by StopFrequency and this property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `-5e3`

`StopFrequency`

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to `'Start and stop frequencies'`. The overall span, defined by this property and the StartFrequency property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is set to `true`, the interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `5e3`

TimeResolution

Time resolution

Specify the time resolution of each spectrogram line as a positive scalar, expressed in seconds. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum and spectrogram'`, and the TimeResolutionSource property to `'Property'`.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
RBW (Hz)	`Auto`	`Auto`	1/RBW s
RBW (Hz)	`Auto`	Manually entered	Time Resolution s
RBW (Hz)	Manually entered	`Auto`	1/RBW s
RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW s. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.
Window length	—	`Auto`	1/RBW s RBW = *(NENBW**Fs)/Window Length, where *NENBW* is the normalized effective noise bandwidth of the specified window.
Window length	—	Manually entered	Must be equal to or greater than the minimum attainable

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
			time resolution, (*NENBW**Fs)/ Window Length. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

This property is Tunable (Simulink).

Default: `0.001`

`TimeResolutionSource`

Source of the time resolution value.

Specify the source for the time resolution of each spectrogram line as either `'Auto'` or `'Property'`. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum and spectrogram'`. See the time resolution table at TimeResolution.

This property is Tunable (Simulink).

Default: `'Auto'`

`TimeSpan`

Time span

Specify the time span of the spectrogram display as a positive scalar in seconds. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum and spectrogram'` and the TimeSpanSource property to `'Property'`. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

This property is Tunable (Simulink).

Default: `0.1`

`TimeSpanSource`

Source of time span value

Specify the source for the time span of the spectrogram as either `'Auto'` or `'Property'`. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum and spectrogram'`. If you set this property to `'Auto'`, the spectrogram displays 100 spectrogram lines at any given time. If you set this property to `'Property'`, the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

This property is Tunable (Simulink).

Default: `'Auto'`

`Title`

Display title

Specify the display title as a character vector. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable (Simulink).

Default: `''`

`ViewType`

Viewer type

Specify the spectrum type as one of `'Spectrum'`, `'Spectrogram'`, or `'Spectrum and spectrogram'`.

- `'Spectrum'` — the Spectrum Analyzer shows the spectrum.
- `'Spectrogram'` — the Spectrum Analyzer opens a spectrogram view, which shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.
- `'Spectrum and Spectrogram'` — the Spectrum Analyzer shows a dual view of a spectrum and spectrogram.

This property is Tunable (Simulink).

Default: `'Spectrum'`

Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser

This property is Tunable (Simulink).

Default: 'Hann'

WindowLength

The window length

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2. This property applies only when you set the FrequencyResolutionMethod property to 'WindowLength', which controls the frequency resolution based on your window length setting. The resulting resolution bandwidth (RBW) is $\frac{NENBW * Fs}{N_{window}}$

where N_{window} is the WindowLength value.

This property is Tunable (Simulink).

See also: Window.

Default: 1024

`YLabel`

The label for the *y*-axis

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`. Regardless of this property, Spectrum Analyzer always displays power units as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`, `'Vrms'`, `'dBV'`.

See also: SpectrumUnits.

Default: `''`

`YLimits`

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable (Simulink).

This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`. The units directly depend upon the SpectrumUnits property.

Default: `[-80, 20]`

Methods

getSpectralMaskStatus	Get test results of current spectral mask
hide	Hide Spectrum Analyzer window
reset	Reset internal states of Spectrum Analyzer object
show	Make Spectrum Analyzer window visible
step	Update spectrum in Spectrum Analyzer figure

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

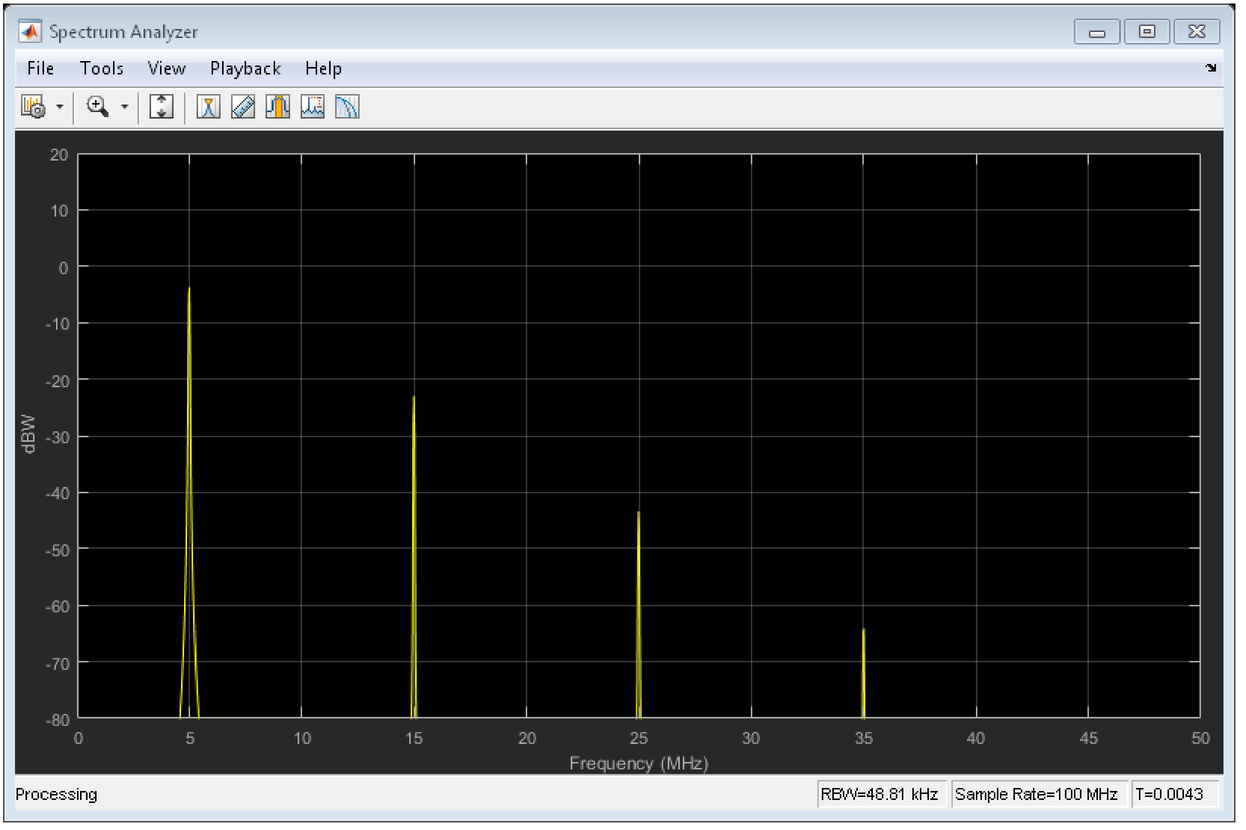
Spectrum Analyzer for One-Sided Power Spectrum

View a one-sided power spectrum made from the sum of fixe real sine waves with different amplitudes and frequencies.

```
Fs = 100e6;  % Sampling frequency
fSz = 5000;  % Frame size

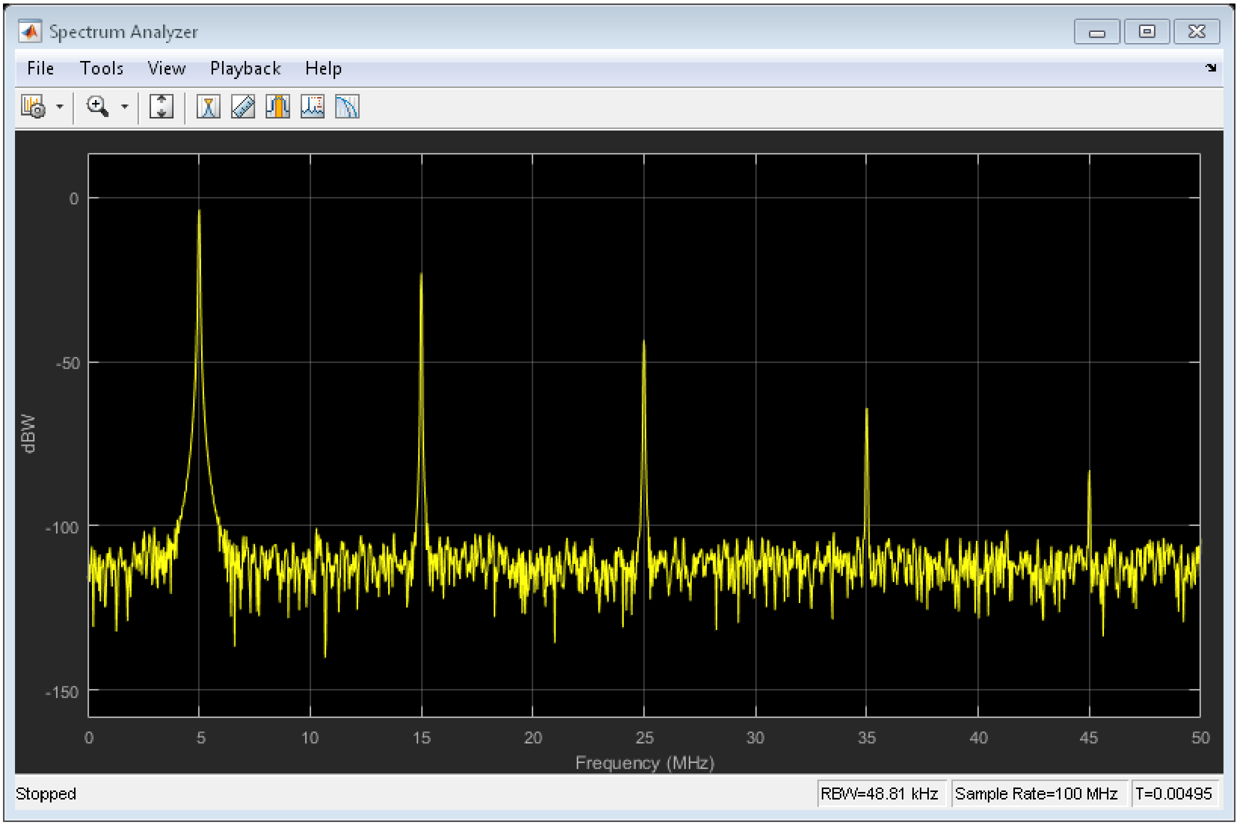
sin1 = dsp.SineWave(1e0,  5e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);
sin2 = dsp.SineWave(1e-1,15e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);
sin3 = dsp.SineWave(1e-2,25e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);
sin4 = dsp.SineWave(1e-3,35e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);
sin5 = dsp.SineWave(1e-4,45e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);

scope = dsp.SpectrumAnalyzer;
scope.SampleRate = Fs;
scope.SpectralAverages = 1;
scope.PlotAsTwoSidedSpectrum = false;
scope.RBWSource = 'Auto';
scope.PowerUnits = 'dBW';
for idx = 1:1e2
     y1 = sin1();
     y2 = sin2();
     y3 = sin3();
     y4 = sin4();
     y5 = sin5();
     scope(y1+y2+y3+y4+y5+0.0001*randn(fSz,1));
end
```



Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(scope)
```



Run the `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

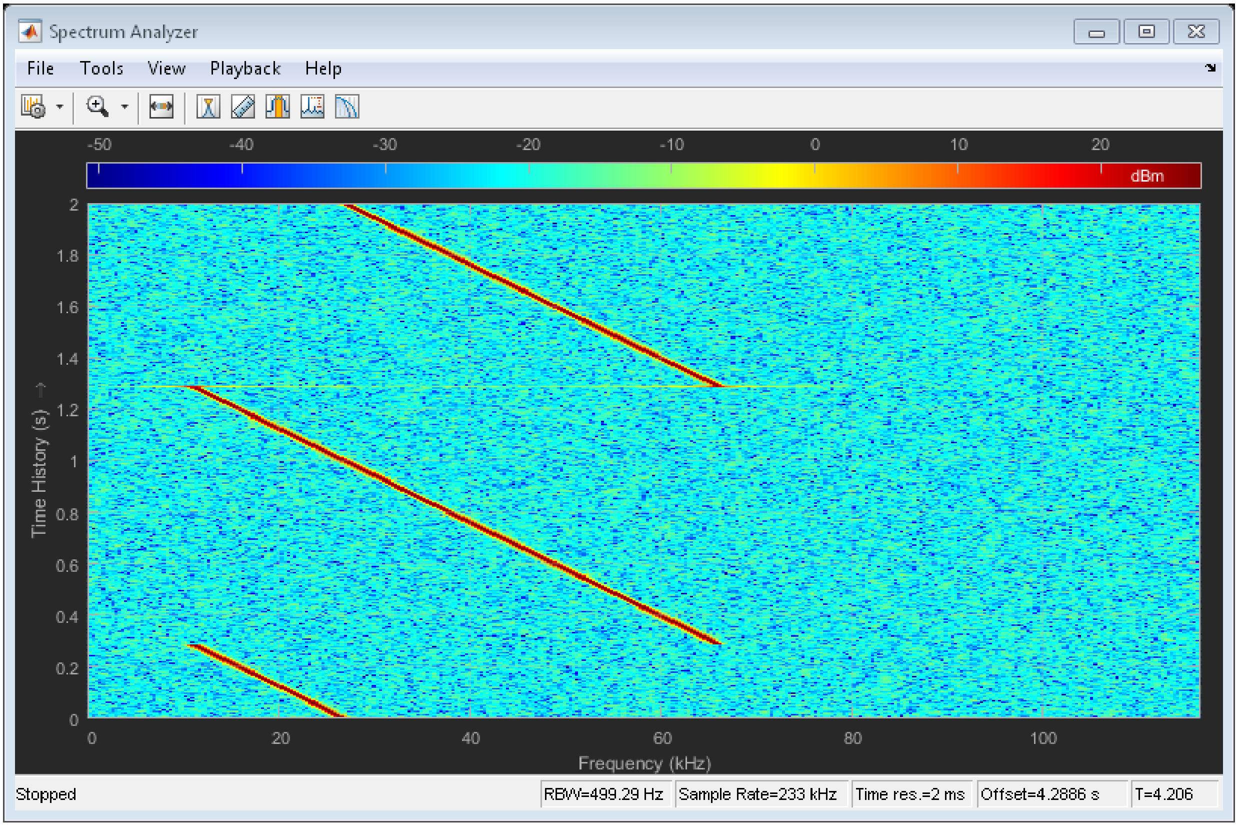
Spectrogram of Chirp Signal

This example shows the spectrogram for a chirp signal with added random noise.

```
Fs = 233e3;
frameSize = 20e3;
chirp = dsp.Chirp('SampleRate',Fs,...
  'SamplesPerFrame',frameSize,...
  'InitialFrequency',11e3,...
  'TargetFrequency',11e3+55e3);
```

```
scope = dsp.SpectrumAnalyzer('SampleRate',Fs);
scope.SpectrumType = 'Spectrogram';
scope.RBWSource = 'Property';
scope.RBW = 500;
scope.TimeSpanSource = 'Property';
scope.TimeSpan = 2;
scope.PlotAsTwoSidedSpectrum = false;

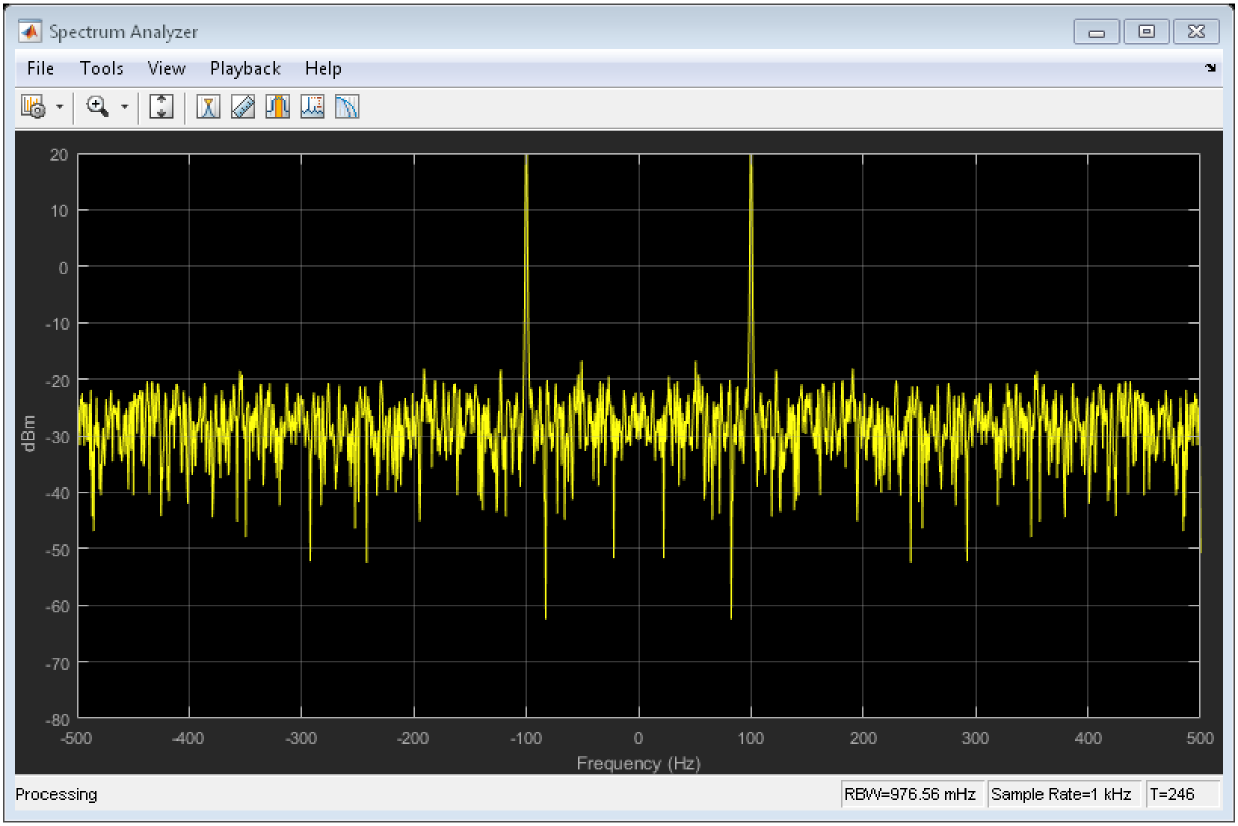
for idx = 1:50
  y = chirp()+ 0.05*randn(frameSize,1);
  scope(y);
end
release(scope)
```



Spectrum Analyzer For Two-Sided Power Spectrum

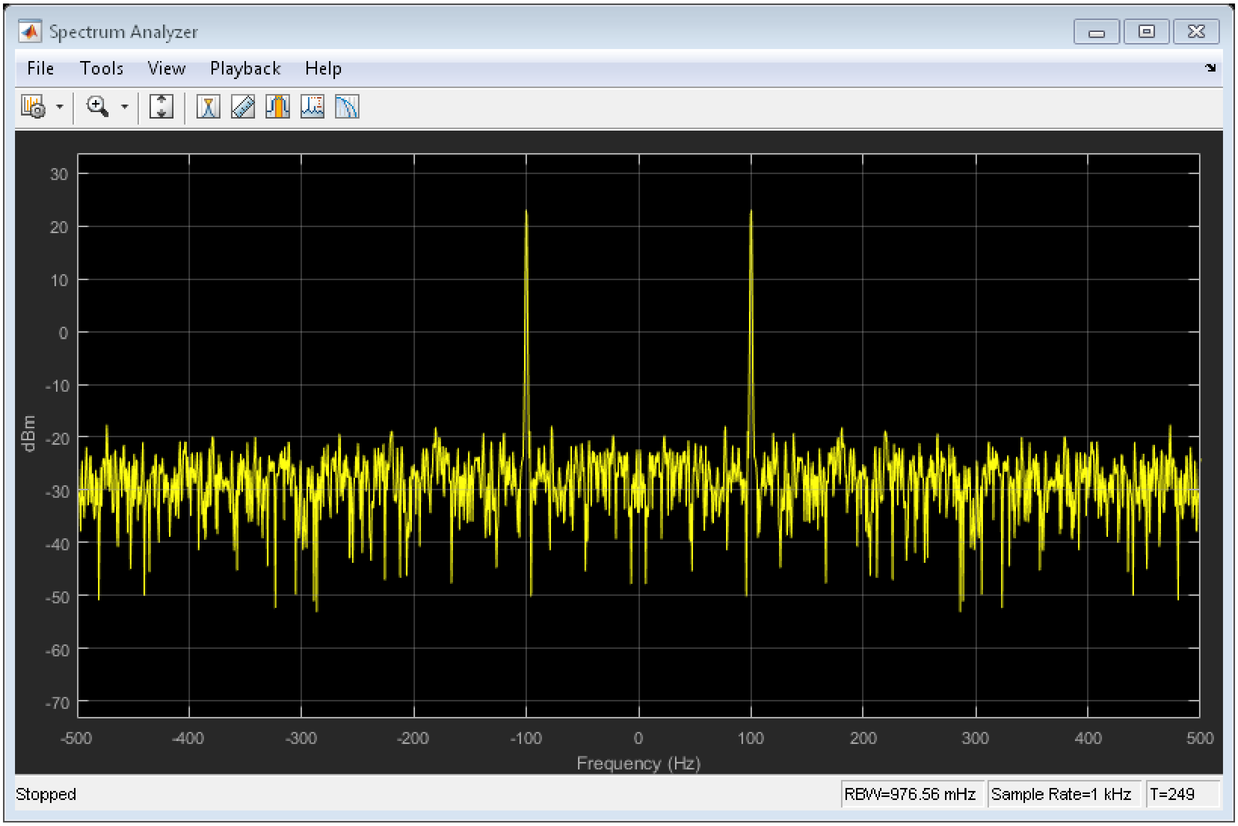
View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```
sin = dsp.SineWave('Frequency',100,'SampleRate',1000);
sin.SamplesPerFrame = 1000;
scope = dsp.SpectrumAnalyzer('SampleRate',sin.SampleRate);
for ii = 1:250
  x = sin() + 0.05*randn(1000,1);
  scope(x);
end
```



Run the `release` method to change property values and input characteristics. The scope automatically scales the axes. It updates the display one more time if any data is in the internal buffer.

```
release(scope);
```

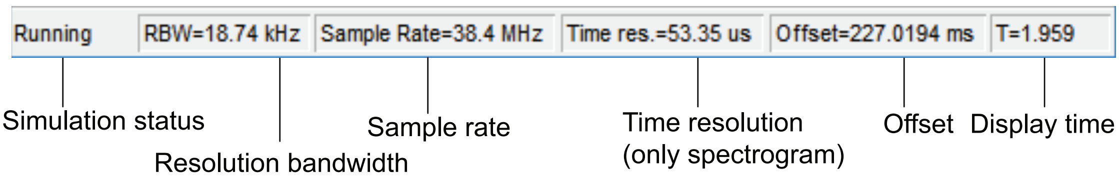


Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the *Resolution Bandwidth*, *Time Resolution*, and *Offset* indicators in the scope status bar for this information. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the *Simulation status* and *Display time* indicators for this information. The following figure highlights these aspects of the Spectrum Analyzer window.



- *Resolution Bandwidth* — The smallest positive frequency or frequency interval that can be resolved.

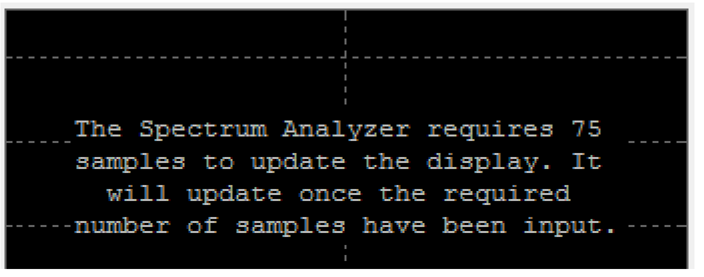
  Details

  Spectrum Analyzer sets the resolution bandwidth based on the `FrequencyResolutionMethod` property setting on the **Main options** pane of the **Spectrum Settings** panel. If `FrequencyResolutionMethod` is `RBW (Hz)` then the specified value of RBW is used. You can also get or set this value from the RBW property when RBWSource is set to `'Property'`. By default, the `RBW (Hz)` parameter on the **Main options** pane and the related `RBWSource` property are set to `'Auto'`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified **Frequency Span**.

  You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to *RBW* by the following equation:

  $$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

  . Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer shows a warning message on the display.



Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

If the `FrequencyResolutionMethod` property setting on the **Main options** pane of the **Spectrum Settings** is `Window length`, you specify the window length and the resulting RBW is $\frac{NENBW * Fs}{N_{window}}$. The **Samples/update** in this case is directly related to *RBW* by the following equation: $N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$

- *Time Resolution* — The time resolution for a spectrogram line.

  Details

  Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The **Time Resolution** parameter is available only when the spectrum **Type** is `Spectrogram`. The *minimum attainable resolution* is the amount of data time required to compute a single spectral estimate. When the SpectrumType property is set to `'Spectrogram'`, you can get or set the minimum attainable resolution value from the TimeResolution property. See the time resolution table in the `TimeResolution` property description.

- *Offset* — The constant frequency offset to apply to the entire spectrum or a vector of frequency offsets to apply to each spectrum for multiple inputs.

Details

Spectrum Analyzer adds this constant offset or the vector of offsets to the values on the *frequency*-axis using the value of **Offset** on the **Trace options** pane of the **Spectrum Settings** panel. You can also set the offset from the FrequencyOffset property. The offset is the current time value at the middle of the interval of the line displayed at 0 seconds. The actual time of a particular spectrogram line is the offset minus the *y*-axis time listing. The offset is displayed on the plot only when the spectrum **Type** is `Spectrogram`.

- *Simulation Status* — Provides the current status of the model simulation.

Details

The status can be one of the following conditions:

- `Processing` — Occurs after you construct the `SpectrumAnalyzer` object and before you run the `release` method.
- `Stopped` — Occurs after you run the `release` method.

The *Simulation Status* is part of the *Status Bar* in the Spectrum Analyzer window. You can choose to hide or display the entire *Status Bar*. From the Spectrum Analyzer menu, select **View > Status Bar**.

- *Display time* — The amount of time that has progressed since the last update to the Spectrum Analyzer display.

Details

Every time you call the step method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula: $t_{sim} = t_{sim} + \frac{\text{length(0:length(xsine))-1}}{\text{SampleRate}}$. At the beginning of a simulation, you can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel. You can also set the sample rate using the SampleRate property. The display time is updated each time the display is updated. When ReducePlotRate is `true`, the simulation time and display time might differ. If at the end of a for loop that includes the Spectrum Analyzer, the times differ, you can call the `release` method to update the display with any data left in the buffer. Note, however, that if the remaining data is not a complete window interval, the display is not updated.

The *Display time* indicator is a component of the *Status Bar* in the Spectrum Analyzer window. You can choose to hide or display the entire *Status Bar*. From the Spectrum Analyzer menu, select **View** > **Status Bar** .

- *Frequency span* — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

Details

Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

- `Span(Hz)` and `CF(Hz)` visible — The *Frequency span* value equals the **Span** parameter in the **Main options** pane. You can also get or set this value from the Span property when the FrequencySpan property is set to `'Span and Center Frequency'`.
- `FStart(Hz)` and `FStop(Hz)` — The *Frequency span* value equals the difference of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the formula: $f_{span} = f_{stop} - f_{start}$. You can also get or set these values from the StartFrequency and StopFrequency properties when the `FrequencySpan` property is set to `'Start and stop frequencies'`.

By default, the **Full Span** check box in the **Main options** pane is enabled, and its equivalent FrequencySpan property is set to `'Full'`. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, and its equivalent PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

For more information, see “Spectrum Settings” on page 4-1601.

Reduce Plot Rate to Improve Performance

By default, Spectrum Analyzer updates the display at fixed intervals of time at a rate not exceeding 20 hertz. If you want Spectrum Analyzer to plot a spectrum on every simulation time step, you can disable the **Reduce Plot Rate to Improve Performance** option. In the Spectrum Analyzer menu, select **Simulation** > **Reduce Plot Rate to Improve Performance** to clear the check box. Tunable (Simulink).

Note: When this check box is selected, Spectrum Analyzer may display a misleading spectrum in some situations. For example, if the input signal is wide-band with non-stationary behavior, such as a chirp signal, Spectrum Analyzer might display a stationary spectrum. The reason for this behavior is that Spectrum Analyzer buffers the input signal data and only updates the display periodically at approximately 20 times per second. Therefore, Spectrum Analyzer does not render changes to the spectrum that occur and elapse between updates, which gives the impression of an incorrect spectrum. To ensure that spectral estimates are as accurate as possible, clear the **Reduce Plot Rate to Improve Performance** check box. When you clear this box, Spectrum Analyzer calculates spectra whenever there is enough data, rendering results correctly.

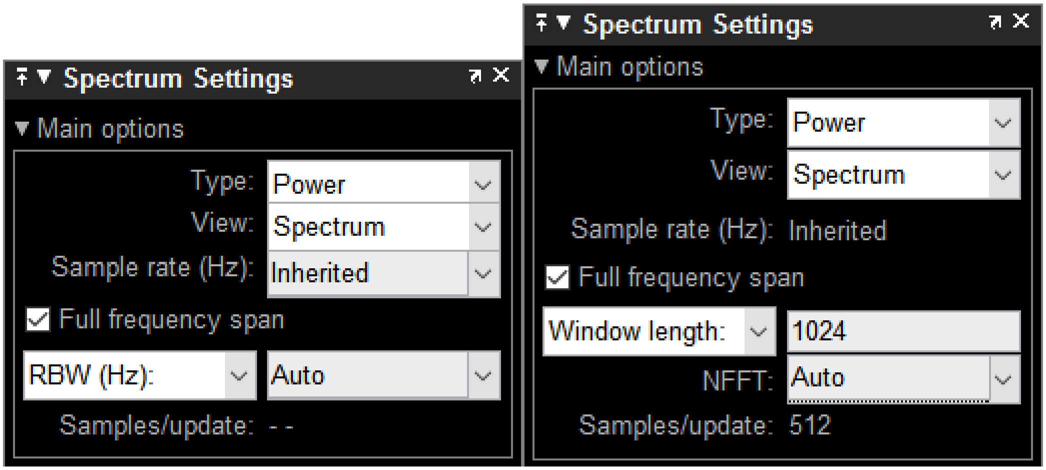
Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View** > **Spectrum Settings**. Alternatively, in the Spectrum Analyzer toolbar, select the Spectrum Settings  button.

The **Spectrum Settings** panel is separated into four expandable panes, labeled **Main options**, **Spectrogram options**, **Window options**, and **Trace options**.

Main Options Pane

The **Main Options** pane enables you to modify or view the main options.



- **Type** — The type of spectrum to display. Tunable (Simulink)
  - `Power` — power spectrum
  - `Power density` — power spectral density, the magnitude of the spectrum normalized to a bandwidth of 1 hertz
  - `RMS` — root mean squared of the spectrum
- **View** — The spectrum view to display. Tunable (Simulink)
  - `Spectrum` — frequency spectrum
  - `Spectrogram` — frequency spectrum over time. The most recent spectrogram update is at the bottom of the display and time scrolls from the bottom to the top of the display.
  - `Spectrum and spectrogram` — duel view of spectrum and spectrogram.
- **Sample rate (Hz)** — The sample rate, in hertz, of the input signals. Tunable (Simulink)
- **Full frequency span** — Compute and plot the spectrum over the entire *Nyquist* frequency interval.

  By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$

hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

Enabling this check box is equivalent to setting the FrequencySpan property to `'Full'`..

- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency*-axis values using start frequency and stop frequency instead.

  - **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency*-axis on the Spectrum Analyzer window. When this parameter is set to a numeric value, then it is equivalent to the Span property when the FrequencySpan property is set to `'Span and Center Frequency'`. Tunable (Simulink).
  - **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the CenterFrequency property when the FrequencySpan property is set to `'Span and Center Frequency'`. Tunable (Simulink).
  - **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the `StartFrequency` on page 4-1584 property when the FrequencySpan property is set to `'Start and stop frequencies'`. Tunable (Simulink).
  - **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the StopFrequency property when the FrequencySpan property is set to `'Start and stop frequencies'`. Tunable (Simulink).

- **RBW (Hz) / Window length** — The frequency resolution method.

  If set to **RBW (Hz)**, the resolution bandwidth, in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified *Frequency span*. This case is equivalent to when you set the RBWSource property to `'Auto'`.

If you set this parameter to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall span to *RBW* must be at least two: $\frac{span}{RBW} > 2$. In this case, this parameter is equivalent to the RBW property, when `RBWSource` is set to `'Property'`.

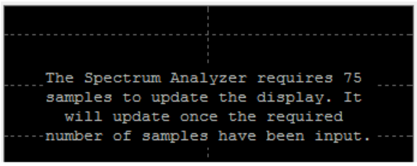
If set to **Window length**, the length of the window, in samples, to compute the spectral estimates. The window length must be an integer scalar greater than 2.

. Tunable (Simulink).

- **NFFT** — The number of Fast Fourier Transform (FFT) points. This parameter is available only when the frequency resolution method is **Window length**. This parameter defines the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive, scalar integer. The **NFFT** (FFTLength) value must be greater than or equal to the WindowLength. By default, when **NFFT** is set to `Auto`, Spectrum Analyzer sets the number of FFT points to the window length or 1024, whichever is larger. This case is equivalent to when you set the FFTLengthSource property to `'Auto'`.

  When this parameter is set to a positive integer, this parameter is equivalent to the `n` parameter that you can set when you run the MATLAB `fft` function. In this case, this parameter is also equivalent to `FFTLength` when you set `FFTLengthSource` to `'Property'`. Tunable (Simulink).
- **Samples/update** — The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown here for display purposes only. This parameter is directly related to *RBW* by the following equation: $N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$ or to the window length by this equation: $N_{samples} = \left(1 - \frac{O_p}{100}\right) x \ WindowLength$. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. If the number of samples provided in the input

are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.



Spectrogram Options Pane

The **Spectrogram options** pane contains options for modifying the spectrogram. These options only display when the **Type** is `Spectrogram` or `Spectrum and spectrogram`

- **Channel** — Select the signal channel for which the spectrogram settings apply. This option displays only if there is more than one signal channel input.
- **Time res. (s)** — The time resolution, in seconds. This parameter is available only in spectrogram mode. *Time resolution* is the amount of data, in seconds, used to compute a spectrogram line. The *minimum attainable resolution* is the amount of time required to compute a single spectral estimate. The tooltip displays the minimum attainable resolution based on the current settings. You can get or set the minimum attainable resolution value from the TimeResolution property. Tunable (Simulink).
- **Time span (s)** — The time span over which the Spectrum Analyzer displays the spectrogram, in seconds. This parameter is available only in spectrogram mode. The *time span* is the product of the number of spectral lines you want and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to `Auto`, 100 spectral lines are used. This parameter is equivalent to the TimeSpan property. Tunable (Simulink).

Window Options Pane

The **Window Options** pane enables you to modify the window options.

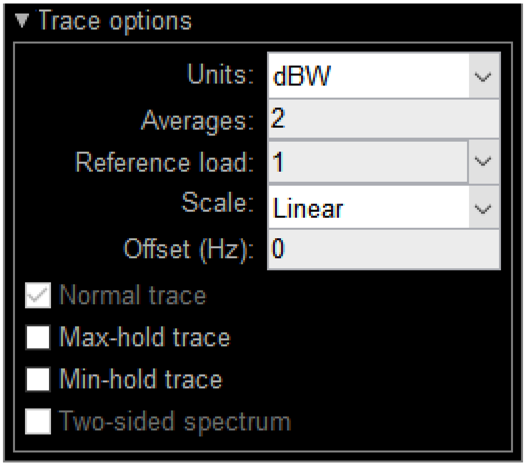
- **Overlap (%)** — The segment overlap percentage. This parameter defines the amount of overlap between the previous and current buffered data segments. The value must be greater than or equal to zero and less than 100. This parameter is equivalent to the OverlapPercent property. Tunable (Simulink).
- **Window** — The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects

the segment length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see the `Window Function` block. This parameter is equivalent to the Window property. Tunable (Simulink).

- **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to `Chebyshev` or `Kaiser`. You must specify a value greater than or equal to `45`. If you use a Chebyshev window and set the sidelobe attenuation to less than 35 dB, the desired resolution bandwidth may not be achieved. This parameter is equivalent to the SidelobeAttenuation property. Tunable (Simulink).
- **NENBW** — Normalized Effective Noise Bandwidth of the window. You cannot modify this parameter; it is a readout shown here for display purposes only. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same noise power with the same peak power gain. NENBW can be calculated from the windowing function using the following equation: $NENBW = N_{window} \dfrac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$. The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.



- **Units** — The units of the spectrum. The available values depends on the value of **Type**. Available options include `dBm`, `dBW`, `Watts`, `Vrms`, and `dBV`. This parameter is equivalent to the SpectrumUnits property. Tunable (Simulink).
- **Averages** — Specify as a positive, scalar integer the number of spectral averages. This parameter applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. Spectrum Analyzer computes the current power spectrum estimate by averaging the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*. This parameter is equivalent to the SpectralAverages property. Tunable (Simulink).
- **Reference load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. This parameter is equivalent to the ReferenceLoad property. Tunable (Simulink).
- **Scale** — Linear or logarithmic scale. When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. This parameter is equivalent to the FrequencyScale property. Tunable (Simulink).
- **Offset** — The constant frequency offset to apply to the entire spectrum or a vector of frequencies to apply to each spectrum for multiple inputs. The constant offset parameter is added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within Nyquist limits. The Nyquist interval is

$\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz if **Two-sided spectrum** is selected, and $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz otherwise. This parameter is equivalent to the FrequencyOffset property.

- **Normal trace** — Normal trace view. This parameter applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density computed by the *Welch* estimator. The Welch estimator performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. This parameter is equivalent to the PlotNormalTrace property. Tunable (Simulink).
- **Max hold trace** — Maximum hold trace view. This parameter applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. This parameter is equivalent to the PlotMaxHoldTrace property. Tunable (Simulink).
- **Min hold trace** — Minimum hold trace view. This parameter applies only when the Spectrum **View** is `Spectrum` or `Spectrum and spectrogram`. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. This parameter is equivalent to the PlotMinHoldTrace property. Tunable (Simulink).
- **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued. When your signal includes DC input, you should display a two-sided spectrum to resolve low frequency power and DC power. This parameter is equivalent to the property.

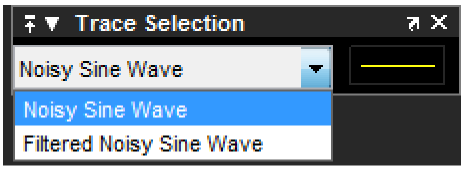
Measurements Panels

The Measurements panels are the panels that appear to the right side of the Spectrum Analyzer figure.

Note: When **View** is `Spectrogram`, the Measurements panels are not available.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

Cursor Measurements Panel

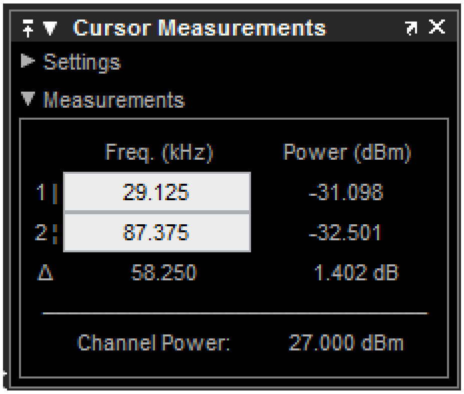
The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note: If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

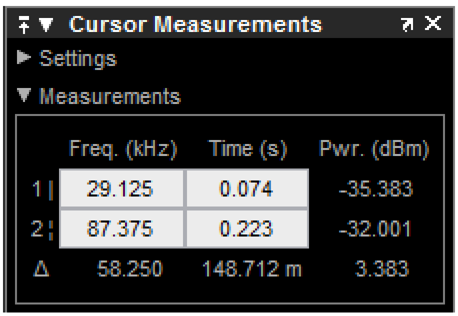
In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel appears as follows for the spectrum and dual view.



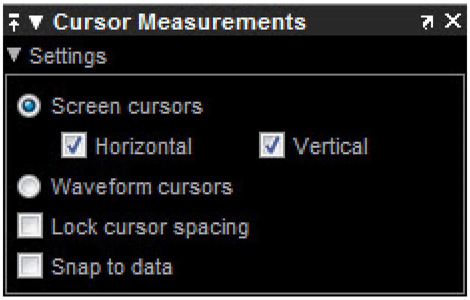
The **Cursor Measurements** panel appears as follows for the spectrogram view. You must pause the spectrogram display before you can use cursors.



The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.



- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

Measurements Pane

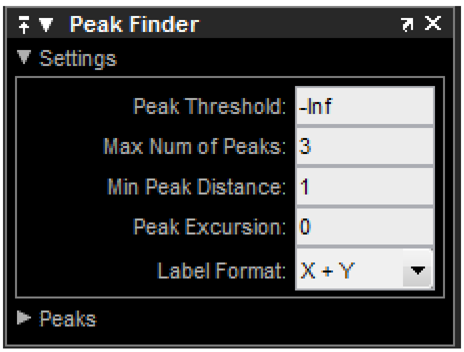
The **Measurements** pane displays the frequency (Hz) , time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.



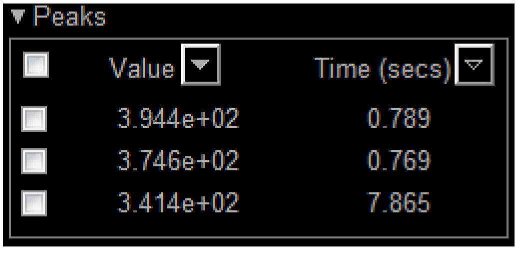
The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.

- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button ( ) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button ( ). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled

( ), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Channel Measurements Panel

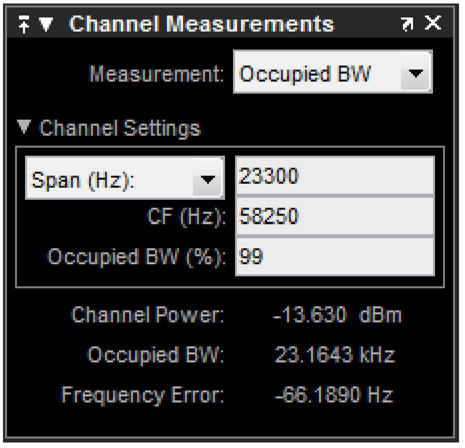
The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements. You can choose to hide or display this pane in the Scope menu by selecting **Tools** > **Measurements** > **Channel Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are `Occupied BW` or `ACPR`. See "Algorithms" on page 2-1592 for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select `Occupied BW` as the **Measurement**, the following fields appear.

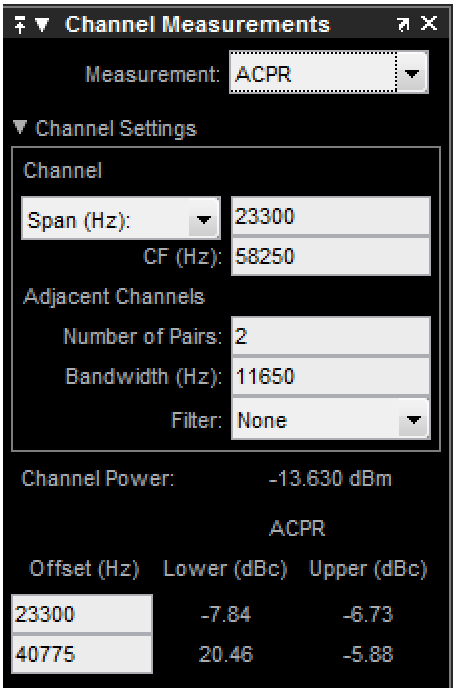


- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

  Channel Settings for Occupied BW

  - Select the frequency span of the channel, `Span(Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
  - **CF (Hz)** — The center frequency of the channel.
  - **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.
- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select `Occupied BW` as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select `Occupied BW` as the **Measurement** type.

When you select `ACPR` as the **Measurement**, the following fields appear.



- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

  ### Channel Settings for ACPR

  - Select the frequency span of the channel, `Span (Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
  - **CF (Hz)** — The center frequency of the channel.
  - **Number of Pairs** — The number of pairs of adjacent channels.
  - **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
  - **Filter** — The filter to use for both main and adjacent channels. Available filters are `None`, `Gaussian`, and `RRC` (root-raised cosine).
- **Channel Power** — The total power in the channel.

- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.

Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements. You can choose to hide or display this panel in the Scope menu by selecting **Tools** > **Measurements** > **Distortion Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements  button.

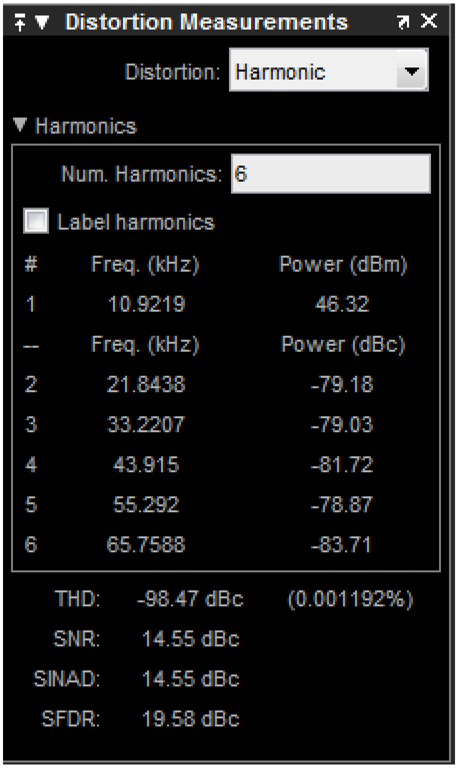
The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note: For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are `Harmonic` or `Intermodulation`. Select `Harmonic` if your system input is a single sinusoid. Select `Intermodulation` if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

  See “Algorithms” on page 2-1592 for information on how distortion measurements are calculated.

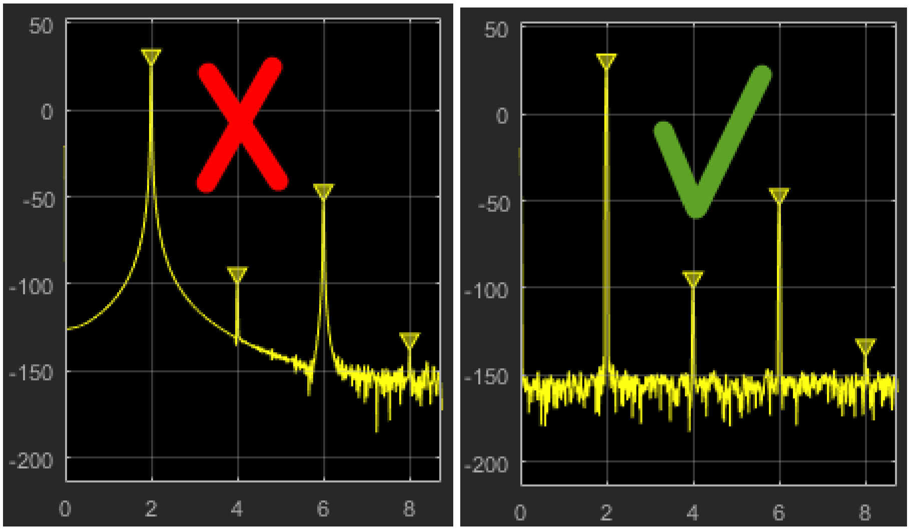
When you select `Harmonic` as the **Distortion**, the following fields appear.



The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note: To best view the harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Additionally, the noise floor should be visible.

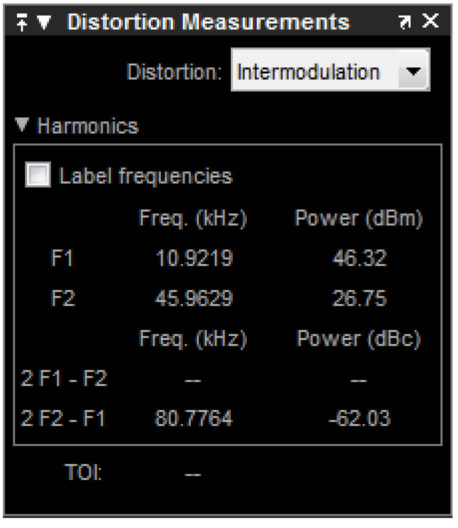
For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).



- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from 2 to 99. The default value is 6.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to one milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, D, to the power in the fundamental frequency, S. If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window. $THD = 10\log_{10}(D/S)$.
- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, S, to the power of all nonharmonic content, N, including spurious signals, in decibels relative to the carrier (dBc). $SNR = 10\log_{10}(S/N)$. If you see – – as the reported SNR, your signal's total non-harmonic content is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, S to all other content (including noise, N, and harmonic distortion, D), in decibels relative to the carrier (dBc). $SINAD = 10\log_{10}(S/(N+D))$.
- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, S, to power of the largest spurious signal, R, regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics. $SFDR = 10\log_{10}(S/R)$.

When you select `Intermodulation` as the **Distortion**, the following fields appear.



The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products (2*F1-F2 and 2*F2-F1).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency

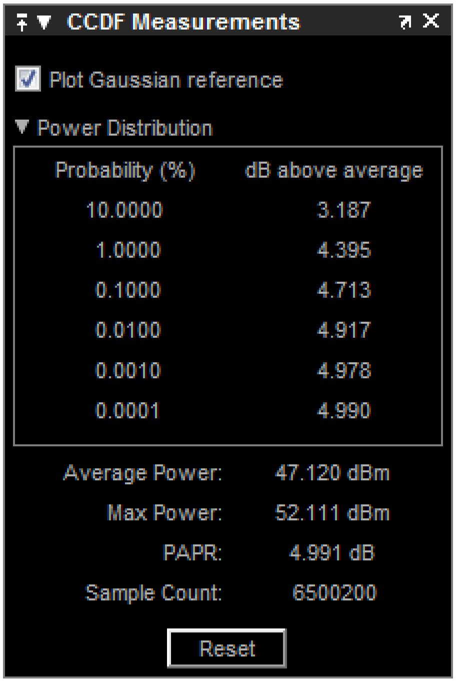
- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal's instantaneous power being a specified level above the signal's average power. These measurements are useful indicators of a signal's dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

You can choose to hide or display this panel in the Scope menu by selecting **Tools** > **Measurements** > **CCDF Measurements**. Alternatively, in the Scope toolbar, click the CCDF Measurements  button.



- **Plot Gaussian reference** — Select **Plot Gaussian reference** to show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.
- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.

  Max Power — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less that 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — The total number of samples used to compute the CCDF.

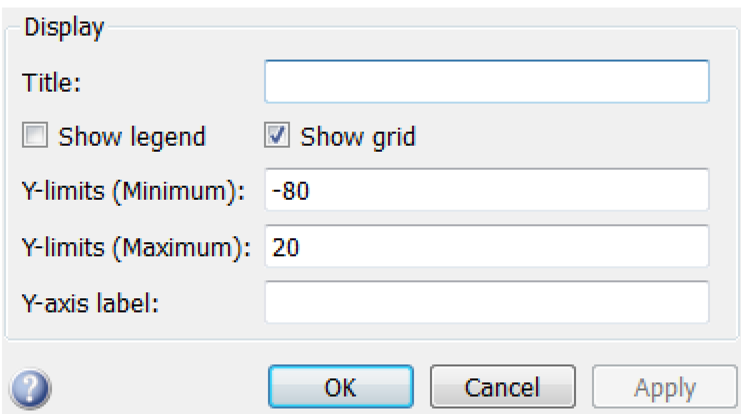
- **Reset** — Clear all current CCDF measurements and restart.

Visuals — Spectrum Properties

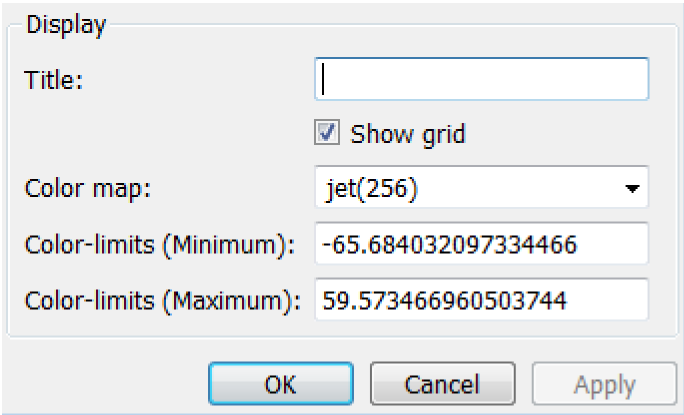
The Visuals—Spectrum Properties dialog box controls the visual configuration settings of the Spectrum Analyzer display. From the Spectrum Analyzer menu, select **View** > **Configuration Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the Configuration Properties  button.

Display Pane

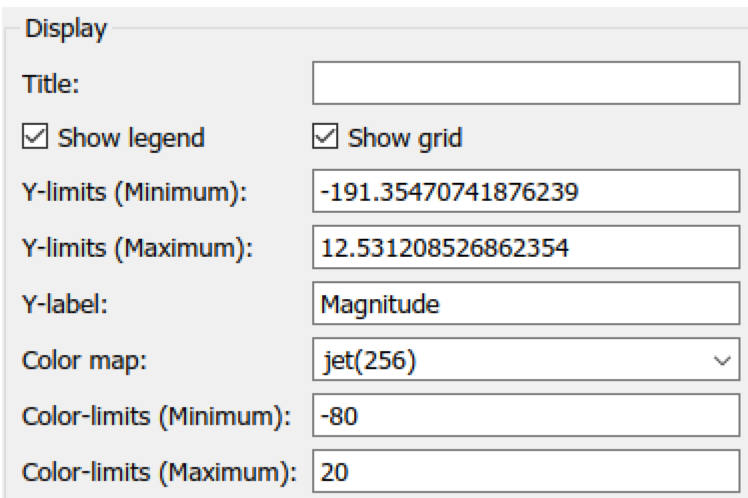
When the Spectrum **View** is `Spectrum`, the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



When the Spectrum **View** is `Spectrogram` the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



When the Spectrum **View** is `Spectrum or spectroogram` the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



Title

Specify the display title as a character vector. Enter %<SignalLabel> to use the signal labels in the Simulink Model as the axes titles. This property is Tunable (Simulink).

By default, the display has no title.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn off the legend, clear the **Show legend** check box.

You can edit the name of any channel in the legend by double-clicking the current name and entering a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View** > **Style**.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

This parameter applies only when the **View Type** is `Spectrum` or `Spectrum and spectrogram`. Tunable (Simulink)

Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable (Simulink)

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. Tunable (Simulink)

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable (Simulink)

Y-axis label

Specify the text for the scope to display to the left of the *y*-axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`, `Vrms`, or `dBV`Tunable (Simulink).

Color map

Select the color map for the spectrogram, or enter a 3-column matrix expression for the color map. See `colormap` for information. Tunable (Simulink).

Color-limits (Minimum)

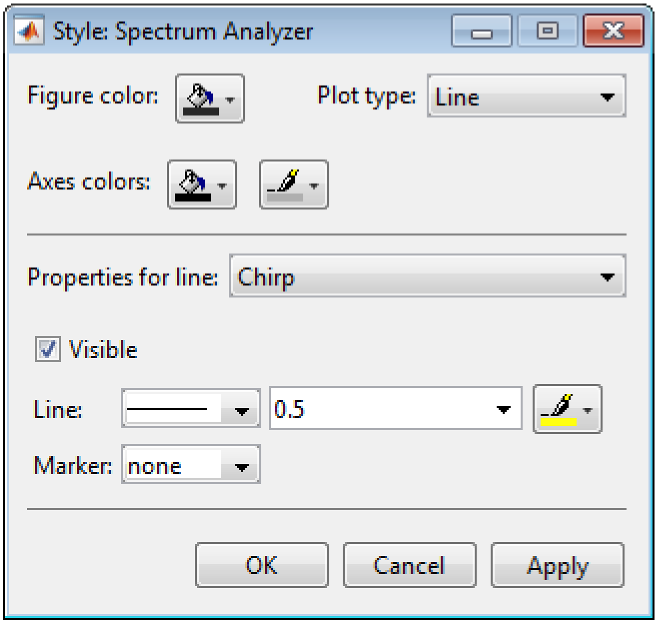
Set the signal power for the minimum color value of the spectrogram. Tunable (Simulink).

Color-limits (Maximum)

Set the signal power for the maximum color value of the spectrogram. Tunable (Simulink).

Style Dialog Box

In the **Style** dialog box, you can customize the style of spectrum display. This dialog box is not available for the spectrogram view. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View** > **Style** to open this dialog box.



Properties

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify whether to display a `Line` or `Stem` plot.

Axes colors

Specify the color that you want to apply to the background of the axes.

Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected channel.

Marker

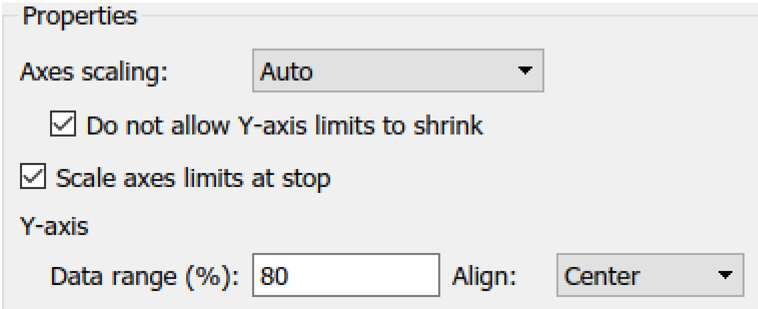
Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for plot objects. You can choose any of the marker symbols from the dropdown.

Tools — Axes Scaling Properties

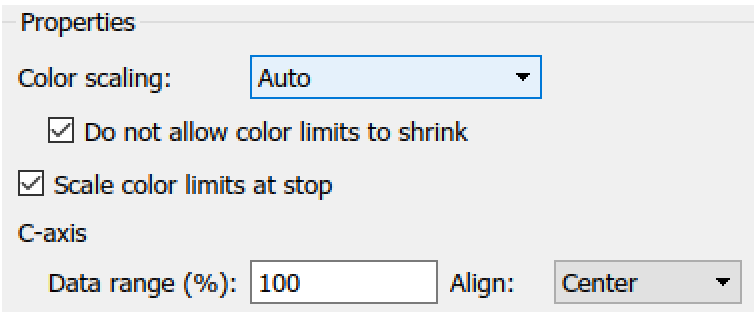
The Tools—Axes Scaling Properties dialog box allows you to zoom in on and zoom out of your data automatically. You can also scale the axes of the Spectrum Analyzer. In the Spectrum Analyzer menu, select **Tools** > **Scaling Properties** to open this dialog box.

Properties

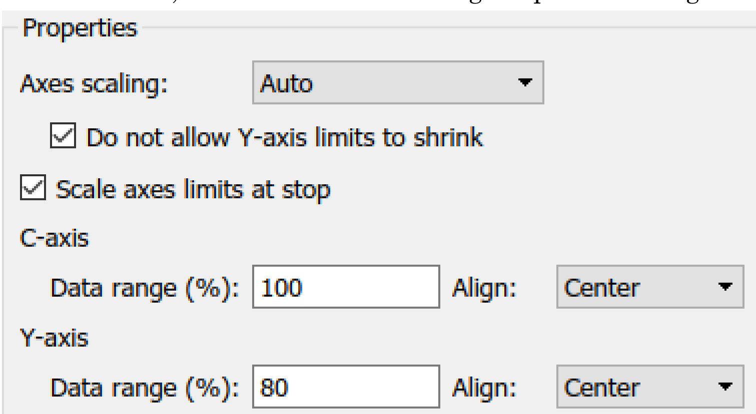
For the spectrum view, the Tools—Axes Scaling Properties dialog box appears as:



For spectrogram view, the Tools—Axes Scaling Properties dialog box appears as:



For dual view, the Tools—Axes Scaling Properties dialog box appears as:



Note: The X-axis scaling options only apply when using CCDF measurements.

Axes scaling/Color scaling

Specify when the scope automatically scales the axes. If the spectrogram is displayed, specify when the scope automatically scales the color. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
  - Select **Tools** > **Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink** .
- `After N Updates` — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this parameter is set to `Auto`, and the scope does not shrink the *y*-axis limits when scaling the axes or color. Tunable (Simulink).

Do not allow Y-axis limits to shrink / Do not allow color limits to shrink

When you select this property, the *y*-axis are allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this property allows the color limits to grow during axis scaling. If you clear this check box, the *y*-axis or color limits can shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** or **Color scaling** property. When you set the **Axes scaling** or **Color scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits can shrink. Tunable (Simulink).

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. If the spectrogram is displayed, this property specifies the number of updates after which to scale the color. This property appears only when you select `After N Updates` for the **Axes scaling** or **Color scaling** property. Tunable (Simulink).

Scale axes limits at stop/Scale color limits at stop

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%) / Color-limits Data range

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range or color such that your data uses only 30% of the *y*-axis range or color. Tunable (Simulink).

Y-axis Align / Color-limits Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the *y*-axis when it scales the color. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable (Simulink).

X-axis Data range (%)

Set the percentage of the *x*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement along the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

X-axis Align

Specify how the scope aligns your data along the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

Algorithms

Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** panel to determine the data window length. The value of the `FrequencyResolutionMethod` property determines whether RBW or window length is used. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

1. Spectrum Analyzer requires that a minimum number of samples have been provided before it computes a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation or to the window length, by the equation shown in step 1b.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

   The normalized effective noise bandwidth, *NENBW*, is a factor that depends on the windowing method. Spectrum Analyzer shows NENBW in the **Window Options** pane of the **Spectrum Settings** panel. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** panel.

   a. When in RBW mode, the window length required to compute one spectral update, N_{window}, is directly related to the resolution bandwidth and normalized effective noise bandwidth by the following equation.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in WindowLength mode, the window length is used as specified.

b The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

c The normalized effective noise bandwidth, *NENBW*, is a window parameter determined by the window length, N_{window}, and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then *NENBW* is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

d When in RBW mode, you can set the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two, as given in the following equation.

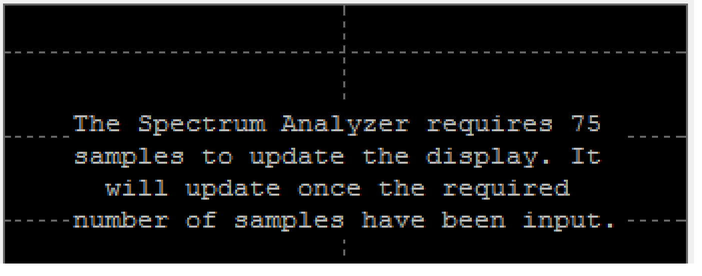
$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to `Auto`, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

e When in window length mode, you specify N_{window} and the resulting RBW is

$$\frac{NENBW * Fs}{N_{window}}$$

In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.



Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input. Notice that this behavior differs from the Spectrum Scope block in versions R2012b and earlier. If the **Buffer input** check box was selected, the Spectrum Scope block computed a spectral update using the number of samples given by the **Buffer size** parameter. Otherwise, the Spectrum Scope block computed a spectral update using the number of samples in each frame.

2 Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified *Periodogram* estimator. For more information about the Periodogram method, see `periodogram` in the Signal Processing Toolbox documentation.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^2}{\left[\sum_{n=1}^{N_{window}} w[n]\right]^2}$$

Spectrogram — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is 1/RBW, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms may be combined. You then use interpolation to calculate noninteger values of 1/RBW. In the spectrogram display, time scrolls from bottom to top, so the most recent data is shown at the bottom of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Note: The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values provided that N_{fft} is greater than or equal to N_{window}.

The *Occupied BW* is calculated as follows.

- Calculate the total power in the measured frequency range.
- Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this sum is $\frac{100 \text{ - } Occupied\ BW\ \%}{2}$ of the total power.
- Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until it reaches $\frac{100 \text{ - } Occupied\ BW\ \%}{2}$ of the total power.
- The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- The frequency halfway between the lower and upper frequency values is the center frequency.

The *Distortion Measurements* are computed as follows.

1. Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it clears all monotonically decreasing values (that is, it treats all of these values as if they belong to the peak). Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
2. The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power associated from the fundamental is removed as in step 1.
3. The power and width of the second, and higher order harmonics (P_2, W_2, P_3, W_3, etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases in a monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.

4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$) peak value ($P_{maxspur}$), and its median value ($P_{estnoise}$).

5 The sum of all the removed bandwidth is computed as $W_{sum} = W_0+W_1+W_2+...+W_n$.

The sum of powers of the second and higher order harmonics are computed as $P_{harmonic} = P_2+P_3+P_4+...+P_n$.

6 The sum of the noise power is then estimated as $P_{noise} = (P_{remaining}$*dF + $P_{estnoise}*W_{sum})/RBW$, where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10}\left(\frac{P_{harmonic}}{P_1}\right)$$

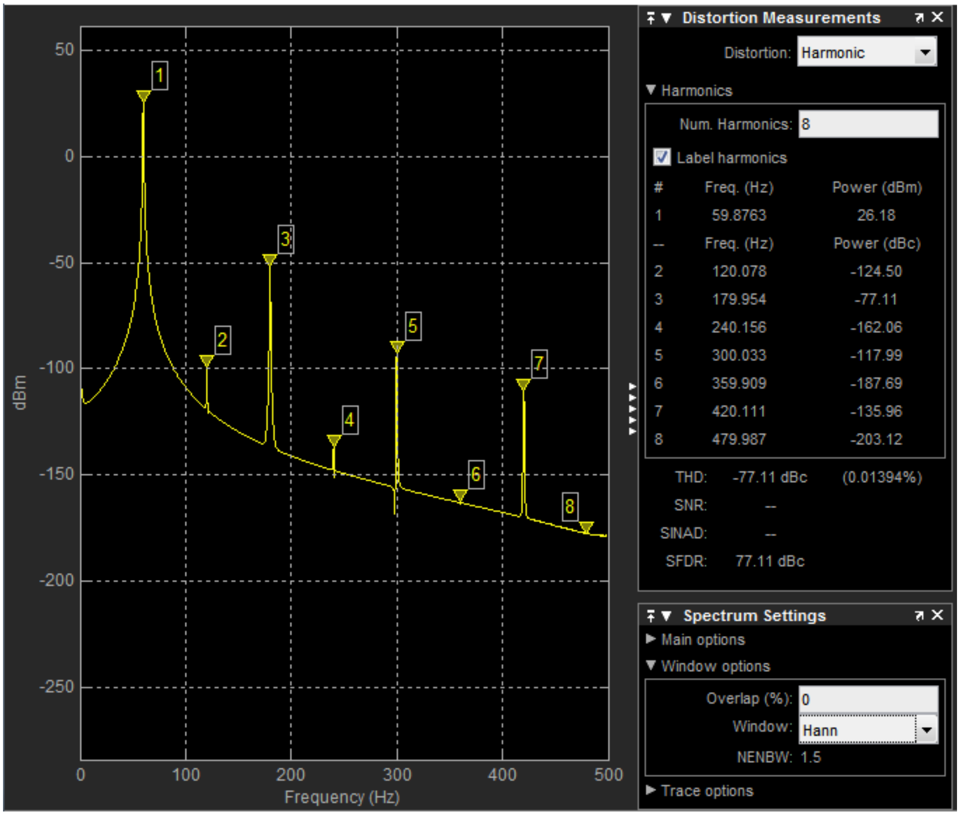
$$SINAD = 10 \cdot \log_{10}\left(\frac{P_1}{P_{harmonic} + P_{noise}}\right)$$

$$SNR = 10 \cdot \log_{10}\left(\frac{P_1}{P_{noise}}\right)$$

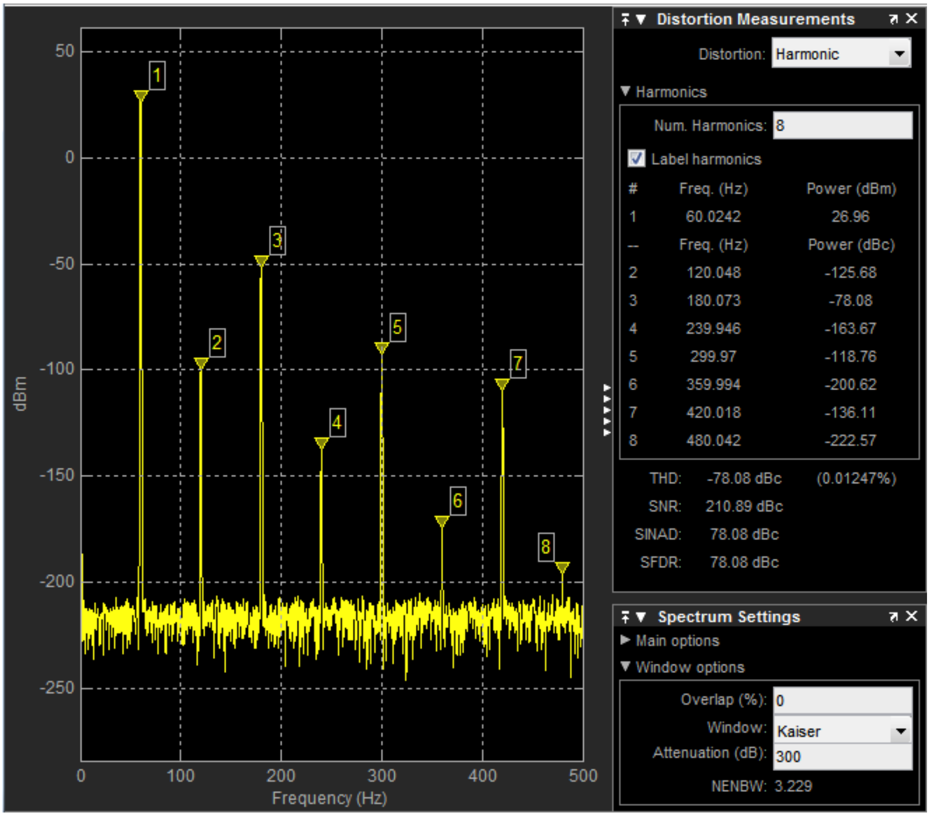
$$SFDR = 10 \cdot \log_{10}\left(\frac{P_1}{\max\left(P_{maxspur}, \max\left(P_2, P_3, \ldots, P_n\right)\right)}\right)$$

The following considerations apply to *Distortion Measurements*.

- The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default `Hann` window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.



The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. Consider using a Kaiser window with a high attenuation (up to 330dB) to minimize spectral leakage if your application can tolerate the increased equivalent noise bandwidth (ENBW) of the Kaiser window.



- The DC component is ignored.
- After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- *N*th order intermodulation products occur at

  $A*F1 + B*F2$

  where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

- For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to one milliwatt (dBm).:
  - $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1\text{-}F2)})/2$
  - $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2\text{-}F1)})/2$
  - $TOI \ = + (TOI_{lower} + TOI_{upper})/2$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`Spectrum Analyzer` | dsp.TimeScope | dsp.LogicAnalyzer | dsp.ArrayPlot

Introduced in R2012b

getSpectralMaskStatus

System object: dsp.SpectrumAnalyzer
Package: dsp

Get test results of current spectral mask

Syntax

```
results = getSpectralMaskStatus(scope)
```

Description

`results = getSpectralMaskStatus(scope)` returns the current status of the spectral mask on the spectrum analyzer, `scope`, in a structure, `results`.

`results` has the following information.

Field	Description
`IsCurrentlyPassing`	Indicator of whether one or more masks are currently passing `1` — All masks are passing `0` — One or more masks are failing
`NumPassedTests`	Number of mask tests that have passed
`NumTotalTests`	Total number of mask tests
`SuccessRate`	Percentage of tests that have passed
`FailingChannels`	Array of channel numbers that are currently failing the mask test
`FailingMasks`	Character array of which masks are currently failing: `'None'`, `'Upper'`, `'Lower'`, or `'Upper and lower'`
`SimulationTime`	Simulation time

dsp.SpectrumAnalyzer | spbscopes.SpectrumAnalyzerConfiguration

hide

System object: dsp.SpectrumAnalyzer
Package: dsp

Hide Spectrum Analyzer window

Syntax

```
hide(scope)
```

Description

`hide(scope)` hides the Spectrum Analyzer window, associated with System object, `scope`.

See Also

dsp.SpectrumAnalyzer.show | dsp.SpectrumAnalyzer

reset

System object: dsp.SpectrumAnalyzer
Package: dsp

Reset internal states of Spectrum Analyzer object

Syntax

`reset(scope)`

Description

`reset(scope)` sets the internal states of the `SpectrumAnalyzer` object `scope` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the Spectrum Analyzer figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

step

System object: dsp.SpectrumAnalyzer
Package: dsp

Update spectrum in Spectrum Analyzer figure

Syntax

`step(scope,signal)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(scope,signal)` updates the spectrum of the signal, `signal`, in the Spectrum Analyzer figure.

dsp.SpectrumEstimator System object

Package: dsp

Estimate power spectrum or power density spectrum

Description

The `dsp.SpectrumEstimator` computes the power spectrum or the power density spectrum of a signal, using the Welch algorithm and the filter bank approach.

When you choose the Welch method, the object computes the averaged modified periodograms to compute the spectral estimate. When you choose the filter bank approach, an analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band and the computed value is the spectral estimate over the respective frequency band. The filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and more precise peaks than the Welch method, with low or no spectral leakage. They come at the expense of increased computation and slower tracking.

The spectrum can be expressed in Watts or in decibels. This object can also estimate the max-hold and min-hold spectra of the signal.

To estimate the power density spectrum:

1. Define and set up your spectrum estimator object. See “Construction” on page 4-1647.
2. Call step to estimate the power density spectrum according to the properties of the object.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`SE = dsp.SpectrumEstimator` returns a System object, `SE`, that computes the frequency power spectrum or the power density spectrum of real or complex signals. This System object uses the Welch's averaged modified periodogram method and filter bank based spectral estimation method.

`SE = dsp.SpectrumEstimator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `Spectrum Estimator` System object, `SE`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1,Value1`, ..., `NameN,ValueN`).

Properties

`SampleRate`

Sample rate of input

Specify the sample rate of the input in, hertz, as a finite numeric scalar. The default value is `1 Hz`. The sample rate is the rate at which the signal is sampled in time.

`SpectrumType`

Spectrum type

Specify the spectrum type as one of `'Power' | 'Power density'`. When the spectrum type is `'Power'`, the power density spectrum is scaled by the equivalent noise bandwidth of the window (in Hz). The default value is `'Power'`. This property is tunable.

`SpectralAverages`

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Spectrum Estimator computes the current power spectrum or power density spectrum estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property. The default value is `8`.

`FFTLengthSource`

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` | `'Property'`. The default value is `'Auto'`. If you set this property to `'Auto'`, the Spectrum Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Spectrum Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is `128`.

Method

Welch or filter bank

Specify the spectral estimation method as one of `'Welch'` | `'Filter bank'`.

- `'Welch'` — The object uses Welch's averaged modified periodograms method.
- `'Filter bank'` — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band and the computed value is the spectral estimate over the respective frequency band.

  The default is `'Welch'`.

NumTapsPerBand

Number of filter taps per frequency band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is given by `NumTapsPerBand` × `FFTLength`. This property applies when you set `Method` to `'Filter bank'`. The default is 12.

Window

Window function

Specify a window function for the spectral estimator as one of `'Rectangular'` | `'Chebyshev'` | `'Flat Top'` | `'Hamming'` | `'Hann'` | `'Kaiser'`. The default value is `'Hann'`.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default value is `60 dB`.

FrequencyRange

Frequency range of the spectrum estimate

Specify the frequency range of the spectrum estimator as one of `'twosided' | 'onesided' | 'centered'`.

If you set the `FrequencyRange` to `'onesided'`, then the Spectrum Estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length (`NFFT`/2) + 1 and is computed over the frequency range `[0 SampleRate/2]`, where `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length (`NFFT` + 1)/2 and is computed over the frequency range [`0 SampleRate/2`).

If you set the `FrequencyRange` to `'twosided'`, then the Spectrum Estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range [`0 SampleRate`), where `SampleRate` is the sample rate of the input signal.

If you set the `FrequencyRange` to `'centered'`, then the Spectrum Estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range (`-SampleRate/2 SampleRate/2`] when the FFT length is even and `(-SampleRate/2 SampleRate/2)` when the FFT length is odd.

The default value is `'twosided'`.

PowerUnits

Power units

Specify the units used to measure power as one of `'Watts' | 'dBW' | 'dBm'`. The default value is `'Watts'`.

`ReferenceLoad`

Reference load

Specify the load that the spectrum estimator uses as a reference to compute power values as a real, positive scalar in ohms. The default value is `1 ohm`.

`OutputMaxHoldSpectrum`

Output max-hold spectrum

Set this property to `true` so that the Spectrum Estimator computes and outputs the max-hold spectrum of each input channel. The max-hold spectrum is computed by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. The default is `false`.

`OutputMinHoldSpectrum`

Output min-hold spectrum

Set this property to `true` so that the Spectrum Estimator computes and outputs the min-hold spectrum of each input channel. The min-hold spectrum is computed by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. The default is `false`.

Methods

getFrequencyVector	Get the vector of frequencies at which the spectrum is estimated
getRBW	Get the resolution bandwidth of the spectrum
reset	Reset the internal states of the spectrum estimator
step	Estimate the power spectrum or power-density spectrum of a signal

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Spectral Estimation Using Filter Bank

Compare spectral estimates of sinusoids embedded in white Gaussian noise using a Hann window based Welch method and filter bank method.

Initialization

Initialize two `dsp.SpectrumEstimator` objects. Specify one estimator to use the Welch-based spectral estimation technique with a Hann window. Specify the other estimator to use an analysis filter bank to perform the spectral estimation. Specify a noisy sine wave input signal with 4 sinusoids at 0.16, 0.2, 0.205, and 0.25 cycles/sample. View the spectral estimate using an array plot.

```
FrameSize = 420;
Fs = 1;
sinegen = dsp.SineWave('SampleRate',Fs,...
    'SamplesPerFrame',FrameSize,...
    'Frequency',[0.16 0.2 0.205 0.25],...
    'Amplitude',[2e-5 1  0.05  0.5]);
NoiseVar = 1e-10;
numAvgs = 8;

hannEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Window','Hann','FrequencyRange','onesided',...
    'SpectralAverages',numAvgs,'SampleRate',Fs);

filterBankEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Method','Filter bank','FrequencyRange','onesided',...
    'SpectralAverages',numAvgs,'SampleRate',Fs);

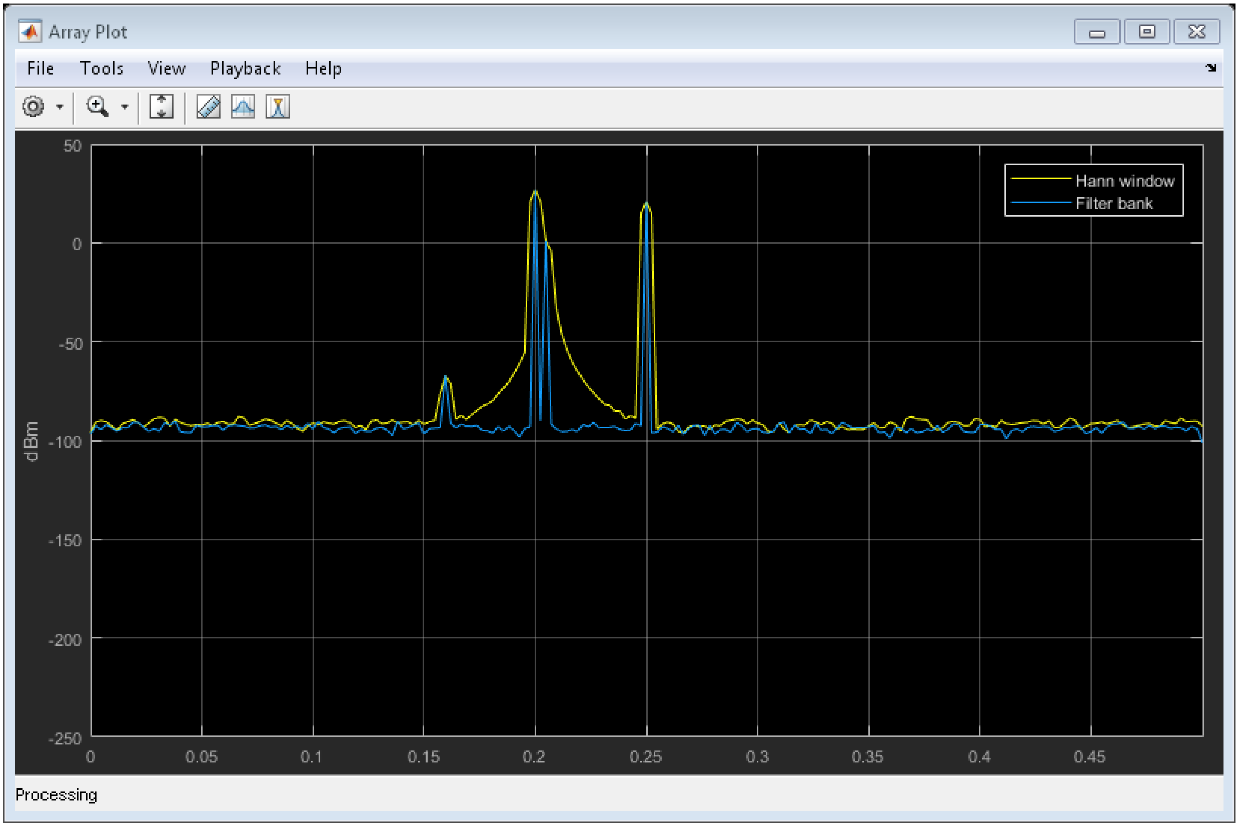
spectrumPlotter = dsp.ArrayPlot(...
```

```
    'PlotType','Line','SampleIncrement',Fs/FrameSize,...
    'YLimits',[-250,50],'YLabel','dBm',...
    'ShowLegend',true,'ChannelNames',{'Hann window','Filter bank'});
```

Streaming

Stream the input. Compare the spectral estimates computed using the Hann window and the analysis filter bank

```
for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
    spectrumPlotter([Pse_hann,Pfb]);
end
```



The Hann window misses the peak at 0.205 cycles/sample. In addition, the window has a significant spectral leakage that makes the peak at 0.16 cycles/sample hard to distinguish, and the noise floor is not correct.

The filter bank estimate has a very good resolution with no spectral leakage.

Power and Max-Hold Spectra of Noisy Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Generate a sine wave.

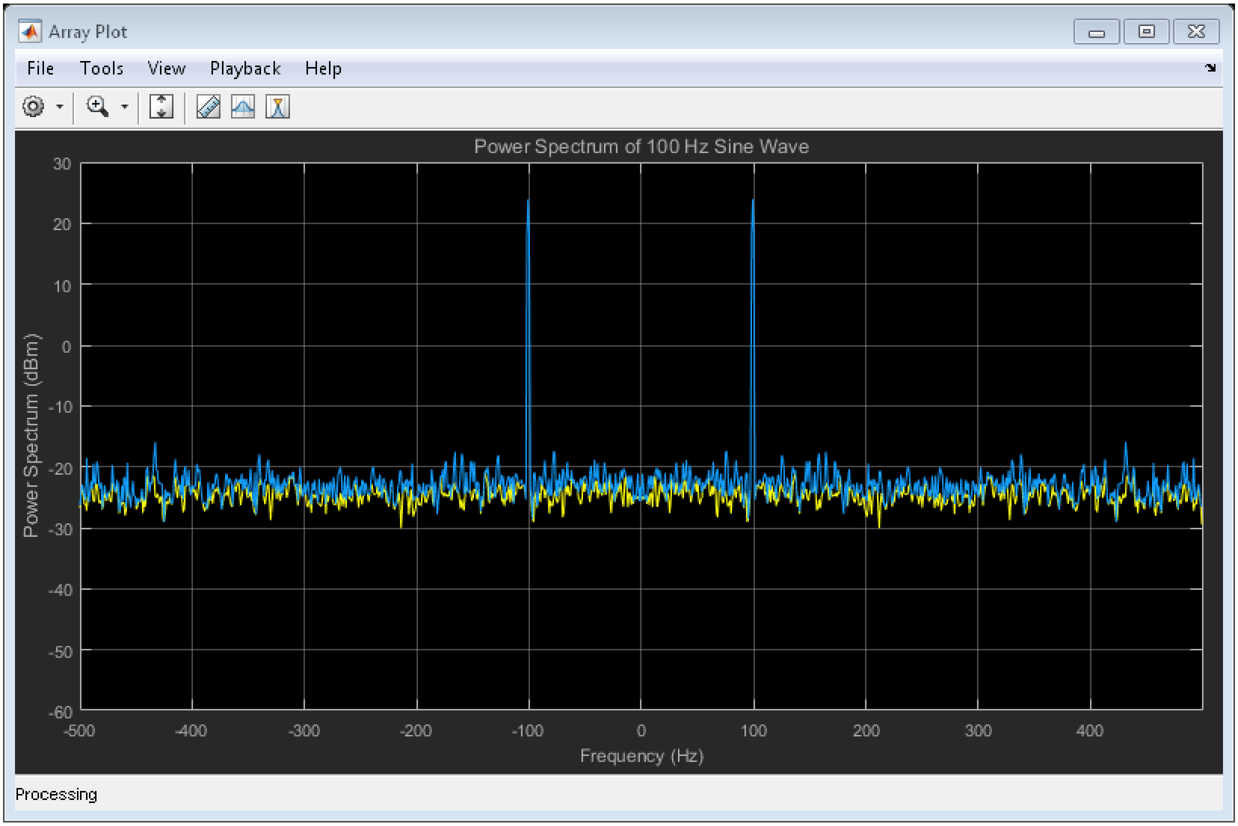
```
SINE = dsp.SineWave('Frequency',100,'SampleRate',1000, ...
    'SamplesPerFrame',1000);
```

Use the Spectrum Estimator to compute the power spectrum and the max-hold spectrum of the sine wave. Use the Array Plot to display the spectra.

```
SE = dsp.SpectrumEstimator('SampleRate',SINE.SampleRate, ...
    'SpectrumType','Power','PowerUnits','dBm', ...
    'FrequencyRange','centered','OutputMaxHoldSpectrum',true);
PLOTTER = dsp.ArrayPlot('PlotType','Line','XOffset',-500, ...
    'YLimits',[-60 30], 'Title','Power Spectrum of 100 Hz Sine Wave', ...
    'YLabel','Power Spectrum (dBm)','XLabel','Frequency (Hz)');
```

Add random noise to the sine wave. Stream in the data, and plot the power spectrum of the signal.

```
for ii = 1:10
    x = SINE() + 0.05*randn(1000,1);
    [Pxx,Pmax] = SE(x);
    PLOTTER([Pxx Pmax]);
end
```



Algorithms

Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

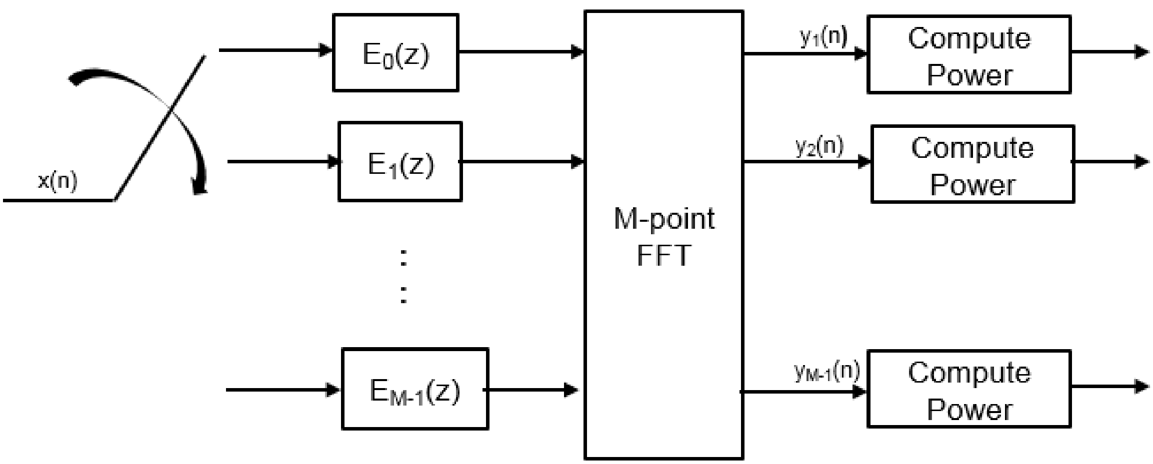
Let `x` be the input frame. Multiply `x` by the window and scale the result by the window power. Take the FFT of the signal, `Y`, and take the square magnitude using `Z = Y*conj(Y)`. Compute the current power spectrum estimate by averaging the last N `Z`s and scaling the answer by the sample rate. N is the number of spectral averages.

For further information refer to the “Algorithms” on page 2-1592 section in Spectrum Analyzer, which uses the same algorithm.

Filter Bank

The spectrum estimator uses an analysis filter bank to estimate the power spectrum. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the FFT length.

The filter-bank-based spectrum estimator splits the broadband input signal, *x(n)*, into multiple narrow bands and computes the power in each band. Each value becomes the estimate of the power over that narrow frequency band. The power in all the narrow bands forms the spectral estimate vector.



For more details on the implementation, see the “Algorithm” on page 2-214 section in `dsp.Channelizer`.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

System Objects
dsp.CrossSpectrumEstimator | dsp.SpectrumAnalyzer | dsp.TransferFunctionEstimator

Blocks
`Spectrum Estimator`

Introduced in R2013b

getFrequencyVector

System object: dsp.SpectrumEstimator
Package: dsp

Get the vector of frequencies at which the spectrum is estimated

Syntax

```
getFrequencyVector(SE)
```

Description

`getFrequencyVector(SE)` returns the vector of frequencies at which the spectrum is estimated.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length `NFFT/2+1`, and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length `(NFFT+1)/2` and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval `[0, SampleRate]`. If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range `[-SampleRate/2, SampleRate/2]` and `[-SampleRate/2, SampleRate/2]` for even and odd length `NFFT`, respectively.

getRBW

System object: dsp.SpectrumEstimator
Package: dsp

Get the resolution bandwidth of the spectrum

Syntax

`getRBW(SE)`

Description

`getRBW(SE)` returns the resolution bandwidth of the spectrum.

The resolution bandwidth, `RBW`, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to `ENBW*SampleRate/ L`, where `L` is the input length, and `ENBW` is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, `RBW=enbw(hann(1024))*100/1024`.

reset

System object: dsp.SpectrumEstimator
Package: dsp

Reset the internal states of the spectrum estimator

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.SpectrumEstimator
Package: dsp

Estimate the power spectrum or power-density spectrum of a signal

Syntax

```
pxx = step(SE,x)
[pxx,pmax] = step(SE,x)
[pxx,pmin] = step(SE,x)
[pxx,pmax,pmin] = step(SE,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`pxx = step(SE,x)` computes the power spectrum or power-density spectrum, `pxx`, of the input signal, `x`. The System object treats the columns of `x` as independent channels.

`[pxx,pmax] = step(SE,x)` also computes the max-hold frequency spectrum, `pmax`, of `x`. To determine the max-hold spectrum, the method keeps the maximum of all the power spectrum estimates computed at each frequency bin. Set `OutputMaxHoldSpectrum` to `true` to obtain the max-hold spectrum.

`[pxx,pmin] = step(SE,x)` also computes the min-hold frequency spectrum, `pmin`, of `x`. To determine the min-hold spectrum, the method keeps the minimum of all the power spectrum estimates computed at each frequency bin. Set `OutputMinHoldSpectrum` to `true` to obtain the min-hold spectrum.

`[pxx,pmax,pmin] = step(SE,x)` computes the power spectrum or power-density spectrum, the max-hold spectrum, and the min-hold spectrum of `x`. Set

OutputMaxHoldSpectrum and OutputMinHoldSpectrum to true to obtain the max-hold and min-hold spectra.

Input Arguments

SE — Frequency spectrum estimator

SpectrumEstimator System object

Frequency spectrum estimate, specified as a SpectrumEstimator System object

x — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of x is the frame size or channel length. Each column of x is treated as a separate channel. The column length of x is the number of channels.

Output Arguments

pxx — Power or power-density spectrum estimate

vector | matrix

Power or power-density spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal, x. By default, the unit is 'Watts'. You can also specify the spectrum to be in 'dBm' or 'dBW' through the PowerUnits property of the SpectrumEstimator System object.

pmax — Max-hold spectrum estimate

vector | matrix

Max-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal, x.

pmin — Min-hold spectrum estimate

vector | matrix

Min-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the input signal, x.

Examples

Power Spectrum of Multichannel Sinusoidal Signal

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by $\pi/2$ and $\pi/4$, respectively.

```
SINE = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the Spectrum Estimator for the computation and the Array Plot for the plotting.

```
SE = dsp.SpectrumEstimator('FrequencyRange','onesided');
PLOTTER = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = step(SINE);
pxx = step(SE,y);
step(PLOTTER,pxx)
```

dsp.StandardDeviation System object

Package: dsp

Standard deviation of input or sequence of inputs

Description

The `dsp.StandardDeviation` object computes the standard deviation for an input or sequence of inputs.

To compute the standard deviation for an input or sequence of inputs:

1 Define and set up your standard deviation object. See "Construction" on page 4-1665.
2 Call step to compute the standard deviation according to the properties of `dsp.StandardDeviation`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note: The `Running` mode in the `dsp.StandardDeviation` System object will be removed in a future release. To compute the running standard deviation in MATLAB, use the dsp.MovingStandardDeviation System object instead.

Construction

`std = dsp.StandardDeviation` returns a standard deviation System object, `std`, that computes the standard deviation for the columns of input.

`std = dsp.StandardDeviation('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a standard deviation System object, `std`, with each specified property set to the specified value.

Properties

RunningStandardDeviation

Enable calculation over successive calls to the `step` method

Set this property to `true` to enable the calculation of standard deviation over successive calls to the `step` method. The default is `false`.

ResetInputPort

Enable resetting in running standard deviation mode

Set this property to `true` to enable resetting for the running standard deviation. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running standard deviation. This property applies only when you set the `RunningStandardDeviation` on page 4-1666 property to `true`. The default is `false`.

ResetCondition

Reset condition for running standard deviation mode

Specify event to reset the running standard deviation as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the `ResetInputPort on page 4-1666` property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the standard deviation calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies only when you set the `RunningStandardDeviation on page 4-1666` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based value) of the input signal, over which the object computes the standard deviation. The cannot exceed the number of dimensions for the input signal. This property applies when you set the `Dimension on page 4-1666` property to `Custom`. The default is `1`.

Methods

reset	Reset states for running standard deviation computation
step	Calculate standard deviation of input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Running Standard Deviation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the running standard deviation of a signal using `dsp.StandardDeviation` object. To activate this mode, set the `RunningStandardDeviation` property to `true`.

```
std2 = dsp.StandardDeviation;
std2.RunningStandardDeviation = true;
x = randn(100,1);
y = std2(x);
```

y(i) is the standard deviation of the ith input sample with respect to all the past input samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Standard Deviation` block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to the `ResetInputPort` and `ResetCondition` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

dsp.MovingStandardDeviation | dsp.MovingRMS | dsp.RMS | dsp.MovingVariance | dsp.Variance | dsp.Minimum

Blocks

`Moving RMS` | `Moving Standard Deviation` | `Moving Variance` | `RMS` | `Standard Deviation` | `Variance`

Introduced in R2012a

reset

System object: dsp.StandardDeviation
Package: dsp

Reset states for running standard deviation computation

Syntax

`reset(std)`

Description

`reset(std)` sets the internal states of the `StandardDeviation` object `std` to their initial values when computing the running standard deviation.

step

System object: dsp.StandardDeviation
Package: dsp

Calculate standard deviation of input

Syntax

```
Y = step(std,X)
Y = step(std,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(std,X)` computes the standard deviation,`Y`, of input `X`. The object computes the standard deviation over successive calls to the `step` method when the `RunningStandardDeviation` property is `true`.

`Y = step(std,X,R)` resets its state based on the value of reset signal `R` and the `ResetCondition` property. You can use this option only when the `RunningStandardDeviation` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.StateLevels System object

Package: dsp

State-level estimation for bilevel rectangular waveform

Description

The `StateLevels` object estimates the state levels of a bilevel rectangular waveform.

To estimate the state levels of a bilevel waveform:

1. Define and set up your state-level estimation. See "Construction" on page 4-1671.
2. Call step to estimate the state levels for an input vector according to the properties of `dsp.StateLevels`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sl = dsp.StateLevels` creates a state-level estimation System object, `sl`, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.

`sl = dsp.StateLevels('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `StateLevels` System object, `sl`, with each specified property set to the specified value.

Properties

`HistogramBounds`

Minimum and maximum levels of the histogram. Specify the range of the histogram as a 2-element real–valued row vector. Signal values outside the range defined by this property are ignored. This property applies when you set the `Method` property to`'Histogram mode'` or `'Histogram mean'`, and either `RunningStateLevels` is `true`, or the `HistogramBoundsSource` property is set to `'Property'`.

Default: `[0 5]`

HistogramBoundsSource

Source of histogram bounds. Specify how to determine the histogram bounds as one of `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the histogram bounds are determined by the minimum and maximum input values. When you set this property to `'Property'`, the histogram bounds are determined by the value of the `HistogramBounds` property. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`, and the `RunningStateLevels` property is `false`.

Default: `'Auto'`

HistogramNumBins

Number of bins in the histogram. Specify the number of bins in the histogram. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Default: `100`

HistogramOutputPort

Enable histogram output. Set this property to `true` to output the histogram used in the computation of the state levels. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Default: `false`

Method

Algorithm used to compute state levels. Specify the method used to compute state levels as one of `'Histogram mean'`, `'Histogram mode'`, or `'Peak to peak'`.

Default: `'Histogram mode'`

RunningStateLevels

Calculation over successive calls to step. Set this property to `true` to enable computation of the state levels over successive calls to the `step`. Otherwise, compute the state levels of the current input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to `'Property'`.

State

A particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

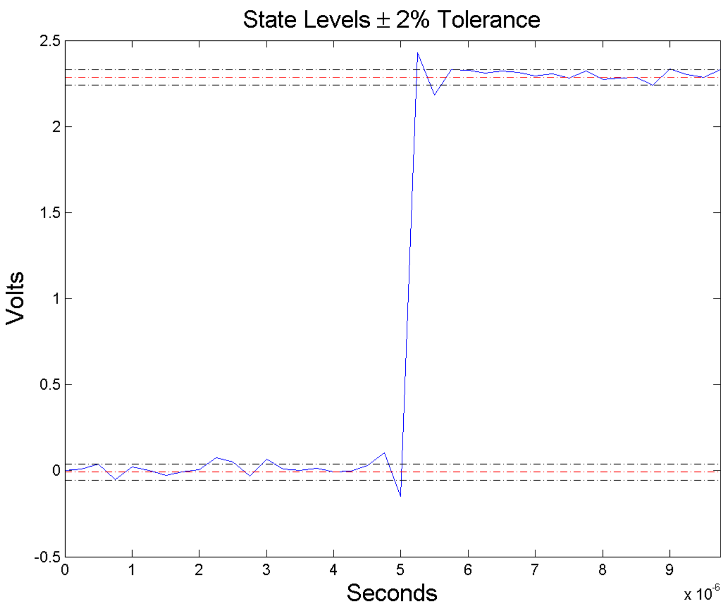
State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state. To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the α% tolerance region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1)$$

where S_1 is the low-state level and S_2 is the high-state level. Replace the first term in the equation with S_2 to obtain the α% tolerance region for the high state.

The following figure illustrates lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.



Methods

plot	Plot signal, state levels, and histogram
reset	Reset internal states of state levels object
step	Estimate state levels for bilevel rectangular waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

State Levels of 2.3 V Underdamped Noisy Clock

Compute and plot the state levels of a 2.3 V underdamped noisy clock. Load the clock data in the variable, `x`, and the sampling instants in the variable `t`.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

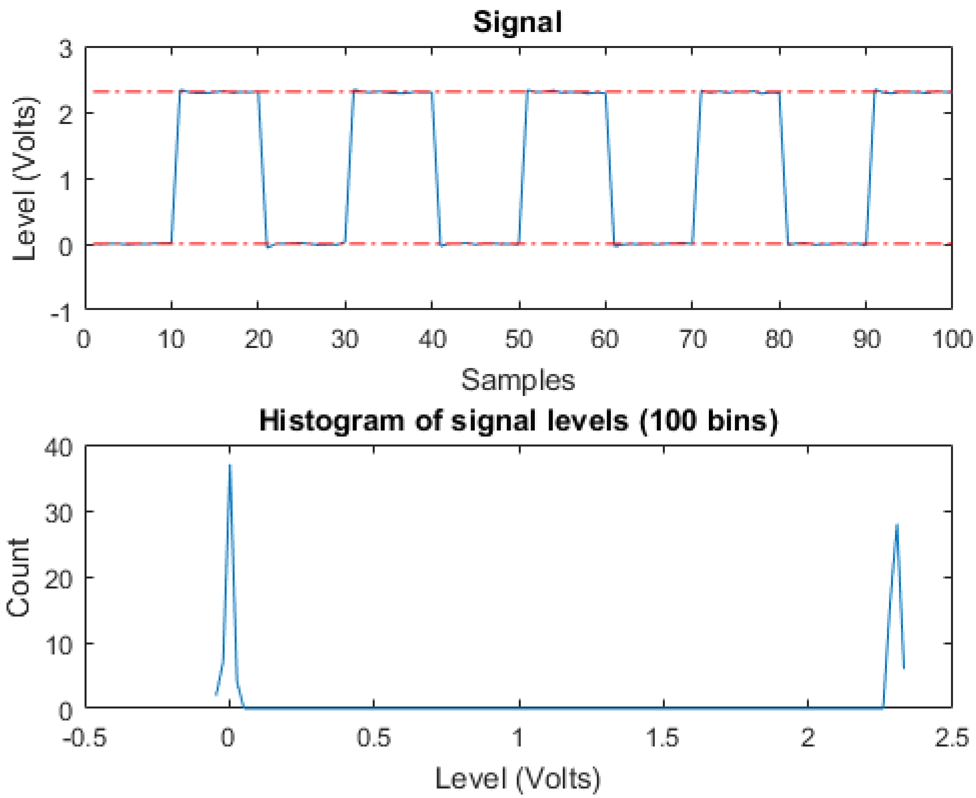
```
load('clockex.mat', 'x', 't');
```

Estimate the state levels.

```
sl = dsp.StateLevels;
levels = sl(x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(sl)
```



Algorithms

The `StateLevels` System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

1. Determine the maximum and minimum amplitudes and amplitude range of the data.
2. For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.
3. Sort the data values into the histogram bins.
4. Identify the lowest-indexed histogram bin, i_{low}, and highest-indexed histogram bin, i_{high}, with nonzero counts.

5 Divide the histogram into two subhistograms. The lower-histogram bins are $i_{low} \leq i \leq 1/2(i_{high} — i_{low})$.

The upper-histogram bins are $i_{low} + 1/2(i_{high} - i_{low}) \leq i \leq i_{high}$.

6 Compute the state levels by determining the mode or mean of the lower and upper histograms.

dsp.PulseMetrics | dsp.TransitionMetrics

Introduced in R2012a

plot

System object: dsp.StateLevels
Package: dsp

Plot signal, state levels, and histogram

Syntax

`plot(sl)`

Description

`plot(sl)` plots the signal and state levels computed in the last call to the `step` method. If the `Method` property of the state levels object is set to `'Histogram mode'` or `'Histogram Mean'`, the histogram is plotted in a subplot below the signal.

reset

System object: dsp.StateLevels
Package: dsp

Reset internal states of state levels object

Syntax

`reset(sl)`

Description

`reset(sl)` resets the state levels object, `sl`, to clear information accumulated from previous calls to `step`.

step

System object: dsp.StateLevels
Package: dsp

Estimate state levels for bilevel rectangular waveform

Syntax

```
LEVELS = step(sl,X)
[LEVELS,HISTOGRAM] = step(sl,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`LEVELS = step(sl,X)` returns a 2-element row vector, `LEVELS`, containing the estimated state levels for `X`. `X` is a real-valued column vector.

`[LEVELS,HISTOGRAM] = step(sl,X)` returns a double-precision column vector, `HISTOGRAM`, containing the histogram of the sample values in `X`. You can obtain this output only when you set the `Method` property to either `'Histogram mean'` or `'Histogram mode'`, and you set the `HistogramOutputPort` property to `true`.

dsp.SubbandAnalysisFilter System object

Package: dsp

Decompose signal into high-frequency and low-frequency subbands

Description

The `SubbandAnalysisFilter` object decomposes a signal into high-frequency and low-frequency subbands.

To decompose a signal into high-frequency and low-frequency subbands:

1. Define and set up your two-channel subband analysis filter. See “Construction” on page 4-1681.
2. Call step to decompose the signal according to the properties of `dsp.SubbandAnalysisFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`subAna = dsp.SubbandAnalysisFilter` returns a two-channel subband analysis filter, `subAna`, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

`subAna = dsp.SubbandAnalysisFilter('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a two-channel subband analysis filter, `subAna`, with each specified property set to the specified value.

`subAna = dsp.SubbandAnalysisFilter(lpc,hpc,` *'PropertyName'*,*PropertyValue*,...) returns a two-channel subband analysis filter, subAna, with the LowpassCoefficients on page 4-1682 property set to lpc, the HighpassCoefficients on page 4-1682 property set to hpc, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the HighpassCoefficients on page 4-1682 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficient

Specify a vector of highpass FIR filter coefficients, in descending powers of z. For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the LowpassCoefficients on page 4-1682 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | Same word length as input | Custom |. The default is Same word length as input.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the CoefficientsDataType on page 4-1683 property to Custom. The default is numerictype([],16,15).

ProductDataType

Data type of product

Specify the product data type as one of | Full precision | Same as input | Custom |. The default is Full precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` on page 4-1683 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1684 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1684 property to `Custom`. The default is `numerictype([],16,14)`.

Methods

reset	Reset filter states of subband analysis filter object

step	Decompose signal into high- and low-frequency subbands

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Decompose and Reconstruct a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

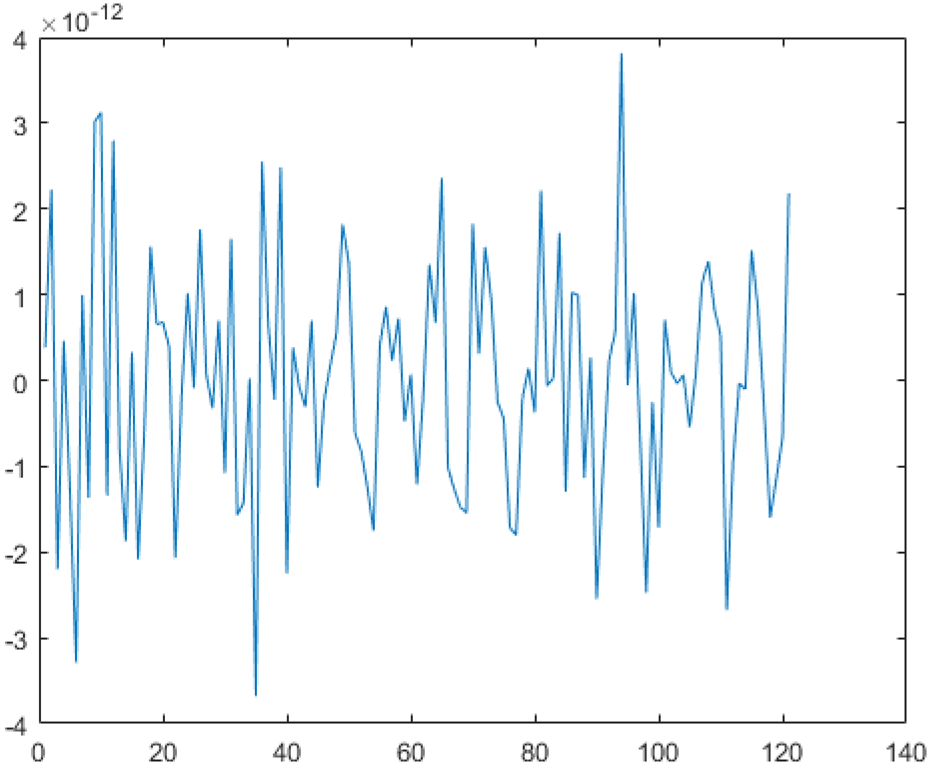
Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Two-Channel Analysis Subband Filter` block reference page. The object properties correspond to the block parameters, except:

- The `SubbandAnalysisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `dsp.SubbandAnalysisFilter` object.

Extended Capabilities

reset

System object: dsp.SubbandAnalysisFilter
Package: dsp

Reset filter states of subband analysis filter object

Syntax

`reset(subAna)`

Description

`reset(subAna)` sets the filter states of the `SubbandAnalysisFilter` object `subAna` to `0`.

step

System object: dsp.SubbandAnalysisFilter
Package: dsp

Decompose signal into high- and low-frequency subbands

Syntax

`[HI,LO] = step(subAna,SIG)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[HI,LO] = step(subAna,SIG)` decomposes the input signal, `SIG`, into a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SubbandSynthesisFilter System object

Package: dsp

Reconstruct signal from high-frequency and low-frequency subbands

Description

The `SubbandSynthesisFilter` object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

1. Define and set up your two-channel subband synthesis filter. See "Construction" on page 4-1690.
2. Call step to reconstruct the signal according to the properties of `dsp.SubbandSynthesisFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`subSyn = dsp.SubbandSynthesisFilter` returns a two-channel subband synthesis filter, `subSyn`, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

`subSyn = dsp.SubbandSynthesisFilter('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a two-channel subband synthesis filter, `subSyn`, with each specified property set to the specified value.

`subSyn = dsp.SubbandSynthesisFilter(lpc,hpc,` `'PropertyName',PropertyValue,...)` returns a two-channel subband synthesis filter, `subSyn`. The object has the `LowpassCoefficients` on page 4-1691 property set to `lpc`, the `HighpassCoefficients` on page 4-1691 property set to `hpc`, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` on page 4-1691 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z. For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` on page 4-1691 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` on page 4-1692 property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Data type of product

Specify the product data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` on page 4-1692 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1693 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1693 property to `Custom`. The default is `numerictype([],16,14)`.

Methods

reset	Reset internal states of subband synthesis filter object

step	Reconstruct signal from high- and low-frequency subbands

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decompose and Reconstruct a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

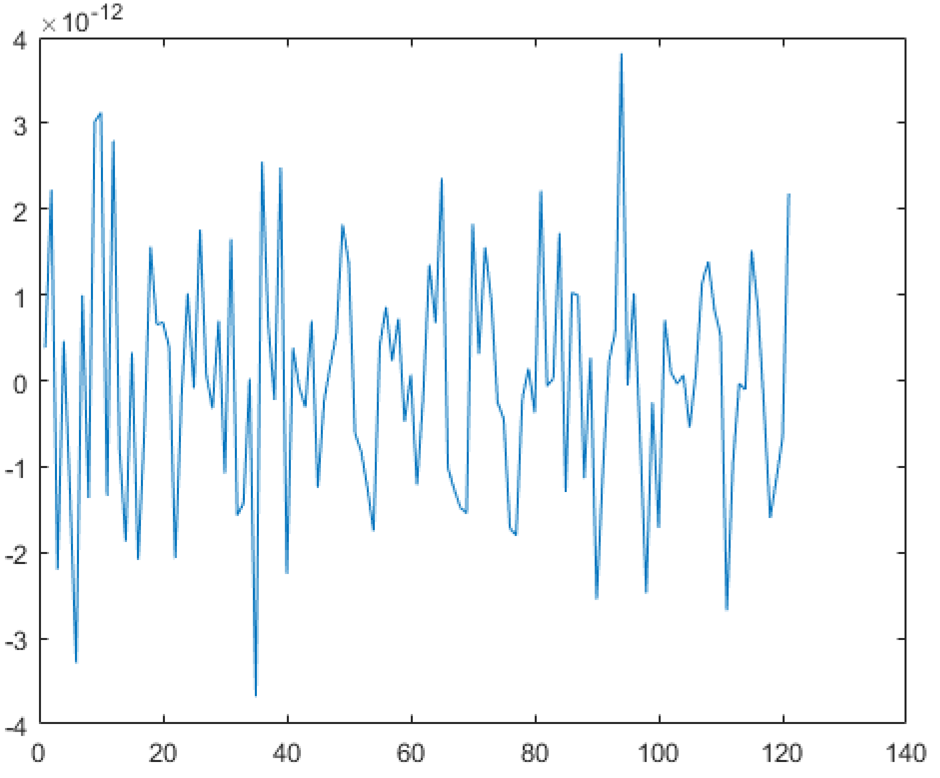
Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Two-Channel Synthesis Subband Filter` block reference page. The object properties correspond to the block parameters, except:

- The `SubbandSynthesisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `SubbandSynthesisFilter` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

dsp.SubbandAnalysisFilter | dsp.DyadicSynthesisFilterBank

Introduced in R2012a

reset

System object: dsp.SubbandSynthesisFilter
Package: dsp

Reset internal states of subband synthesis filter object

Syntax

`reset(subSyn)`

Description

`reset(subSyn)` sets the internal states of the `SubbandSynthesisFilter` object `subSyn` to their initial values.

step

System object: dsp.SubbandSynthesisFilter
Package: dsp

Reconstruct signal from high- and low-frequency subbands

Syntax

`Y = step(subSyn,HI,LO)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(subSyn,HI,LO)` reconstructs a signal from a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.TimeScope System object

Package: dsp

Time domain signal display

Description

The `TimeScope` object displays time-domain signals.

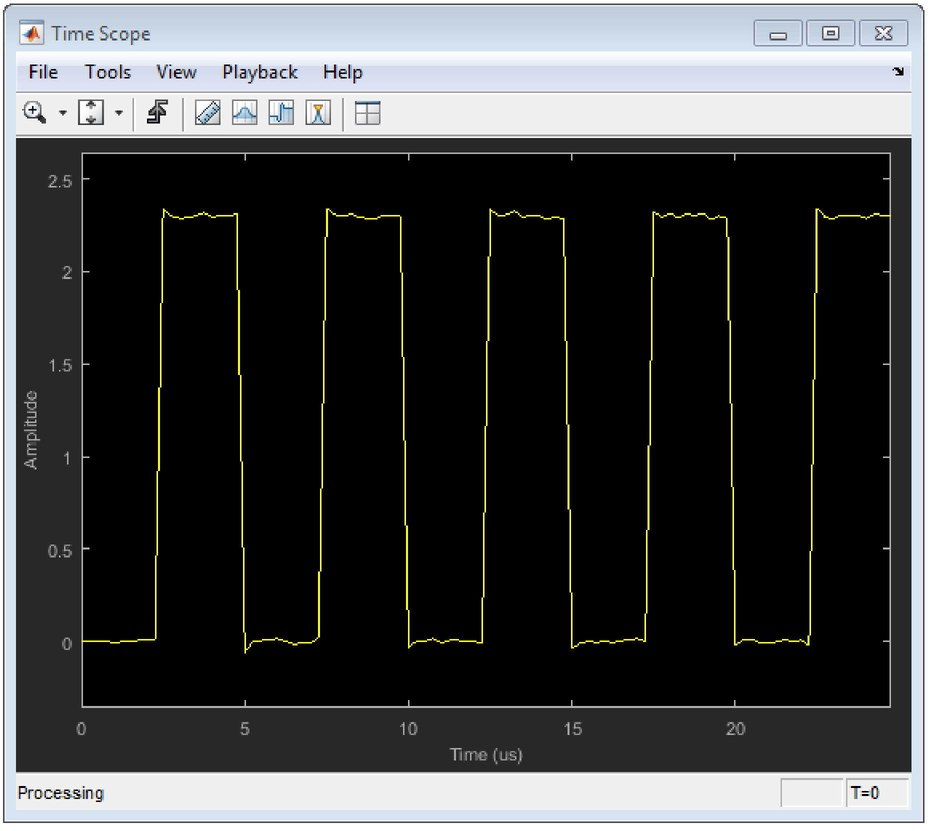
To display time-domain signals in the Time Scope:

1. Define and set up your Time Scope. See "Construction" on page 4-1701.
2. Call step to display the signal in the Time Scope figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Time Scope figure window.

Use the MATLAB `mcc` function to compile code containing a Time Scope.

Note: You cannot open scope configuration dialogs if you have more than one compiled component in your application.



See the following sections for information on the Time Scope System object:

- “Construction” on page 4-1701
- “Properties” on page 4-1702
- “Methods” on page 4-1710

See the following sections for information on the Time Scope Graphical User Interface:

- “Displaying Multiple Signals” on page 4-1710
- “Signal Display” on page 4-1713
- “Measurements Panels” on page 4-1716
- “Style Dialog Box” on page 2-1698

- “Visuals — Time Domain Properties” on page 4-1750
- “Tools — Axes Scaling Properties” on page 4-1758
- “Sources — Streaming Properties” on page 4-1760

For examples on how to use the Time Scope System object, see “Examples” on page 4-1761.

Note: For information about the Time Scope block, see `Time Scope`.

Note: If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an *extrinsic* variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see “DSP System Toolbox” (MATLAB Coder).

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`scope = dsp.TimeScope` returns a Time Scope System object, `scope`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`scope = dsp.TimeScope('`*`PropertyName`*`',`*`PropertyValue`*`,...)` creates a Time Scope System object, `scope`, with each specified property *`PropertyName`* set to the specified value.

`scope = dsp.TimeScope(NUMINPUTS,SAMPLERATE,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` creates a Time Scope System object, `scope`. This object has the `NumInputPorts` property set to *`NUMINPUTS`*, the `SampleRate` property set to *`SAMPLERATE`*, and other specified properties set to the specified values. *`NUMINPUTS`* and *`SAMPLERATE`* are value-only arguments. You can specify `PropertyName`–`PropertyValue` arguments in any order.

Properties

`ActiveDisplay`

Active display for display-specific properties

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed. Tunable (Simulink)

Setting this property controls which display is used for `ShowGrid`, `ShowLegend`, `Title`, `PlotAsMagnitudePhase`, `YLabel`, and `YLimits`.

Default: `1`

`AxesScaling`

Enable axes scaling mode

Specify when the scope automatically scales the axes. Valid values are

- `'Auto'` — The scope scales the axes as needed to fit the data, both during and after simulation.
- `'Updates'` — The scope scales the axes after 10 updates.
- `'Manual'` — The scope does not scale the axes automatically.
- `'OnceAtStop'` — The scope scales the axes when the simulation stops.

`BufferLength`

Number of data points in buffer

Specify the size of the buffer that the scope holds in its memory cache. Memory is limited by available memory on your system. If your signal has M rows of data and N data points in each row, M x N is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 (which is 10 x 100 x 10) as the buffer length.

Default: 5000

ChannelNames

Names of input signals to display in scope legend

Specify the names of the input signals to display in the scope legend. Enter the names in a cell array of character vectors. If you do not specify any names, they default to `Channel 1`, `Channel 2`, etc.

FrameBasedProcessing

Process input in frames or as samples

When you set this property to `true`, you enable frame-based processing. When you set this property to `false`, you enable sample-based processing.

Default: `true`

LayoutDimensions

Layout grid dimensions

Specify the layout grid dimensions as a 2-element vector: `[numberOfRows, numberOfColumns]`. You can use no more than 16 rows and 16 columns. This property is Tunable (Simulink).

Default: `[1,1]`

MaximizeAxes

Maximize axes control

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.

- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

Default: `'Auto'`

`Name`

Caption to display on the Time Scope window

Specify as a character vector the caption to display on the scope window. This property is Tunable (Simulink).

Default: `'Time Scope'`

`NumInputPorts`

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

This property does not apply to Floating Scopes and Scope Viewers.

Default: `1`

`PlotAsMagnitudePhase`

Plot signal magnitude and phase

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display. This property is particularly useful for complex-valued input signals. Selecting this check box affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees. This property is Tunable (Simulink).

When set, `ActiveDisplay` controls which displays are updated. The active display shows the magnitude of the input signal on the top axes and its phase, in degrees, on the bottom axes.

Default: `false`

`PlotType`

Option to control the type of plot

Specify the type of plot to use. The default setting is `Line`.

- `Line` — line graph, similar to the `line` or `plot` function.
- `Stairs` — *stair-step* graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable (Simulink).

Default: `'Line'`

`Position`

Scope or Time Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable (Simulink).

Default: The default depends on your screen resolution. By default, a scope window appears in the center of your screen with a width of 410 pixels and height of 300 pixels.

`ReduceUpdates`

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable (Simulink).

You can also modify this property from the Time Scope GUI. Opening the **Simulation** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

Default: `true`

SampleRate

Sample rate of inputs

Specify the sample rate, in hertz, of the input signals.

You can specify a scalar or as a numeric vector with length equal to the value of NumInputPorts. The inverse of the sample rate determines the spacing between points on the time axis in the displayed signal. When you set SampleRate to a scalar value and NumInputPorts is greater than 1, the object uses the same sample rate for all inputs.

Default: 1

ShowGrid

Option to enable or disable grid display

When you set this property to true, the grid appears. When you set this property to false, the grid is hidden. This property is Tunable (Simulink).

When set, ActiveDisplay controls which display is updated.

Default: false

ShowLegend

When you set this property to true, the scope displays a legend with input channel names. When you set this property to false, the scope does not display a legend. This property is Tunable (Simulink)

See FrameBasedProcessing on page 4-1703 for information on input channels.

When set, ActiveDisplay controls which display is updated.

Default: false

ShowTimeAxisLabel

When you set this property to true, the scope displays the time-axis label. When you set this property to false, the scope does not display the time-axis label, but still displays tick marks and other time-axis items. This property applies only if the TimeAxisLabels property is All or Bottom. This property is Tunable (Simulink)

`TimeAxisLabels`

Time-axis labels

Specify how time-axis labels should appear in the scope displays as one of `'All'`, `'Bottom`, or `'None'`.

- When you set this property to `'All'`, time-axis labels appear in all displays.
- When you set this property to `'Bottom'`, time-axis labels appear in the bottom display of each column.
- When you set this property to `'None'`, there are no labels in any displays.

This property is Tunable (Simulink).

Default: `'All'`

`TimeDisplayOffset`

Time display offset

Specify the offset, in seconds, to apply to the time axis. This property can be either a numeric scalar or a vector of length equal to the number of input channels. If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored. This property is Tunable (Simulink).

See FrameBasedProcessing on page 4-1703 for information on input channels. See `TimeSpan` on page 4-1707 and `TimeSpanSource` on page 4-1708 for information on the *x*-axis limits and time span settings.

Default: `0`

`TimeSpan`

Time span

Specify the time span, in seconds, as a positive, numeric scalar value. This property applies when `FrameBasedProcessing` is `false`. This property also applies when

FrameBasedProcessing is true and TimeSpanSource is Property. The time-axis limits are calculated as follows.

- Minimum time-axis limit = min(TimeDisplayOffset)
- Maximum time-axis limit = max(TimeDisplayOffset) + TimeSpan

where TimeDisplayOffset and TimeSpan are the values of their respective properties. This property is Tunable (Simulink).

Default: 10

TimeSpanOverrunAction

Wrap or scroll when the TimeSpan value is overrun

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- Wrap — In this mode, the scope displays new data until the data reaches the maximum time-axis limit. When the data reaches the maximum time-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum time-axis limit.
- Scroll — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This property is Tunable (Simulink).

Default: 'Wrap'

TimeSpanSource

Source of time span

Specify the source of the time span for frame-based input signals as one of 'Auto' or 'Property'. This property applies when FrameBasedProcessing is set to true. When you set this property to 'Property', the object derives the *x*-axis limits from the TimeDisplayOffset and TimeSpan properties. When you set this property to Auto, the time-axis limits are the following:

- Minimum time-axis limit = min(TimeDisplayOffset)

- Maximum time-axis limit = max(`TimeDisplayOffset`) + max(1/`SampleRate`.**FrameSize*)

where `TimeDisplayOffset` and `SampleRate` are the values of their respective properties. *FrameSize* is a vector equal to the number of rows in each input signal. This property is Tunable (Simulink).

Default: `'Property'`

`TimeUnits`

Units of the time axis

Specify the units used to describe the time axis. You can select one of the following options:

- `Metric` — In this mode, the scope converts the times on the time axis to the most appropriate measurement units. These units include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum time-axis limit and the maximum time-axis limit of the scope window.
- `Seconds` — In this mode, the scope always displays the units on the time axis as seconds.
- `None` — In this mode, the scope does not display any units on the time axis. The scope only shows the word `Time` on the time axis.

This property is Tunable (Simulink).

Default: `'Metric'`

`Title`

Display title

Specify the display title as a character vector. When set, `ActiveDisplay` controls which display is updated.

Default: `''`

`YLabel`

The label for the *y*-axis

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two *y*-axis labels are read-only values. The *y*-axis labels are set to `'Magnitude'` and `'Phase'` for the magnitude plot and the phase plot, respectively. When set, `ActiveDisplay` controls which display is updated.

Default: `'Amplitude'` if `PlotAsMagnitudePhase` is `false`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable (Simulink).

When `PlotAsMagnitudePhase` is `true`, this property specifies the *y*-axis limits of only the magnitude plot. The *y*-axis limits of the phase plot are always `[-180, 180]`. When set, `ActiveDisplay` controls which display is updated.

Default: `[-10, 10]`, if `PlotAsMagnitudePhase` is `false`, or `[0, 10]`, if `PlotAsMagnitudePhase` is `true`.

Methods

hide	Hide time scope window
reset	Reset internal states of time scope object
show	Make time scope window visible
step	Display signal in time scope figure

Displaying Multiple Signals

Multiple Signal Input

You can configure the Time Scope to show multiple signals within the same display or on separate displays. By default, the signals appear as different-colored lines on the same display. The signals can have different dimensions, sample rates, and data types. Each signal can be either real or complex valued. You can set the number of input ports on the Time Scope in the following ways:

- Set the `NumInputPorts` on page 4-1704 property. This property is nontunable, so you should set it before you run the step method.
- Run the show method to open the scope window. In the scope menu, select **File** > **Number of Input Ports**.
- Run the show method to open the scope window. In the scope menu, select **View** > **Configuration Properties** and set the **Number of input ports** on the **Main** tab.

An input signal may contain multiple channels, depending on its dimensions. Multiple channels of data always appear as different-colored lines on the same display.

Multiple Signal Names and Colors

By default, if the input signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: `Channel 1`, `Channel 2`. To show the legend, select **View** > **Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. If there are a total of 7 input channels, the following legend appears in the display.

By default, the scope has a black axes background and chooses line colors for each channel in a manner similar to the Simulink Scope block. When the scope axes background is black, it assigns each channel of each input signal a line color in the order shown in the above figure.

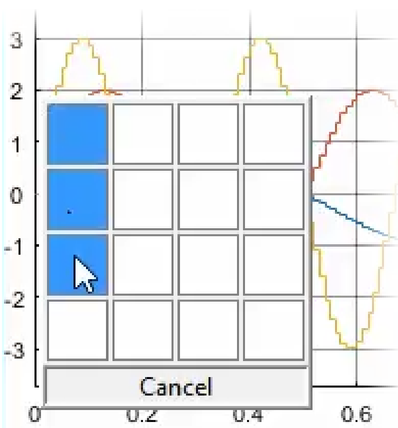
If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel, change the axes background color to any color except black. To change the axes background color to white, select **View** > **Style**, click the Axes background color button (), and select white from the color palette. Run the simulation again. The following legend appears in the display. This is the color order when the background is not black.

Multiple Displays

You can display multiple channels of data on different displays in the scope window. In the scope toolbar, select **View** > **Layout**, or select the Layout button ( ).

Note: The **Layout** menu item and button are not available when the scope is in snapshot mode.

You can tile the window into multiple displays. For example, if there are three inputs to the scope, you can display the signals in three separate displays. The layout grid shows a 4 by 4 grid, but you can select up to 16 by 16 by clicking and dragging within the layout grid.



When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The scope dialog boxes reference the active display.

Signal Display

Time Scope uses the **Time span** and **Time display offset** parameters to determine the time range. To change the signal display settings, select **View** > **Configuration Properties** to bring up the Visuals—Time Domain Properties dialog box. Then, modify the values for the **Time span** and **Time display offset** parameters on the **Main** tab. For example, if you set the **Time span** to 25 seconds, the scope displays 25 seconds' worth of simulation data at a time. If you also set the **Time display offset** to 5 seconds, the scope displays values on the time axis from 5 to 30 seconds. The values on the time axis of the Time Scope display remain the same throughout simulation.

To communicate the simulation time that corresponds to the current display, the scope uses the *Time units*, *Time offset*, and *Simulation time* indicators on the scope window. The following figure highlights these and other important aspects of the Time Scope window.

Time Indicators

- *Minimum time-axis limit* — The Time Scope sets the minimum time-axis limit using the value of the **Time display offset** parameter on the **Main** tab of the Visuals—Time Domain Properties dialog box. If you specify a vector of values for the **Time display offset** parameter, the scope uses the smallest of those values to set the minimum time-axis limit.
- *Maximum time-axis limit* — The Time Scope sets the maximum time-axis limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter. If you specify a vector of values for the **Time display offset**

parameter, the scope sets the maximum time-axis limit by summing the largest of those values with the value of the **Time span** parameter.

- *Time units* — The units used to describe the time-axis. The Time Scope sets the time units using the value of the **Time Units** parameter on the **Time** tab of the Configuration Properties dialog box. By default, this parameter is set to `Metric (based on Time Span)` and displays in metric units such as milliseconds, microseconds, minutes, days, etc. You can change it to `Seconds` to always display the time-axis values in units of seconds. You can change it to `None` to not display any units on the time axis. When you set this parameter to `None`, then Time Scope shows only the word `Time` on the time axis.

  To hide both the word `Time` and the values on the time axis, set the **Show time-axis labels** parameter to `None`. To hide both the word `Time` and the values on the time axis in all displays, except the bottom ones in each column of displays, set this parameter to `Bottom Displays Only`. This behavior differs from the Simulink Scope block, which always shows the values but never shows a label on the *x*-axis.

For more information, see "Visuals — Time Domain Properties" on page 4-1750.

Simulation Indicators

- *Simulation status* — Provides the current status of the model simulation. The status can be either of the following conditions:

  - `Processing` — Occurs after you run the `step` method and before you run the `release` method.
  - `Stopped` — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

  The *Simulation status* is part of the *Status Bar* in the scope window. You can choose to hide or display the entire *Status Bar*. From the scope menu, select **View > Status Bar**.
- *Time offset* — The `Offset` value helps you determine the simulation times for which the scope is displaying data. The value is always in the range `0`≤ `Offset`≤ *Simulation time*. If the time offset is 0, the Scope does not display the `Offset` status field. Add the Time offset to the fixed time span values on the time-axis to get the overall simulation time.

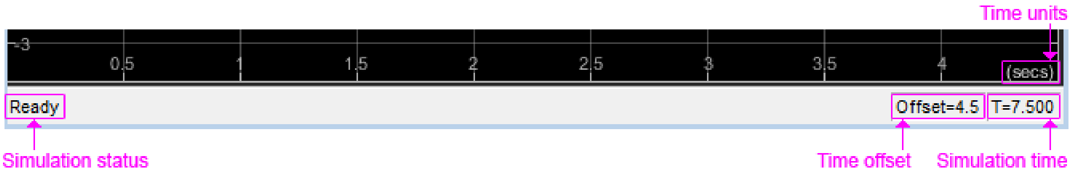
  For example, if you set the **Time span** to `20` seconds, and you see an `Offset` of `0 (secs)` on the scope window. This value indicates that the scope is displaying data for the first `0` to `20` seconds of simulation time. If the **Offset** changes to `20 (secs)`, the scope displays data for simulation times from `20` seconds to `40` seconds. The scope continues to update the `Offset` value until the simulation is complete.

- *Simulation time* — The amount of time that the Time Scope has spent processing the input. Every time you call the step method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula: $t_{sim} = t_{sim} + \frac{\text{length(0:length(xsine))-1}}{\text{SampleRate}}$. You can set the sample rate using the `SampleRate` on page 4-1706 property. For frame-based inputs, the displayed Simulation time is the time at the beginning of the frame.

  The *Simulation time* is part of the *Status Bar* in the Time Scope window. You can choose to hide or display the entire *Status Bar*. From the Time Scope menu, select **View** > **Status Bar** .

Axes Maximization

When the scope is in maximized axes mode, the following figure highlights the important indicators on the scope window.



To toggle this mode, in the scope menu, select **View** > **Configuration Properties**. In the **Main** pane, locate the **Maximize axes** parameter.

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.

- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

The default setting is `Auto`.

Reduce Updates to Improve Performance

By default, the scope updates the displays periodically at a rate not exceeding 20 hertz. If you would like the scope to update on every simulation time step, you can disable the **Reduce Updates to Improve Performance** option. However, as a recommended practice, leave this option enabled because doing so can significantly improve the speed of the simulation.

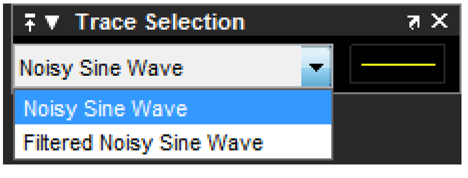
In the Time Scope menu, select **Playback** > **Reduce Updates to Improve Performance** to clear the check box. Alternatively, use the **Ctrl+R** shortcut to toggle this setting. You can also set the `ReduceUpdates` on page 4-1705 property to `false` to disable this option.

Measurements Panels

The Measurements panels are the five panels that appear to the right side of the Time Scope GUI. .

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



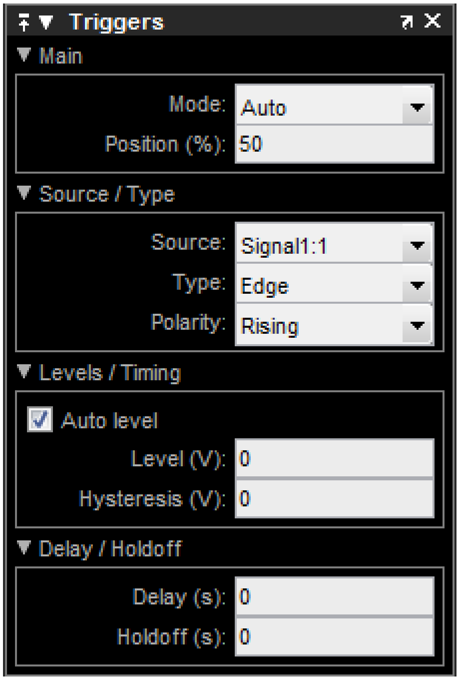
You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

Triggers Panel

The **Triggers** panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. You can configure triggers to both select and align specific regions of interest in the display area of the scope. Triggers work across multiple displays. You can also choose to hide or display the **Triggers** panel.

Note: If triggers are on and the model is

In the scope toolbar, click the Triggers button ( ). Alternatively, in the scope menu, select **Tools** > **Triggers**.



When the **Triggers** panel is displayed, triangle pointers appear at the top and right side of the axes on each display. These markers indicate the time position ( ) and level ( ) at the event. The color of the markers corresponds to the color of the source signal.

Note: The scope does not display an event until at least a full-time span is completely viewable inside the display. To prevent data from being shown twice in the display, the scope suppresses the alignment of recurring events until a full-time span has elapsed since the previous update.

Main Pane

The **Main** pane lets you choose how often the display updates and in what position the trigger indicator appears.

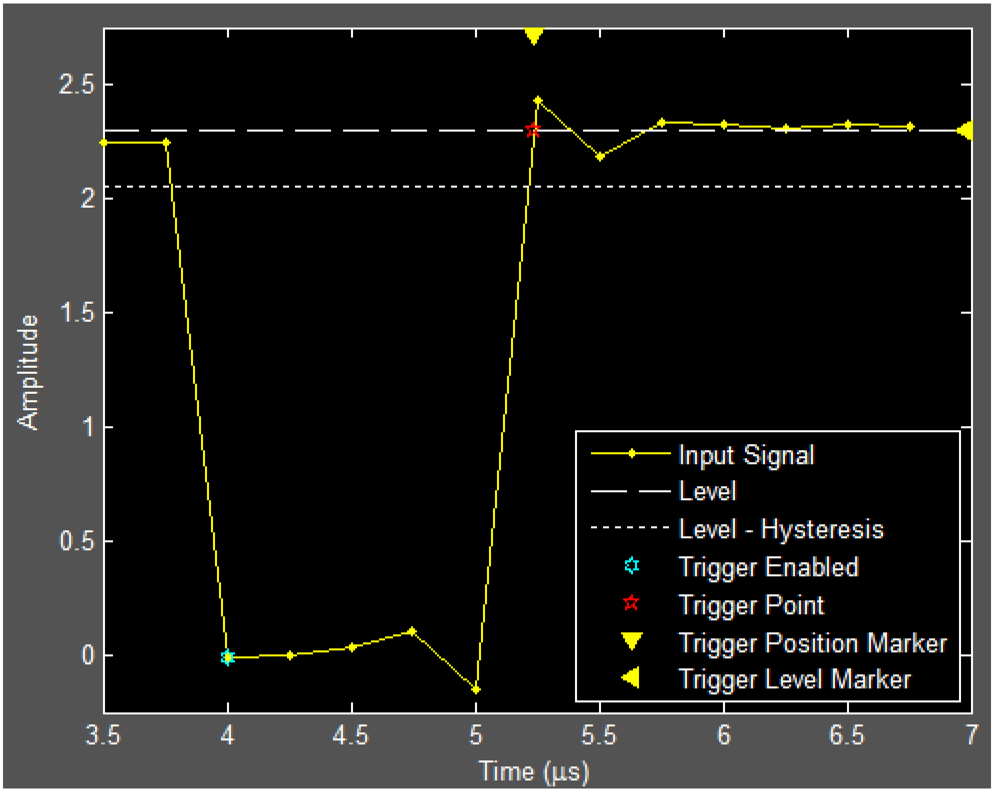
- **Mode** — Define how often the display should update.
  - `Auto` — The scope aligns and displays data from the latest trigger event. Data between trigger events is displayed. If no trigger event is found after an entire time span has elapsed, the scope displays that time span of data. Use this mode to see your data and have it align whenever a trigger event occurs.
  - `Normal` — The scope aligns and displays data only from the last trigger event in the time span and freezes the display. Data between trigger events is not displayed. Use this mode to search for infrequently occurring events in your data.
  - `Once` — The scope aligns and displays data on the first encountered trigger event and freezes the display. The scope ignores subsequent data until you press the **Rearm** button. If no trigger event is found, no data is shown in the display.
  - `Off` — Triggering is disabled. This setting is equivalent to hiding the **Triggers** panel. You can use panning only if **Mode** is set to `Off`.

  If mode is set to either `Normal` or `Once` and no trigger event occurs, the display remains blank. Set **Mode** to `Auto` to display all signal data, in addition to trigger events.
- **Position (%)** — Specify, as a percentage of the total time span within the active display, the horizontal position in which the trigger indicator appears. A position value of `0` corresponds to the minimum time-axis value at the far-left side of the display. A position value of `100` corresponds to the maximum time-axis value at the far-right side of the display. Drag the trigger position indicator to the left or right to adjust its position.

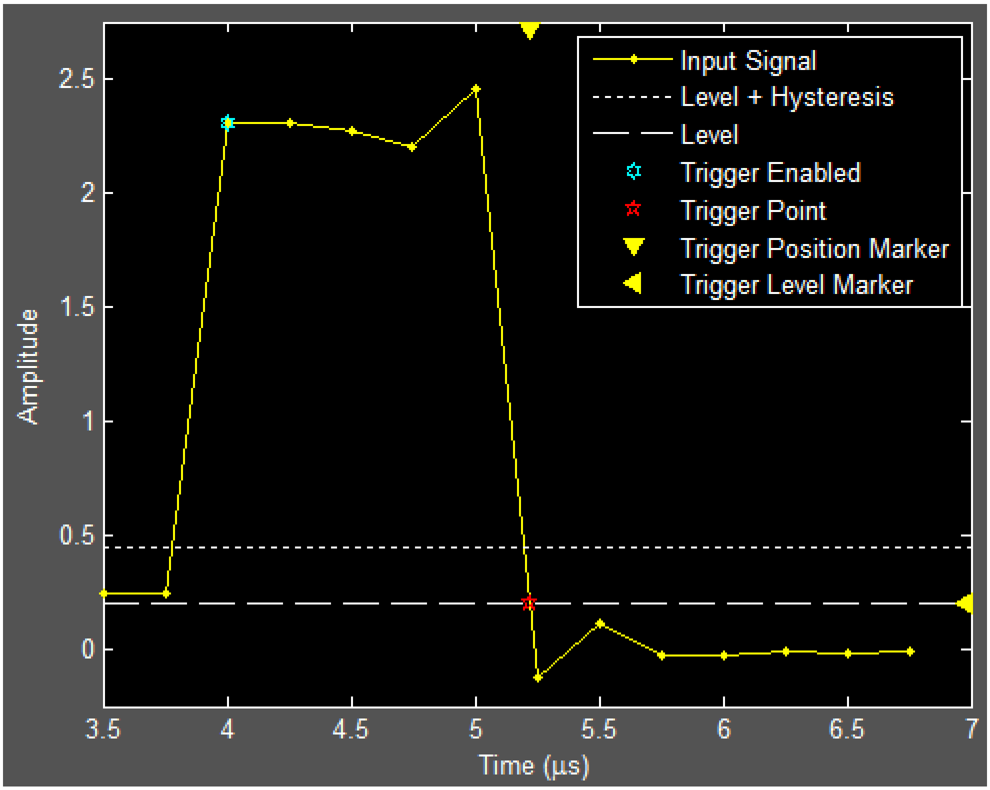
Source / Type Pane

The **Source / Type** pane lets you choose the source of the trigger and the type of events on which to stop.

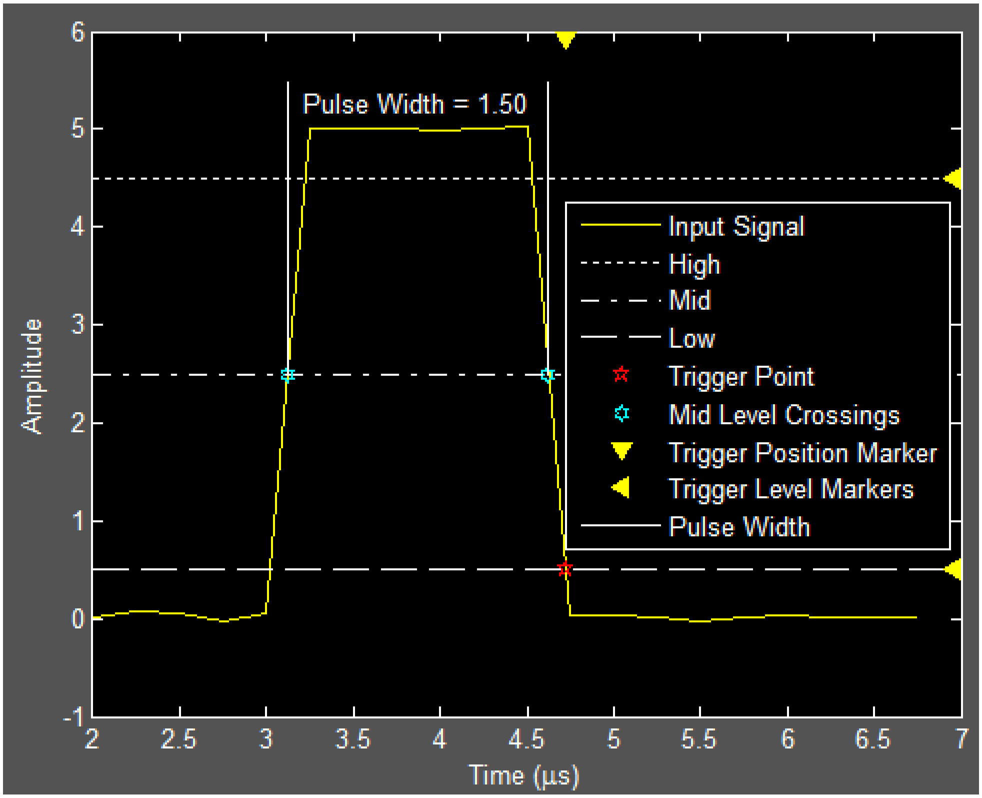
- **Source** — Assign the trigger source to a particular channel. If you are viewing a magnitude/phase plot, you can trigger off the magnitude or the phase. If you are not viewing the magnitude/phase plot, you can trigger off the real or imaginary data. If the input signal has multiple channels, the scope assigns an index number to identify each channel of that signal. For more information, see "Display Multiple Signals in the Time Scope".
- **Type** — Select the type of trigger to use.
  - `Edge` — Trigger when the scope crosses a level threshold. In the case of a rising edge, the scope enables the trigger event when the signal value becomes less than the level threshold minus hysteresis. The scope disables the trigger event when the signal becomes greater than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.



In the case of a falling edge, the scope enables the trigger event when the signal value becomes greater than the level threshold plus hysteresis. The scope disables the trigger event when the signal becomes less than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.

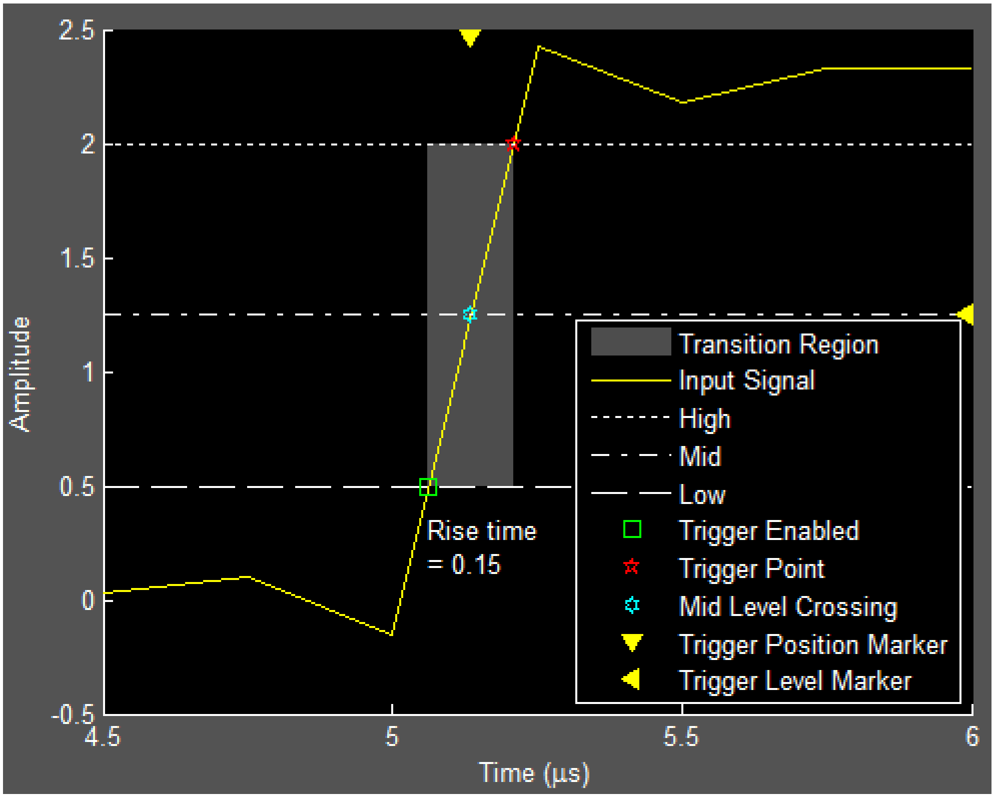


- `Pulse Width` — Trigger when the scope encounters a pulse whose width falls inside or outside specified time limits. You specify the range of valid time limits in the **Levels / Timing** pane. In the case of a positive-polarity pulse, the scope encounters a trigger event when the signal crosses the low threshold for the second time. The scope measures the pulse width as the time between the first and second crossings of the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.

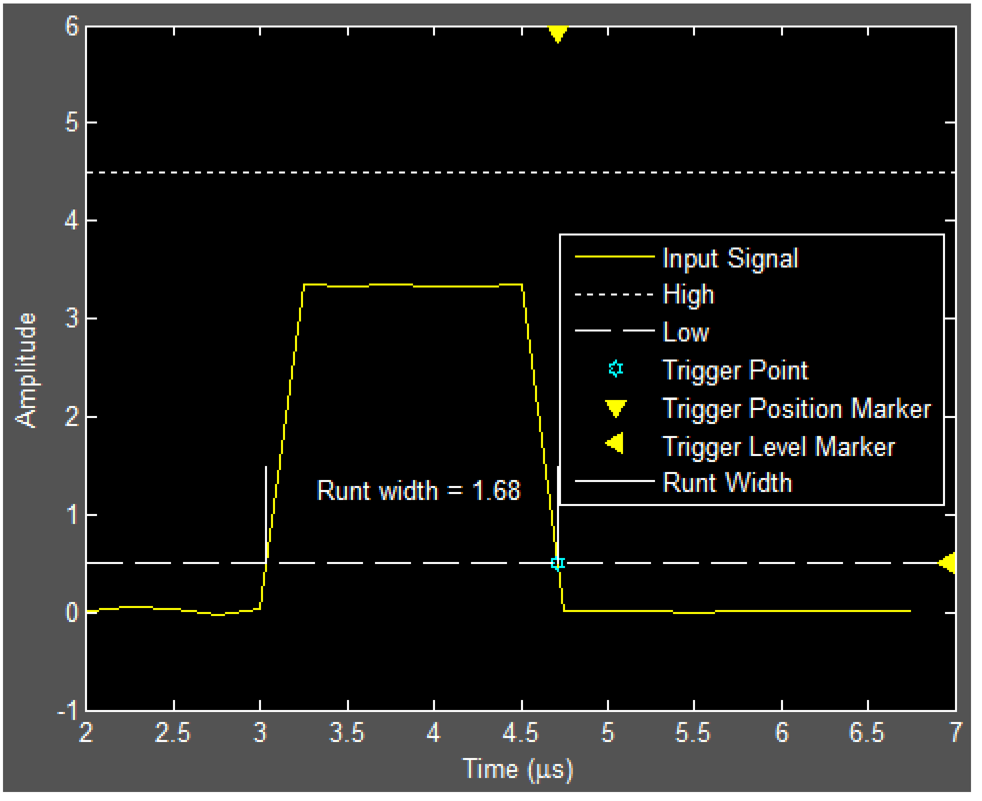


Note: A *Glitch*-type trigger looks for a pulse or spike whose duration is less than a specified amount. You can implement a *Glitch* type trigger by using a `Pulse Width` type trigger and manually setting the **Max Width** parameter.

- `Transition` — Trigger on a rising or falling edge that crosses two levels, high and low, inside or outside a specified time interval. You specify the range of valid transition times in the **Levels / Timing** pane. In the case of a rising transition, the scope encounters the trigger event when the signal crosses the high threshold. The transition time is when the signal crosses the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.

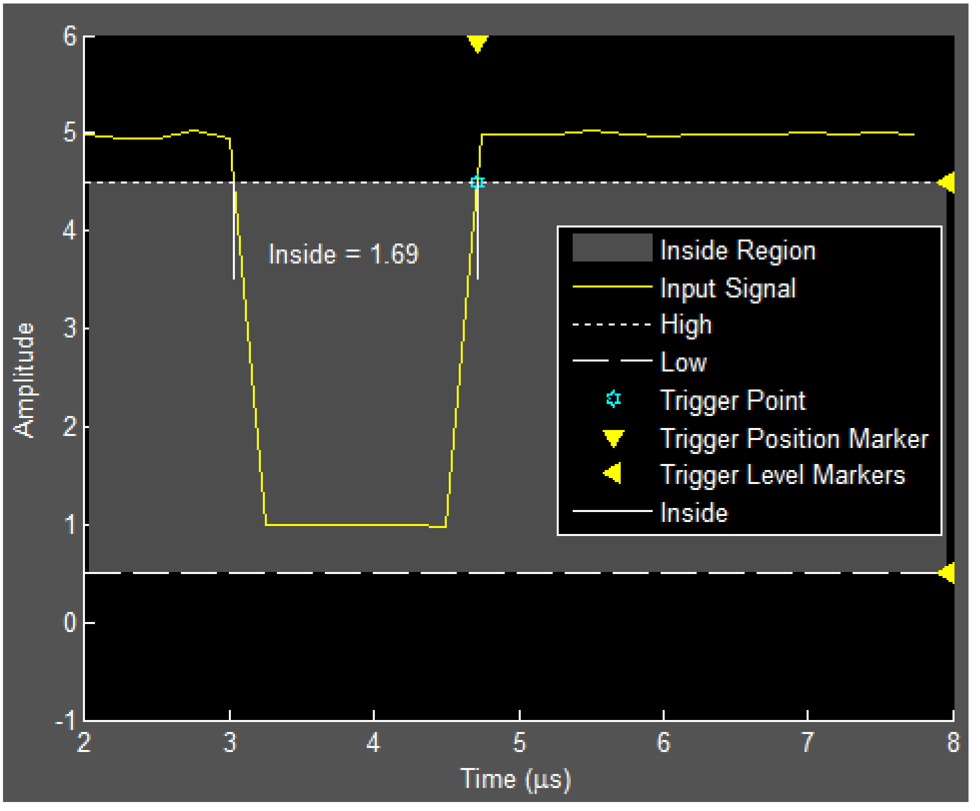


- `Runt` — Trigger on a runt pulse, which crosses one threshold, high or low, but not both. In the case of a positive-polarity runt pulse, the scope encounters a trigger event when the signal crosses the low threshold the second time, without ever crossing the high threshold. The scope measures the runt width as the time between the first and second crossings of the low threshold, as shown in the following figure. The runt width is the **Max Width** – **Min Width**. Any runt pulse width that is less than the minimum width or greater than the maximum width will not generate a trigger event.

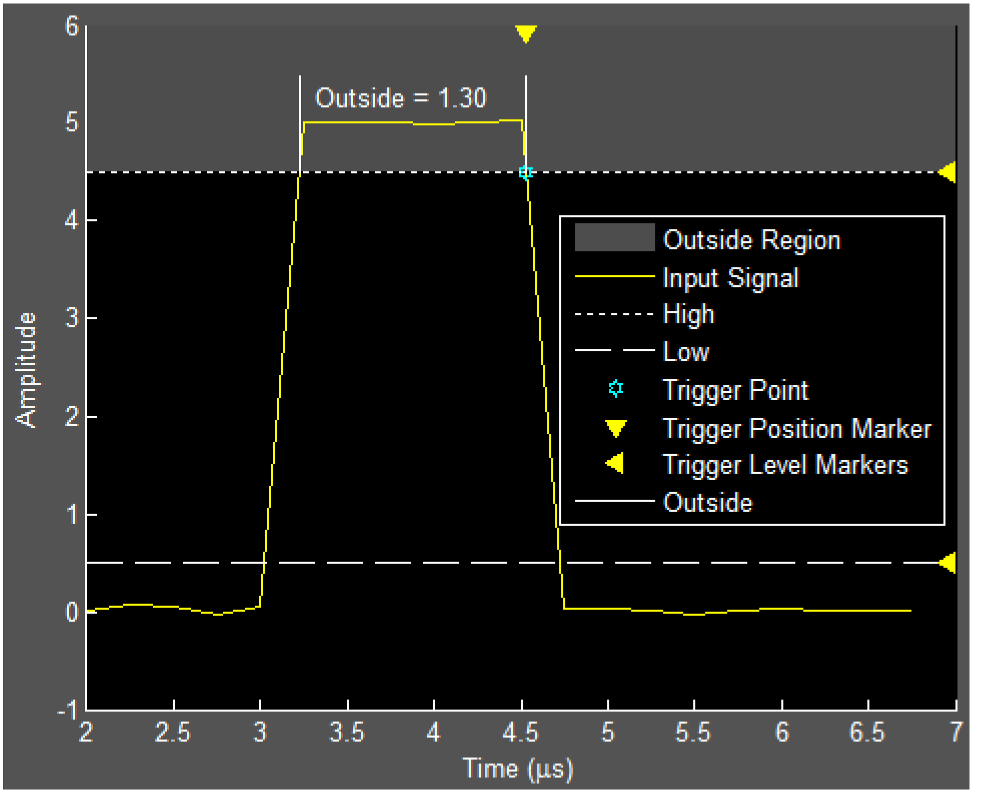


Note: You can also replicate a runt-type trigger by using a window-type trigger and setting **Polarity** to `Inside`.

- `Window` — Trigger when the input signal stays within or outside the region defined by the high and low thresholds for a period of time. In the case of an inside window, the scope encounters a trigger event when the signal enters and exits the inside region, as shown in the following figure.

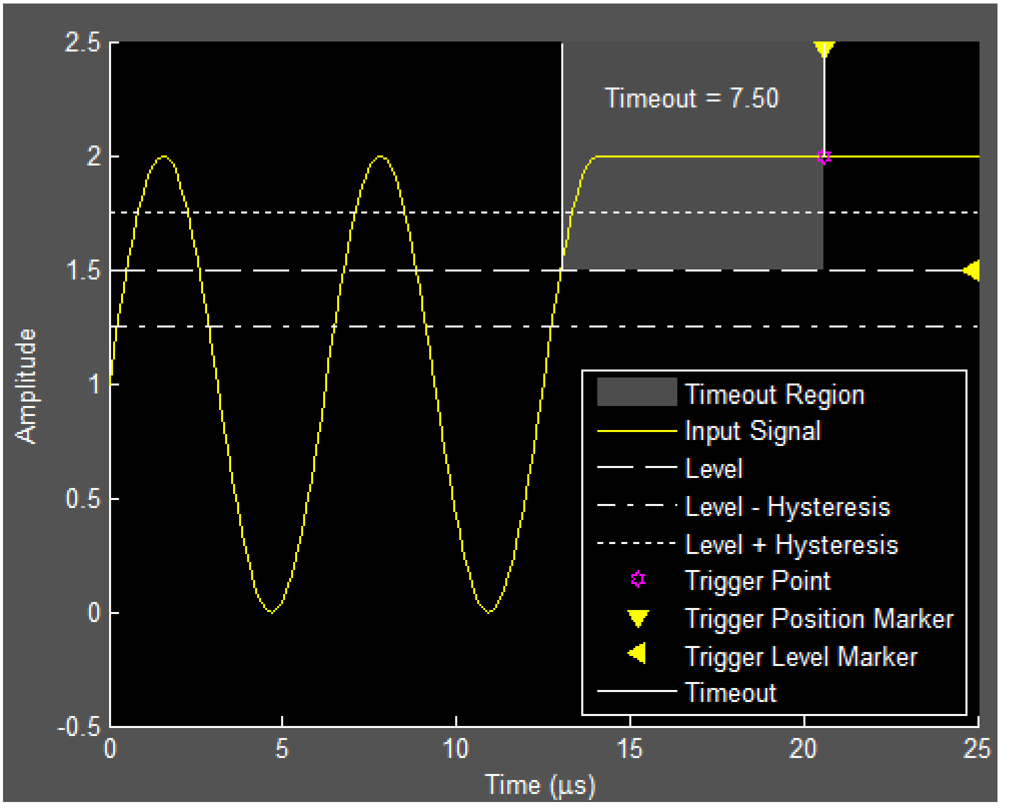


In the case of an outside window, the scope encounters a trigger event when the signal enters and exits the outside region, as shown in the following figure.

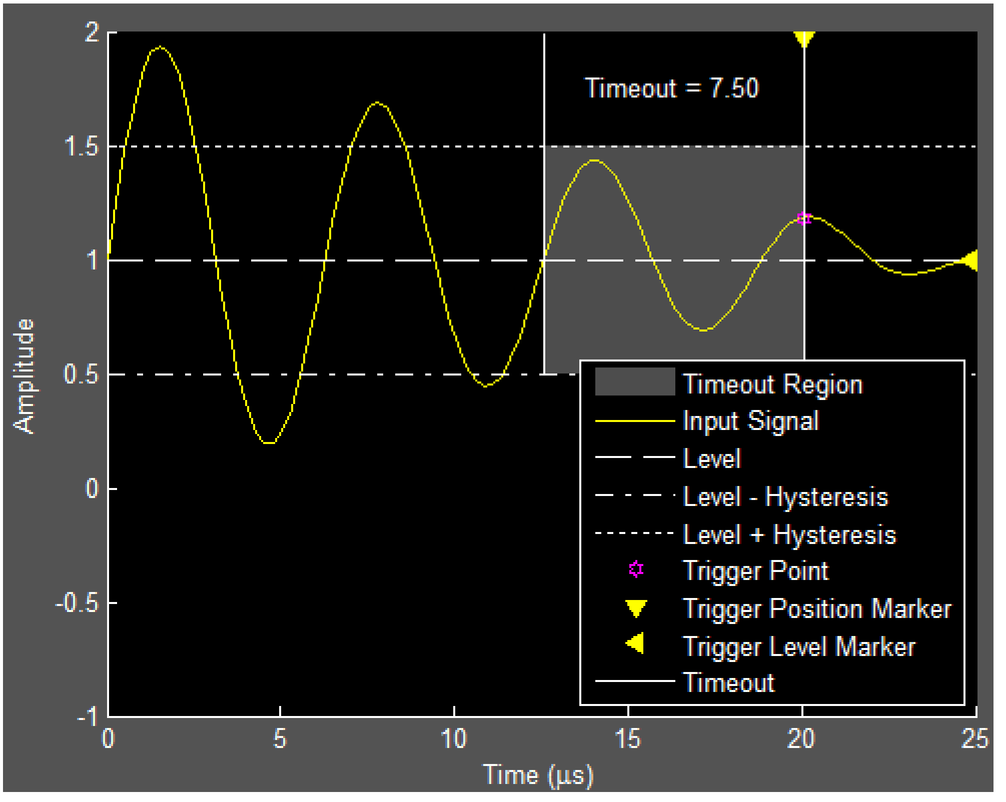


The scope encounters a trigger event when the signal crosses either the high or low threshold the second time.

- `Timeout` — Trigger when the input signal stays above or below a voltage threshold longer than a specified time. In the case of a timeout trigger with polarity set to `Either` and a timeout duration of 7.50 seconds, the scope can encounter the trigger event 7.50 seconds after the signal crosses the level threshold the last time, as shown in the following figure.



Alternatively, the scope can encounter the trigger event when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the level threshold, as shown in the following figure.



- **Polarity** — Select the polarity of the trigger type. The option you choose for **Type** directly affects the options available for **Polarity**, as shown in the following table.

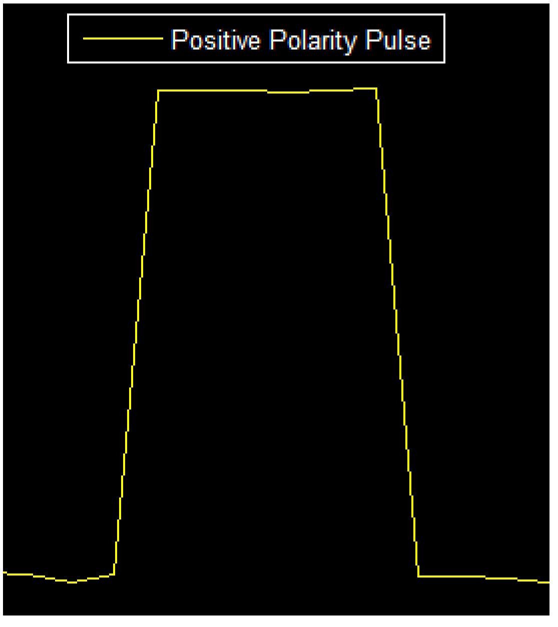
Trigger Type	Polarity Options
`Edge`	`Rising`, `Falling`, `Either`
`Pulse Width`	`Positive`, `Negative`, `Either`
`Transition`	`Rise Time`, `Fall Time`, `Either`
`Runt`	`Positive`, `Negative`, `Either`
`Window`	`Inside`, `Outside`, `Either`
`Timeout`	`Rising`, `Falling`, `Either`

When you set **Type** to `Edge`, the polarity options are:

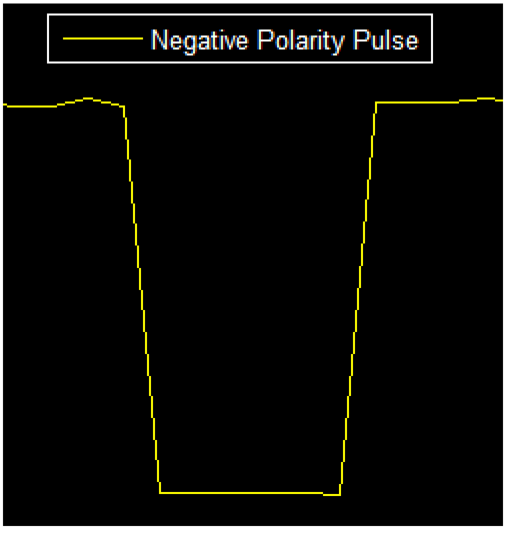
- `Rising` — Trigger on a *rising edge*, a transition from a low-state level to a high-state level.
- `Falling` — Trigger on a *falling edge*, transition from a high-state level to a low-state level.
- `Either` — Trigger on both rising edges and falling edges.

When you set **Type** to `Pulse Width` or `Runt`, the polarity options are:

- `Positive` — Trigger on a positive-polarity pulse, as shown in the following figure.



- `Negative` — Trigger on a negative-polarity pulse, as shown in the following figure.



- `Either` — Trigger on both positive-polarity and negative-polarity pulses.

When you set **Type** to `Transition`, the polarity options are:

- `Rise Time` — Trigger based on how long the signal takes to transition from the low threshold to the high threshold.
- `Fall Time` — Trigger based on how long the signal takes to transition from the high threshold to the low threshold.
- `Either` — Trigger based on how long it takes to make either a rising or falling transition.

When you set **Type** to `Window`, the polarity options are:

- `Inside` — Trigger when the signal stays within the low and high levels for a specified time duration.
- `Outside` — Trigger when the signal stays outside of the low and high levels for a specified time duration.
- `Either` — Trigger on both inside and outside windows.

When you set **Type** to `Timeout`, the polarity options are:

- `Rising` — Trigger when the signal does not cross the reference level from below.

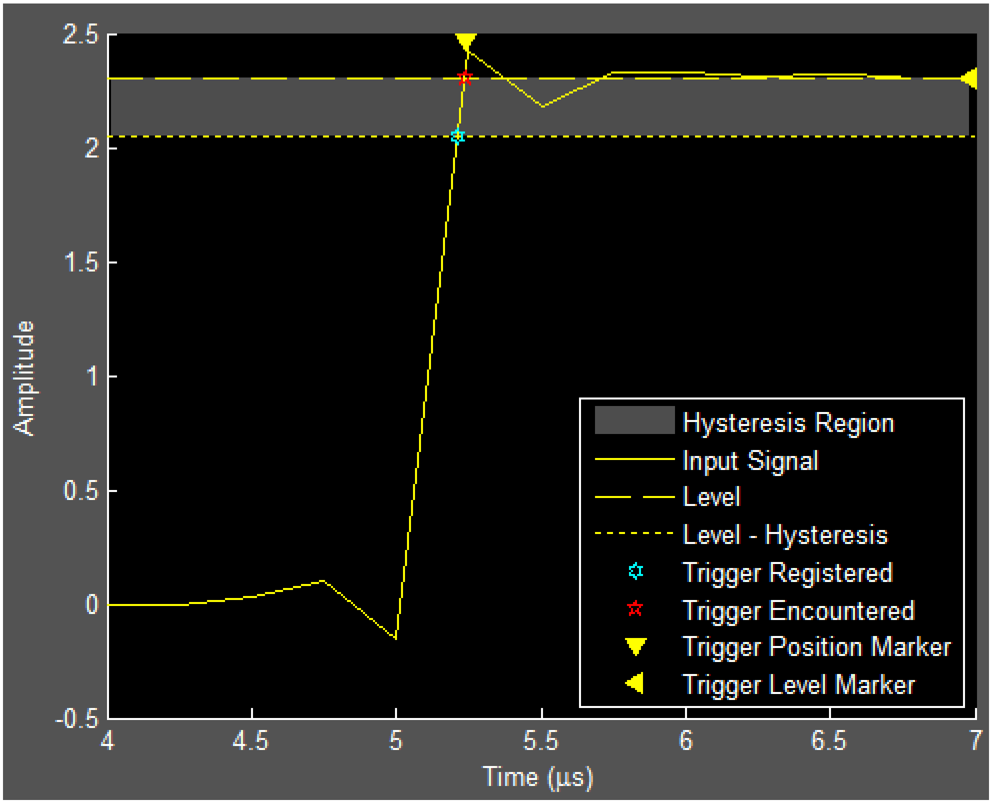
- `Falling` — Trigger when the signal does not cross the reference level from above.
- `Either` — Trigger when the signal does not cross the reference level from either direction.

Levels / Timing Pane

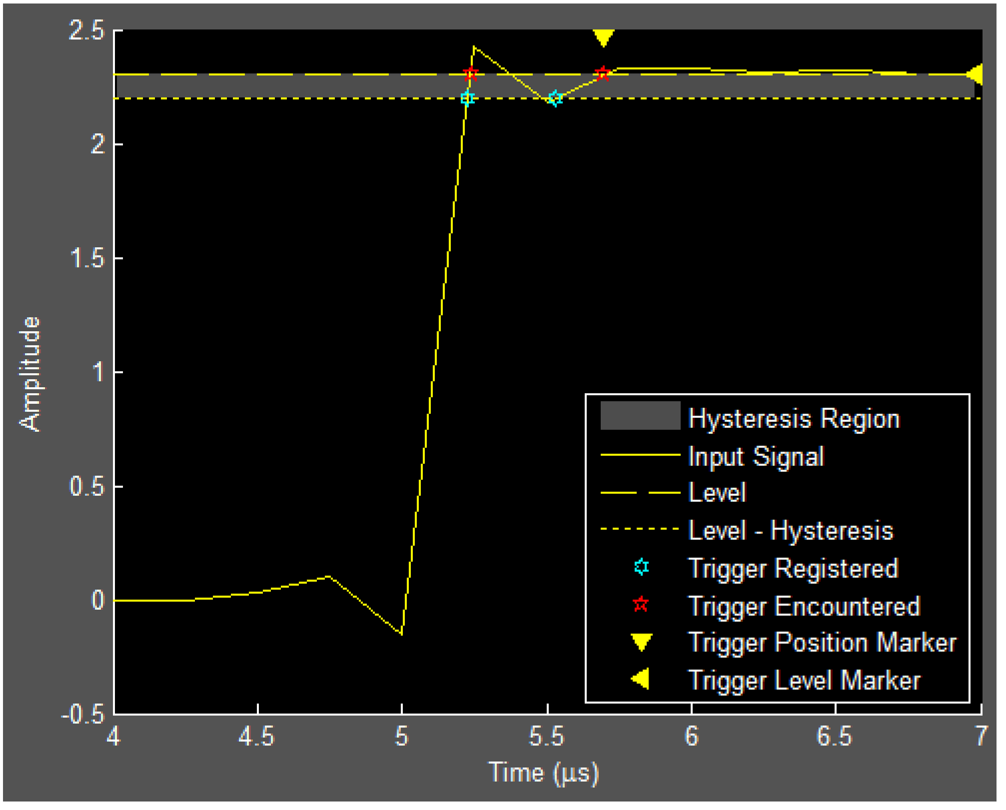
The **Levels / Timing** pane enables you to set the trigger level and hysteresis value. The option you choose for **Type** directly affects which level and timing parameters are available, as shown in the following table.

Trigger Type	Level Parameters	Auto-Level Setting	Timing Parameters
`Edge`	Level, Hysteresis	Level = 50%	n/a
`Pulse Width`	High, Low	High = 90%, Low = 10%	Min Width, Max Width
`Transition`	High, Low	High = 90%, Low = 10%	Min Time, Max Time
`Runt`	High, Low	High = 90%, Low = 10%	Min Width, Max Width
`Window`	High, Low	High = 90%, Low = 10%	Min Time, Max Time
`Timeout`	Level, Hysteresis	n/a	Timeout

- **Auto level** — Enable the Triggers panel to automatically choose the level parameters. If you set the trigger **Type** to `Edge`, this option sets the **Level** parameter to 50% of the range of the source signal. If you set the trigger **Type** to `Timeout`, the Triggers panel does not show this option. Setting the trigger **Type** to other menu choices results in **High** and **Low** parameter adjustment. **Auto level** sets the **High** parameter to 90% of the range of the source signal and the **Low** parameter to 10% of the range of the source signal.
- **Level (V)** — Specify, in volts, the trigger level. This parameter is visible when you set **Type** to `Edge` or `Timeout`.
- **Hysteresis (V)** — Specify, in volts, the hysteresis or noise reject value. This parameter is visible when you set **Type** to `Edge` or `Timeout`. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores any times that the signal crosses the trigger level within the hysteresis region, as shown in the following figure.



You can reduce the hysteresis region size by decreasing the hysteresis value. If you set the hysteresis value to 0.07 in this example, then the scope also considers the second rising edge to be a trigger event, as shown in the following figure.



- **High (V)** — Specify, in volts, the value that denotes a positive polarity, or high-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Low (V)** — Specify, in volts, the value that denotes a negative polarity, or low-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Min Width (s)** — Specify, in seconds, the minimum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Max Width (s)** — Specify, in seconds, the maximum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Min Time (s)** — Specify, in seconds, the minimum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.

- **Max Time (s)** — Specify, in seconds, the maximum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.
- **Timeout (s)** — Specify, in seconds, the timeout duration. This parameter is visible when you set **Type** to `Timeout`.

Delay / Holdoff Pane

The **Delay / Holdoff** pane enables you to offset the trigger position by a fixed delay or set the minimum possible time between trigger events.

- **Delay (s)** — Specify, in seconds, the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify, in seconds, the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event is encountered. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the portion of a burst that is of interest.

Cursor Measurements Panel

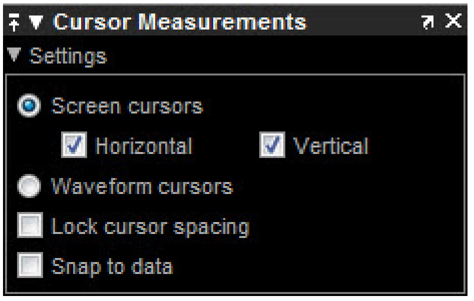
The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note: If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

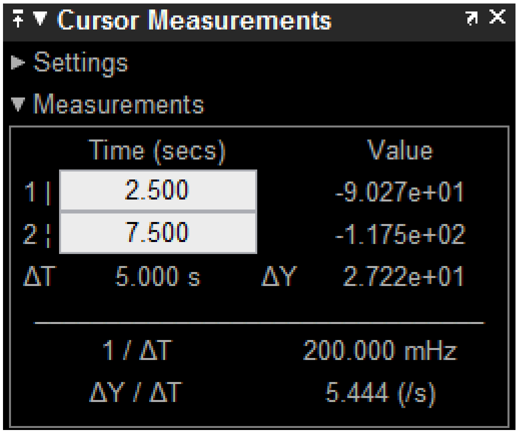
In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.



- **Screen Cursors** — Shows screen cursors.
- **Horizontal** — Shows horizontal screen cursors.
- **Vertical** — Shows vertical screen cursors.
- **Waveform Cursors** — Shows cursors that attach to the input signals.
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.



You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

The **Measurements** pane shows the time and value measurements.

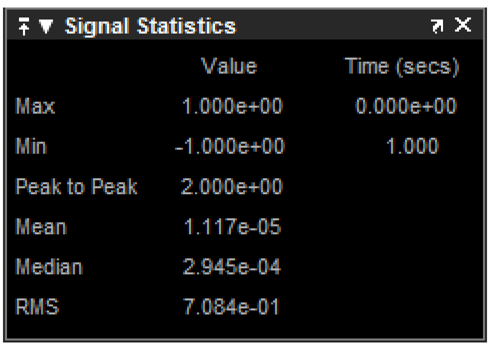
- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.

- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the scope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

Signal Statistics Panel

Note: The **Signal Statistics** panel requires a DSP System Toolbox or Simscape license.

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. In the Scope menu, select **Tools** > **Measurements** > **Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.



The statistics shown are:

- **Max** — The maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.

- **Min** — The minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — The difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** —The average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — The median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

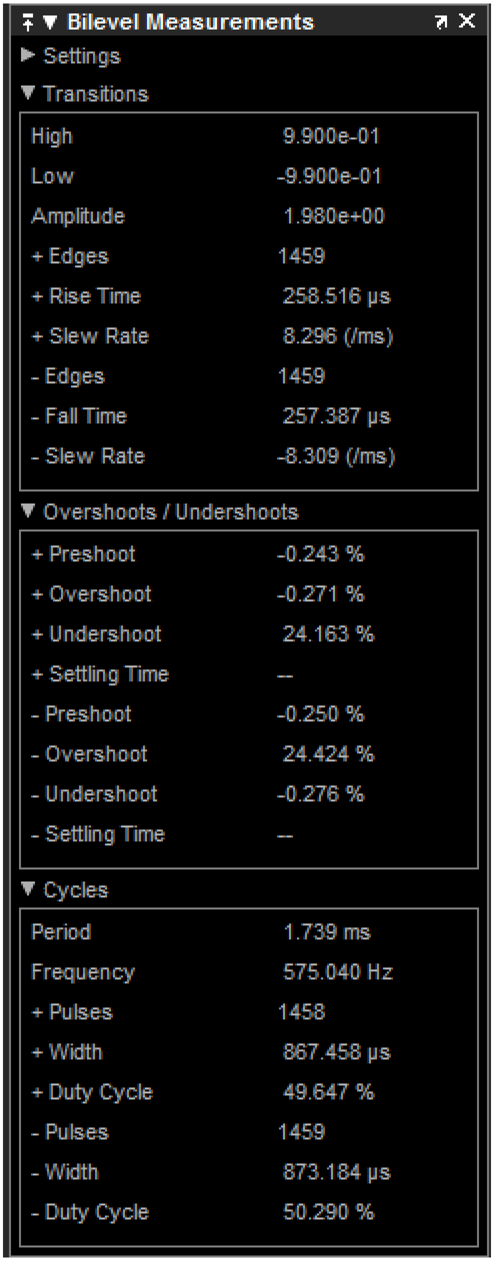
The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Bilevel Measurements Panel

Note: The **Bilevel Measurements** panel requires a DSP System Toolbox or Simscape license.

The **Bilevel Measurements** panel shows information about transitions, overshoots, undershoots, and cycles for a selected signal. You can choose to hide or display the **Bilevel Measurements** panel. In the scope menu, select **Tools** > **Measurements** > **Bilevel Measurements**. Alternatively, in the scope toolbar, you can select the Bilevel Measurements  button.

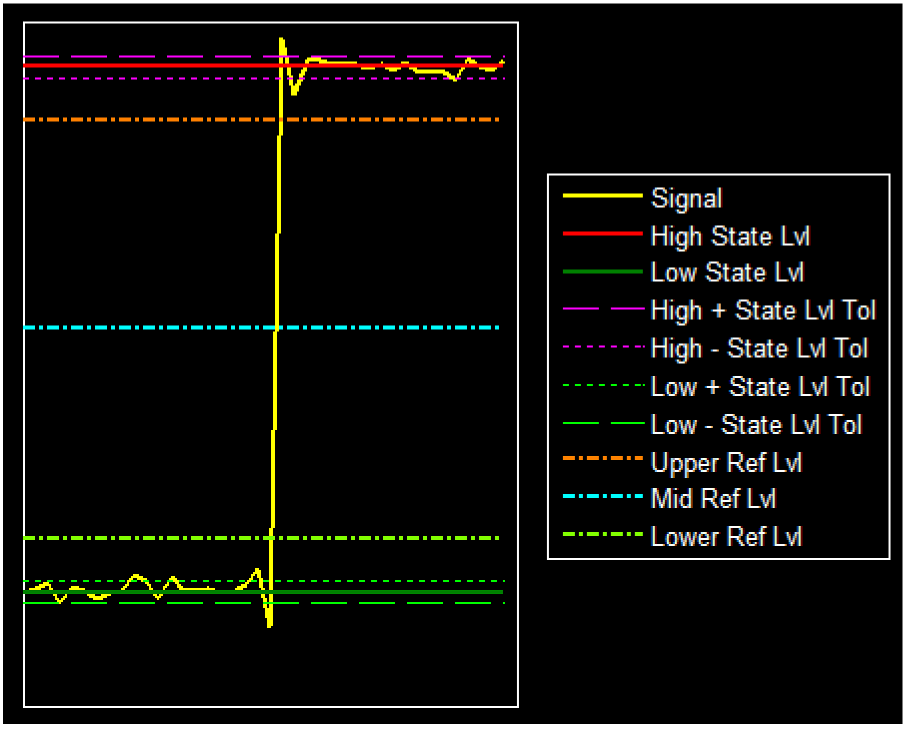
When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. This feature does not apply to the **High** and **Low** measurements.



Bilevel Measurements
Settings
Transitions
High 9.900e-01
Low -9.900e-01
Amplitude 1.980e+00
+ Edges 1459
+ Rise Time 258.516 μs
+ Slew Rate 8.296 (/ms)
- Edges 1459
- Fall Time 257.387 μs
- Slew Rate -8.309 (/ms)
Overshoots / Undershoots
+ Preshoot -0.243 %
+ Overshoot -0.271 %
+ Undershoot 24.163 %
+ Settling Time --
- Preshoot -0.250 %
- Overshoot 24.424 %
- Undershoot -0.276 %
- Settling Time --
Cycles
Period 1.739 ms
Frequency 575.040 Hz
+ Pulses 1458
+ Width 867.458 μs
+ Duty Cycle 49.647 %
- Pulses 1459
- Width 873.184 μs
- Duty Cycle 50.290 %

The **Bilevel Measurements** panel is separated into four panes, labeled **Settings**, **Transitions**, **Overshoots/Undershoots**, and **Cycles**. You can expand each pane to see the available options.

Bilevel Measurements Plot



Note: Opening the **Overshoots/Undershoots** pane may reduce the number of available edges by 1 if the last edge of the pulse is not within the **Settle Seek** time of the end of the plot. This reduction in the number of edges changes the values of **Edges**, **Fall Time**, and **Slew Rate** in the **Transitions** pane.

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level, as shown in the following figure.

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel autodetects the high- and low- state levels of a bilevel waveform. For more information on the algorithm this option uses, see the Signal Processing Toolbox `statelevels` function reference. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
  - **High** — Manually specify the value for a positive polarity or high-state level.
  - **Low** — Manually specify the value for a negative polarity or low-state level.
- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. The mid-reference level is shown as a horizontal line, and its corresponding mid-reference level instant is shown as a vertical line.
- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

The **Transitions** pane displays calculated measurements associated with the input signal changing between its two possible state level values, high and low. The Transition measurements assume that the amplitude of the input signal is in units of volts. Convert all input signals to volts for the Transition measurements to be valid.

A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

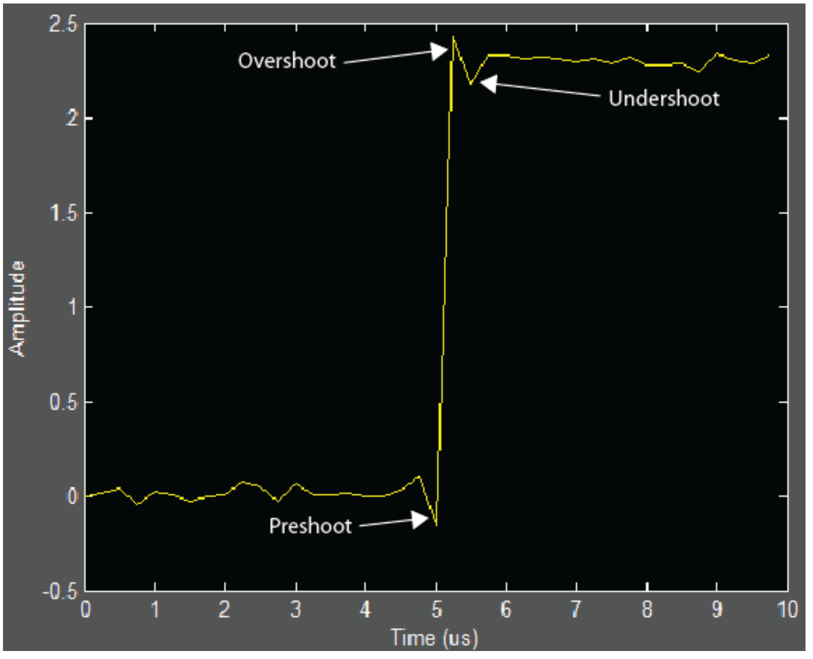
- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** or**Time** tab of the Visuals—Time Domain Properties dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** or **Time** tab of the Visuals—Time Domain Properties dialog box. The tab in which **Time Span** appears depends on whether you launched the scope from a from a MATLAB System object or from a Simulink block, respectively. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `risetime` function reference.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray.

  For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.
- **– Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- **– Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `falltime` function reference.
- **– Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. For

more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal, respectively, exceeds and falls below its final steady-state value. *Preshoot* refers to the amount before a transition that a signal varies from its initial steady-state value. This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

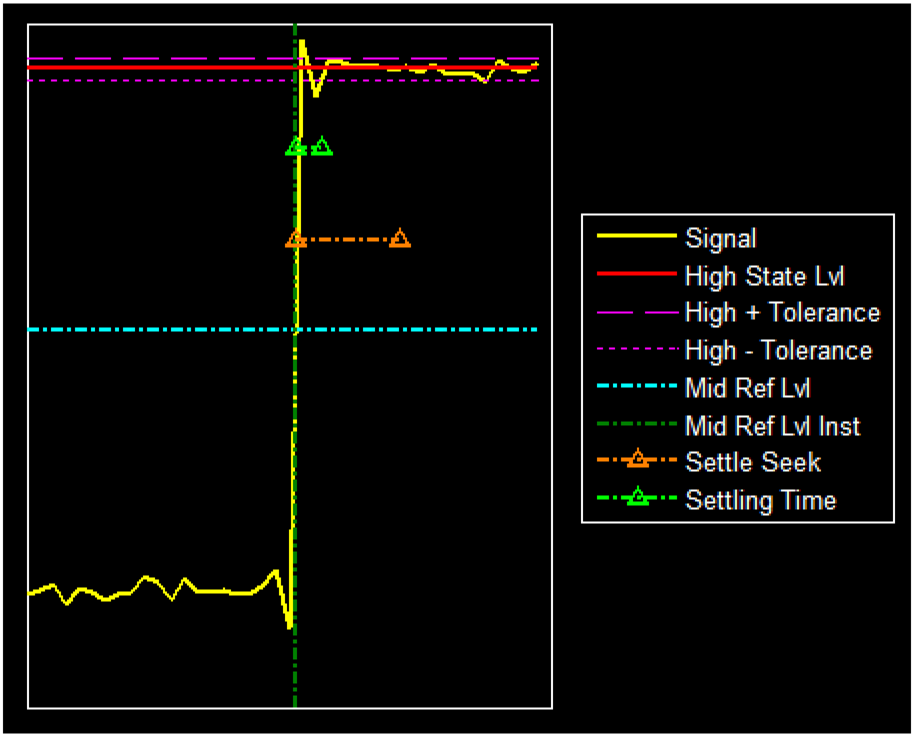
Overshoot/Undershoot Plot



- + *Preshoot* — Average lowest aberration in the region immediately preceding each rising transition.
- + *Overshoot* — Average highest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- + *Undershoot* — Average lowest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.

- + *Settling Time* — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

Settling Time Plot



You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

- – *Preshoot* — Average highest aberration in the region immediately preceding each falling transition.

- – *Overshoot* — Average highest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- – *Undershoot* — Average lowest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- – *Settling Time* — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

The **Cycles** pane displays calculated measurements of to repetitions or trends in the displayed portion of the input signal.

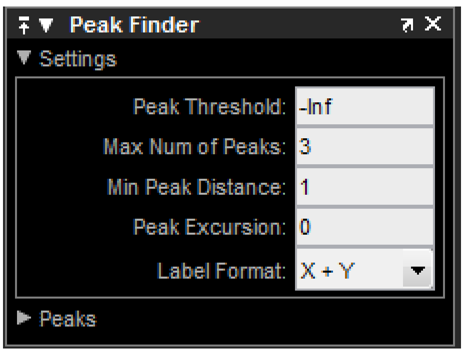
- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots.

  For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulseperiod` function reference.
- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.
- **– Pulses** — Number of negative-polarity pulses counted.

- – **Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- – **Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.

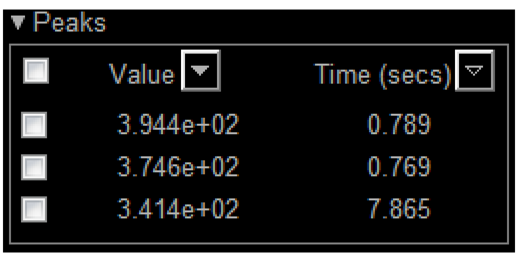


The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values

displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

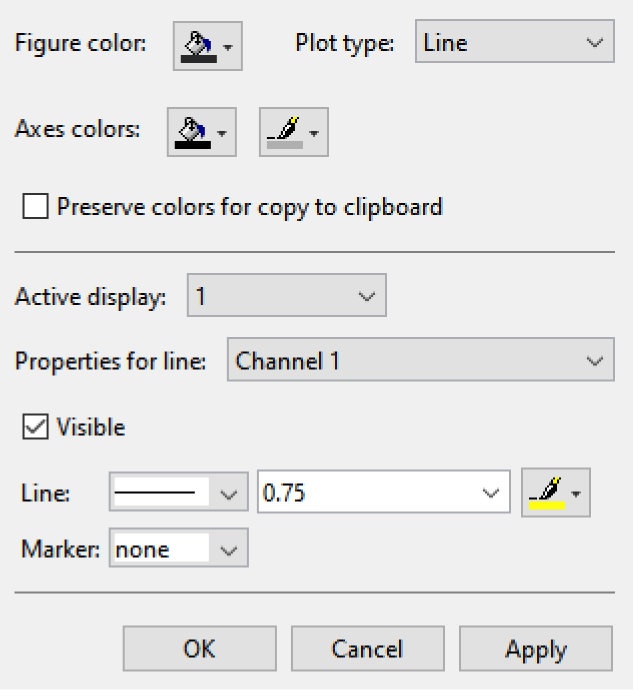
The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button ( ) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button ( ). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled ( ), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Style Dialog Box

Select **View > Style** or the Style button ( ) in the dropdown below the Configuration Properties button to open the Style dialog box. In this dialog box, you can change the figure colors, background axes colors, foreground axes colors, and properties of lines in a display.



Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify the type of plot to use. The default setting is `Line`. Valid values for **Plot type** are:

- `Line` — line graph, similar to the `line` or `plot` function.
- `Stairs` — *stair-step* graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable (Simulink).

Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed. Tunable (Simulink)

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is 1.

Axes colors

Specify the color that you want to apply to the background of the axes for the active display.

Preserve colors for copy to clipboard

Specify whether or not to use the displayed color of the scope when copying.

When you select **File** > **Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Default: Off

Properties for line

Specify the signal for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected signal on the active display is visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected signal on the active display.

Marker

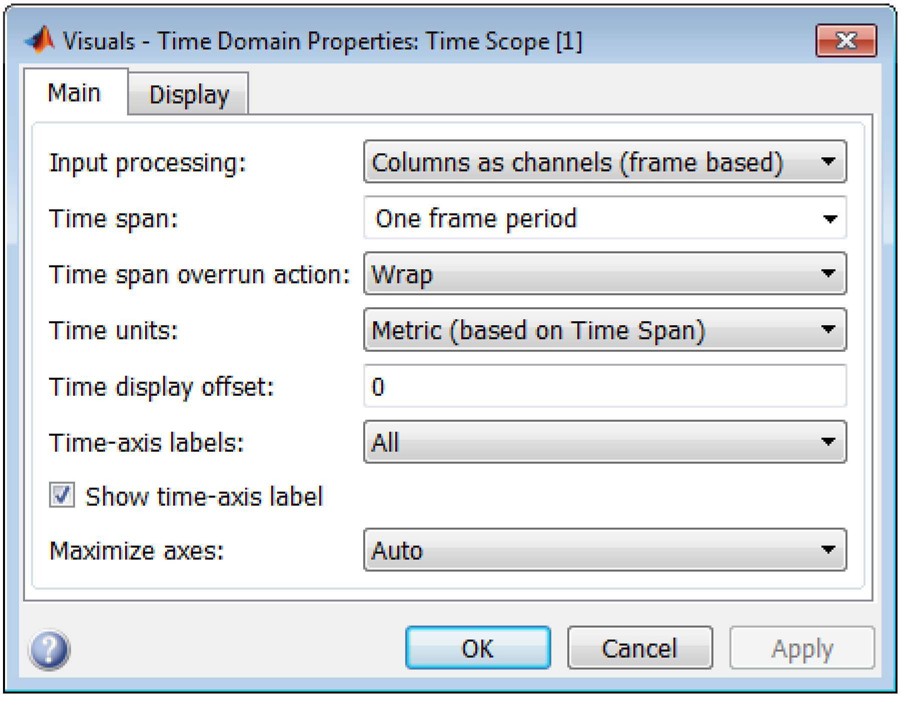
Specify marks for the selected signal on the active display to show at data points. This property is similar to the `Marker` property for plot objects. Choose any of the marker symbols from the dropdown list.

Visuals — Time Domain Properties

The Visuals — Time Domain Properties dialog box controls the visual configuration settings of the Time Scope displays. From the Time Scope menu, select **View** > **Configuration Properties** to open this dialog box.

Main Pane

The **Main** pane of the Time Scope Visuals—Time Domain Properties dialog box appears as follows.



Input processing

Specify whether the Time Scope treats the input signal as `Columns as channels (frame based)` or `Elements as channels (sample based)`.

Frame-based processing is only available for discrete input signals. For more information about frame-based input channels, see “What Is Frame-Based Processing?”. For an example that uses the Time Scope block and frame-based input signals, see “Display Time-Domain Data”.

Time span

Specify the time span, either by selecting a predefined option or by entering a numeric value in seconds. You can select one of the following options:

- `Auto` — In this mode, the Time Scope automatically calculates the appropriate value for time span from the difference between the simulation “Start time” (Simulink) and “Stop time” (Simulink) properties. This option is available only for the Time Scope block but not for the `dsp.TimeScope` System object.
- `One frame period` — In this mode, the Time Scope uses the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`. This option is not available when you set the **Input processing** parameter to `Elements as channels (sample based)`.
- `<user defined>` — In this mode, you specify the time span by replacing the text `<user defined>` with a numeric value in seconds.

The scope sets the time-axis limits using the value of this property and the value of the **Time display offset** property. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the time-axis limits to a minimum value of 5 μs and a maximum value of 30 μs.

This property is Tunable (Simulink).

Time span overrun action

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- `Wrap` — In this mode, the scope displays new data until the data reaches the maximum time-axis limit. When the data reaches the maximum time-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum time-axis limit.

- `Scroll` — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This property is Tunable (Simulink).

The default setting is `Wrap`.

Time units

Specify the units used to describe the time axis. The default setting is `Metric`. You can select one of the following options:

- `Metric` — In this mode, Time Scope converts the times on the time axis to some metric units such as milliseconds, microseconds, days, etc. Time Scope chooses the appropriate metric units, based on the minimum time-axis limit and the maximum time-axis limit of the scope window.
- `Seconds` — In this mode, Time Scope always displays the units on the time axis as seconds.
- `None` — In this mode, Time Scope displays no units on the time axis. Time Scope shows only the word `Time` on the time axis.

This property is Tunable (Simulink).

Time display offset

This property allows you to offset the values displayed on the time axis by a specified number of seconds. When you specify a scalar value, the scope offsets all channels equally. When you specify a vector of offset values, the scope offsets each channel independently. Tunable (Simulink).

When you specify a **Time display offset** vector of length *N*, the scope offsets the input channels as follows:

- When *N* is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.

- When N is less than the number of input channels, the scope applies the values you specify in the offset vector to the first N input channels. The scope does not offset the remaining channels.
- When N is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

The scope computes the time-axis range using the values of the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the time-axis limits to a minimum value of 5 μs and a maximum value of 30 μs.

Similarly, when you specify a vector of values, the scope sets the minimum time-axis limit using the smallest value in the vector. To set the maximum time-axis limit, the scope sums the largest value in the vector with the value of the **Time span** property. For more information, see "Signal Display" on page 4-1713.

Time-axis labels

Specify how to display the time units used to describe the time axis. The default setting is `All`. You can select one of the following options:

- `All` — In this mode, the time-axis labels appear in all displays.
- `None` — In this mode, the time-axis labels do not appear in the displays.
- `Bottom Displays Only` — In this mode, the time-axis labels appear in only the bottom row of the displays.

Tunable (Simulink).

Show time-axis label

Select this check box to show the time-axis label on the scope display. This check box is not available if **Time-axis labels** is `None`.

Tunable (Simulink).

Maximize axes

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

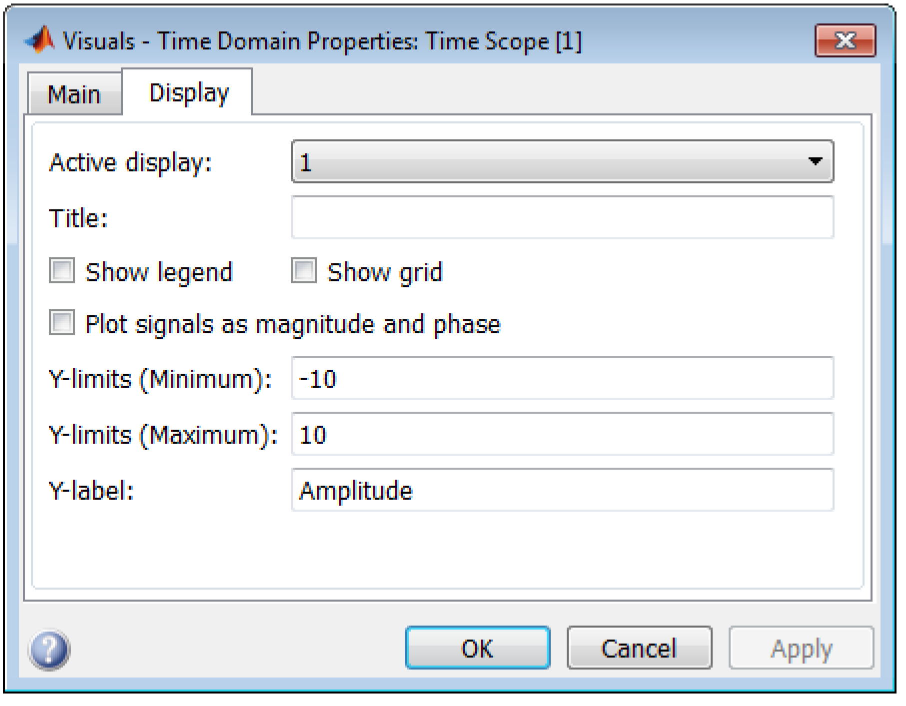
- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

The default setting is `Auto`.

Display Pane

The **Display** pane of the Visuals—Time Domain Properties dialog box appears as follows.



Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed. Tunable (Simulink)

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is 1.

Title

Specify the active display title as a character vector. By default, the active display has no title. Tunable (Simulink).

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn off the legend, clear the **Show legend** check box.Tunable (Simulink)

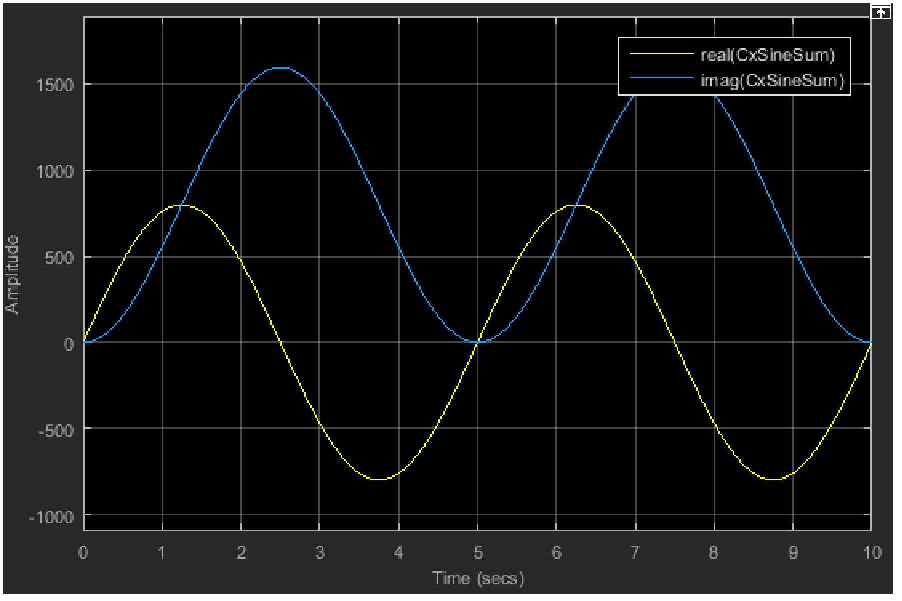
You can edit the name of any channel in the legend by double-clicking the current name and entering a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View** > **Style**. The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

Show grid

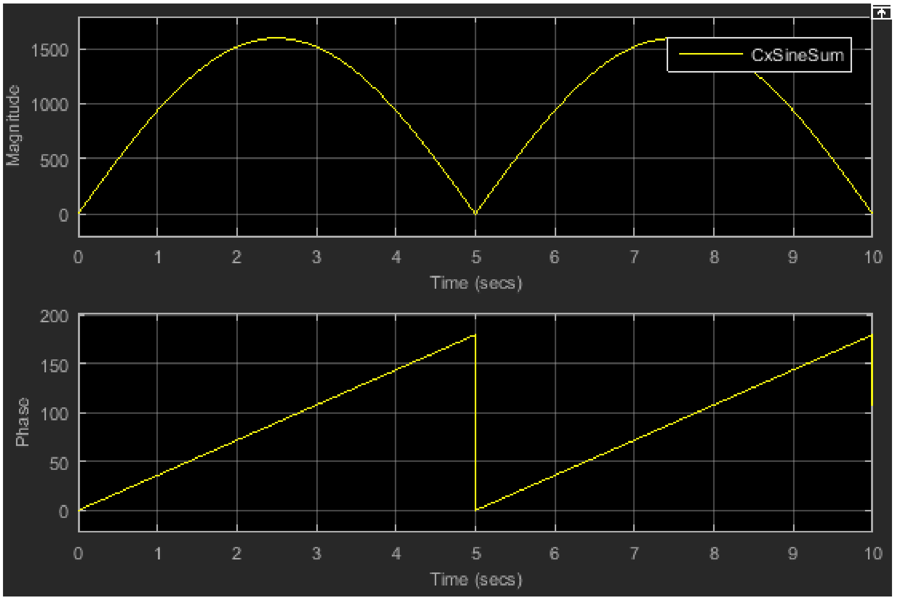
When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable (Simulink)

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal has complex values, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. Tunable (Simulink)

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. Tunable (Simulink)

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a minimum value of -180 degrees.

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable (Simulink)

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a maximum value of 180 degrees.

Y-label

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

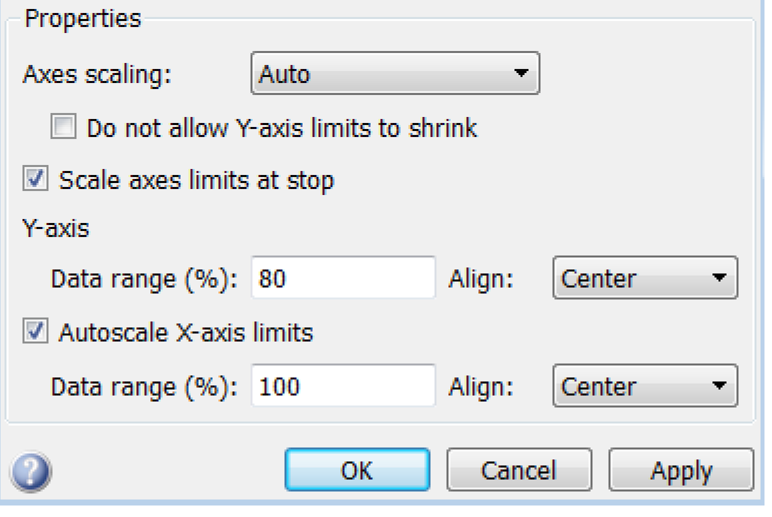
This property becomes invisible when you select the **Plot signal(s) as magnitude and phase** check box. When you enable that property, the *y*-axis label always appears as `Magnitude` on the top axes and `Phase` on the bottom axes.

Tools — Axes Scaling Properties

The Axes Scaling Properties: Time Scope dialog box provides you with the ability to automatically zoom in on and zoom out of your data, and to scale the axes of the Time Scope. In the Time Scope menu, select **Tools** > **Axes Scaling** > **Axes Scaling Properties** to open this dialog box.

Properties

The Tools—Axes Scaling Properties dialog box appears as follows.



Axes scaling

Specify when the scope automatically scales the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable (Simulink).

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable (Simulink).

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. This property appears only when you select `After N Updates` for the **Axes scaling** property. Tunable (Simulink).

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable (Simulink).

Y-axis Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable (Simulink).

X-axis Data range (%)

Set the percentage of the *x*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement along the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

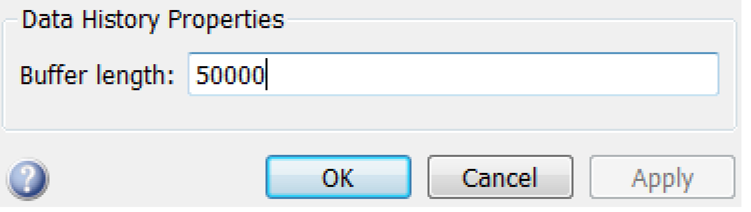
X-axis Align

Specify how the scope aligns your data along the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

Sources — Streaming Properties

The Sources – Streaming Properties dialog box lets you control the number of input signal samples that Time Scope holds in memory. In the Time Scope menu, select **View** > **Data History Properties** to open this dialog box.

Data History Properties



Buffer length

Specify the size of the buffer that the scope holds in its memory cache. Memory is limited by available memory on your system. If your signal has *M* rows of data and *N* data points in each row, *M* x *N* is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 (which is 10 x 100 x 10) as the buffer length.

The default setting is `50000`.

Examples

The first four examples show how to use the Time Scope object to view a variety of input signals in the time domain. The remaining two examples show how to use the Measurements panels in the Time Scope UI to glean information about the input signals.

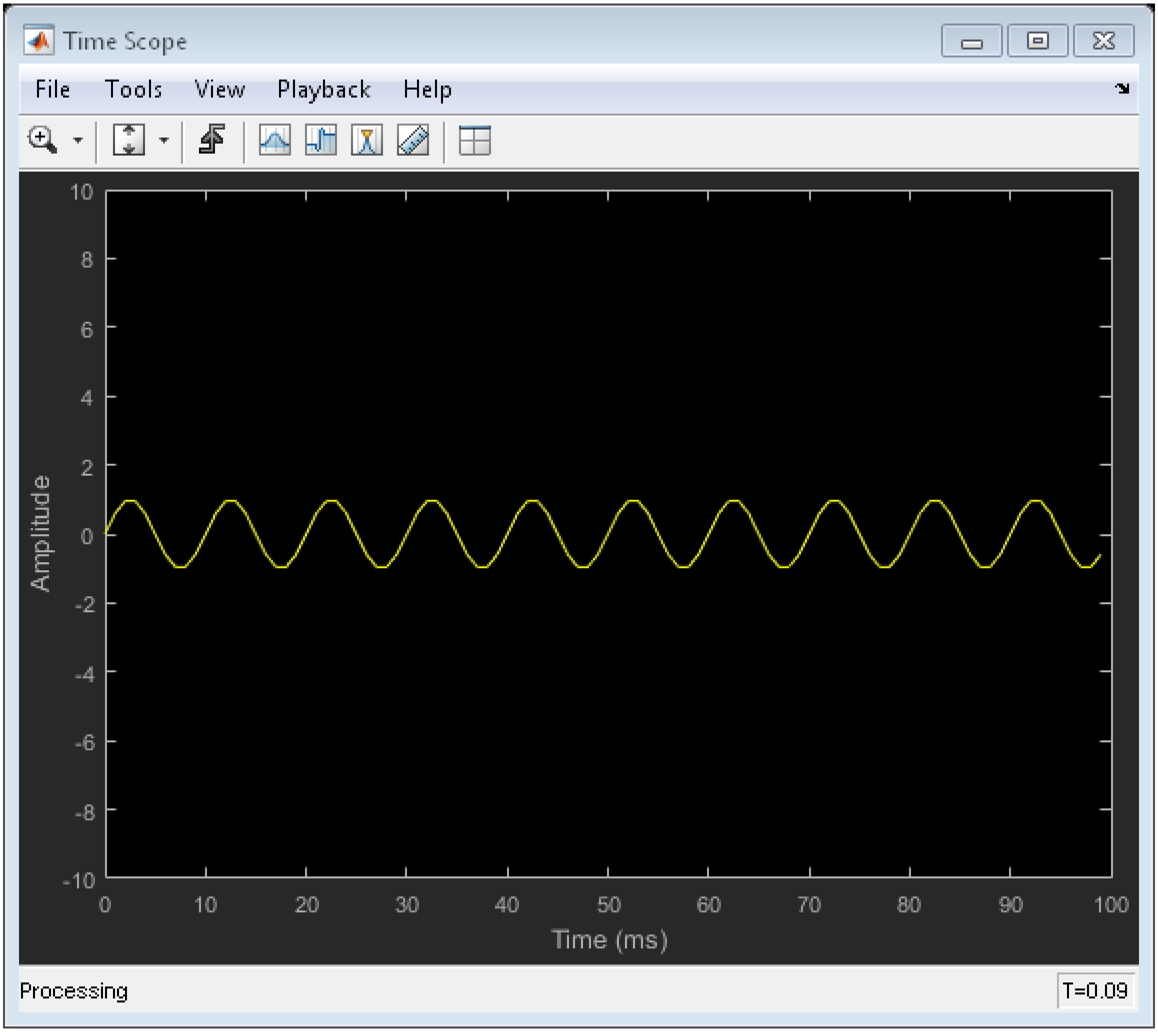
- "Display Simple Sine Wave Input Signal" on page 4-1761
- "View Sine Wave Input Signals at Different Sample Rates and Offsets" on page 4-1764
- "Display Complex-Valued Input Signal" on page 4-1765
- "Display Input Signal of Changing Size" on page 4-1769
- "Use Bilevel Measurements Panel with Clock Input Signal" on page 4-1772
- "Find Heart Rate Using Peak Finder Panel with ECG Input Signal" on page 4-1775

Display Simple Sine Wave Input Signal

Display a sine wave on a time scope.

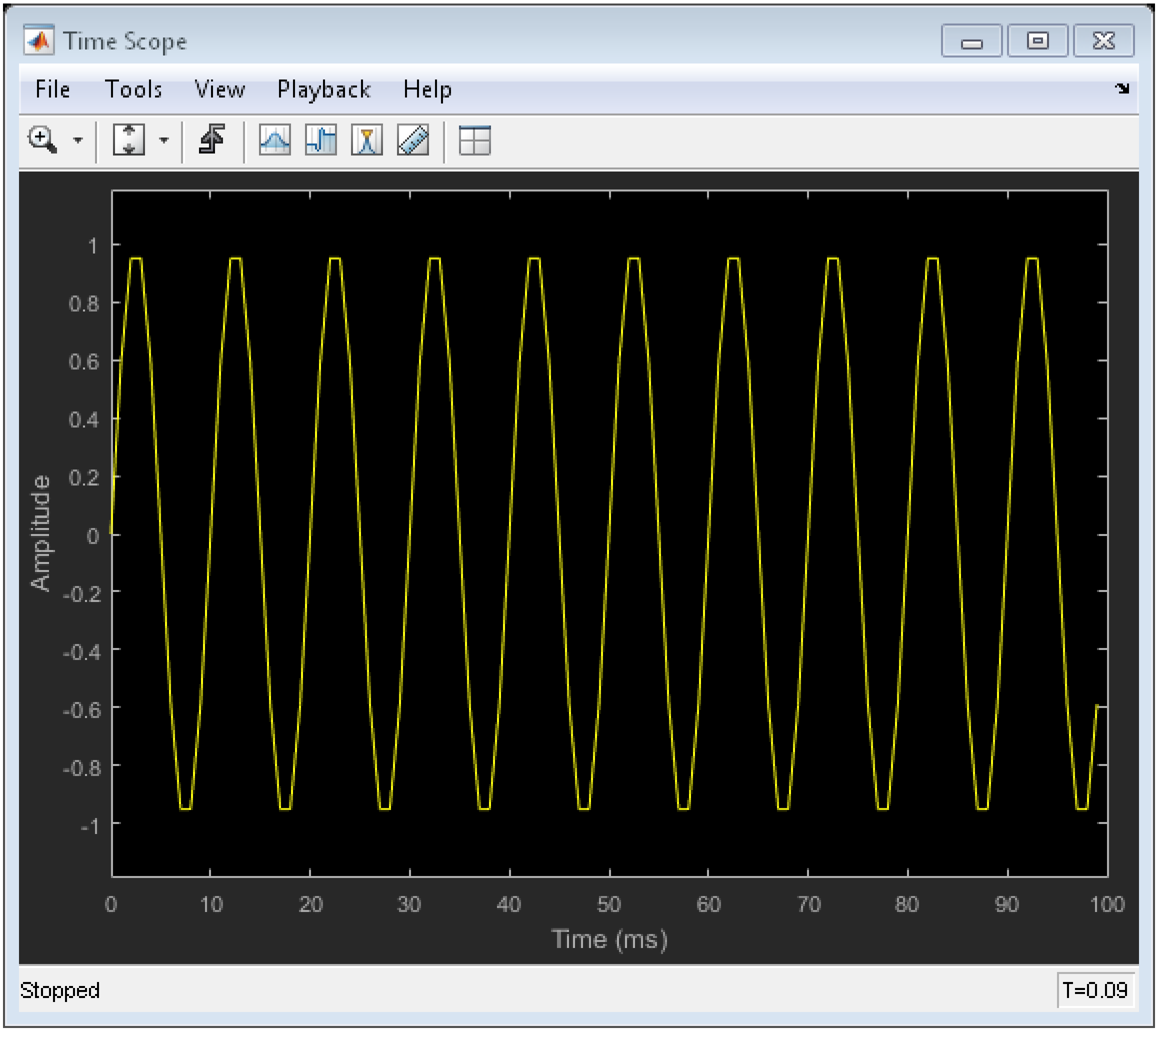
Create `dsp.SineWave` and `dsp.TimeScope` objects. Run the scope to display the signal

```
sine = dsp.SineWave('Frequency',100,'SampleRate',1000);
sine.SamplesPerFrame = 10;
scope = dsp.TimeScope('SampleRate',sine.SampleRate,'TimeSpan',0.1);
for ii = 1:10
     x = sine();
     scope(x);
end
```



Run the `release` method to allow changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope)
```



Close the Time Scope window and clear the variables.

```
clear scope sine x;
```

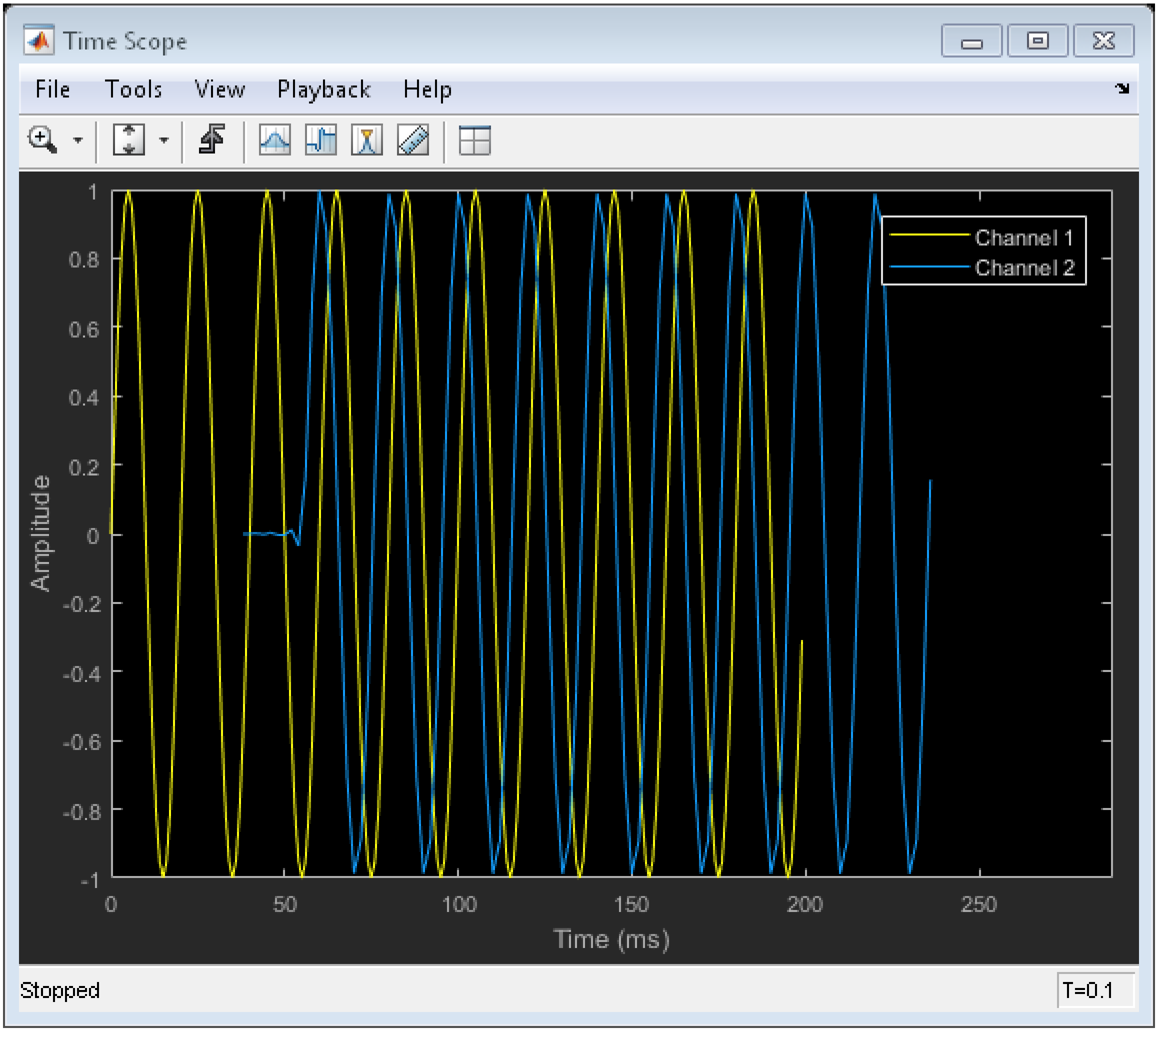
View Sine Wave Input Signals at Different Sample Rates and Offsets

Create a `dsp.SineWave` with a 1000 Hz sampling frequency. Create a `dsp.FIRDecimator` object to decimate the sine wave by 2. Create a `dsp.TimeScope` object with two input ports.

```
Fs = 1000;  % Sampling frequency
sine = dsp.SineWave('Frequency',50,...
   'SampleRate',Fs, ...
   'SamplesPerFrame',100);
decimate = dsp.FIRDecimator; % To decimate sine by 2
scope = dsp.TimeScope(2,[Fs Fs/2], ...
   'TimeDisplayOffset',[0 38/Fs], ...
   'TimeSpan',0.25, ...
   'YLimits',[-1 1], ...
   'ShowLegend', true);
```

Call the `dsp.SineWave` object to create a sine wave signal. Use the `dsp.FIRDecimator` object to create a second signal that equals the original signal, but decimated by a factor of 2. Display the signals by calling the `dsp.TimeScope` object.

```
for ii = 1:2
     xsine = sine();
     xdec = decimate(xsine);
     scope(xsine,xdec)
end
release(scope)
```



Close the Time Scope window and clear the variables.

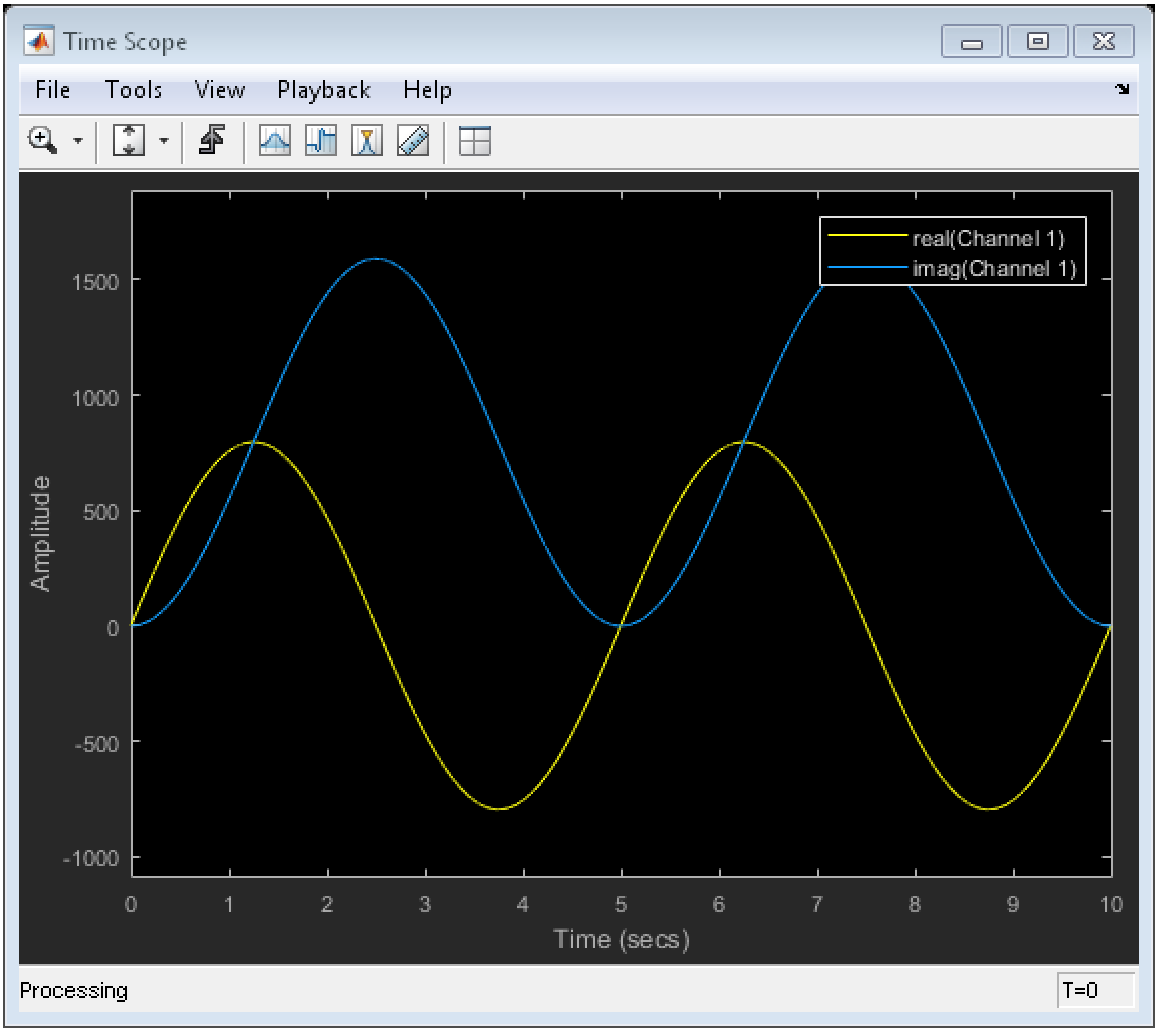
```
clear scope Fs sine decimate ii xsine xdec
```

Display Complex-Valued Input Signal

Use the time scope to show complex signals.

Create a vector representing a complex-valued sinusoidal signal, and create a `dsp.TimeScope` object. Call the scope to display the signal.

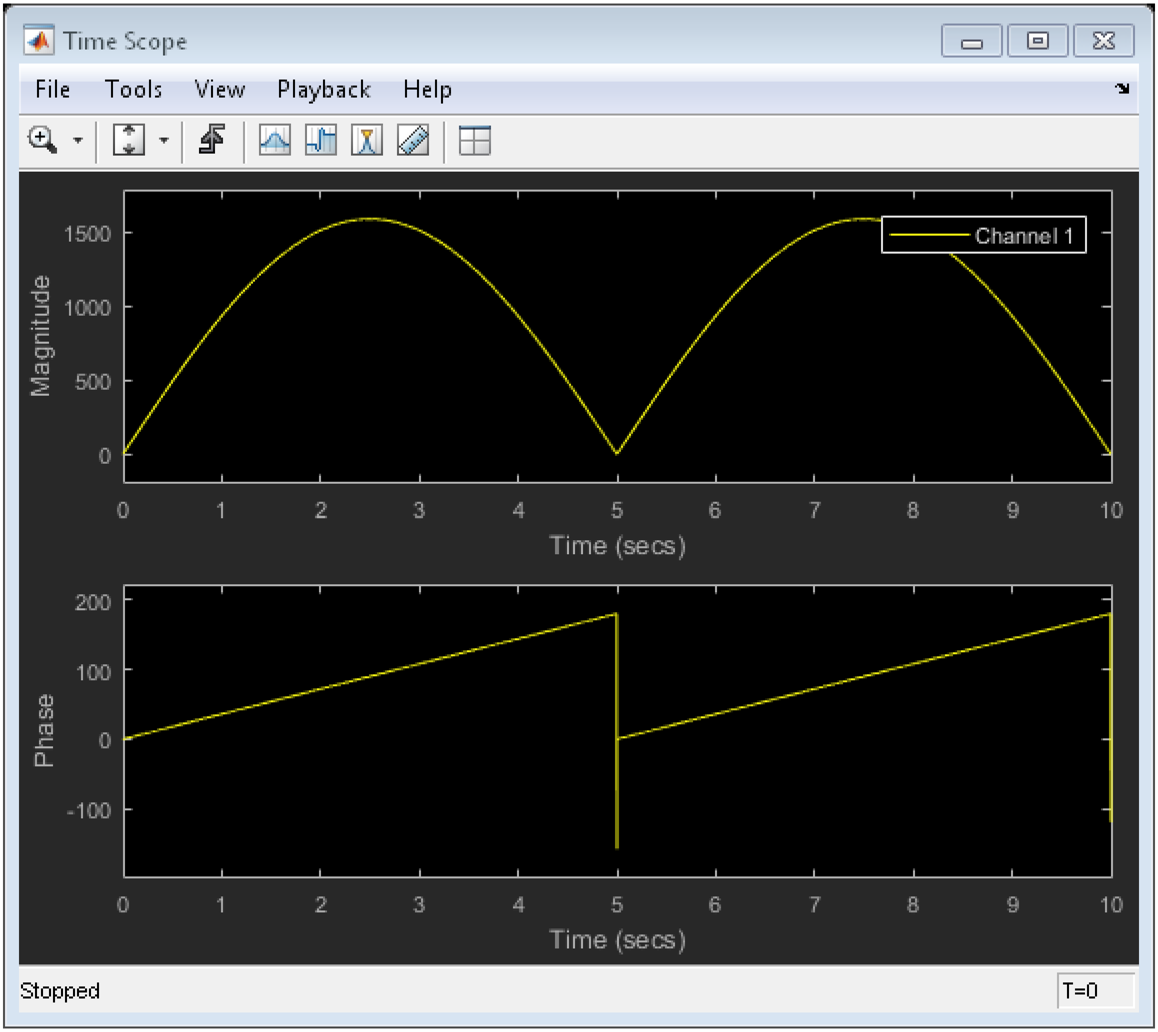
```
fs = 1000;
t = (0:1/fs:10)';
CxSine = cos(2*pi*0.2*t) + 1i*sin(2*pi*0.2*t);
CxSineSum = cumsum(CxSine);
scope = dsp.TimeScope(1,fs,'TimeSpanSource','Auto','ShowLegend',1);
scope(CxSineSum);
scope.AxesScaling = 'Auto';
```



By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display.

Change the `PlotAsMagnitudePhase` property to `true` and call `release`.

```
scope.PlotAsMagnitudePhase = true;
release(scope)
```



Time Scope now plots the magnitude and phase of the input signal on two separate axes within the same active display. The top axes display magnitude and the bottom axes display the phase, in degrees.

Close the Time Scope window and remove the variables you created.

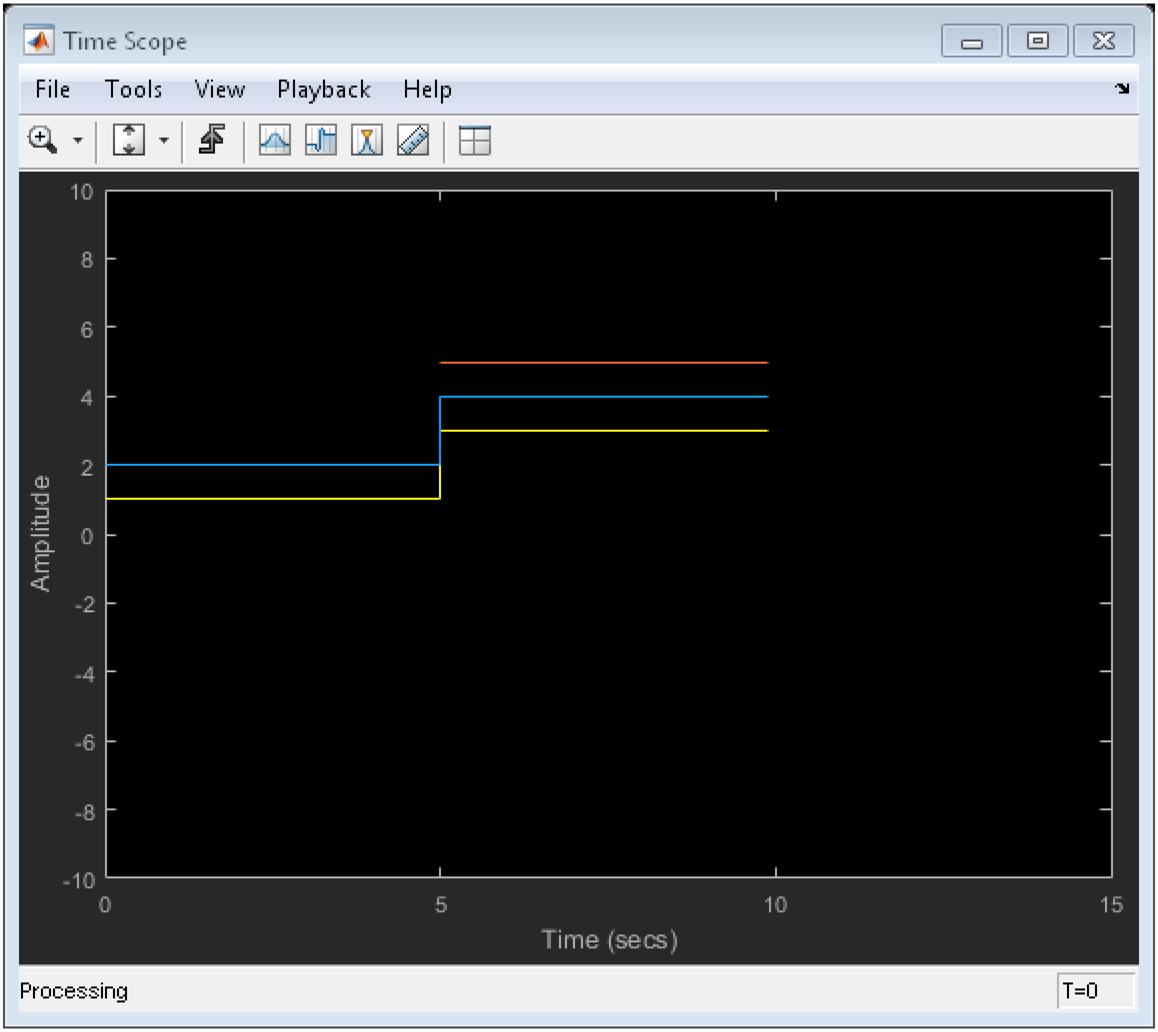
```
clear scope fs t CxSine CxSineSum
```

Display Input Signal of Changing Size

Use a Time Scope to display a variable-size signal.

Create a vector that represents a two-channel constant signal. Create another vector that represents a three-channel constant signal. Construct a `dsp.TimeScope` object with two input ports. Call the scope to display the signal.

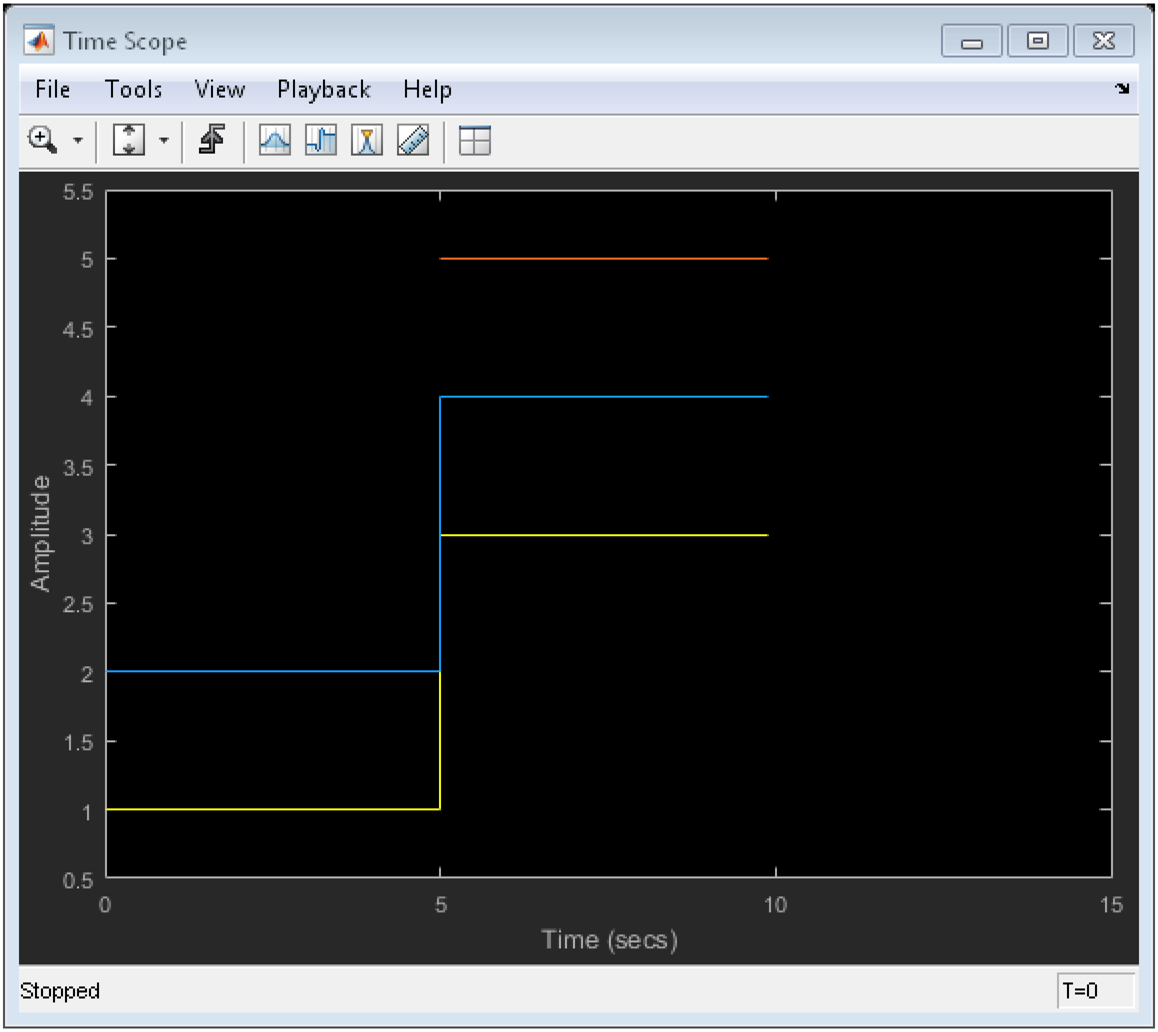
```
fs = 10;
sigdim2 = [ones(5*fs,1) 1+ones(5*fs,1)];                    % 2-dim 0-5 s
sigdim3 = [2+ones(5*fs,1) 3+ones(5*fs,1) 4+ones(5*fs,1)];  % 3-dim 5-10 s
scope = dsp.TimeScope(2,fs,'TimeSpanSource','Property');
scope.PlotType = 'Stairs';
scope.TimeSpanOverrunAction = 'Scroll';
scope.TimeDisplayOffset = [0 0 5];
scope([sigdim2; sigdim3(:,1:2)], sigdim3(:,3));
```



In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots only the two-channel signal, `sigdim2`. After 5 seconds, Time Scope also plots the three-channel signal, `sigdim3`.

Run the `release` method to enable changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope)
```



Close the Time Scope window and remove the variables you created from the workspace.

```
clear scope fs sigdim2 sigdim3
```

Use Bilevel Measurements Panel with Clock Input Signal

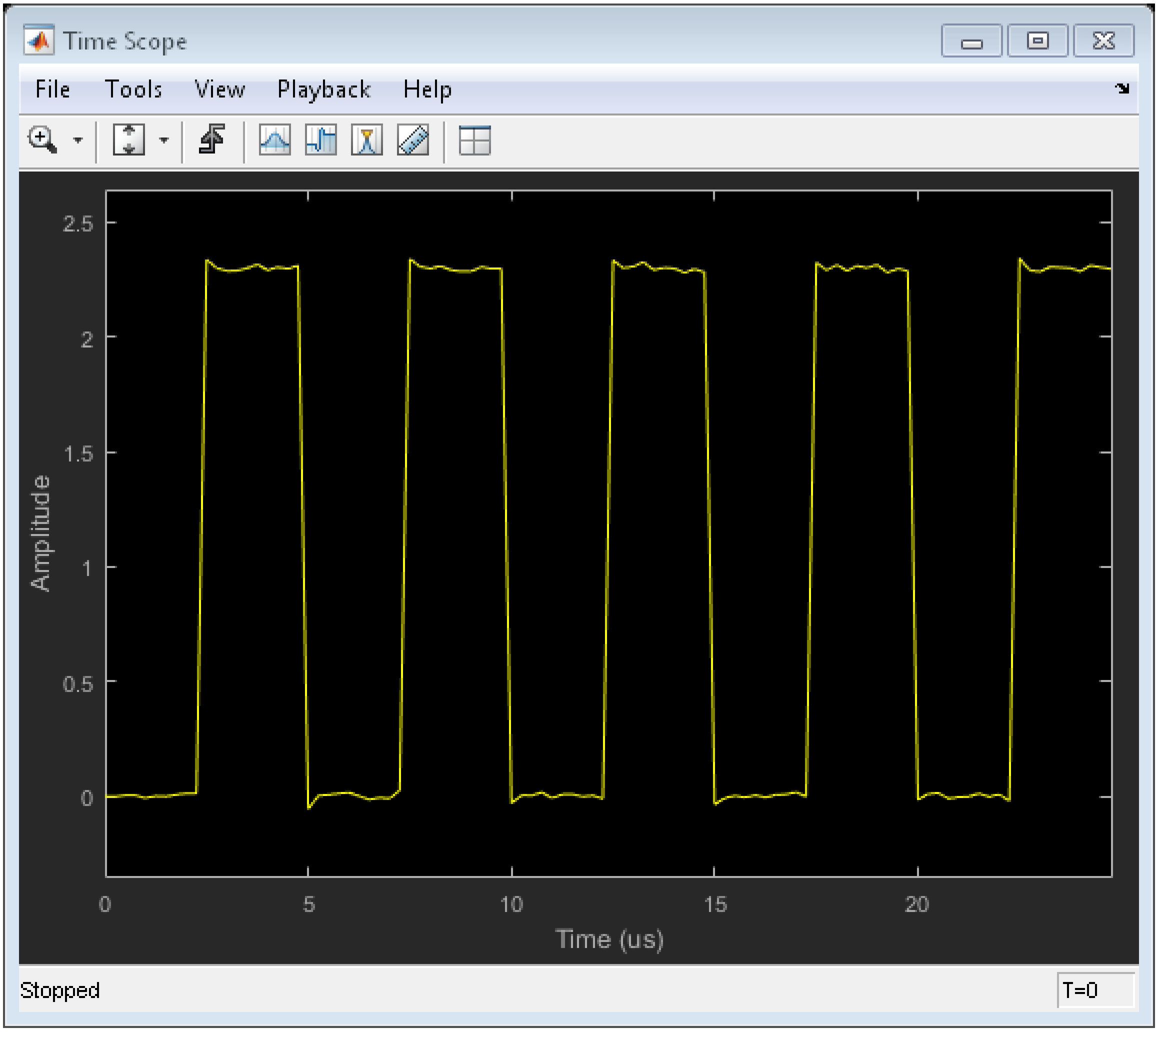
Create and Display Clock Input Signal

Load the clock data, `x` and `t`. Find the sample time, `ts`.

```
load clockex
ts = t(2)-t(1);
```

Create a `dsp.TimeScope` object and call the object to display the signal. To autoscale the axes and enable changes to property values and input characteristics, call `release`.

```
scope = dsp.TimeScope(1,1/ts,'TimeSpanSource','Auto');
scope(x);
release(scope)
```

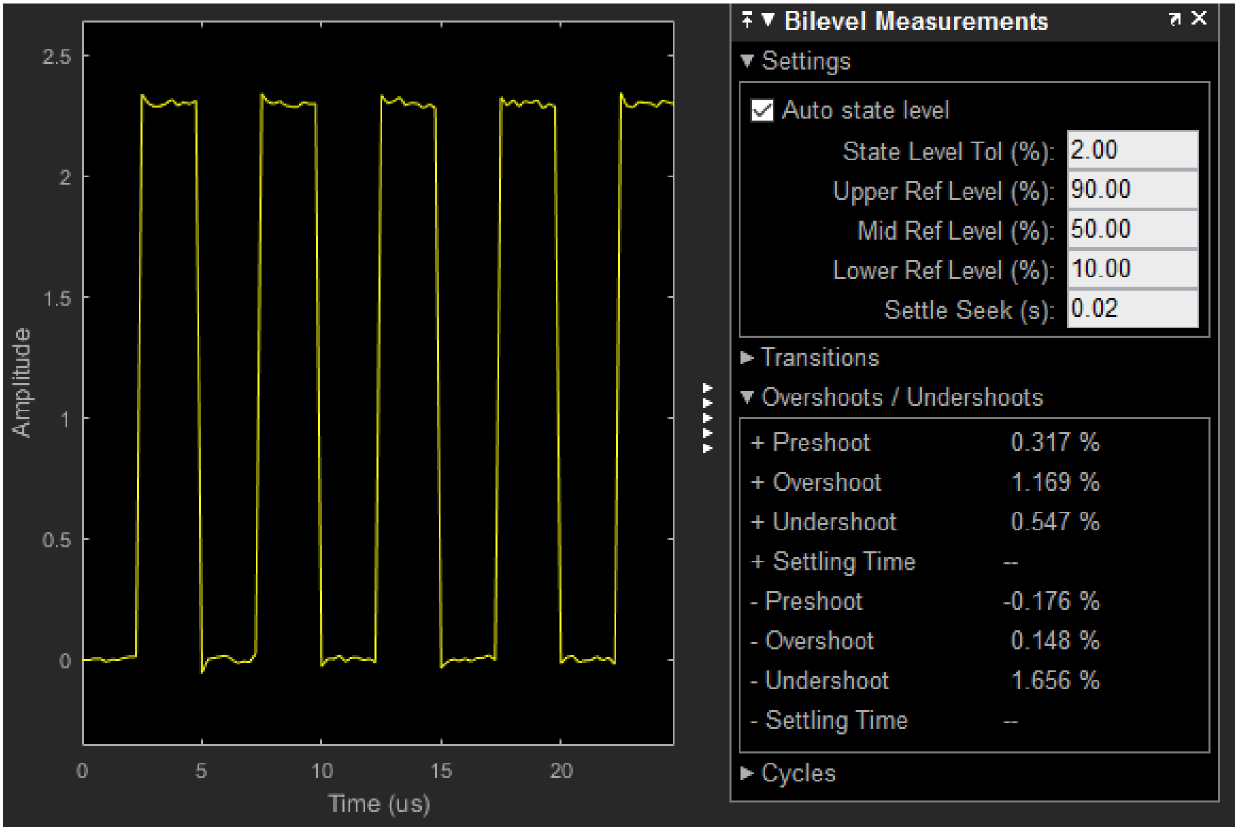


Use Bilevel Measurements Panel to Find Settling Time

1. From the Time Scope menu, select **Tools > Measurements > Bilevel Measurements**.

2. Expand the **Settings** pane and the **Overshoots / Undershoots** pane.

Initially, the Time Scope does not display the rising edge **Settling Time** parameter. This absence occurs because the default value of the **Settle Seek** parameter is longer than the entire simulation duration.



3. In the **Settle Seek** box, enter `2e-6` and press **Enter**.

Time Scope now displays a rising edge **Settling Time** value of `118.392` ns.

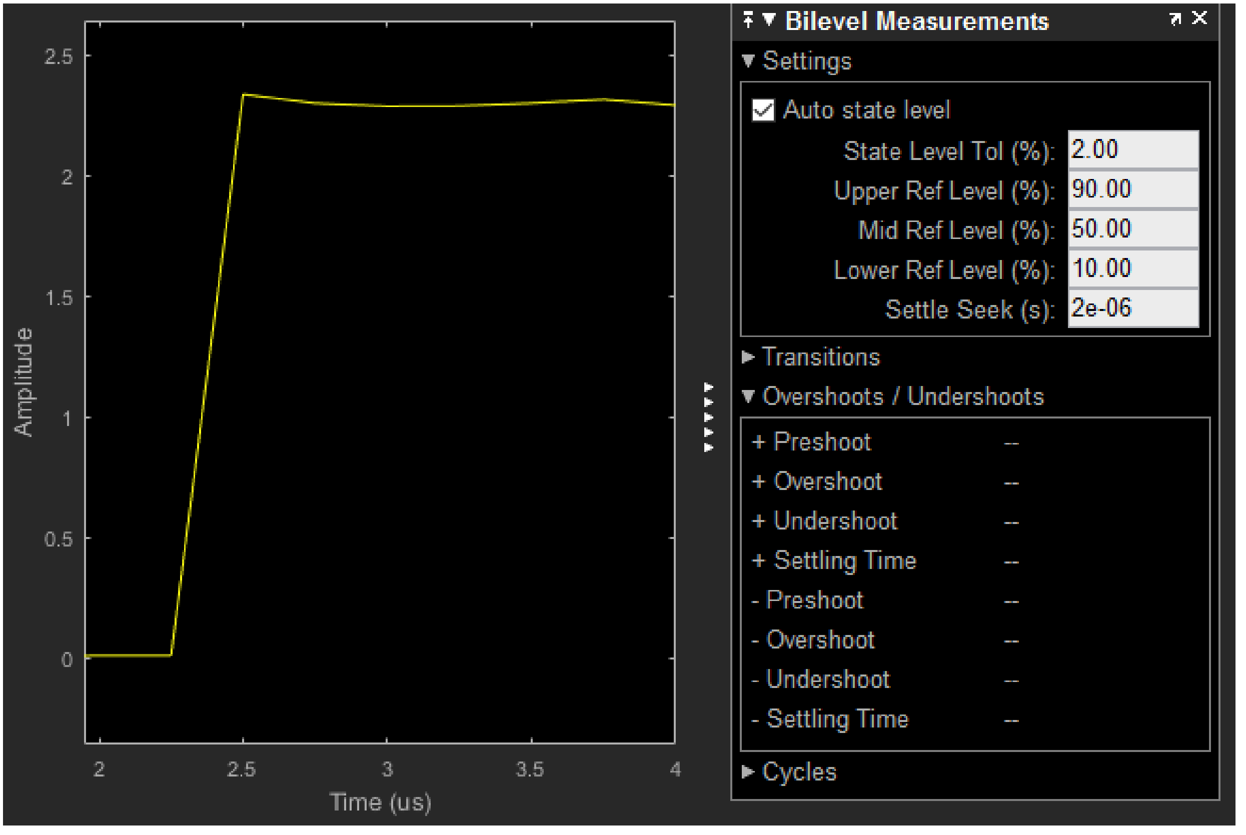
This settling time value is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition.

4. In the Time Scope toolbar, click the arrow next to the Zoom button, and then click the Zoom X button.

5. Click the display near a value of 2 microseconds on the time axis.

6. Drag your cursor right and release it near a value of 4 microseconds on the time axis.

Time Scope updates the rising edge **Settling Time** value to reflect the new time window.



7. Close the Time Scope and remove the variables you created from the workspace.

```
clear scope x t ts
```

Find Heart Rate Using Peak Finder Panel with ECG Input Signal

Use Peak Finder panel of the Time Scope to measure a heart rate.

Create and Display ECG Signal

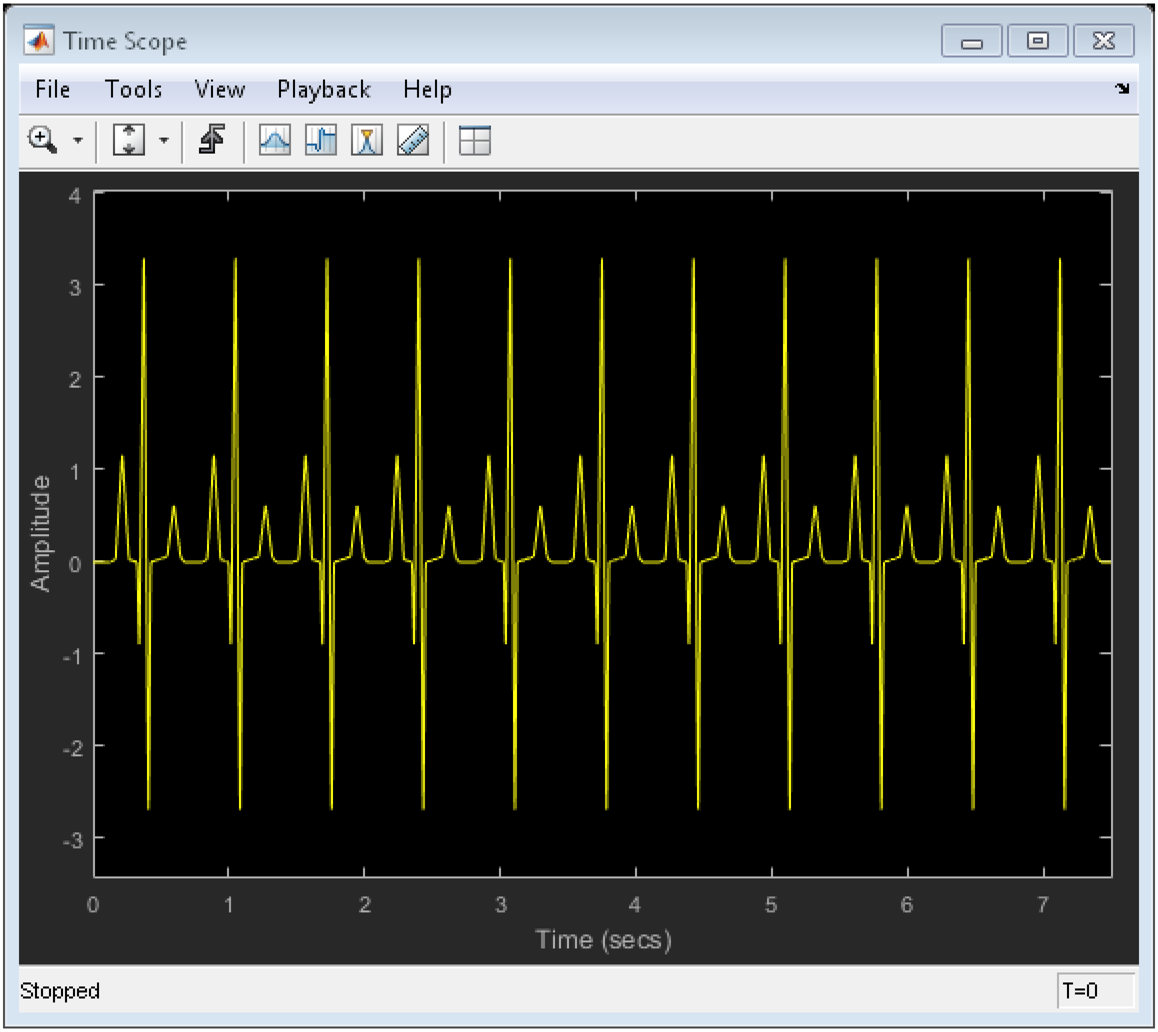
Create the electrocardiogram (ECG) signal. The custom `ecg` fuction helps generate the heartbeat signal.

```
function x = ecg(L)
a0 = [0,  1, 40,  1,   0, -34, 118, -99,   0,   2,  21,   2,   0,   0,   0];
d0 = [0, 27, 59, 91, 131, 141, 163, 185, 195, 275, 307, 339, 357, 390, 440];
a = a0 / max(a0);
d = round(d0 * L / d0(15));
d(15) = L;
for i = 1:14
    m = d(i) : d(i+1) - 1;
    slope = (a(i+1) - a(i)) / (d(i+1) - d(i));
    x(m+1) = a(i) + slope * (m - d(i));
end
```

```
x1 = 3.5*ecg(2700).';
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

Create a `dsp.TimeScope` object and call the object to display the signal. To autoscale the axes and enable changes to property values and input characteristics, call `release`.

```
scope = dsp.TimeScope(1,1/ts,'TimeSpanSource','Auto');
scope(mhb);
release(scope)
```

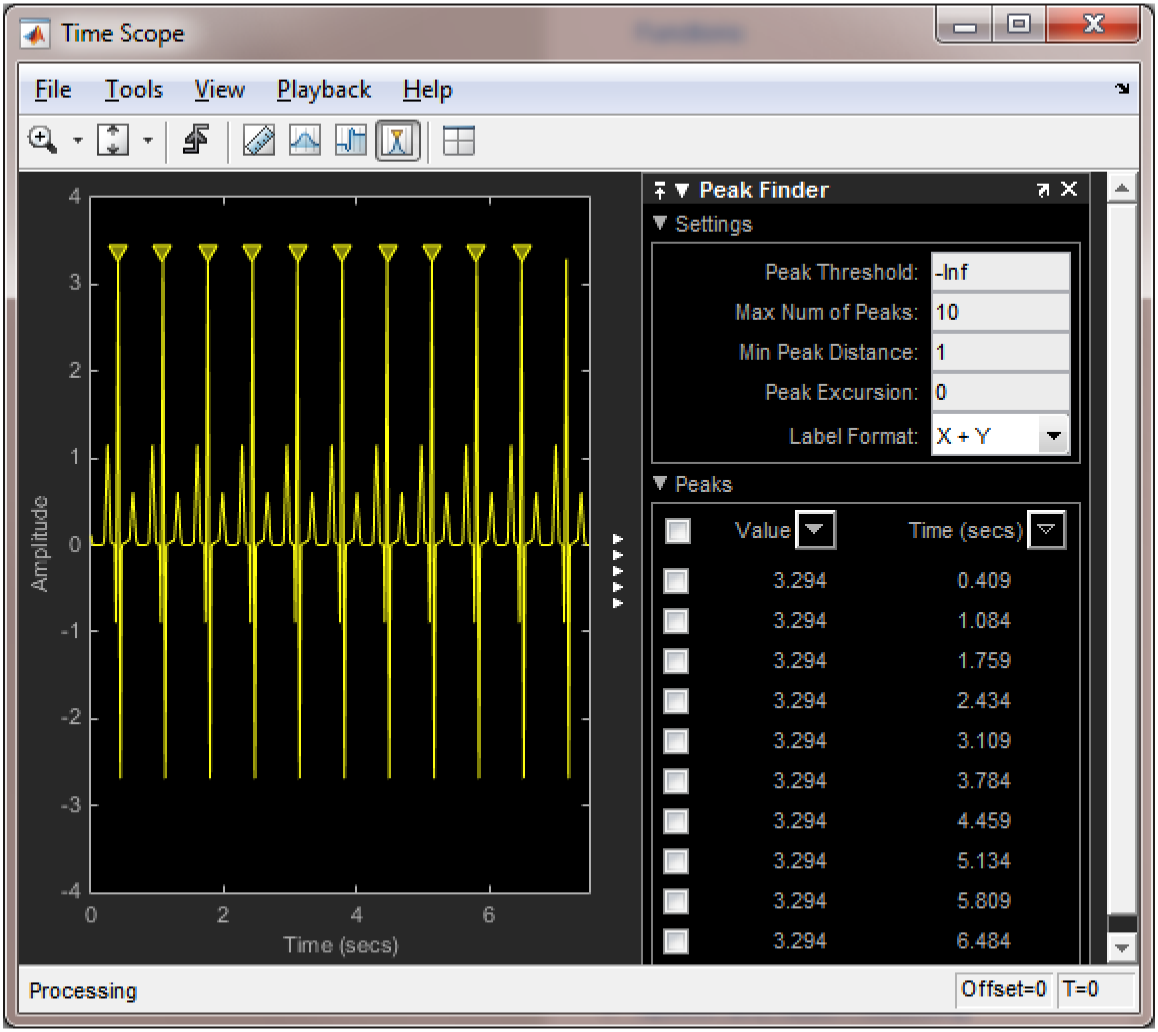


Find Heart Rate

Use the Peak Finder measurements to measure the time between heart beats.

1 In the Time Scope menu, select **Tools > Measurements > Peak Finder**.
2 Expand the **Settings** pane.
3 In the **Max Num of Peaks** property, enter 10 and press **Enter**.

In the **Peaks** pane, Time Scope displays a list of ten peak amplitude values and the times at which they occur.



The list of peak values shows a constant time difference of 0.675 second between each heartbeat. Based on the following equation, the heart rate of this ECG signal is about 89 beats per minute.

$$\frac{60\ \mathrm{s/min}}{0.675\ \mathrm{s/beat}} = 88.89\ \mathrm{bpm}$$

Close the Time Scope window and remove the variables you created from the workspace.

```
clear scope x1 y1 n del mhb ts
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

hide

System object: dsp.TimeScope
Package: dsp

Hide time scope window

Syntax

```
hide(scope)
```

Description

`hide(scope)` hides the time scope window, associated with System object, `scope`.

See Also

dsp.TimeScope.show

reset

System object: dsp.TimeScope
Package: dsp

Reset internal states of time scope object

Syntax

```
reset(scope)
```

Description

`reset(scope)` sets the internal states of the `TimeScope` object `scope` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the Time Scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Examples

View a sine wave on the time scope. When you finish the simulation, pause for 5 seconds and then reset the screen. Then, view a different sine wave on the same time scope.

```
sinSignal1 = dsp.SineWave('Frequency', 100, 'SampleRate', 1000, 'SamplesPerFrame', 10);
sinSignal2 = dsp.SineWave('Frequency', 50, 'SampleRate', 1000, 'SamplesPerFrame', 10);

scope = dsp.TimeScope('SampleRate', sinSignal1.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
     x = step(sinSignal1);
     step(singSignal2, x);
end

% Pause and then reset internal states
```

```
pause(5);
reset(scope);

for ii = 1:10
     x = step(sinSignal1);
     step(sinSignal2, x);
end

release(scope);
```

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

dsp.TimeScope.hide

step

System object: dsp.TimeScope
Package: dsp

Display signal in time scope figure

Syntax

```
step(scope,signal)
step(scope,signal1,signal2,...,signalN)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(scope,signal)` displays the signal, `signal`, in the time scope figure.

`step(scope,signal1,signal2,...,signalN)` displays the signals `signal1`, `signal2`,...,`signalN` in the time scope figure when you set the `NumInputPorts` property to `N`. In this case, `signal1`, `signal2`,...,`signalN` can have different data types and dimensions.

dsp.TransferFunctionEstimator System object

Package: dsp

Estimate transfer function

Description

The `dsp.TransferFunctionEstimator` computes the transfer function of a system, using the Welch algorithm and the Periodogram method.

To implement the transfer function estimation object:

1. Define and set up your transfer function estimator object. See "Construction" on page 4-1785.
2. Call step to implement the estimator according to the properties of `dsp.TransferFunctionEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`tfe = dsp.TransferFunctionEstimator` returns a System object, `tfe`, that computes the transfer function of real or complex signals. This System object uses the periodogram method and Welch's averaged, modified periodogram method.

`tfe = dsp.TransferFunctionEstimator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `Transfer Function Estimator` System object, `tfe`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Transfer Function Estimator computes the current estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property. The default value is `8`.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto' | 'Property'`. The default value is `'Auto'`. If you set this property to `'Auto'`, the Transfer function Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Transfer Function Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is `128`.

Window

Window function

Specify a window function for the Transfer Function estimator as one of `'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'`. The default value is `'Hann'`.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default value is `60 dB`.

FrequencyRange

Frequency range of the transfer function estimate

Specify the frequency range of the transfer function estimator as one of `'twosided' | 'onesided' | 'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the transfer function estimator computes the onesided transfer function of real input signals, `x` and `y`. If the FFT length, NFFT, is even, the length of the transfer function estimate is `NFFT/2+1` and is computed over the interval `[0,SampleRate/2]`. If NFFT is odd, the length of the transfer function estimate is equal to `(NFFT+1)/2` and the interval is `[0,SampleRate/2]`.

If `FrequencyRange` is set to `'twosided'`, the transfer function estimator computes the twosided transfer function of complex or real input signals, `x` and `y`. The length of the transfer function estimate is equal to NFFT and is computed over `[0, SampleRate]`.

If you set the `FrequencyRange` to `'centered'`, the transfer function estimator computes the centered twosided transfer function of complex or real input signals, `x` and `y`. The length of the transfer function estimate is equal to NFFT and it is computed over `[-SampleRate/2, SampleRate/2]` for even lengths, and `[-SampleRate/2, SampleRate/2]` for odd lengths. The default value is `'Twosided'`.

OutputCoherence

Magnitude squared coherence estimate

Specify `true` to compute and output the magnitude squared coherence estimate using Welch's averaged, modified periodogram method. The magnitude squared coherence estimate has values between 0 and 1 that indicate the correspondence at each frequency between two input signals. If you specify `false`, the magnitude squared coherence estimate is not computed. The default value is `false`.

Methods

getFrequencyVector	Get vector of frequencies at which transfer function is estimated
getRBW	Get resolution bandwidth of transfer function

reset	Reset internal states of transfer function estimator
step	Estimate transfer function of system

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Estimate transfer function of a system represented by an order-64 FIR filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

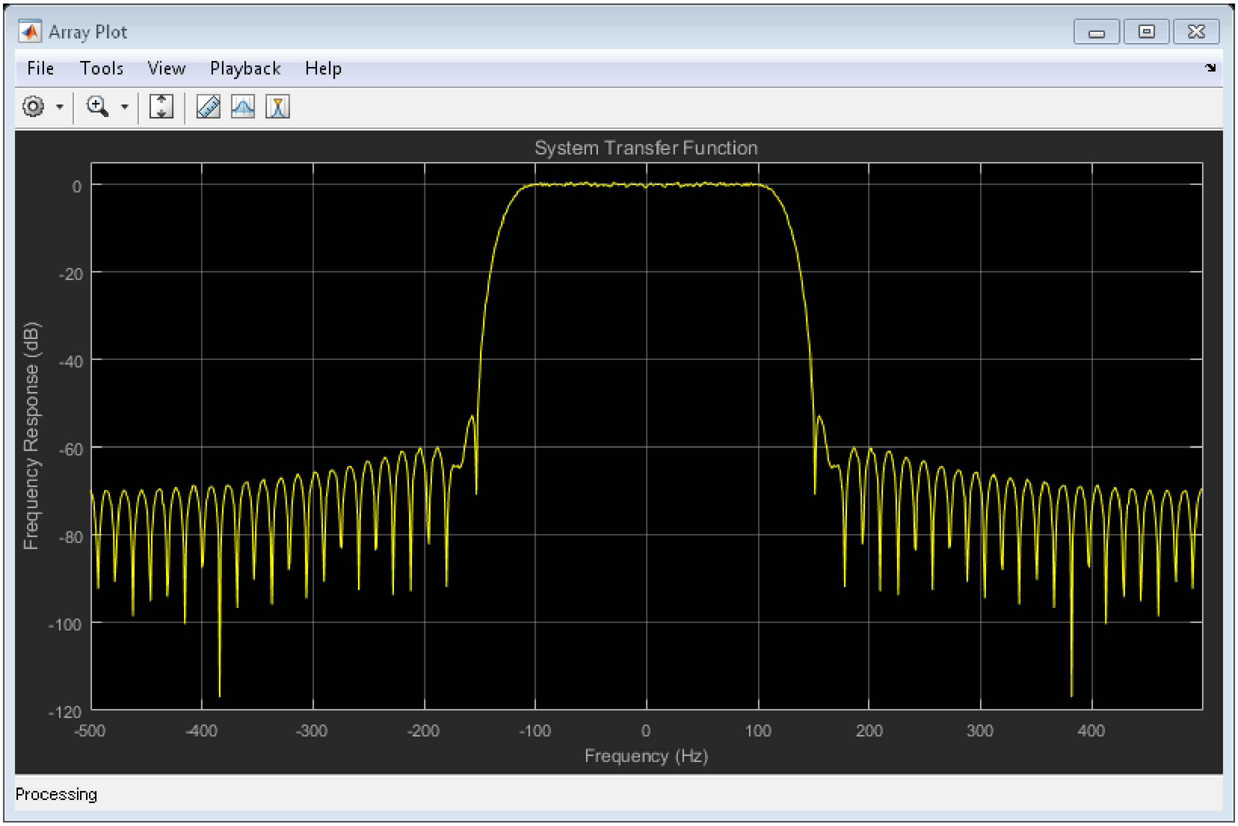
Generate a sine wave. Use the dsp.TransferFunctionEstimator System object to estimate the system transfer function, and the dsp.ArrayPlot System object to display it.

```
sin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
sin.SamplesPerFrame = 1000;
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
        [-120 5],'YLabel','Frequency Response (dB)',...
        'XLabel','Frequency (Hz)',...
        'Title','System Transfer Function');
```

Create an FIR Filter System object of order 64 and (normalized) cutoff frequency of 1/4. Add random noise to the sine wave. Step through the System objects to obtain the data streams, and plot the log of the magnitude of the transfer function.

```
firFilt = dsp.FIRFilter('Numerator',fir1(64,1/4));
for ii = 1:100
x = sin() + 0.05*randn(1000,1);
```

```
y = firFilt(x);
Txy = tfe(x,y);
aplot(20*log10(abs(Txy)))
end
```



Algorithms

Given two signals `x` and `y` as inputs. We first window the two inputs, and scale them by the window power. We then take FFT of the signals, calling them X and Y. This is followed by calculating P_{xx} which is the square magnitude of the FFT, X, and P_{yx} which is X multiplied by the conjugate of Y. The transfer function estimate is calculated by dividing P_{yx} by P_{xx}.

For further information refer to the "Algorithms" on page 2-1592 section in Spectrum Analyzer, which uses the same algorithm.

The magnitude squared coherence, C_{xy}, is defined as

$$C_{xy} = \frac{\left(abs\left(P_{xy}\right).\hat{}2\right)}{\left(P_{xx}.*P_{yy}\right)}$$

where, x and y are input signals. P_{xx} and P_{yy} are the power spectral density (PSD) estimates of x and y, respectively. P_{xy} is the cross power spectral density (CPSD) estimate of x and y.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- "System Objects in MATLAB Code Generation" (MATLAB Coder)

- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

System Objects

dsp.CrossSpectrumEstimator | dsp.SpectrumAnalyzer | dsp.SpectrumEstimator

Introduced in R2013b

getFrequencyVector

System object: dsp.TransferFunctionEstimator
Package: dsp

Get vector of frequencies at which transfer function is estimated

Syntax

`getFrequencyVector(tfe)`

Description

`getFrequencyVector(tfe)` returns the vector of frequencies at which the transfer function is estimated.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length `NFFT/2+1`, and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length `(NFFT+1)/2` and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval `[0, SampleRate]`. If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range `[-SampleRate/2, SampleRate/2]` and `[-SampleRate/2, SampleRate/2]` for even and odd length `NFFT`, respectively.

getRBW

System object: dsp.TransferFunctionEstimator
Package: dsp

Get resolution bandwidth of transfer function

Syntax

```
getRBW(tfe)
```

Description

`getRBW(tfe)` returns the resolution bandwidth of the transfer function.

The resolution bandwidth, `RBW`, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to `ENBW*SampleRate/ L`, where `L` is the input length, and `ENBW` is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, `RBW=enbw(hann(1024))*100/1024`.

reset

System object: dsp.TransferFunctionEstimator
Package: dsp

Reset internal states of transfer function estimator

Syntax

`reset(sysObj)`

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.TransferFunctionEstimator
Package: dsp

Estimate transfer function of system

Syntax

```
Txy = step(tfe,x,y)
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Txy = step(tfe,x,y)` computes the transfer function, `Txy`, of the system with input x and output y. This computation uses the Welch's averaged periodogram method. `Txy` is the ratio of the Cross Power Spectral Density of `x` and `y`, and the Power Spectral Density of `x`. The columns of `x` and `y` are treated as independent channels.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.TransitionMetrics System object

Package: dsp

Transition metrics of bilevel waveforms

Description

The `TransitionMetrics` object extracts information such as duration, slew rate, and reference-level crossings for each transition found in the bilevel waveform. The `TransitionMetrics` object can additionally return preshoot, postshoot and settling metrics for the regions immediately before and after each transition.

To obtain transition metrics for a bilevel waveform:

1. Define and set up your transition metrics. See "Construction" on page 4-1797.
2. Call step to calculate the transition metrics according to the properties of `dsp.TransitionMetrics`. The behavior of step is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`tm = dsp.TransitionMetrics` creates a transition metrics System object, `tm`. The object computes the rise time, fall time and width of a pulse. `TransitionMetrics` additionally computes cycle metrics such as pulse separations, periods, and duty cycles.

`tm = dsp.TransitionMetrics('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `TransitionMetrics` System object, `tm`, with each specified property set to the specified value.

Properties

MaximumRecordLength

Maximum samples to preserve between calls to step. This property requires a positive integer that specifies the maximum number of samples to save between calls to the step method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when RunningMetrics is true and is tunable.

Default: 1000

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a 3-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the low and high states of the waveform when computing the duration of each transition.

Default: [10 50 90]

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: 2

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set totrue, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of PostshootSeekFactor times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

Default: false

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Default: 3

PreshootOutputPort

Enable pretransition aberration metrics. If the `PreshootOutputPort` property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

Default: `false`

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Default: 3

RunningMetrics

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to `step` is made with enough data to compute all enabled metrics for that transition.

Default: `false`

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

Default: `1`

SettlingOutputPort

Enable settling metrics. If `SettlingOutputPort` is set to true, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time `step` is called if the `RunningMetrics` property is set to `true`.

Default: `false`

SettlingSeekDuration

Duration of time over which to search for settling. This property is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `TransitionMetrics` object reports `NaN` for all settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2-element numeric row vector that contains the low and high state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state level computation. If the `StateLevelsSource` property is set to `'Auto'`, the first record sent to `step` is sent to dsp.StateLevels with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

`TimeInputPort`

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

Default: `false`

Methods

plot	Plots signal and metrics computed in last call to `step`
reset	Reset the running transition metrics object
step	Transition metrics of bilevel waveform

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Transition and Preshoot Information of a 2.3 V Step Waveform

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute transition and preshoot information of a 2.3 V step waveform sampled at 4 MHz. Load the data.

```
load('transitionex.mat', 'x');
```

Construct the `dsp.TransitionMetrics` object. Set the `SampleRate` property to `4 MHz`, `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data. Set the `PreshootOutputPort` property to `true` to output pretransition aberration metrics when you call `step`.

```
tm = dsp.TransitionMetrics('SampleRate',4e6, ...
                           'StateLevelsSource','Auto', ...
                           'PreshootOutputPort',true)
```

```
tm = 

  dsp.TransitionMetrics with properties:

            StateLevelsSource: 'Auto'
                  StateLevels: [0 2.3000]
    PercentStateLevelTolerance: 2
       PercentReferenceLevels: [10 50 90]
               RunningMetrics: false
                TimeInputPort: false
                   SampleRate: 4000000
           PreshootOutputPort: true
           PreshootSeekFactor: 3
          PostshootOutputPort: false
           SettlingOutputPort: false
```

Call `step` to compute the transition and preshoot information. Plot the result.

```
[transition, preshoot] = tm(x)
```

```
plot(tm)
```

```
transition =

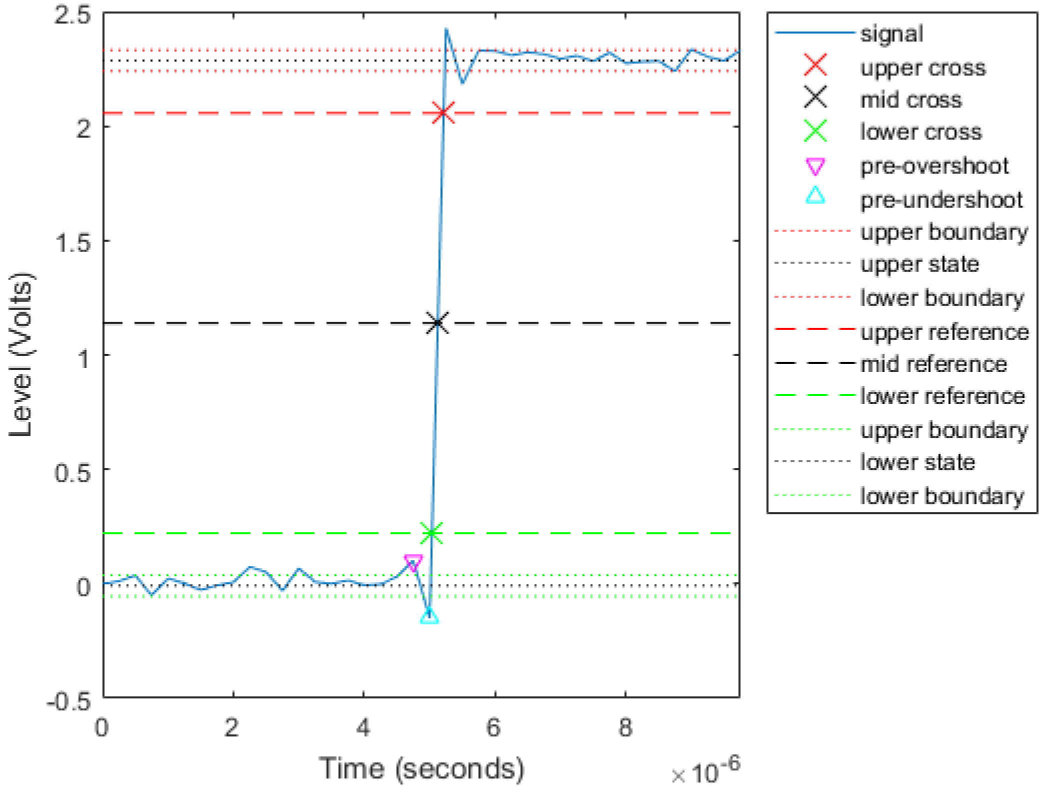
  struct with fields:

        Duration: 1.7800e-07
        Polarity: 1
        SlewRate: 1.0310e+07
     MiddleCross: 5.1250e-06
      LowerCross: 5.0360e-06
      UpperCross: 5.2140e-06

preshoot =

  struct with fields:

             Overshoot: 4.8050
            Undershoot: 6.1798
        OvershootLevel: 0.1020
       UndershootLevel: -0.1500
      OvershootInstant: 4.7500e-06
     UndershootInstant: 5.0000e-06
```



Transition, Postshoot, and Settling Information of a 2.3 V Step Waveform

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute transition, postshoot, and settling information of a 2.3 V step waveform sampled at 4 MHz. Load the data along with the sampling instants.

```
load('transitionex.mat', 'x', 't');
```

Construct the `dsp.TransitionMetrics` object. Set the `TimeInputPort` property to `true`, `StateLevels` property to `[0 2.3]` to match waveform statelevels. To output the postshoot information and settling information, set the `PostShootOutputPort` and

`SettlingOutputPort` properties to `true`. Set the `SettlingSeekDuration` property to `2 ms`.

```
tm = dsp.TransitionMetrics('TimeInputPort',true, ...
                                 'StateLevels',[0 2.3], ...
                                 'PostshootOutputPort',true, ...
                                 'SettlingOutputPort',true, ...
                                 'SettlingSeekDuration',2e-6)
```

```
tm =

  dsp.TransitionMetrics with properties:

             StateLevelsSource: 'Property'
                   StateLevels: [0 2.3000]
    PercentStateLevelTolerance: 2
        PercentReferenceLevels: [10 50 90]
                RunningMetrics: false
                 TimeInputPort: true
             PreshootOutputPort: false
           PostshootOutputPort: true
           PostshootSeekFactor: 3
            SettlingOutputPort: true
          SettlingSeekDuration: 2.0000e-06
```

Compute the transition, postshoot, and settling information with `step` and plot the result.

```
 [transition, postshoot, settling] = tm(x,t)
 plot(tm)
```

```
transition =

  struct with fields:

       Duration: 1.7846e-07
       Polarity: 1
       SlewRate: 1.0310e+07
    MiddleCross: 5.1261e-06
     LowerCross: 5.0369e-06
     UpperCross: 5.2153e-06
```

```
postshoot = 

  struct with fields:

            Overshoot: 5.5483
           Undershoot: 5.1051
       OvershootLevel: 2.4276
      UndershootLevel: 2.1826
     OvershootInstant: 5.2500e-06
    UndershootInstant: 5.5000e-06

settling = 

  struct with fields:

    Duration: 4.9529e-07
       Level: 2.2540
     Instant: 5.6214e-06

dsp.PulseMetrics | dsp.StateLevels

Introduced in R2012a

plot

System object: dsp.TransitionMetrics
Package: dsp

Plots signal and metrics computed in last call to `step`

Syntax

`plot(tm)`

Description

`plot(tm)` plots the signal and metrics resulting from the last call of the step method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When you set the `TransitionOutputPort` property to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or non-inverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the upper- and lower-state boundaries over the specified seek duration are plotted.

reset

System object: dsp.TransitionMetrics
Package: dsp

Reset the running transition metrics object

Syntax

`reset(tm)`

Description

`reset(tm)` clears information from previous calls to step.

step

System object: dsp.TransitionMetrics
Package: dsp

Transition metrics of bilevel waveform

Syntax

```
PULSE = step(tm,X)
[PULSE,CYCLE] = step(tm,X)
[PULSE,TRANSITION] = step(tm,X)
[PULSE,PRESHOOT] = step(tm,X)
[PULSE,POSTSHOOT] = step(tm,X)
[PULSE,SETTLING] = step(tm,X)
[...] = step(tm,X,T)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`PULSE = step(tm,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse

- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE,CYCLE] = step(tm,X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `X`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found the input, `X`, does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

`CYCLE` fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE,TRANSITION] = step(tm,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`TRANSITION` fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- `SlewRate` — Ratio of absolute difference between the upper- and lower-reference levels to the transition duration
- `MiddleCross` — Linearly-interpolated instant where the transition first crosses the mid-reference level
- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level
- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE,PRESHOOT] = step(tm,X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure.

`[PULSE,POSTSHOOT] = step(tm,X)` returns a structure array, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`PRESHOOT` and `POSTSHOOT` fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE,SETTLING] = step(tm,X)` returns a structure, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of `SETTLING` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

`SETTLING` fields:

- `Duration` — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- `Instant` — Instant in time where the signal enters and remains within the specified tolerance
- `Level` — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

`[PULSE,CYCLE,TRANSITION,PRESHOOT,POSTSHOOT,SETTLING] = step(tm,X)` which returns the `PULSE`, `CYCLE`, `TRANSITION`, `PRESHOOT`, `POSTSHOOT`, and `SETTLING` structure arrays when the `CycleOutputPort`, `PreshootOutputPort`, `PostshootPort`, and `SettlingOutputPort` properties are `true`. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

`[...] = step(tm,X,T)` performs the above metrics with respect to a sampled signal, whose sample values, `X`, and sample instants, `T`, are real-valued column vectors of the same length. The additional input `T` applies only when you set the `TimeInputPort` property to `true`.

dsp.UDPReceiver System object

Package: dsp

Receive UDP packets from network

Description

The `UDPReceiver` object receives UDP packets from the network.

To receive UDP packets from the network:

1. Define and set up your UDP receiver. See "Construction" on page 4-1815.
2. Call step to receive the UDP packets according to the properties of `dsp.UDPReceiver`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`udpr = dsp.UDPReceiver` returns a UDP receiver System object, `udpr`, that receives UDP packets from a specified port.

`udpr = dsp.UDPReceiver('PropertyName',PropertyValue, ...)` returns a window object, `udpr`, with each property set to the specified value.

Properties

`LocalIPPort`

Local port on which to receive data

Specify the port on which to receive data. This property is tunable in generated code but not tunable during simulation. The default is `25000`. The value can be in the range [1 65535].

`RemoteIPAddress`

Address from which data was sent

Specify the remote IP address from which to receive data. The default is `'0.0.0.0'`, which indicates that data can be accepted from any remote IP address.

`ReceiveBufferSize`

Maximum size of internal buffer

Specify the size of the buffer that receives UDP packets, in bytes. The default is `8192`.

`MaximumMessageLength`

Maximum size of output message

Specify the size of the output message. If received packets exceed the specified value, their contents are truncated. The default is `255`.

`MessageDataType`

Data type of the message

Specify the data type of the message as `| double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical |`. The default is `uint8`.

Methods

step	Receive UDP packet

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Byte Transmission using UDP

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.UDPReceiver` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

Send some UDP packets, and calculate the number of successfully transmitted bytes:

```
udpr = dsp.UDPReceiver('LocalIPPort',31000);
udps = dsp.UDPSender('RemoteIPPort',31000);
% To prevent the loss of packets, call the |setup| method
% on the object before the first call to the |step| method.
setup(udpr);

bytesSent = 0;
bytesReceived = 0;
dataLength = 128;

for k = 1:20
   dataSent = uint8(255*rand(1,dataLength));
   bytesSent = bytesSent + dataLength;
   udps(dataSent);
   dataReceived = udpr();
   bytesReceived = bytesReceived + length(dataReceived);
end

release(udps);
release(udpr);

fprintf('Bytes sent:     %d\n', bytesSent);
```

```
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes sent:     2560
Bytes received: 2560
```

Tune the UDP Port Number in MATLAB

Note: This example runs only in R2017a or later.

The `TunableUDP` function contains the algorithm to send and receive sine wave data over a UDP network. The inputs to this function are the local IP port number and the remote IP port number of the `dsp.UDPReceiver` and the `dsp.UDPSender` System objects, respectively. The outputs of this function are the number of bytes sent and received over the UDP network.

```
type TunableUDP
```

```
function [bytesSent,bytesReceived] = TunableUDP(localipport,remoteipport)

persistent udpRx
persistent udpSend
persistent sine

if isempty(udpRx)
    udpRx = dsp.UDPReceiver('MessageDataType','double');
    udpSend = dsp.UDPSender;
    sine = dsp.SineWave('SamplesPerFrame',250);
end

udpRx.LocalIPPort = localipport;
udpSend.RemoteIPPort = remoteipport;

bytesSent = 0;
bytesReceived = 0;
dataLength = 250;
setup(udpRx);
dataSent = sine();
udpSend(dataSent);
udpRx();

for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
```

```
    udpSend(dataSent);
    dataReceived = udpRx();
    bytesReceived = bytesReceived + length(dataReceived);
end
```

You can change the local IP port number and the remote IP port number in the generated code without having to regenerate the code. Generate a MEX file from the `TunableUDP.m` function.

```
codegen TunableUDP -args {65000,65000}
```

Call the MEX function, `TunableUDP_mex`, with `RemoteIPPort` and `LocalIPPort` numbers set to `65000`.

```
[bytesSentPort65000,bytesReceivedPort65000] = TunableUDP_mex(65000,65000)
```

```
bytesSentPort65000 =

        2500

bytesReceivedPort65000 =

        2500
```

All the 2500 bytes sent are successfully received.

Clear the MEX function and change the port numbers to `25000`, `20000`, and `45000`. Verify the number of bytes transmitted and received.

```
clear mex;
[bytesSentPort25000,bytesReceivedPort25000] = TunableUDP_mex(25000,25000)
```

```
bytesSentPort25000 =

        2500

bytesReceivedPort25000 =

        2500
```

Clear the MEX function and change the port numbers to 20000.

```
clear mex;
[bytesSentPort20000,bytesReceivedPort20000] = TunableUDP_mex(20000,20000)
```

```
bytesSentPort20000 =

        2500

bytesReceivedPort20000 =

        2500
```

Clear the MEX function and change the port numbers to 45000.

```
clear mex;
[bytesSentPort45000,bytesReceivedPort45000] = TunableUDP_mex(45000,45000)
```

```
bytesSentPort45000 =

        2500

bytesReceivedPort45000 =

        2500
```

- “Voice Over IP (VOIP)”

Algorithms

This object implements the algorithm, inputs, and outputs described on the `UDP Receive` block reference page. The object properties correspond to the block parameters, except:

- The **Output variable-size signal** parameter is not included in the System object.
- The **Sample time** parameter is not included in the System object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- "System Objects in MATLAB Code Generation" (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

The `LocalIPPort` property is tunable in generated code but not tunable during simulation.

System object: dsp.UDPReceiver
Package: dsp

Receive UDP packet

Syntax

```
P = step (udpr)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`P = step (udpr)` receives one UDP packet, `P`, from the network. The input argument, `udpr`, is a `dsp.UDPReceiver` object.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

The first time you call the `step` method on a `UDPReceiver` object, the object also allocates resources and begins listening for data. As a result, the first `step` call may not receive data. To prevent the loss of packets, call the `setup` method on the object before the first call to the `step` method.

Examples

Receive one UDP Packet

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.UDPReceiver` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

This example shows how to send and receive one UDP packet. Set up the objects to send and receive UDP packets.

```
udps = dsp.UDPSender('RemoteIPPort',31000);
udpr = dsp.UDPReceiver('LocalIPPort',31000);
```

Create some data to send and receive.

```
dataSent = uint8(255*rand(1,128));
bytessent = length(dataSent);
```

Send and receive the data. Verify that the number of bytes is equal.

```
udps(dataSent);
datain = udpr();
bytesreceived = length(datain);
isequal(length(bytessent),length(bytesreceived))
```

```

```

```
release(udps);
release(udpr);
```

dsp.UDPSender System object

Package: dsp

Send UDP packets to network

Description

The `UDPSender` object sends UDP packets to the network.

To send UDP packets to the network:

1. Define and set up your UDP sender. See “Construction” on page 4-1824.
2. Call step to send the packets according to the properties of `dsp.UDPSender`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`udps = dsp.UDPSender` returns a UDP sender object, `udps`, that sends UDP packets to a specified port.

`udps = dsp.UDPSender('PropertyName',PropertyValue, ...)` returns a UDP sender object, `udps`, with each property set to the specified value.

Properties

`RemoteIPAddress`

Remote address to which to send data

Specify the remote (that is, host) IP address to which the data is sent. The default is '127.0.0.1', which is the local host.

RemoteIPPort

Remote port to which to send data

Specify the port at the remote IP address to which the data is sent. This property is tunable in generated code but not tunable during simulation. The default is 25000.

LocalIPPortSource

Source of the LocalIPPort property

Specify how to determine the port on the host as | Auto | Property |. If you specify Auto, the object selects the port dynamically from the available ports. If you specify Property, the object uses the source specified in the LocalIPPort property. The default is Auto.

LocalIPPort

Local port from which to send data

Specify the port from which to send data. This property applies when you set the LocalIPPortSource property to Auto. The default is 25000.

Methods

step	Send a UDP packet to network

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Byte Transmission using UDP

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.UDPReceiver` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

Send some UDP packets, and calculate the number of successfully transmitted bytes:

```
udpr = dsp.UDPReceiver('LocalIPPort',31000);
udps = dsp.UDPSender('RemoteIPPort',31000);
% To prevent the loss of packets, call the |setup| method
% on the object before the first call to the |step| method.
setup(udpr);

bytesSent = 0;
bytesReceived = 0;
dataLength = 128;

for k = 1:20
   dataSent = uint8(255*rand(1,dataLength));
   bytesSent = bytesSent + dataLength;
   udps(dataSent);
   dataReceived = udpr();
   bytesReceived = bytesReceived + length(dataReceived);
end

release(udps);
release(udpr);

fprintf('Bytes sent:     %d\n', bytesSent);
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes sent:     2560
Bytes received: 2560
```

Tune the UDP Port Number in MATLAB

Note: This example runs only in R2017a or later.

The `TunableUDP` function contains the algorithm to send and receive sine wave data over a UDP network. The inputs to this function are the local IP port number and the remote IP port number of the `dsp.UDPReceiver` and the `dsp.UDPSender` System objects, respectively. The outputs of this function are the number of bytes sent and received over the UDP network.

```
type TunableUDP
```

```
function [bytesSent,bytesReceived] = TunableUDP(localipport,remoteipport)

persistent udpRx
persistent udpSend
persistent sine

if isempty(udpRx)
    udpRx = dsp.UDPReceiver('MessageDataType','double');
    udpSend = dsp.UDPSender;
    sine = dsp.SineWave('SamplesPerFrame',250);
end

udpRx.LocalIPPort = localipport;
udpSend.RemoteIPPort = remoteipport;

bytesSent = 0;
bytesReceived = 0;
dataLength = 250;
setup(udpRx);
dataSent = sine();
udpSend(dataSent);
udpRx();

for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    dataReceived = udpRx();
    bytesReceived = bytesReceived + length(dataReceived);
end
```

You can change the local IP port number and the remote IP port number in the generated code without having to regenerate the code. Generate a MEX file from the `TunableUDP.m` function.

```
codegen TunableUDP -args {65000,65000}
```

Call the MEX function, `TunableUDP_mex`, with `RemoteIPPort` and `LocalIPPort` numbers set to `65000`.

```
[bytesSentPort65000,bytesReceivedPort65000] = TunableUDP_mex(65000,65000)
```

```
bytesSentPort65000 =

        2500

bytesReceivedPort65000 =

        2500
```

All the 2500 bytes sent are successfully received.

Clear the MEX function and change the port numbers to `25000`, `20000`, and `45000`. Verify the number of bytes transmitted and received.

```
clear mex;
[bytesSentPort25000,bytesReceivedPort25000] = TunableUDP_mex(25000,25000)
```

```
bytesSentPort25000 =

        2500

bytesReceivedPort25000 =

        2500
```

Clear the MEX function and change the port numbers to `20000`.

```
clear mex;
[bytesSentPort20000,bytesReceivedPort20000] = TunableUDP_mex(20000,20000)
```

```
bytesSentPort20000 =

        2500
```

```
bytesReceivedPort20000 =

        2500
```

Clear the MEX function and change the port numbers to 45000.

```
clear mex;
[bytesSentPort45000,bytesReceivedPort45000] = TunableUDP_mex(45000,45000)
```

```
bytesSentPort45000 =

        2500

bytesReceivedPort45000 =

        2500
```

---

dsp.UniformDecoder System object

Package: dsp

Decode integer input into floating-point output

Description

The `UniformDecoder` object decodes integer input into floating-point output. The decoder adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

To decode an integer input into a floating-point output:

1. Define and set up your uniform decoder. See "Construction" on page 4-1832.
2. Call step to decode the input according to the properties of `dsp.UniformDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ud = dsp.UniformDecoder` returns a uniform decoder, `ud`, that performs the inverse operation of the `UniformEncoder` on page 4-1837 object, reconstructing quantized floating-point values from encoded integer input.

`ud = dsp.UniformDecoder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a uniform decoder, `ud`, with each specified property set to the specified value.

`ud = dsp.UniformDecoder(peakvalue,numbits,` `'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a uniform decoder, `ud`, with the `PeakValue` on page 4-1833 property set to `peakvalue`, the `NumBits` on page 4-1833 property set to `numbits`, and other specified properties set to the specified values.

Properties

PeakValue

Largest amplitude represented in encoded input

Specify the largest amplitude represented in the encoded input as a nonnegative numeric scalar. To correctly decode values encoded with the `UniformEncoder` on page 4-1837 object, set the `PeakValue` property in both objects to the same value. For more information on setting this property, see the `PeakValue` on page 4-1833 property description on the `dsp.UniformEncoder` reference page. The default is `1`.

NumBits

Number of input bits used to encode data

Specify the number of bits used to encode the input data as an integer value between `2` and `32`. The value of this property can be less than the total number of bits supplied by the input data type. To correctly decode values encoded with the `UniformEncoder` on page 4-1837 object, set the `NumBits` property in both objects to the same value. For more information on setting this property, see the `NumBits` on page 4-1838 property description on the `dsp.UniformEncoder` reference page. The default is `3`.

OverflowAction

Action to take when integer input is out of range

Specify the behavior of the uniform decoder when the integer input is out of range as `Saturate` or `Wrap`. The value of the `NumBits` on page 4-1833 property specifies the representable range of the input. The default is `Saturate`.

OutputDataType

Output data type as single or double

Specify the data type of the output as `single` or `double`. The default is `double`.

Methods

step	Decode integer input into quantized floating-point output

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decode An Encoded Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
ue = dsp.UniformEncoder;
ue.PeakValue = 2;
ue.NumBits = 4;
ue.OutputDataType = 'Signed integer';
x = (0:0.25:2)'; % Create an input sequence
ud = dsp.UniformDecoder;
ud.PeakValue = 2;
ud.NumBits = 4;
x_encoded = ue(x);
```

Check that the last element has been saturated.

dsp.UniformEncoder

Introduced in R2012a

step

System object: dsp.UniformDecoder
Package: dsp

Decode integer input into quantized floating-point output

Syntax

`Y = step(ud,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ud,X)` reconstructs quantized floating-point output `Y` from the encoded integer input `X`. Input `X` can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.UniformEncoder System object

Package: dsp

Quantize and encode floating-point input into integer output

Description

The `UniformEncoder` object quantizes floating-point input, using the precision you specify in the `NumBits` on page 4-1838 property, and encodes the quantized input into integer output. The operations of the uniform encoder adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

To quantize and encode a floating-point input into an integer output:

1. Define and set up your uniform encoder. See "Construction" on page 4-1837.
2. Call step to encode the input according to the properties of `dsp.UniformEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ue = dsp.UniformEncoder` returns a uniform encoder, `ue`, that quantizes floating-point input samples and encodes them as integers using 2*N*-level quantization, where *N* is an integer.

`ue = dsp.UniformEncoder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an uniform encoder, `ue`, with each specified property set to the specified value.

`ue = dsp.UniformEncoder(peakvalue,numbits,`
`'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a uniform encoder, `ue`, with the `PeakValue` on page 4-1838 property set to `peakvalue`, the `NumBits` on page 4-1838 property set to `numbits`, and other specified properties set to the specified values.

Properties

PeakValue

Largest input amplitude to be encoded

Specify the largest input amplitude to be encoded, as a nonnegative numeric scalar. If the real or imaginary input are outside of the interval $[-P,(1-2^{(1-B)})P]$, where P is the peak value and B is the value of the `NumBits` on page 4-1838 property, the uniform encoder saturates (independently for complex inputs) at those limits. The default is `1`.

NumBits

Number of bits needed to represent output

Specify the number of bits needed to represent the integer output as an integer value between `2` and `32`. The number of levels at which the uniform encoder quantizes the floating-point input is 2^B, where B is the number of bits. The default is `8`.

OutputDataType

Data type of output

Specify the data type of the output as `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, and signed outputs are `int8`, `int16`, or `int32`. The quantized inputs are linearly (uniformly) mapped to the intermediate integers in the interval $[0,2^{(B-1)}]$ when you set this property to `Unsigned integer`, and in the interval $[-2^{(B-1)},2^{(B-1)}-1]$ when you set this property to `Signed integer`. The variable B in both expressions corresponds to the value of the `NumBits` on page 4-1838 property.

Methods

step	Quantize and encode input

Common to All System Objects	
`clone`	Create System object with same property values

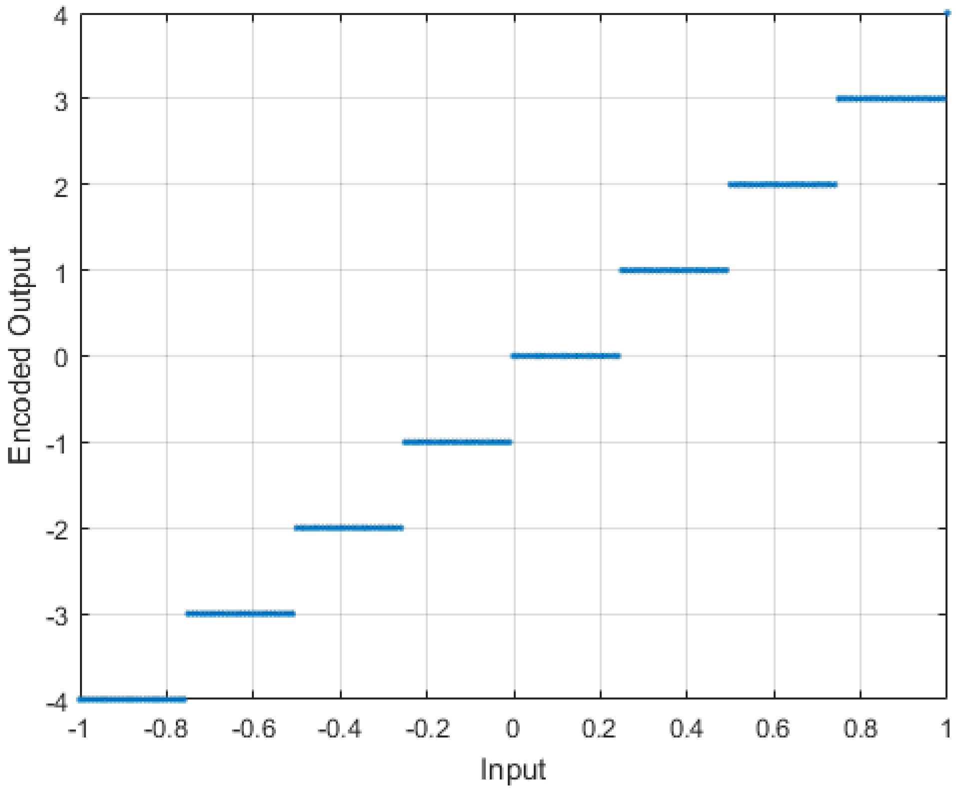
Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Encode a Sequence Of Numbers

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
ue = dsp.UniformEncoder;
ue.PeakValue = 2;
ue.NumBits = 4;
ue.OutputDataType = 'Signed integer';
x = [-1:0.01:1]'; % Create an input sequence
x_encoded = ue(x);
plot(x, x_encoded,'.');
xlabel('Input'); ylabel('Encoded Output'); grid
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Uniform Encoder` block reference page. The object properties correspond to the block parameters.

dsp.UniformDecoder

Introduced in R2012a

step

System object: dsp.UniformEncoder
Package: dsp

Quantize and encode input

Syntax

```
Y = step(ue,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ue,X)` quantizes and encodes the input `X` to `Y`. Input `X` can be real or complex, double-, or single-precision values. The uniform encoder chooses the output data type according to the following table.

Number of Bits	Unsigned Integer	Signed Integer
2 to 8	`uint8`	`int8`
9 to 16	`uint16`	`int16`
17 to 32	`uint32`	`int32`

The row corresponds to the value of the `NumBits` property, and the column corresponds to the value of the `OutputDataType` property.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.UpperTriangularSolver System object

Package: dsp

Solve upper-triangular matrix equation

Description

The `UpperTriangularSolver` object solves $UX = B$ for X when U is a square, upper-triangular matrix with the same number of rows as B.

To solve $UX = B$:

1 Define and set up your linear system solver. See "Construction" on page 4-1843.
2 Call step to solve the equation according to the properties of `dsp.UpperTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.UpperTriangularSolver` returns a linear system solver, `H`, used to solve $UX = B$ where U is an upper (or unit-upper) triangular matrix.

`H = dsp.UpperTriangularSolver('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a linear system solver, `H`, with each specified property set to the specified value.

Properties

`OverwriteDiagonal`

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, *U*, with ones. Set this property to either `true` or `false`. The default is `false`.

`RealDiagonalElements`

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input, *U*, are real. This property applies only when you set the `OverwriteDiagonal` on page 4-1843 property to `false`. Set this property to either `true` or `false`. The default is `false`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

`ProductDataType`

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` on page 4-1844 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1845 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1845 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

dsp.VariableBandwidthFIRFilter System object

Package: dsp

Variable bandwidth FIR filter

Description

The `VariableBandwidthFIRFilter` object filters each channel of the input using FIR filter implementations. It does so while having the capability of tuning the bandwidth. This filter supports double and single precision inputs.

To filter each channel of the input:

1. Define and set up your variable bandwidth FIR filter. See “Construction” on page 4-1849.
2. Call step to filter each channel of the input according to the properties of `dsp.VariableBandwidthFIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`vbw = dsp.VariableBandwidthFIRFilter` returns a System object, `vbw`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified FIR filter implementation. The filter’s cutoff frequency may be tuned during the filtering operation. The variable bandwidth FIR filter is designed using the window method.

`vbw = dsp.VariableBandwidthFIRFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a variable bandwidth FIR filter System object, `vbw`, with each property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SampleRate

Input sample rate

Specify the sampling rate of the input in Hertz as a finite numeric scalar. The default is 44.1 kHz. This property is non-tunable.

FilterType

Filter type

Specify the type of the filter as one of 'Lowpass' | 'Highpass' | 'Bandpass' | 'Bandstop'. The default is 'Lowpass'. This property is non-tunable.

FilterOrder

FIR filter order

Specify the order of the FIR filter as a positive integer scalar. The default is 30. This property is non-tunable.

Window

Window function

Specify the window function used to design the FIR filter as one of 'Hann' | 'Hamming' | 'Chebyshev' | 'Kaiser'. The default is 'Hann'. This property is non-tunable.

KaiserWindowParameter

Kaiser window parameter

Specify the Kaiser window parameter as a real scalar. This property applies when you set the window property to 'Kaiser'. The default is 0.5. This property is non-tunable.

CutoffFrequency

Filter cutoff frequency

Specify the filter cutoff frequency in Hz as a real, positive scalar, smaller than the `SampleRate/2`. This property applies if you set the `FilterType` property to `'Lowpass'` or `'Highpass'`. The default is 512 Hz. This property is tunable.

`CenterFrequency`

Filter center frequency

Specify the filter center frequency in Hz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 11025 Hz. This property is tunable.

`Bandwidth`

Filter bandwidth

Specify the filter bandwidth in Hertz as a real, positive scalar, smaller than `SampleRate/2`. This property applies if you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 7680 Hz. This property is tunable.

`SidelobeAttenuation`

Chebyshev window sidelobe attenuation

Specify the Chebyshev window attenuation as a real, positive scalar in decibels (dB). This property applies if you set the `Window` property to `'Chebyshev'`. The default is 60 dB. This property is non-tunable.

Methods

reset	Reset internal states of variable bandwidth FIR filter
step	Filter signal using variable bandwidth algorithm

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

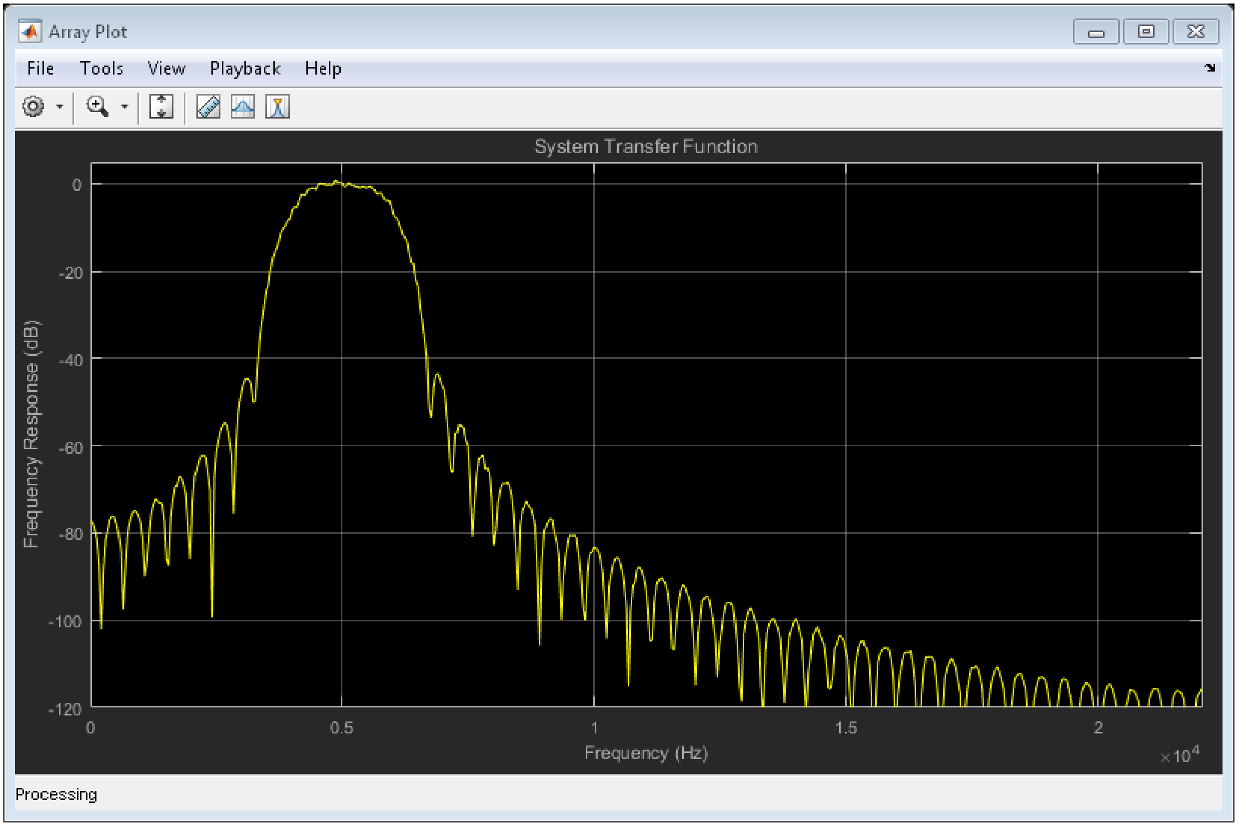
Filtering through a variable bandwidth bandpass FIR filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows you how to tune the center frequency and the bandwidth of the FIR filter.

```
Fs = 44100; % Input sample rate
% Define a bandpass variable bandwidth FIR filter:
vbw = dsp.VariableBandwidthFIRFilter('FilterType','Bandpass',...
    'FilterOrder',100,...
    'SampleRate',Fs,...
    'CenterFrequency',1e4,...
    'Bandwidth',4e3);
tfe = dsp.TransferFunctionEstimator('FrequencyRange','onesided');
aplot = dsp.ArrayPlot('PlotType','Line',...
    'XOffset',0,...
    'YLimits',[-120 5], ...
    'SampleIncrement', 44100/1024,...
    'YLabel','Frequency Response (dB)',...
    'XLabel','Frequency (Hz)',...
    'Title','System Transfer Function');
FrameLength = 1024;
sine = dsp.SineWave('SamplesPerFrame',FrameLength);
for i=1:500
    % Generate input
    x = sine() + randn(FrameLength,1);
    % Pass input through the filter
    y = vbw(x);
    % Transfer function estimation
    h = tfe(x,y);
    % Plot transfer function
```

```
    aplot(20*log10(abs(h)))
    % Tune bandwidth and center frequency of the FIR filter
    if (i==250)
        vbw.CenterFrequency = 5000;
        vbw.Bandwidth = 2000;
    end
end
```



Algorithms

FIR Transformations

All transformations assume a lowpass filter of length 2N+1.

Lowpass to Lowpass

Consider an ideal lowpass brickwall filter with normalized cutoff frequency ω_{c1}. By taking the inverse Discrete Fourier Transform of the ideal frequency response, and clipping the resulting sequence to length 2N+1, the impulse response is:

$$\begin{aligned}
&\textit{for } n = 0 \\
&h_{LP}(n) = \frac{\omega_c}{\pi}.w(0) \\
&\textit{for } 1 \le |n| \le N \\
&h_{LP}(n) = \frac{\sin(\omega_c n)}{\pi n}.w(n)
\end{aligned}$$

where w(n) is the window vector. The lowpass filter coefficients are tuned to a new cutoff frequency ω_{c2} as follows:

$$\begin{aligned}
&\textit{for } n = 0 \\
&h_{LP}(n) = \frac{\omega_{c2}}{\pi}.\omega(0) \\
&\textit{for } 1 \le |n| \le N \\
&h_{LP}(n) = \frac{\sin(\omega_{c2} n)}{\pi n}.\omega(n)
\end{aligned}$$

There is no need to recompute the window every time you tune the cutoff frequency.

Lowpass to Highpass

Assuming a lowpass filter with normalized 6–dB cutoff frequency ω_c, a highpass filter with the same cutoff frequency can be obtained by taking the complementary of the lowpass frequency response: $H_{HP}(e^{j\omega}) = 1 — H_{LP}(e^{j\omega})$

Taking the inverse discrete Fourier transform of the above response, we get the following highpass filter coefficients:

$$\begin{aligned}
&\textit{for } n = 0 \\
&h_{hp}(n) = 1 - h_{LP}(n) \\
&\textit{for } 1 \le |n| \le N \\
&h_{hp}(n) = -h_{LP}(n)
\end{aligned}$$

Lowpass to Bandpass

A bandpass filtered centered at frequency ω_0 can be obtained by shifting the lowpass response:

$H_{BP}(e^{j\omega}) = H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega-\omega_0)})$

The bandwidth of the resulting bandpass filter is $2\omega_c$, as measured between the two cutoff frequencies of the bandpass filter. The equivalent bandpass filter coefficients are then:

$$h_{BP}(n) = (e^{j\omega_0 n} + e^{-j\omega_0 n})h_{LP}(n)$$

which can be written as:

$$h_{BP}(n) = 2\cos(\omega_0 n)h_{LP}(n)$$

Lowpass to Bandstop

We can transform a lowpass filter to a bandstop filter by combining the highpass and bandpass transformations. That is, first make the filter bandpass by shifting the lowpass response, and then invert in to get a bandstop response centered at ω_0.

$H_{BS}(e^{j\omega}) = 1 - (H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)}))$

This yields the following coefficients:

$$\textit{for } n = 0$$
$$h_{BS}(n) = 1 - 2\cos(\omega_0 n)h_{LP}(n)$$
$$\textit{for } 1 \leq |n| \leq N$$
$$h_{BS}(n) = -2\cos(\omega_0 n)h_{LP}(n)$$

Generalized Transformation

The transformations highlighted above can be combined to transform a lowpass filter to a lowpass, highpass, bandpass or bandstop filter with arbitrary cutoffs.

For example, to transform a lowpass filter with cutoff ω_{c1} to a highpass with cutoff ω_{c2}, you first apply the lowpass-to-lowpass transformation to get a lowpass filter with cutoff ω_{c2}, and then apply the lowpass-to-highpass transformation to get the highpass with cutoff ω_{c2}.

To get a bandpass filter with center frequency ω_0 and bandwidth ß, we first apply the lowpass-to-lowpass transformation to go from a lowpass with cutoff ω_c to a lowpass with cutoff ß/2, and then apply the lowpass-to-bandpass transformation to get the desired bandpass filter. The same approach can be applied to a bandstop filter.

Introduced in R2014a

reset

System object: dsp.VariableBandwidthFIRFilter
Package: dsp

Reset internal states of variable bandwidth FIR filter

Syntax

```
reset(vbw)
```

Description

`reset(vbw)` resets the filter states of the variable bandwidth FIR filter object, `vbw`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the variable bandwidth FIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

step

System object: dsp.VariableBandwidthFIRFilter
Package: dsp

Filter signal using variable bandwidth algorithm

Syntax

`Y = step(vbw,x)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(vbw,x)` filters the real or complex input signal `X` using the variable bandwidth FIR filter, `vbw`, to produce the output `Y` . The variable bandwidth FIR filter object operates on each channel, which means every column of the input signal independently over successive calls to step method.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VariableBandwidthIIRFilter System object

Package: dsp

Variable bandwidth IIR filter

Description

The `VariableBandwidthIIRFilter` object filters each channel of the input using IIR filter implementations. It does so while having the capability of tuning the bandwidth. This filter supports double and single precision inputs.

To filter each channel of the input:

1. Define and set up your variable bandwidth IIR filter. See "Construction" on page 4-1859.
2. Call step to filter each channel of the input according to the properties of `dsp.VariableBandwidthIIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`vbwIIR = dsp.VariableBandwidthIIRFilter` returns a System object, `vbwIIR`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified IIR filter implementation. The filter's passband frequency may be tuned during the filtering operation. The variable bandwidth IIR filter is designed using the elliptical method. The filter is tuned using IIR spectral transformations based on allpass filters.

```
vbwIIR =
dsp.VariableBandwidthIIRFilter('PropertyName',PropertyValue, ...)
```

returns a variable bandwidth IIR filter System object, `vbwIIR`, with each property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

`SampleRate`

Input sample rate

Specify the sampling rate of the input in Hertz as a finite numeric scalar. The default is 44.1 kHz. This property is non-tunable.

`FilterType`

Filter type

Specify the type of the filter as one of `'Lowpass' | 'Highpass' | 'Bandpass' | 'Bandstop'`. The default is `'Lowpass'`. This property is non-tunable.

`FilterOrder`

IIR filter order

Specify the order of the IIR filter as a positive integer scalar. The default is 8. This property is non-tunable.

`PassbandFrequency`

Filter passband frequency

Specify the filter passband frequency in Hz as a real, positive scalar, smaller than the `SampleRate/2`. This property applies when you set the `FilterType` property to `'Lowpass'` or `'Highpass'`. The default is 512 Hz. This property is tunable.

`CenterFrequency`

Filter center frequency

Specify the filter center frequency in Hz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 11025 Hz. This property is tunable.

Bandwidth

Filter bandwidth

Specify the filter bandwidth in Hertz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 7680 Hz. This property is tunable.

PassbandRipple

Filter passband ripple

Specify the filter passband ripple as a real, positive scalar in decibels (dB). The default is 1 dB. This property is non-tunable.

StopbandAttenuation

Filter Stopband attenuation

Specify the filter stopband attenuation as a real, positive scalar in decibels (dB). The default is 60 dB. This property is non-tunable.

Methods

reset	Reset internal states of variable bandwidth IIR filter
step	Filter signal using variable bandwidth algorithm

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Filtering Through a Variable Bandwidth Bandpass IIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This examples shows you how to tune the center frequency and bandwidth of the IIR filter.

```
Fs = 44100; % Input sample rate
% Define a bandpass variable bandwidth IIR filter:
vbwiir = dsp.VariableBandwidthIIRFilter('FilterType','Bandpass',...
                                      'FilterOrder',8,...
                                      'SampleRate',Fs,...

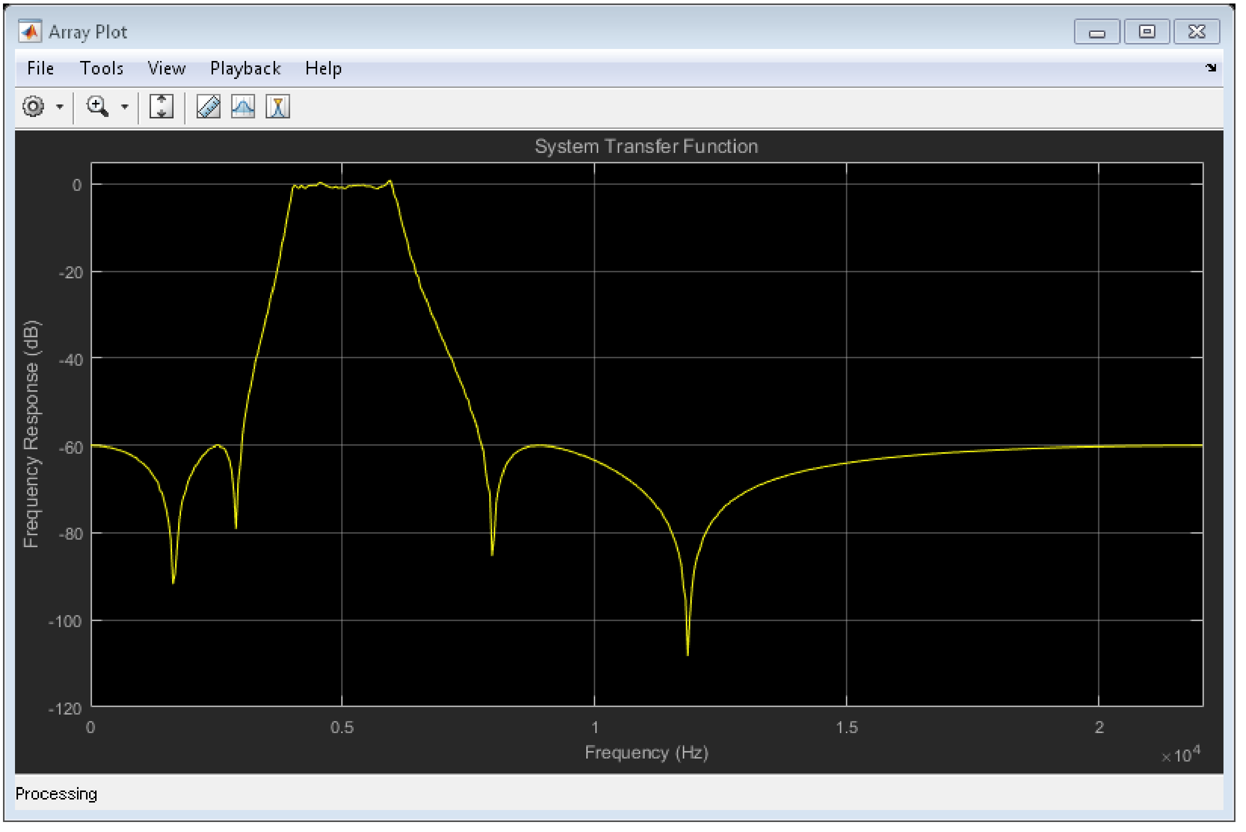
   % Pass input through the filter
   y = vbwiir(x);
   % Transfer function estimation
   h = tfe(x,y);
   % plot transfer function
   aplot(20*log10(abs(h)))
   % Tune bandwidth and center frequency of the IIR filter
```

```
      if (i==250)
        vbwiir.CenterFrequency = 5000;
        vbwiir.Bandwidth = 2000;
      end
    end
```



Algorithms

This filter covers frequency transformations. A lowpass IIR prototype is designed, using the elliptical method by specifying its order, passband frequency, passband ripple and stopband attenuation. The passband ripple and stopband attenuation are equal to the values of the `PassbandRipple` and `StopbandAttenuation` properties. The prototype passband frequency is set to 0.5. If the `FilterType` property is `'Lowpass'` or `'Highpass'`, the prototype's order is equal to the value of `FilterOrder`. If the `FilterType` property is `'Bandpass'` or `'Bandstop'`, the prototype filter order is equal to `FilterOrder/2`. The prototype is a Direct Form II Transposed cascade of second-order sections (Biquad filter). The prototype is transformed into the desired filter using the algorithms used in "Digital Frequency Transformations". Each prototype SOS section is transformed separately. When `FilterType` is `'Lowpass'` or `'Highpass'`, the resulting filter remains a Direct Form II Transposed cascade of second order sections. If the `FilterType` is `'Bandpass'` or `'Bandstop'`, the resulting filter is a cascade of Direct Form II Transposed cascade of fourth order sections.

Introduced in R2014a

reset

System object: dsp.VariableBandwidthIIRFilter
Package: dsp

Reset internal states of variable bandwidth IIR filter

Syntax

```
reset(vbwIIR)
```

Description

`reset(vbwIIR)` resets the filter states of the variable bandwidth IIR filter object, `vbwIIR`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the variable bandwidth IIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

step

System object: dsp.VariableBandwidthIIRFilter
Package: dsp

Filter signal using variable bandwidth algorithm

Syntax

`Y = step(vbwIIR,x)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(vbwIIR,x)` filters the real or complex input signal `X` using the variable bandwidth IIR filter, `vbwIIR`, to produce the output `Y`. The variable bandwidth IIR filter object operates on each channel, which means every column of the input signal independently over successive calls to step method.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VariableFractionalDelay System object

Package: dsp

Delay input by time-varying fractional number of sample periods

Description

The `VariableFractionalDelay` object delays the input by a time-varying fractional number of sample periods.

To delay the input by a time-varying fractional number of sample periods:

1. Define and set up your variable fractional delay object. See "Construction" on page 4-1867.
2. Call step to delay the input according to the properties of `dsp.VariableFractionalDelay`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`vfd = dsp.VariableFractionalDelay` returns a variable fractional delay System object, `vfd`, that delays a discrete-time input by a time-varying fractional number of sample periods.

`vfd = dsp.VariableFractionalDelay('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a variable fractional delay System object, `vfd`, with each property set to the specified value.

Properties

InterpolationMethod

Interpolation method

Specify the method by which the block interpolates between adjacent stored samples to obtain a value for the sample indexed by the input. You can set this property to one of | Linear | FIR | Farrow. When you set this property to FIR, the value of the Bandwidth property is used to generate the FIR filter for interpolation. If the value of the Bandwidth property is 1 (default value), the FIR filter is generated using the firnyquist function. If the value of the Bandwidth property is smaller than 1, the FIR filter is generated using the intfilt function from Signal Processing Toolbox. The default is Linear.

FilterHalfLength

FIR interpolation filter half-length

Specify the half-length of the FIR interpolation filter as a positive scalar integer. This property applies only when you set the InterpolationMethod on page 4-1868 property to FIR. For periodic signals, a larger value of this property (that is, a higher order filter) yields a better estimate of the delayed output sample. Setting this property to a value between 4 and 6 (that is, a 7th to 11th order filter) is usually adequate. The default is 4.

FilterLength

Length of Farrow filter

Specify the length of the FIR filter implemented using the Farrow structure, as a positive scalar integer. This property applies only when you set the InterpolationMethod on page 4-1868 property to Farrow. The default is 4.

InterpolationPointsPerSample

Number of interpolation points per input sample

Specify the number of interpolation points per input sample at which a unique FIR interpolation filter is computed. You must specify the number of interpolation points per input sample as a positive scalar integer. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `FIR`. The default is `10`.

Bandwidth

Normalized input bandwidth

Specify the bandwidth to which you want to constrain the interpolated output samples. You must enter the bandwidth as a scalar value between `0` and `1`. You can use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above `Fs/4` (where `Fs` is the sampling frequency), you can specify a value of `0.5` for the `Bandwidth` property. A value of `1` for the `Bandwidth` property corresponds to half the sampling frequency (`Fs`). This property applies only when you set the `InterpolationMethod` on page 4-1868property to `FIR`. The default is `1`.

InitialConditions

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on whether you want fixed or time-varying initial conditions. The default is `0`.

For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property. To specify different time-varying initial conditions for each channel, set the `InitialConditions` property as follows:
  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of size `1`-by-N-by-D, where D is the value of the `MaximumDelay` property.
  - If you set the `InterpolationMethod` property to `FIR` or `Farrow`, set the `InitialConditions` property to an array of size 1-by-N-by-(D+L), where D is the value of the `MaximumDelay` property. For FIR interpolation, `L` is the value of the

FilterHalfLength property. For Farrow interpolation, L equals floor of half the value of the FilterLength property (floor(FilterLength/2)).

MaximumDelay

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the MaximumDelay to the MaximumDelay. The default is 100.

FIRSmallDelayAction

Action for small input delay values in FIR interpolation mode

Specify the action the object should take for small input delay values when using the FIR interpolation method. You can set this property to Clip to the minimum value necessary for centered kernel, or Switch to linear interpolation if kernel cannot be centered. This property applies only when you set the InterpolationMethod on page 4-1868 property to FIR. The default is Clip to the minimum value necessary for centered kernel.

FarrowSmallDelayAction

Action for small input delay values in Farrow interpolation mode

Specify the action the object should take for small input delay values when using the Farrow interpolation method. You can set this property to Clip to the minimum value necessary for centered kernel, or Use off-centered kernel. This property applies only when you set the InterpolationMethod on page 4-1868 property to Farrow. The default is Clip to the minimum value necessary for centered kernel.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent, | Floor | Nearest | Round | Simplest | Zero |. The default is Zero.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

CoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficients word length

Specify the coefficients word length as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` on page 4-1871 property to `Custom`. The default is `numerictype([],32)`.

ProductPolynomialValueDataType

Product polynomial values word and fraction lengths

Specify the product polynomial value data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `Farrow`. The default is `Same as first input`.

CustomProductPolynomialValueDataType

Product polynomial values word and

fraction lengths Specify the product polynomial values fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `Farrow` and the `ProductPolynomialValueDataType` on page 4-1871 property to `Custom`. The default is `numerictype([],32,10)`.

AccumulatorPolynomialValueDataType

Accumulator polynomial value word and fraction lengths

Specify the accumulator polynomial value data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `Farrow`. The default is `Same as first input`.

CustomAccumulatorPolynomialValueDataType

Accumulator polynomial value word and fraction lengths

Specify the data type of the accumulator polynomial values as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `Farrow` and the `AccumulatorPolynomialValueDataType` on page 4-1871 property to `Custom`. The default is `numerictype([],32,10)`.

MultiplicandPolynomialValueDataType

Multiplicand polynomial value word and fraction lengths

Specify the multiplicand polynomial values data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `Farrow`. The default is `Same as first input`.

CustomMultiplicandPolynomialValueDataType

Multiplicand polynomial value word and fraction lengths

Specify the fixed-point data type of the multiplicand polynomial values as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` on page 4-1868 property to `Farrow` and the `MultiplicandPolynomialValueDataType` on page 4-1872 property to `Custom`. The default is `numerictype([],32,10)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of | `Same as first input` | `Custom` |. The default is `Same as first input`.

CustomProductDataType

Product word and fraction lengths

Specify the product data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` on page 4-1872 property to `Custom`. The default is `numerictype([],32,10)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as one of | `Same as product` | `Same as first input` | `Custom` |. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1873 property to `Custom`. The default is `numerictype([],32,10)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of | `Same as accumulator` | `Same as first input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the data type of the output as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1873 property to `Custom`. The default is `numerictype([],32,10)`.

Methods

info	Characteristic information about valid delay range

reset	Reset internal states of variable fractional delay object
step	Delay input by time-varying fractional number of sample periods

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Signal Delay using a Variable Fractional Delay

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Delay a signal by a varying fractional number of sample periods.

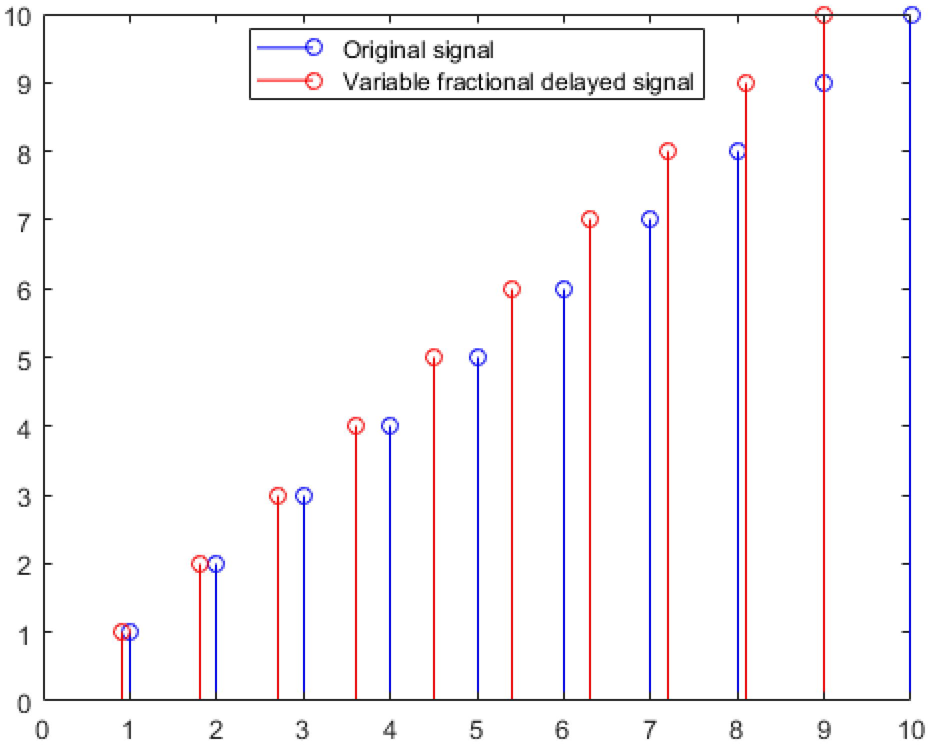
```
sr = dsp.SignalSource;
vfd = dsp.VariableFractionalDelay;
sink = dsp.SignalSink;

for ii = 1:10
    delayedsig = vfd(sr(), ii/10);
    sink(delayedsig);
end

sigd = sink.Buffer;
```

The output `sigd` corresponds to the values of the delayed signal that are sampled at fixed-time intervals. For visualization purposes, we can instead plot the time instants at which the amplitudes of signal samples are constant by treating the signals as the sampling instants.

```
stem(sr.Signal, 1:10, 'b')
hold on;
stem(sigd.', 1:10, 'r');
legend('Original signal',...
    'Variable fractional delayed signal', ...
    'Location','best')
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Variable Fractional Delay` block reference page.

info

System object: dsp.VariableFractionalDelay
Package: dsp

Characteristic information about valid delay range

Syntax

```
S = info(vfd)
```

Description

`S = info(vfd)` returns a structure, `S` , containing characteristic information about the `VariableFractionalDelay` System object, `vfd` . `S` has one field, `ValidDelayRange` which is a string containing the possible range of delay values based on the current property values of the `VariableFractionalDelay` object. The `ValidDelayRange` is in the format `[MinValidDelay, MaxValidDelay]`. The object clips all input delay values to be within this `ValidDelayRange`.

reset

System object: dsp.VariableFractionalDelay
Package: dsp

Reset internal states of variable fractional delay object

Syntax

`reset(vfd)`

Description

`reset(vfd)` resets the internal states of the `VariableFractionalDelay` System object `vfd` to their initial values.

step

System object: dsp.VariableFractionalDelay
Package: dsp

Delay input by time-varying fractional number of sample periods

Syntax

`Y = step(vfd,X,D)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(vfd,X,D)` delays the input `X` by `D` samples, where `D` should be less than or equal to the value specified in the `MaximumDelay` property.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VariableIntegerDelay System object

Package: dsp

Delay input by time-varying integer number of sample periods

Description

Note: Certain functionality of this object will be removed in future releases. See "Functionality being removed or replaced for blocks and System objects".

The `VariableIntegerDelay` object delays input by time-varying integer number of sample periods.

To delay the input by a time-varying integer number of sample periods:

1. Define and set up your variable integer delay object. See "Construction" on page 4-1880.
2. Call step to delay the input according to the properties of `dsp.VariableIntegerDelay`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`vid = dsp.VariableIntegerDelay` returns a variable integer delay System object, `vid`, that delays discrete-time input by a time-varying integer number of sample periods.

`vid = dsp.VariableIntegerDelay('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a variable integer delay System object, `vid`, with each property set to the specified value.

Properties

`MaximumDelay`

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`. The default is `100`.

`InitialConditions`

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on whether you want fixed or time-varying initial conditions. The default is `0`.

For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify different time-varying initial conditions for each channel, set the `InitialConditions` property to an array of size 1-by-N-by-D, where D is the value of the `MaximumDelay` property.

`DirectFeedthrough`

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

Methods

reset	Reset internal states of variable integer delay object

step	Delay input by time-varying integer number of sample periods

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Delay a Signal with VariableIntegerDelay Object

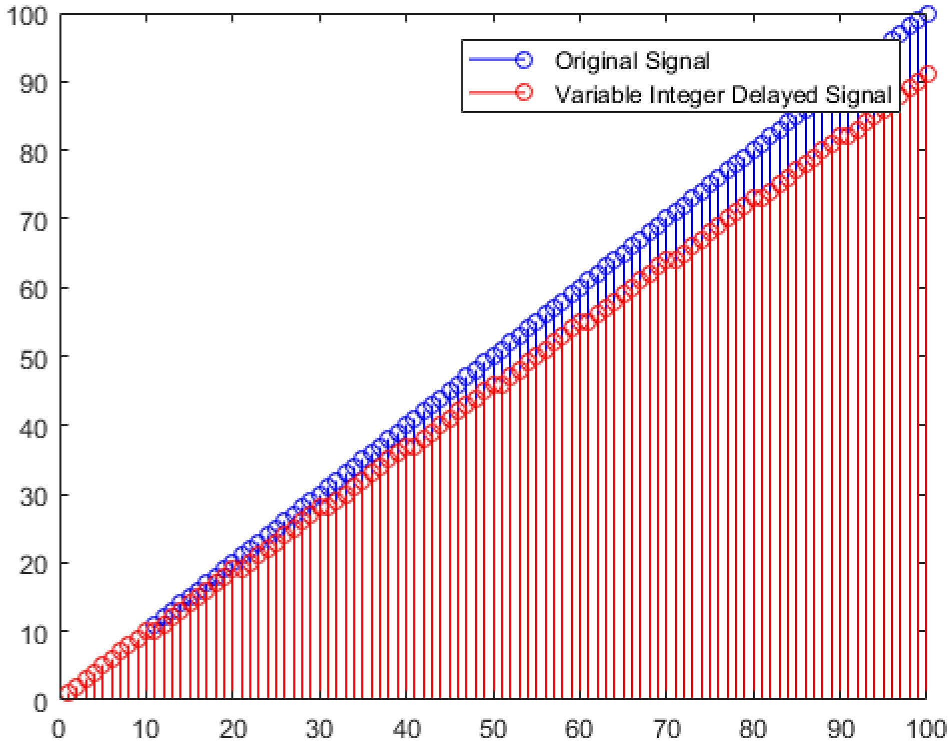
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Delay a signal by a varying number of integer sample periods.

```
vid = dsp.VariableIntegerDelay;
x = 1:100;
ii = 0;
k = 0;
yout = [];

while(ii+10 <= 100)
     y = vid(x(ii+1:ii+10)',k*ones(10,1));
     yout = [yout;y];
     ii = ii+10;
     k = k+1;
end

stem(x,'b');
hold on; stem(yout,'r');
legend('Original Signal', 'Variable Integer Delayed Signal')
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Integer Delay block reference page. The object properties correspond to the block properties, except:

When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

`reset(vid)`

Description

`reset(vid)` resets the internal states of the `VariableIntegerDelay` System object `vid` to their initial values.

step

System object: dsp.VariableIntegerDelay
Package: dsp

Delay input by time-varying integer number of sample periods

Syntax

```
Y = step(vid,X,D)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(vid,X,D)` delays the input `X` by `D` samples, where `D` should be less than or equal to the value specified in the `MaximumDelay` property and greater than or equal to `0`. The object clips delay values greater than the `MaximumDelay` to the `MaximumDelay`, and clips values less than zero to zero. If you enter a noninteger delay value, the object rounds that value to the nearest integer value.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Variance System object

Package: dsp

Variance of input or sequence of inputs

Description

The `Variance` object computes variance for an input or sequence of inputs.

To compute the variance of an input or sequence of inputs:

1. Define and set up your variance System object. See "Construction" on page 4-1887.
2. Call step to compute the variance according to the properties of `dsp.Variance`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note: The `Running` mode in the `dsp.Variance` System object will be removed in a future release. To compute the running variance in MATLAB, use the dsp.MovingVariance System object instead.

Construction

`var = dsp.Variance` returns a variance System object, `var`, that computes the variance of an input or a sequence of inputs over the specified `Dimension`.

`var = dsp.Variance('PropertyName',PropertyValue,...)` returns a variance System object, `var`, with each specified property set to the specified value.

Properties

`RunningVariance`

Enable calculation over time

Set this property to `true` to enable variance calculation over successive calls to the `step` method. The default is `false`.

`ResetInputPort`

Enable reset input port

Set this property to `true` to enable reset input port. When you set the property to `true`, specify a reset input for the step method. The running variance resets anytime the variance object achieves the condition you specify for the `ResetCondition on page 4-1888` property. This property applies when you set the `RunningVariance on page 4-1888` property to `true`. The default is `false`.

`ResetCondition`

Reset condition for running variance mode

Specify which event resets the running variance as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies when you set the `ResetInputPort on page 4-1888` property to `true`.

`Dimension`

Dimension to operate along

Specify how the object performs the variance calculation over the data as one of `| All | Row | Column | Custom |`. This property applies when you set the `RunningVariance on page 4-1888` property to `false`. The default is `Column`.

`CustomDimension`

Numerical dimension to operate along

Specify the input signal dimension (one-based value) the object uses to compute variance. The cannot exceed the number of dimensions in the input signal. This property applies when you set the `Dimension on page 4-1888` property to `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

InputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomInputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the InputSquaredProductDataType on page 4-1889 property to Custom. The default is numerictype([],32,15).

InputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point data type as one of | Same as input-squared product | Custom |. The default is Same as input-squared product.

CustomInputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the

InputSumSquaredProductDataType on page 4-1889 property to Custom. The default is numerictype([],32,23).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Same as input-squared product | Same as input | Custom |. The default is Same as input-squared product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the AccumulatorDataType on page 4-1890 property to Custom. The default is numerictype([],32,0).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input-squared product | Same as input | Custom |. The default is Same as input-squared product.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property only applies when the OutputDataType on page 4-1890 property to Custom. The default is numerictype([],16,0).

Methods

reset	Reset variance to zero
step	Variance of input

Common to All System Objects	
clone	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Running Variance

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the running variance of the signal. That is, compute the variance of each sample in the input signal with respect to all the previous samples.

```
var = dsp.Variance;
var.RunningVariance = true;
input = randn(100,1);
variance = var(input);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Variance` block reference page. The object properties correspond to the block parameters, except:

- **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Blocks

`Moving RMS` | `Moving Standard Deviation` | `Moving Variance` | `RMS` | `Standard Deviation` | `Variance`

Introduced in R2012a

reset

System object: dsp.Variance
Package: dsp

Reset variance to zero

Syntax

```
reset(var)
```

Description

`reset(var)` sets the variance to zero when the `RunningVariance` property is `true`.

step

System object: dsp.Variance
Package: dsp

Variance of input

Syntax

```
Y = step(var,X)
Y = step(var,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(var,X)` computes the variance, `Y`, of input `X` over successive calls to the `step` method, when the `RunningVariance` property is `true`.

`Y = step(var,X,R)` resets its state based on the value of reset signal `R` , the `ResetInputPort` property and the `ResetCondition` property. This option applies when the `RunningVariance` property is `true` and the `ResetInputPort` property is set to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VectorQuantizerDecoder System object

Package: dsp

Vector quantizer codeword for given index value

Description

The `VectorQuantizerDecoder` object returns the vector quantizer codeword for a given index value. Each column of the `Codebook` property is a codeword.

To obtain the vector quantizer codeword for a given index value:

1. Define and set up your vector quantizer decoder. See "Construction" on page 4-1895.
2. Call step to get the vector quantizer codeword according to the properties of `dsp.VectorQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`vqdec = dsp.VectorQuantizerDecoder` creates a vector quantizer decoder System object, `vqdec`, that returns a vector quantizer codeword corresponding to a given, zero-based index value.

`vqdec = dsp.VectorQuantizerDecoder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a vector quantizer decoder, `vqdec`, with each specified property set to the specified value.

Properties

`CodebookSource`

Source of codebook values

Specify the codebook source as `Property` or `Input port`. When you select `Property`, the object reads the codebook from the `codebook` on page 4-1896 property. When you select `Input port`, the object reads the codebook from the input of the `step` method.

The default is `Property`.

`Codebook`

codebook

Specify quantized output values as a k-by-N matrix, where $k \geq 1$ and $N \geq 1$. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. This property applies when you set the `CodebookSource on page 4-1896` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

`OutputDataType`

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as: `Same as input`, `double`, `single` or `Custom`. This property applies only when you set `CodebookSource` on page 4-1896 to `Property`. The default is `double`.

Fixed-Point Properties

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numerictype` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16)`.

Methods

step	Perform vector quantization decoding

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Determine Vector Quantizer Codeword

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Given index values as an input, determine the corresponding vector quantized codewords for a specified codebook.

```
vqdec = dsp.VectorQuantizerDecoder;
vqdec.Codebook = [1 10 100;2 20 200;3 30 300];
indices = uint8([1 0 2 0]);
qout = vqdec(indices)
```

```
qout =

    10     1   100     1
    20     2   200     2
    30     3   300     3
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Vector Quantizer Decoder` block reference page. The object properties correspond to the block parameters, except:
There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than `0` to `0` and any index values greater than or equal to N to N-1.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

dsp.VectorQuantizerEncoder | dsp.ScalarQuantizerDecoder

Introduced in R2012a

step

System object: dsp.VectorQuantizerDecoder
Package: dsp

Perform vector quantization decoding

Syntax

```
Q = step(vqdec,I)
Q = step(vqdec,I,C)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Q = step(vqdec,I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type of `Q`.

`Q = step(vqdec,I,C)` uses input `C` as the `codebook` values when the `CodebookSource` property is `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the `codebook` input `C`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VectorQuantizerEncoder System object

Package: dsp

Vector quantization encoding

Description

The `VectorQuantizerEncoder` object performs vector quantization encoding. The object finds the nearest codeword by computing a distortion based on Euclidean or weighted Euclidean distance.

To perform vector quantization encoding:

1. Define and set up your vector quantizer encoder. See "Construction" on page 4-1900.
2. Call step to perform the quantization encoding according to the properties of `dsp.VectorQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`vqenc = dsp.VectorQuantizerEncoder` returns a vector quantizer encoder System object, `vqenc`. This object finds a zero-based index of the nearest codeword for each given input column vector.

`vqenc = dsp.VectorQuantizerEncoder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a vector quantizer encoder System object, `vqenc`, with each specified property set to the specified value.

Properties

CodebookSource

Source of codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

Codebook

Codebook

Specify the codebook to which the input column vector or matrix is compared, as a *k*-by-*N* matrix. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. The codeword vectors must have the same number of rows as the input. The first codeword vector corresponds to an index value of `0`, the second codeword vector corresponds to an index value of `1`, and so on. This property applies when you set the `CodebookSource on page 4-1901` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

DistortionMeasure

Distortion calculation method

Specify how to calculate the distortion as `Squared error` or `Weighted squared error`. If you set this property to `Squared error`, the object calculates the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. If you set this property to `Weighted squared error`, the object calculates the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values. The default is `Squared error`.

WeightsSource

Source of weighting factor

Specify how to determine weighting factor as `Property` or `Input port`. This property applies when you set the `DistortionMeasure on page 4-1901` property to `Weighted squared error`. The default is `Property`.

Weights

Weighting factor

Specify the weighting factor as a vector of length equal to the number of rows of the input. This property applies when you set the `DistortionMeasure on page 4-1901` property to `Weighted squared error` and `WeightsSource on page 4-1901` property is `Property`. The default is [1 1 1]. This property is tunable.

TiebreakerRule

Behavior when input column vector is equidistant from two codewords.

Specify whether to represent the input column vector by the lower index valued codeword or higher indexed valued codeword when an input column vector is equidistant from two codewords. You can set this property to `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

CodewordOutputPort

Enable output of codeword value

Set this property to `true` to output the codeword vectors nearest to the input column vectors. The default is `false`.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error value that results when the object represents the input column vector by the nearest codeword. The default is `false`.

OutputIndexDataType

Data type of index output

Specify the data type of the index output as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType on page 4-1903` property to `Custom`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Same as input`, or `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType on page 4-1903` property to`Custom`.

Methods

step	Perform vector quantization encoding

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Find Indices of Nearest Codewords

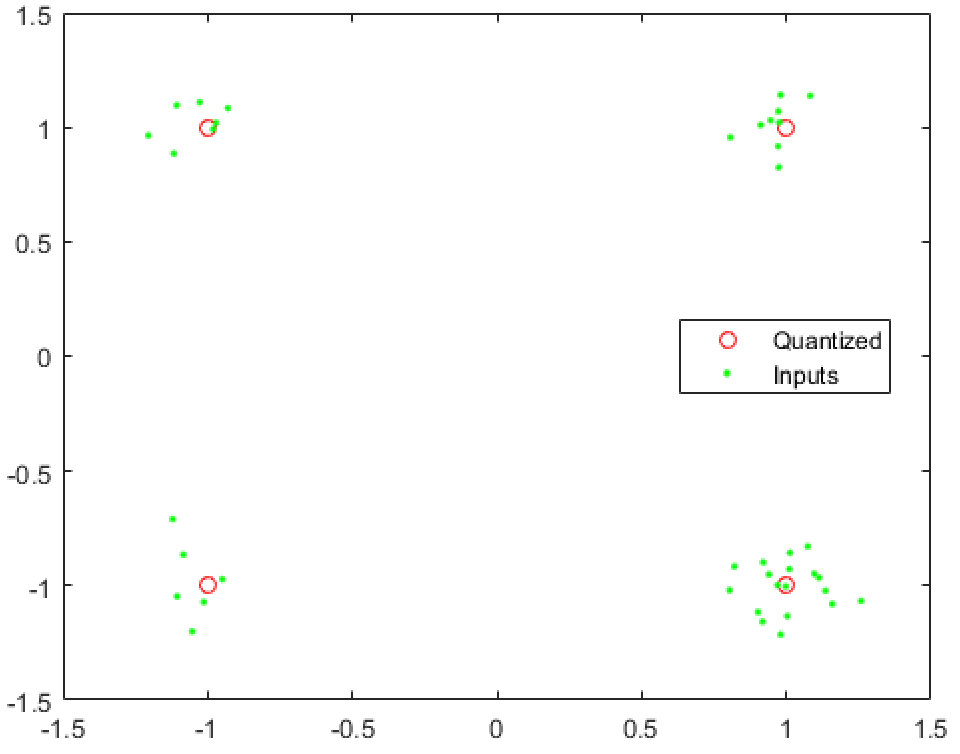
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Find the indices of nearest codewords based on Euclidean distances.

```
vqenc = dsp.VectorQuantizerEncoder(...
    'Codebook', [-1 -1 1 1;1 -1 -1 1], ...
    'CodewordOutputPort', true, ...
    'QuantizationErrorOutputPort', true, ...
    'OutputIndexDataType', 'uint8');
```

Generate an input signal with some additive noise

```
x = sign(rand(2,40)-0.5) + 0.1*randn(2,40);
[ind, cw, err] = vqenc(x);
plot(cw(1,:), cw(2,:), 'rO', x(1,:), x(2,:), 'g.');
legend('Quantized', 'Inputs', 'location', 'best');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Vector Quantizer Encoder` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also
dsp.VectorQuantizerDecoder | dsp.ScalarQuantizerEncoder

Introduced in R2012a

step

System object: dsp.VectorQuantizerEncoder
Package: dsp

Perform vector quantization encoding

Syntax

```
INDEX = step(vqenc,INPUT)
INDEX = step(vqenc,...,CODEBOOK)
INDEX = step(vqenc,...,WEIGHTS)
[..., CODEWORD] = step(vqenc, ...)
[..., QERR] = step(vqenc, ...)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`INDEX = step(vqenc,INPUT)` returns `INDEX`, a scalar or column vector representing the quantization region(s) to which `INPUT` belongs. `INPUT` can be a column vector of size k-by-1 or an M multichannel matrix of dimensions k-by-M, where k is the length of each codeword in the codebook. All inputs to the object can be real floating-point or fixed-point values and must be of the same data type. The output index values can be signed or unsigned integers.

`INDEX = step(vqenc,...,CODEBOOK)` uses the codebook given in input `CODEBOOK`, a k-by-N matrix with N codewords each of length k. This option is available when the `CodebookSource` property is `Input port`.

`INDEX = step(vqenc,...,WEIGHTS)` uses the input vector `WEIGHTS` to emphasize or de-emphasize certain input values when calculating the distortion measure. `WEIGHTS` must be a vector of length equal to the number of rows of `INPUT`. This option is available when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

`[..., CODEWORD] = step(vqenc, ...)` outputs the `CODEWORD` values that correspond to each index value when the `CodewordOutputPort` property is `true`.

`[..., QERR] = step(vqenc, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Window System object

Package: dsp

Window object

Description

The `Window` object applies a window to an input signal.

To apply a window to an input signal:

1. Define and set up your window. See “Construction” on page 4-1909.
2. Call step to apply the window according to the properties of `dsp.Window`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`win = dsp.Window` returns a window object, `win`, that applies a Hamming window with symmetric sampling.

`win = dsp.Window('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a window object, `win`, with each property set to the specified value.

`win = dsp.Window(WINDOW,'`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a window object, `win`, with the `WindowFunction` property set to `WINDOW` and other properties set to the specified values.

Properties

`WindowFunction`

Type of window

Specify the type of window to apply as `Bartlett`, `Blackman`, `Boxcar`, `Chebyshev`, `Hamming` , `Hann`, `Hanning`, `Kaiser`, `Taylor`, `Triang`. The default is `Hamming`. If you run this object in simulation, this property is tunable. When you generate code from a function or script that contains this object, and run the generated code, this property is not tunable.

`WeightsOutputPort`

Enable the output of window weights

Set this property to `true` to output the window weights. The weights are an M-by-1 vector with M equal to the first dimension of the input. The default is `false`.

`StopbandAttenuation`

Level of stopband attenuation in decibels

Specify the level of stopband attenuation in decibels. This property only applies when the `WindowFunction` on page 4-1910 property is `Chebyshev`. The default is 50. This property is tunable.

`Beta`

Kaiser window parameter

Specify the Kaiser window parameter as a real number. Increasing the absolute value of `Beta` widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This property only applies when `WindowFunction` on page 4-1910 property is `Kaiser`. The default is 10. This property is tunable.

`NumConstantSidelobes`

Number of constant sidelobes

Specify the number of constant sidelobes as an integer greater than zero. This property only applies when `WindowFunction` on page 4-1910 property is `Taylor`. The default is 4. This property is tunable.

MaximumSidelobeLevel

Maximum sidelobe level relative to mainlobe

Specify, in decibels, the maximum sidelobe level relative to the mainlobe as a real number less than or equal to zero. The default is –30, which produces sidelobes with peaks 30 dB down from the mainlobe peak. This property only applies when `WindowFunction` on page 4-1910 property is `Taylor`. This property is tunable.

Sampling

Window sampling for generalized-cosine windows

Specify the window sampling for generalized-cosine windows as `Symmetric` or `Periodic`. This property only applies when `WindowFunction` on page 4-1910 property is `Blackman`, `Hamming`, `Hann`, or `Hanning`. If you run this object in simulation, this property is tunable. When you generate code from a function or script that contains this object, and run the generated code, this property is not tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

WindowDataType

Window word and fraction lengths

Specify the window fixed-point data type as one of `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomWindowDataType

Window word and fraction lengths

Specify the window fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `WindowDataType` on page 4-1912 property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` on page 4-1912 property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Output data type

Specify the output fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-1912 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Multiply input by window

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

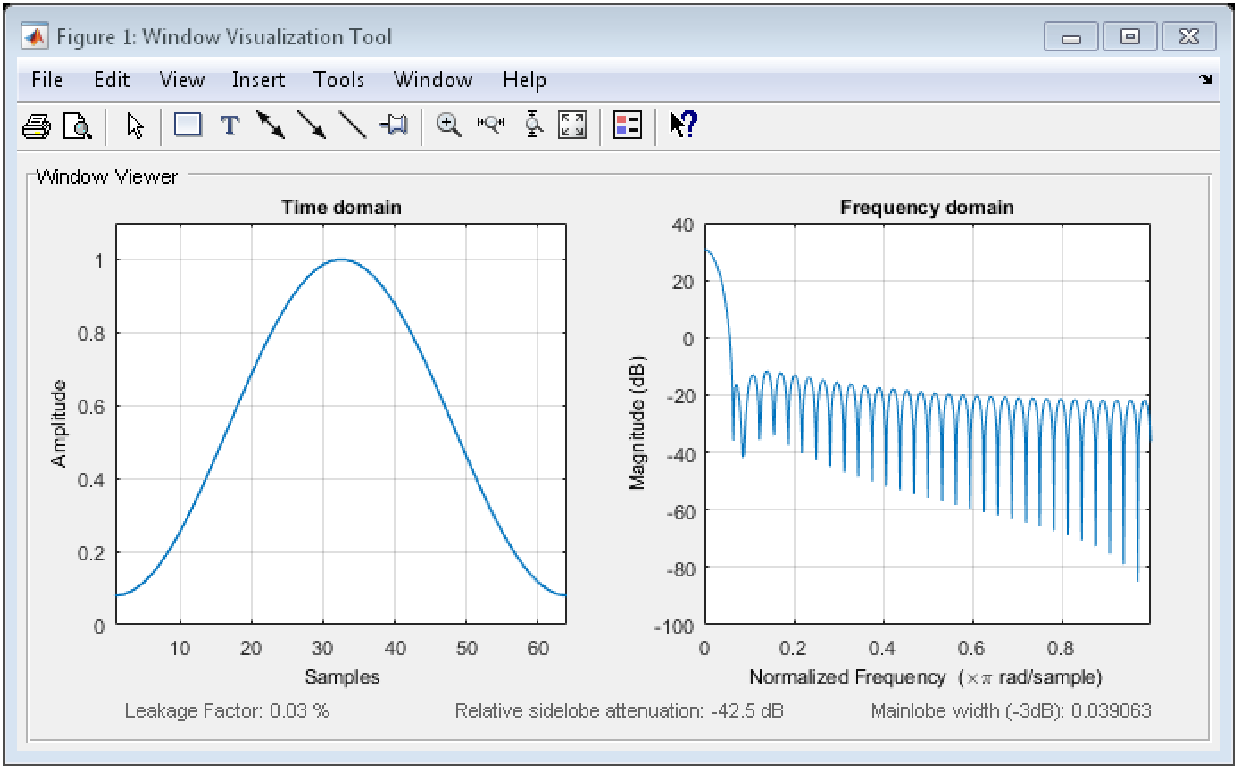
Apply Hamming Window To the Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
win = dsp.Window( ...
    'WindowFunction', 'Hamming', ...
    'WeightsOutputPort',true);
x = rand(64,1);
[y, w] = win(x);
```

View the window's time and frequency domain responses

```
wvtool(w);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Window Function` block reference page. The object properties correspond to the block parameters, except:

- **Operation** — The window object does not support the `Generate window` option.
- **Operation** — The `Generate and apply window` option on the block corresponds to the `WeightsOutputPort` on page 4-1910 property set to `true` on the window object.
- The window object only supports frame-based processing.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: dsp.Window
Package: dsp

Multiply input by window

Syntax

```
Y = step(win,X)
[Y, W] = step(win,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(win,X)` generates the windowed output, `Y` , of the input, `X`, using the specified window.

`[Y, W] = step(win,X)` returns the window values `W` when the `WeightsOutputPort` property is `true`.

This object supports only frame-based processing. To see the effect of the window, the data must have a frame size of at least 2 in each channel.

dsp.ZeroCrossingDetector System object

Package: dsp

Zero crossing detector

Description

The `ZeroCrossingDetector` object counts the number of times the signal crosses zero, or changes sign. The zero crossing detector supports both floating-point and fixed-point data types.

To count the number of times a signal crosses zero or changes sign:

1. Define and set up your zero crossing detector. See "Construction" on page 4-1917.
2. Call step to count the number of times according to the properties of `dsp.ZeroCrossingDetector`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`zcd = dsp.ZeroCrossingDetector` returns a zero crossing detector object, `zcd`, that counts the number of zero crossings in the real-valued,, floating-point, or fixed-point frame-based vector or matrix.

Methods

step	Count zero crossings in input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

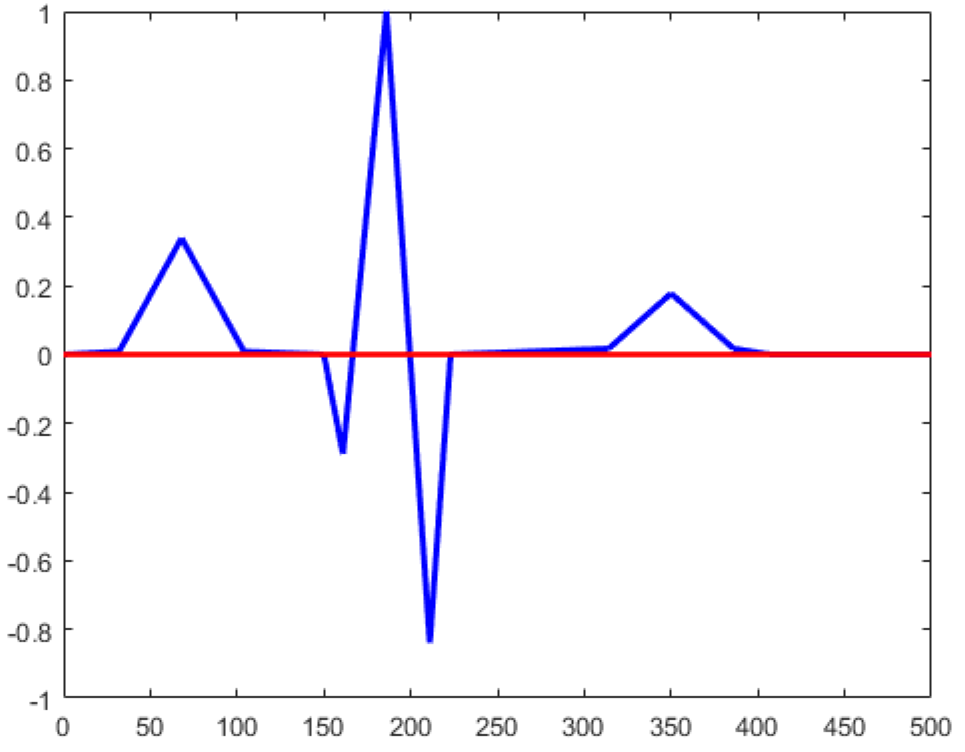
Examples

Determine The Number of Zero Crossings

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Find number of zero crossings in electrocardiogram data.

```
EcgData = ecg(500)';
zcd = dsp.ZeroCrossingDetector;
numZeroCross = zcd(EcgData);  % Equal to 4
plot(1:500,EcgData,'b',[0 500],[0 0],'r','linewidth',2);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Zero Crossing` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

Introduced in R2012a

step

System object: dsp.ZeroCrossingDetector
Package: dsp

Count zero crossings in input

Syntax

`Y = step(zcd,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(zcd,X)` counts the number of zero crossings, `Y`, in the vector or matrix input `X`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

spbscopes.SpectrumAnalyzerConfiguration class

Package: spbscopes

Configure Spectrum Analyzer for programmatic access

Description

The `spbscopes.SpectrumAnalyzerConfiguration` object contains the scope configuration information for the Spectrum Analyzer block.

Construction

Call the `get_param` function, specifying a Spectrum Analyzer block.

`htsc = get_param(gcbh,'ScopeConfiguration')` constructs a new Spectrum Analyzer Configuration object.

Properties

`AxesLayout`

Orientation of the spectrum and spectrogram

Specify the layout type as one of `'Horizontal'` or `'Vertical'`. A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side. This property applies when the `ViewType` is set to `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

Default: `'Vertical'`

`CenterFrequency`

Frequency over which frequency span is centered

Specify as a real scalar the center frequency, in hertz, of the frequency span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the FrequencySpan property to `'Span and center frequency'`. The overall frequency span, defined by the Span and CenterFrequency properties, must fall within the Nyquist frequency interval. When the PlotAsTwoSidedSpectrum property is set to `true`, the interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `0`

ChannelNames

Channel names

Specify as a cell array of character vectors the input channels names to display in the legend, the Style dialog, and in some Measurements panels. The channel names only appear in the legend when the `ShowLegend` property is `true`. The default is an empty cell array, which labels the channels as `Channel 1`, `Channel 2`, etc.

This property is Tunable (Simulink).

FFTLength

FFT length

Specify as a positive, scalar integer the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates. This property applies only when you set the FrequencyResolutionMethod property to `'WindowLength'` and the FFTLengthSource property to `'Property'`. The `FFTLength` must be greater than or equal to the WindowLength. You cannot control the FFT length when the FrequencyResolutionMethod property is `'RBW'`. In that case, the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

This property is Tunable (Simulink).

Default: `128`

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer sets the FFT length to the window length specified in the WindowLength property or to 1024, whichever is larger.
- When you set this property to `'Property'`, specify the number of FFT points using the FFTLength property. The `FFTLength` must be greater than the `WindowLength`.

This property applies only when you set the FrequencyResolutionMethod property to `'WindowLength'`.

`FFTLengthSource` property is Tunable (Simulink).

Default: `'Auto'`

FrequencyOffset

Frequency offset

Specify as a real, scalar value to apply the same frequency offset, in Hertz, to all channels. To apply a specific frequency offset for each channel, specify a vector of real, scalar values. The vector length must be equal to number of input channels. The *frequency*-axis values are offset by the values specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. You can control the overall span in different ways based on how you set the FrequencySpan property.

This property is Tunable (Simulink).

Default: `0`

FrequencyResolutionMethod

Frequency resolution method

Specify how to control the frequency resolution of the spectrum analyzer as either 'RBW' or 'WindowLength'. When you set this property to 'RBW', the RBWSource and RBW properties control the frequency resolution (in Hz) of the analyzer. When you set this property to 'WindowLength', the WindowLength property controls the frequency resolution.

In this case, the frequency resolution of the analyzer is defined as $\frac{NENBW * Fs}{N_{window}}$ where *NENBW* is the normalized effective noise bandwidth of the window currently specified in the Window property. You can control the number of FFT points only when the FrequencyResolutionMethod property is 'WindowLength'. When the FrequencyResolutionMethod property is 'RBW', the FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.

This property is Tunable (Simulink).

Default: 'RBW'

FrequencyScale

Frequency scale

Specify the frequency scale as either 'Linear' or 'Log'. When you set the FrequencyScale property to 'Log', the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the 'Log' setting, you must also set the PlotAsTwoSidedSpectrum property to false. When the PlotAsTwoSidedSpectrum property is true, you must set this property to 'Linear'.

This property is Tunable (Simulink).

Default: 'Linear'

FrequencySpan

Frequency span mode

Specify the frequency span mode as one of 'Full', 'Span and center frequency', or 'Start and stop frequencies'.

- When you set this property to `'Full'`, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.
- When you set this property to `'Span and center frequency'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- When you set this property to `'Start and stop frequencies'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

This property is Tunable (Simulink).

Default: `'Full'`

`Name`

Caption to display on Spectrum Analyzer window

Specify as a character vector the caption to display on the scope window. This property is Tunable (Simulink).

Default: `'Spectrum Analyzer'`

`NumInputPorts`

Number of input ports

Number of input ports, specified as an integer. Each signal coming through an input port becomes a separate channel in the Spectrum Analyzer.

Default: `1`

`OpenAtSimulationStart`

Open scope when starting simulation

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening at the start of simulation.

Default: `true`

`OverlapPercent`

Overlap percentage

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. This property is Tunable (Simulink).

Default: `0`

`PlotAsTwoSidedSpectrum`

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

Default: `true`

`PlotMaxHoldTrace`

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

See also: PlotMinHoldTrace and PlotNormalTrace.

Default: `false`

`PlotMinHoldTrace`

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

See also: PlotMaxHoldTrace andPlotNormalTrace.

Default: `false`

`PlotNormalTrace`

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

See also: PlotMaxHoldTrace and PlotMinHoldTrace.

Default: `true`

`PlotType`

Plot type for normal traces

Specify the type of plot to use for displaying normal traces as either `'Line'` or `'Stem'`. *Normal* traces are traces that display free-running spectral estimates. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'` and the PlotNormalTrace property to `true`.

This property is Tunable (Simulink).

Default: `'Line'`

Position

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable (Simulink).

Default: The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of `800` pixels and height of `450` pixels.

RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the FrequencyResolutionMethod property to `'RBW'` and the RBWSource property to `'Property'`. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two: $\frac{span}{RBW} > 2$. You can specify the overall span in different ways based on how you set the `FrequencySpan` on page 4-1573 property.

This property is Tunable (Simulink).

See also: RBWSource.

Default: `9.76`

RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either `'Auto'` or `'Property'`. This property is relevant only when you set the FrequencyResolutionMethod property to `'RBW'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer adjusts the spectral estimation resolution to ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to `'Property'`, specify the resolution bandwidth directly using the RBW property.

This property is Tunable (Simulink).

See also: RBW.

Default: `'Auto'`

`ReducePlotRate`

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted. When you set this property to `false`, the scope updates every time it computes the power spectrum. Use the `false` setting when you do not want to miss any spectral updates at the expense of slower simulation speed. The simulation speed is faster when this property is set to `true`. This property is Tunable (Simulink).

Default: `true`

`ReferenceLoad`

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable (Simulink).

Default: `1`

`SampleRate`

Sample rate of input

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

Default: `10e3`

`ShowGrid`

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable (Simulink).

Default: `false`

`ShowLegend`

Show or hide legend

When you set this property to `true`, the scope displays a legend with the input channels labels specified in the `ChannelNames` on page 4-1570 property. When you set this property to `false`, the scope does not display a legend.

This property applies only when you set the `ViewType` property to `'Spectrum'` or `'Spectrum and spectrogram'`. This property is Tunable (Simulink).

Default: `false`

`SidelobeAttenuation`

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the Window property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to `45`.

This property is Tunable (Simulink).

Default: `60`

`Span`

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to `'Span and center frequency'`. The overall span, defined by this property and the CenterFrequency property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `10e3`

SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. This property applies only when you set the ViewType property to `'Spectrum'`. The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last N power spectrum estimates. This property defines the number of spectral averages, N.

This property is Tunable (Simulink).

Default: `1`

SpectralMask

Spectral mask lines for a Power or Power Density plot.

Specify whether to display upper and lower spectral masks lines on a spectrum plot. This property uses `SpectralMaskSpecfication` properties to enable and configure the spectral masks. The `SpectralMaskSpecfication` properties are:

- `EnabledMasks` — Masks to enable, specified as a character vector. Valid values are `'None'`, `'Upper'`, `'Lower'`, or `'Upper and lower'`.

  Default: `'None'`
- `UpperMask` — Upper limit spectral mask, specified as a scalar or two-column matrix. If `UpperMask` is a scalar, the upper limit mask uses the power value of the scalar

for all frequency values applicable to the Spectrum Analyzer. If UpperMask is a matrix, the first column contains the frequency values (Hz), which correspond to the *x*-axis values. The second column contains the power values, which correspond to the associated *y*-axis values. To apply offsets to the power and frequency values, use ReferenceLevel and MaskFrequencyOffset property values, respectively.

Default: Inf

- LowerMask — Lower limit spectral mask, specified as a scalar or two-column matrix. If LowerMask is a scalar, the lower limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer. If LowerMask is a matrix, the first column contains the frequency values (Hz), which correspond to the *x*-axis values. The second column contains the power values, which correspond to the associated *y*-axis values. To apply offsets to the power and frequency values, use ReferenceLevel and MaskFrequencyOffset property values, respectively.

  Default: Inf

- ReferenceLevel — Reference level for mask power values, specified as either 'Custom' or 'Spectrum peak'. When ReferenceLevel is 'Custom', the CustomReferenceLevel property value is used as the reference to the power values, in dBr, in the UpperMask and LowerMask properties. When ReferenceLevel is 'Spectrum peak', the peak value of the current spectrum of the SelectedChannel is used.

  Default: 'Custom'

- CustomReferenceLevel — Custom reference level, specified as a real value, in the same units as the power units. The reference level is the value to which to reference the power values in the UpperMask and LowerMask properties. This property applies when ReferenceLevel is set to 'Custom'. This property uses the same units as the PowerUnits property of the Spectrum Analyzer.

  Default: 0

- SelectedChannel — Input channel with peak spectrum to use as the mask reference level, specified as an integer. This property applies when ReferenceLevel is set to 'Spectrum peak'.

  Default: 1

- MaskFrequencyOffset — Frequency offset, specified as a finite, numeric scalar. Frequency offset is the amount of offset to apply to frequency values in the UpperMask and LowerMask properties.

Default: `0`

All `SpectralMaskSpecfication` properties are Tunable (Simulink).

You can check the status of the spectral mask using a method or an event listener.

- To get the status of the spectral masks, call getSpectralMaskStatus.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

For example spectral masks, refer to the dsp.SpectrumAnalzyer System object or `Spectrum Analyzer` block.

SpectrumType

Type of spectrum to show

Specify the spectrum type as one of `'Power'`, `'Power density'`, or `'RMS'`.

- `'Power'`, the Spectrum Analyzer shows the power spectrum.
- `'Power density'`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.
- `'RMS'`, the Spectrum Analyzer shows the root mean squared. The root mean squared shows the square root of the sum of the squared means. This option is useful when viewing the frequency of voltage or current signals.

This property is Tunable (Simulink).

Default: `'Power'`

SpectrumUnits

Units of the spectrum

Specify the units in which the Spectrum Analyzer displays power values as either `'dBm'`, `'dBW'`, `'Watts'`, `'Vrms'`, or `'dBV'`.

The available spectrum units depends on the value of `SpectrumType`.

`SpectrumType`	Allowed `SpectrumUnits`
`Power` or `Power density`	`'dBm'`, `'dBW'`, `'Watts'`
`RMS`	`'Vrms'`, `'dBV'`

This property is Tunable (Simulink).

Default: `'dBm'`

`StartFrequency`

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to `'Start and stop frequencies'`. The overall span, which is defined by StopFrequency and this property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `-5e3`

`StopFrequency`

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the FrequencySpan property to `'Start and stop frequencies'`. The overall span, defined by this property and the StartFrequency property, must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is set to `true`, the interval is $\left[-\frac{SampleRate}{2},\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0,\frac{SampleRate}{2}\right]+FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `5e3`

`TimeResolution`

Time resolution

Specify the time resolution of each spectrogram line as a positive scalar, expressed in seconds. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum and spectrogram'`, and the TimeResolutionSource property to `'Property'`.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
RBW (Hz)	`Auto`	`Auto`	1/RBW s
RBW (Hz)	`Auto`	Manually entered	Time Resolution s
RBW (Hz)	Manually entered	`Auto`	1/RBW s
RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW s. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
Window length	—	`Auto`	1/RBW s RBW = *(NENBW**Fs)/Window Length, where *NENBW* is the normalized effective noise bandwidth of the specified window.
Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, *(NENBW**Fs)/ Window Length. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

This property is Tunable (Simulink).

Default: `0.001`

`TimeResolutionSource`

Source of the time resolution value.

Specify the source for the time resolution of each spectrogram line as either `'Auto'` or `'Property'`. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum and spectrogram'`. See the time resolution table at TimeResolution.

This property is Tunable (Simulink).

Default: `'Auto'`

`TimeSpan`

Time span

Specify the time span of the spectrogram display as a positive scalar in seconds. This property applies when you set the ViewType property to `'Spectrogram'` or `'Spectrum` and spectrogram'and the TimeSpanSource property to 'Property'. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

This property is Tunable (Simulink).

Default: 0.1

TimeSpanSource

Source of time span value

Specify the source for the time span of the spectrogram as either 'Auto' or 'Property'. This property applies when you set the ViewType property to 'Spectrogram' or 'Spectrum and spectrogram'. If you set this property to 'Auto', the spectrogram displays 100 spectrogram lines at any given time. If you set this property to 'Property', the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

This property is Tunable (Simulink).

Default: 'Auto'

Title

Display title

Specify the display title as a character vector. Enter %<SignalLabel> to use the signal labels in the Simulink Model as the axes titles. This property is Tunable (Simulink).

Default: ''

TreatMby1SignalsAsOneChannel

Treat unoriented sample-based input signal as a column vector

Set this property to true to treat M-by-1 and unoriented sample-based inputs as a column vector, or one channel. Set this property to false to treat M-by-1 and unoriented sample-based inputs as a 1-by-M row vector.

Default: true

ViewType

Viewer type

Specify the spectrum type as one of 'Spectrum', 'Spectrogram', or 'Spectrum and spectrogram'.

- 'Spectrum' — the Spectrum Analyzer shows the spectrum.
- 'Spectrogram' — the Spectrum Analyzer opens a spectrogram view, which shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.
- 'Spectrum and Spectrogram' — the Spectrum Analyzer shows a dual view of a spectrum and spectrogram.

This property is Tunable (Simulink).

Default: 'Spectrum'

Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
'Rectangular'	rectwin
'Chebyshev'	chebwin
'Flat Top'	flattopwin
'Hamming'	hamming
'Hann'	hann
'Kaiser'	kaiser

This property is Tunable (Simulink).

Default: 'Hann'

WindowLength

The window length

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2. This property applies only when you set the FrequencyResolutionMethod property to `'WindowLength'`, which controls the frequency resolution based on your window length setting. The resulting resolution bandwidth (RBW) is $\frac{NENBW * Fs}{N_{window}}$ where N_{window} is the `WindowLength` value.

This property is Tunable (Simulink).

See also: Window.

Default: `1024`

YLabel

The label for the *y*-axis

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`. Regardless of this property, Spectrum Analyzer always displays power units as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`, `'Vrms'`, `'dBV'`.

See also: SpectrumUnits.

Default: `''`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable (Simulink).

This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`. The units directly depend upon the SpectrumUnits property.

Default: `[-80, 20]`

Examples

Construct a Spectrum Analyzer Configuration Object

Create a new Simulink® model with a randomly-generated name.

```
sysname=char(randi(26,1,7)+96);
new_system(sysname);
```

Add a new Spectrum Analyzer block to the model.

```
add_block('built-in/SpectrumAnalyzer',[sysname,'/SpectrumAnalyzer'])
```

Call the `get_param (Simulink)` function to retrieve the default Spectrum Analyzer block configuration properties.

```
hsac = get_param([sysname,'/SpectrumAnalyzer'],'ScopeConfiguration')
```

```
hsac =

  SpectrumAnalyzerConfiguration with properties:

                          Name: 'SpectrumAnalyzer'

Adaptive filter

Compatibility

`adaptfilt` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.algorithm('input1',input2,...)
```

Description

`ha = adaptfilt.`*`algorithm`*`('input1',input2,...)` returns the adaptive filter object `ha` that uses the adaptive filtering technique specified by *`algorithm`*. When you construct an adaptive filter object, include an *`algorithm`* specifier to implement a specific adaptive filter. Note that you do not enclose the algorithm option in single quotation marks. To construct an adaptive filter object you must supply an *`algorithm`* name — there is no default algorithm, although every constructor creates a default adaptive filter when you do not provide input arguments such as `input1` or `input2` in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Algorithms

For adaptive filter (`adaptfilt`) objects, the *`algorithm`* name determines which adaptive filter algorithm your `adaptfilt` object implements. Each available algorithm entry appears in one of the tables along with a brief description of the algorithm. Click on the algorithm in the first column to get more information about the associated adaptive filter technique.

Least Mean Squares (LMS) Based FIR Adaptive Filters

adaptfilt.algorithm	Algorithm Used to Generate Filter Coefficients
`adaptfilt.adjlms`	Use the Adjoint LMS FIR adaptive filter algorithm
`adaptfilt.blms`	Use the Block LMS FIR adaptive filter algorithm
`adaptfilt.blmsfft`	Use the FFT-based Block LMS FIR adaptive filter algorithm
`adaptfilt.dlms`	Use the delayed LMS FIR adaptive filter algorithm
`adaptfilt.filtxlms`	Use the filtered-x LMS FIR adaptive filter algorithm
`adaptfilt.lms`	Use the LMS FIR adaptive filter algorithm
`adaptfilt.nlms`	Use the normalized LMS FIR adaptive filter algorithm
`adaptfilt.sd`	Use the sign-data LMS FIR adaptive filter algorithm
`adaptfilt.se`	Use the sign-error LMS FIR adaptive filter algorithm
`adaptfilt.ss`	Use the sign-sign LMS FIR adaptive filter algorithm

For further information about an adapting algorithm, refer to the reference page for the algorithm.

Recursive Least Squares (RLS) Based FIR Adaptive Filters

adaptfilt.algorithm	Algorithm Used to Generate Filter Coefficients
`adaptfilt.ftf`	Use the fast transversal least squares adaptation algorithm
`adaptfilt.qrdrls`	Use the QR-decomposition RLS adaptation algorithm
`adaptfilt.hrls`	Use the householder RLS adaptation algorithm

adaptfilt.algorithm	Algorithm Used to Generate Filter Coefficients
`adaptfilt.hswrls`	Use the householder SWRLS adaptation algorithm
`adaptfilt.rls`	Use the recursive-least squares (RLS) adaptation algorithm
`adaptfilt.swrls`	Use the sliding window (SW) RLS adaptation algorithm
`adaptfilt.swftf`	Use the sliding window FTF adaptation algorithm

For more complete information about an adapting algorithm, refer to the reference page for the algorithm.

Affine Projection (AP) FIR Adaptive Filters

adaptfilt.algorithm	Algorithm Used to Generate Filter Coefficients
`adaptfilt.ap`	Use the affine projection algorithm that uses direct matrix inversion
`adaptfilt.apru`	Use the affine projection algorithm that uses recursive matrix updating
`adaptfilt.bap`	Use the block affine projection adaptation algorithm

To find more information about an adapting algorithm, refer to the reference page for the algorithm.

FIR Adaptive Filters in the Frequency Domain (FD)

adaptfilt.algorithm	Algorithm Used to Generate Filter Coefficients
`adaptfilt.fdaf`	Use the frequency domain adaptation algorithm
`adaptfilt.pbfdaf`	Use the partition block version of the FDAF algorithm
`adaptfilt.pbufdaf`	Use the partition block unconstrained version of the FDAF algorithm
`adaptfilt.tdafdct`	Use the transform domain adaptation algorithm using DCT
`adaptfilt.tdafdft`	Use the transform domain adaptation algorithm using DFT
`adaptfilt.ufdaf`	Use the unconstrained FDAF algorithm for adaptation

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Lattice Based (L) FIR Adaptive Filters

adaptfilt.algorithm	Algorithm Used to Generate Filter Coefficients
`adaptfilt.gal`	Use the gradient adaptive lattice filter adaptation algorithm
`adaptfilt.lsl`	Use the least squares lattice adaptation algorithm
`adaptfilt.qrdlsl`	Use the QR decomposition least squares lattice adaptation algorithm

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Properties for All Adaptive Filter Objects

Each reference page for an algorithm and `adaptfilt.algorithm` object specifies which properties apply to the adapting algorithm and how to use them.

Methods for Adaptive Filter Objects

As is true with all objects, methods enable you to perform various operations on `adaptfilt` objects. To use the methods, you apply them to the object handle that you assigned when you constructed the `adaptfilt` object.

Most of the analysis methods that apply to `dfilt` objects also work with `adaptfilt` objects. Methods like `freqz` rely on the filter coefficients in the `adaptfilt` object. Since the coefficients change each time the filter adapts to data, you should view the results of using a method as an analysis of the filter at a moment in time for the object. Use caution when you apply an analysis method to your adaptive filter objects — always check that your result approached your expectation.

In particular, the Filter Visualization Tool (FVTool) supports all of the `adaptfilt` objects. Analyzing and viewing your `adaptfilt` objects is straightforward — use the `fvtool` method with the name of your object

```
fvtool(objectname)
```

to launch FVTool and work with your object.

Some methods share their names with functions in Signal Processing Toolbox software, or even functions in this toolbox. Functions that share names with methods behave in a similar way. Using the same name for more than one function or method is called *overloading* and is common in many toolboxes.

Method	Description
`adaptfilt/coefficients`	Return the instantaneous adaptive filter coefficients
`adaptfilt/filter`	Apply an `adaptfilt` object to your signal
`adaptfilt/freqz`	Plot the instantaneous adaptive filter frequency response
`adaptfilt/grpdelay`	Plot the instantaneous adaptive filter group delay
`adaptfilt/impz`	Plot the instantaneous adaptive filter impulse response.
`adaptfilt/info`	Return the adaptive filter information.
`adaptfilt/isfir`	Test whether an adaptive filter is an finite impulse response (FIR) filters.
`adaptfilt/islinphase`	Test whether an adaptive filter is linear phase
`adaptfilt/ismaxphase`	Test whether an adaptive filter is maximum phase
`adaptfilt/isminphase`	Test whether an adaptive filter is minimum phase
`adaptfilt/isreal`	True whether an adaptive filter has real coefficients
`adaptfilt/isstable`	Test whether an adaptive filter is stable
`adaptfilt/maxstep`	Return the maximum step size for an adaptive filter
`adaptfilt/msepred`	Return the predicted mean square error
`adaptfilt/msesim`	Return the measured mean square error via simulation.
`adaptfilt/phasez`	Plot the instantaneous adaptive filter phase response
`adaptfilt/reset`	Reset an adaptive filter to initial conditions

Method	Description
`adaptfilt/stepz`	Plot the instantaneous adaptive filter step response
`adaptfilt/tf`	Return the instantaneous adaptive filter transfer function
`adaptfilt/zerophase`	Plot the instantaneous adaptive filter zerophase response
`adaptfilt/zpk`	Return a matrix containing the instantaneous adaptive filter zero, pole, and gain values
`adaptfilt/zplane`	Plot the instantaneous adaptive filter in the Z-plane

Working with Adaptive Filter Objects

The next sections cover viewing and changing the properties of `adaptfilt` objects.

Viewing Object Properties

As with any object, you can use `get` to view a `adaptfilt` object's properties. To see a specific property, use

```
get(ha,'property')
```

To see all properties for an object, use

```
get(ha)
```

Changing Object Properties

To set specific properties, use

```
set(ha,'property1',value1,'property2',value2,...)
```

You must use single quotation marks around the property name so MATLAB treats them as character vectors.

Copying an Object

To create a copy of an object, use `copy`.

```
ha2 = copy(ha)
```

Note Using the syntax `ha2 = ha` copies only the object handle and does not create a new object — `ha` and `ha2` are not independent. When you change the characteristics of `ha2`, those of `ha` change as well.

Using Filter States

Two properties control your adaptive filter states.

- `States` — stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions.
- `PersistentMemory` — resets the filter before filtering. The default value is `false` which causes the properties that are modified by the filter, such as `coefficients` and `states`, to be reset to the value you specified when you constructed the object, before you use the object to filter data. Setting `PersistentMemory` to `true` allows the object to retain its current properties between filtering operations, rather than resetting the filter to its property values at construction.

Examples

Construct an LMS adaptive filter object and use it to identify an unknown system. For this example, use 500 iteration of the adapting process to determine the unknown filter coefficients. Using the LMS algorithm represents one of the most straightforward technique for adaptive filters.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

`dfilt` | `filter`

Introduced in R2011a

adaptfilt.adjlms

FIR adaptive filter that uses adjoint LMS algorithm

Compatibility

`adaptfilt.adjlms` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,...
errstates,pstates,coeffs,states)
```

Note: `adaptfilt.adjlms` will be removed in a future release.

Description

`ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,... errstates,pstates,coeffs,states)` constructs object `ha`, an FIR adjoint LMS adaptive filter. `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10 when you omit the argument. `step` is the adjoint LMS step size. It must be a nonnegative scalar. When you omit the `step` argument, `step` defaults to 0.1.

`leakage` is the adjoint LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, you implement a leaky version of the `adjlms` algorithm to determine the filter coefficients. `leakage` defaults to 1 specifying no leakage in the algorithm.

`pathcoeffs` is the secondary path filter model. This vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.

pathest is the estimate of the secondary path filter model. pathest defaults to the values in pathcoeffs.

errstates is a vector of error states of the adaptive filter. It must have a length equal to the filter order of the secondary path model estimate. errstates defaults to a vector of zeros of appropriate length. pstates contains the secondary path FIR filter states. It must be a vector of length equal to the filter order of the secondary path model. pstates defaults to a vector of zeros of appropriate length. The initial filter coefficients for the secondary path filter compose vector coeffs. It must be a length l vector. coeffs defaults to a length l vector of zeros. states is a vector containing the initial filter states. It must be a vector of length l+ne-1, where ne is the length of errstates. When you omit states, it defaults to an appropriate length vector of zeros.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for filter.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	None	Specifies the adaptive filter algorithm the object uses during adaptation
Coefficients	Length l vector with zeros for all elements	Adjoint LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need l entries in coefficients. Updated filter coefficients are returned in coefficients when you use s as an output argument.
ErrorStates	[0,...,0]	A vector of the error states for your adaptive filter, with length equal to the order of your secondary path filter.
FilterLength	10	The number of coefficients in your adaptive filter.

Property	Default Value	Description
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`SecondaryPathCoeffs`	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
`SecondaryPathEstimate`	`pathcoeffs` values	An estimate of the secondary path filter model.
`SecondaryPathStates`	Length of the secondary path filter. All elements are zeros.	The states of the secondary path filter, the unknown system
`States`	l+ne+1, where ne is `length(errstates)`	Contains the initial conditions for your adaptive filter and returns the states of the FIR filter after adaptation. If omitted, it defaults to a zero vector of length equal to l +ne+1. When you use `adaptfilt.adjlms` in a loop structure, use this element to specify the initial filter states for the adapting FIR filter.
`Stepsize`	0.1	Sets the adjoint LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Demonstrate active noise control of a random noise signal that runs for 1000 samples.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be canceled (desired)
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Adjoint LMS step size
ha = adaptfilt.adjlms(32,mu,1,b);
[y,e] = filter(ha,x,d);
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Reviewing the figure shows that the adaptive filter attenuates the original noise signal as you expect.

`adaptfilt.dlms` | `adaptfilt.filtxlms`

Introduced in R2011a

adaptfilt.ap

FIR adaptive filter that uses direct matrix inversion

Compatibility

`adaptfilt.ap` has been removed. Use dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,...
errstates,epsstates)
```

Description

`ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,...
errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using direct matrix inversion.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ap`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.

Input Argument	Description
projectord	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
offset	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. offset should be positive. offset defaults to one.
coeffs	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
errstates	Vector of the adaptive filter error states. errstates defaults to a zero vector with length equal to (projectord - 1).
epsstates	Vector of the epsilon values of the adaptive filter. epsstates defaults to a vector of zeros with (projectord - 1) elements.

Properties

Since your adaptfilt.ap filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.ap objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix

Name	Range	Description
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`ErrorStates`	Vector of elements	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`EpsilonStates`	Vector of elements	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. Run the adaptation for 1000 iterations.

```
D  = 16;                      % Number of samples of delay
b  = exp(j*pi/4)*[-0.7 1];    % Numerator coefficients of channel
a  = [1 -0.7];                % Denominator coefficients of channel
ntr= 1000;                    % Number of iterations
s  = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D));% Baseband Signal
n  = 0.1*(randn(1,ntr+D) + j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;         % Received signal
```

```
x  = r(1+D:ntr+D);     % Input signal (received signal)
d  = s(1:ntr);         % Desired signal (delayed QPSK signal)
mu = 0.1;              % Step size
po = 4;                % Projection order
offset = 0.05;         % Offset for covariance matrix
ha = adaptfilt.ap(32,mu,po,offset);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

The four plots shown reveal the QPSK process at work.

`msesim`

Introduced in R2011a

adaptfilt.apru

FIR adaptive filter that uses recursive matrix updating

Compatibility

`adaptfilt.apru` has been removed. Use dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,
...errstates,epsstates)
```

Description

`ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,`
`...errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using recursive matrix updating.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.apru`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.

Input Argument	Description
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.
`coeffs`	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`states`	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`errstates`	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`epsstates`	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.

Properties

Since your `adaptfilt.apru` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.apru` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ProjectionOrder`	1 to as large as needed.	Projection order of the affine projection algorithm. `ProjectionOrder` defines the size of the input signal covariance matrix and defaults to two.
`OffsetCov`	Matrix of values	Contains the offset covariance matrix
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector,

Name	Range	Description
		the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`ErrorStates`	Vector of elements	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`EpsilonStates`	Vector of elements	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Demonstrate quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. This example runs the adaptation process for 1000 iterations.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
```

```
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % Baseband
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));  % Noise signal
r  = filter(b,a,s)+n;     % Received signal
x  = r(1+D:ntr+D); % Input signal (received signal)
d  = s(1:ntr);     % Desired signal (delayed QPSK signal)
mu = 0.1;                       % Step size
po = 4;                         % Projection order
offset = 0.05;                     % Offset
ha = adaptfilt.apru(32,mu,po,offset); [y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

In the following component and scatter plots, you see the results of QPSK equalization.

`adaptfilt` | `adaptfilt.ap` | `adaptfilt.bap`

Introduced in R2011a

adaptfilt.bap

FIR adaptive filter that uses block affine projection

Compatibility

`adaptfilt.bap` has been removed. Use dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)
```

Description

`ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)` constructs a block affine projection FIR adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.bap`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.

Input Argument	Description
offset	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. offset should be positive. offset defaults to one.
coeffs	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
states	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Properties

Since your adaptfilt.bap filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.bap objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps
ProjectionOrder	1 to as large as needed.	Projection order of the affine projection algorithm. ProjectionOrder defines the size of the input signal covariance matrix and defaults to two.
OffsetCov	Matrix of values	Contains the offset covariance matrix
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector, the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Name	Range	Description
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Show an example of quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                              % delay
b  = exp(1j*pi/4)*[-0.7 1];           % Numerator coefficients
a  = [1 -0.7];                       % Denominator coefficients
ntr= 1000;                           % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;                          % Received signal
x  = r(1+D:ntr+D);                    % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
mu = 0.5;                        % Step size
po = 4;                          % Projection order
offset = 1.0;                    % Offset for covariance matrix
ha = adaptfilt.bap(32,mu,po,offset);
[y,e] = filter(ha,x,d); subplot(2,2,1);
plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

Using the block affine projection object in QPSK results in the plots shown here.

`adaptfilt` | `adaptfilt.ap` | `adaptfilt.apru`

Introduced in R2011a

adaptfilt.blms

FIR adaptive filter that uses BLMS

Compatibility

`adaptfilt.blms` has been removed. Usedsp.BlockLMSFilter instead.

Syntax

```
ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)
```

Description

`ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)` constructs an FIR block LMS adaptive filter `ha`, where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10.

`step` is the block LMS step size. You must set step to a nonnegative scalar. You can use function `maxstep` to determine a reasonable range of step size values for the signals being processed. When unspecified, `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must be a scalar between 0 and 1. If you set leakage to be less than one, you implement the leaky block LMS algorithm. `leakage` defaults to 1 specifying no leakage in the adapting algorithm.

`blocklen` is the block length used. It must be a positive integer and the signal vectors `d` and `x` should be divisible by `blocklen`. Larger block lengths result in faster per-sample execution times but with poor adaptation characteristics. When you choose `blocklen` such that `blocklen + length(coeffs)` is a power of 2, use `adaptfilt.blmsfft`. `blocklen` defaults to `l`.

`coeffs` is a vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector of zeros.

`states` contains a vector of your initial filter states. It must be a length `l` vector and defaults to a length `l` vector of zeros when you do not include it in your calling function.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`
`Leakage`		Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`BlockLength`	Vector of length `l`	Size of the blocks of data processed in each iteration
`StepSize`	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely

Property	Default Value	Description
		the adaptive filter converges to the filter solution. Use `maxstep` to determine the maximum usable step size.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Use an adaptive filter to identify an unknown 32nd-order FIR filter. In this example 500 input samples result in 500 iterations of the adaptation process. You see in the plot that follows the example code that the adaptive filter has determined the coefficients of the unknown system under test.

```
x  = randn(1,500);        % Input to the filter
b  = fir1(31,0.5);        % FIR system to be identified
no  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+no;    % Desired signal
mu = 0.008;               % Block LMS step size
n  = 5;                   % Block length
ha = adaptfilt.blms(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');
grid on;
```

Based on looking at the figures here, the adaptive filter correctly identified the unknown system after 500 iterations, or fewer. In the lower plot, you see the comparison between the actual filter coefficients and those determined by the adaptation process.

See Also

`adaptfilt.blmsfft` | `adaptfilt.fdaf` | `adaptfilt.lms`

Introduced in R2011a

adaptfilt.blmsfft

FIR adaptive filter that uses FFT-based BLMS

Compatibility

`adaptfilt.blmsfft` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs,
states)
```

Description

`ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs, states)` constructs an FIR block LMS adaptive filter object `ha` where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10. `step` is the block LMS step size. It must be a nonnegative scalar. The function `maxstep` may be helpful to determine a reasonable range of step size values for the signals you are processing. `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must also be a scalar between 0 and 1. When `leakage` is less than one, the `adaptfilt.blmsfft` implements a leaky block LMS algorithm. `leakage` defaults to 1 (no leakage). `blocklen` is the block length used. It must be a positive integer such that

```
blocklen + length(coeffs)
```

is a power of two; otherwise, an `adaptfilt.blms` algorithm is used for adapting. Larger block lengths result in faster execution times, with poor adaptation characteristics as the cost of the speed gained. `blocklen` defaults to `l`. Enter your initial filter coefficients in `coeffs`, a vector of length `l`. When omitted, `coeffs` defaults to a length `l` vector of all zeros. `states` contains a vector of initial filter states; it must be a length `l` vector. `states` defaults to a length `l` vector of all zeros when you omit the `states` argument in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coefficients` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements of length `l`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`BlockLength`	Vector of length `l`	Size of the blocks of data processed in each iteration
`StepSize`	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm.

Property	Default Value	Description
		Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use `maxstep` to determine the maximum usable step size.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Identify an unknown FIR filter with 32 coefficients using 512 iterations of the adapting algorithm.

```
x  = randn(1,512);       % Input to the filter
b  = fir1(31,0.5);       % FIR system to be identified
no  = 0.1*randn(1,512);  % Observation noise signal
d  = filter(b,1,x)+no;   % Desired signal
mu = 0.008;              % Step size
n  = 16;                 % Block length
ha = adaptfilt.blmsfft(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d(1:500);y(1:500);e(1:500)]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error'); xlabel('Time Index');
ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('actual','estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As a result of running the adaptation process, filter object `ha` now matches the unknown system FIR filter `b`, based on comparing the filter coefficients derived during adaptation.

`adaptfilt.blms` | `adaptfilt.fdaf` | `adaptfilt.lms` | `filter`

Introduced in R2011a

adaptfilt.dlms

FIR adaptive filter that uses delayed LMS

Compatibility

`adaptfilt.dlms` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs,
...states)
```

Description

`ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs, ...states)` constructs an FIR delayed LMS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.dlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a

Input Argument	Description
	leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`delay`	Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1.
`errstates`	Vector of the error states of your adaptive filter. It must have a length equal to the update delay (`delay`) in samples. `errstates` defaults to an appropriate length vector of zeros.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input. LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need `l` entries in `coeffs`.
`Delay`	1	Specifies the update delay for the adaptive algorithm.

Property	Default Value	Description
ErrorStates	Vector of zeros with the number of elements equal to delay	A vector comprising the error states for the adaptive filter.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
StepSize	0.1	Sets the LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).

Examples

System identification of a 32-coefficient FIR filter. Refer to the figure that follows to see the results of the adapting filter process.

```
x  = randn(1,500);      % Input to the filter
b  = fir1(31,0.5);      % FIR system to be identified
n  = 0.1*randn(1,500);  % Observation noise signal
d  = filter(b,1,x)+n;   % Desired signal
mu = 0.008;             % LMS step size.
delay = 1;              % Update delay
ha = adaptfilt.dlms(32,mu,1,delay);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using a delayed LMS adaptive filter in the process to identify an unknown filter appears to work as planned, as shown in this figure.

See Also

`adaptfilt.adjlms` | `adaptfilt.filtxlms` | `adaptfilt.lms`

Introduced in R2011a

adaptfilt.fdaf

FIR adaptive filter that uses frequency-domain with bin step size normalization

Compatibility

`adaptfilt.fdaf` has been removed. Use dsp.FrequencyDomainAdaptiveFilter instead.

Syntax

```
ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen,
offset,...coeffs,states)
```

Description

`ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen, offset,...coeffs,states)` constructs a frequency-domain FIR adaptive filter `ha` with bin step size normalization. If you omit all the input arguments you create a default object with l = 10 and `step` = 1.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.fdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). l must be a positive integer; it defaults to 10 when you omit the argument.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.

Input Argument	Description
delta	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
lambda	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + l) should be a power of two. blocklen defaults to l.
offset	Offset for the normalization terms in the coefficient updates. Use this to avoid divide by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. coeff should be a length l vector. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by the blocklen.
states	The adaptive filter states. states defaults to a zero vector that has length equal to l.

Properties

Since your adaptfilt.fdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.fdaf objects. To show you the properties that apply, this table lists and describes each property for the adaptfilt.fdaf filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor	(0, 1]	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. Same as the input argument lambda.

Name	Range	Description
BlockLength	Any integer	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen + l) should be a power of two. blocklen defaults to l.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage		Leakage parameter of the adaptive filter. if this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. leakage defaults to 1 — no leakage provided in the algorithm.
Offset	Any positive real value	Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power		A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates

Examples

Quadrature Phase Shift Keying (QPSK) adaptive equalization using 1024 iterations of a 32-coefficient FIR filter. After this example code, a figure demonstrates the equalization results.

```
D = 16;                          % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                   % Denominator coefficients of channel
ntr= 1024;                       % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));       % Noise signal
r  = filter(b,a,s)+n;            % Received signal
x  = r(1+D:ntr+D);               % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
del = 1;                         % Initial FFT input powers
mu  = 0.1;                       % Step size
lam = 0.9;                       % Averaging factor
ha = adaptfilt.fdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

`adaptfilt.ufdaf` | `adaptfilt.pbfdaf` | `adaptfilt.blms` | `adaptfilt.blmsfft`

Introduced in R2011a

adaptfilt.filtxlms

FIR adaptive filter that uses filtered-x LMS

Compatibility

`adaptfilt.filtxlms` has been removed. Use dsp.FilteredXLMSFilter instead.

Syntax

```
ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs,
pathest,...errstates,pstates,coeffs,states)
```

Description

`ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs,
pathest,...errstates,pstates,coeffs,states)` constructs an filtered-x LMS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.filtxlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Filtered LMS step size. it must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	is the filtered-x LMS leakage factor. it must be a scalar between 0 and 1. If it is less than one, a leaky version of `adaptfilt.filtxlms` is implemented. `leakage` defaults to 1 (no leakage).

Input Argument	Description
`pathcoeffs`	is the secondary path filter model. this vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.
`pathest`	is the estimate of the secondary path filter model. `pathest` defaults to the values in `pathcoeffs`.
`fstates`	is a vector of filtered input states of the adaptive filter. `fstates` defaults to a zero vector of length equal to (`l` - 1).
`pstates`	are the secondary path FIR filter states. it must be a vector of length equal to the (`length`(`pathcoeffs`) - 1). `pstates` defaults to a vector of zeros of appropriate length.
`coeffs`	is a vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length l vector of zeros.
`states`	Vector of initial filter states. `states` defaults to a zero vector of length equal to the larger of (`length`(`pathcoeffs`) - 1) and (`length`(`pathest`) - 1).

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

Property	Default Value	Description
`FilteredInputStates`	`l-1`	Vector of filtered input states with length equal to `l` - 1.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2)
`SecondaryPathCoeffs`	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor
`SecondaryPathEstimate`	`pathcoeffs` values	An estimate of the secondary path filter model
`SecondaryPathStates`	Vector of size (`length` (`pathcoeffs`) -1) with all elements equal to zero.	The states of the secondary path FIR filter — the unknown system
`StepSize`	0.1	Sets the filtered-x algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Demonstrate active noise control of a random noise signal over 1000 iterations.

As the figure that follows this code demonstrates, the filtered-x LMS filter successfully controls random noise in this context.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
```

```
d  = filter(g,1,x)+n;     % Signal to be cancelled
b  = fir1(31,0.5);        % FIR secondary path system model
mu = 0.008;               % Filtered-X LMS step size
ha = adaptfilt.filtxlms(32,mu,1,b);
[y,e] = filter(ha,x,d); plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Introduced in R2011a

adaptfilt.ftf

Fast transversal LMS adaptive filter

Compatibility

`adaptfilt.ftf` has been removed. Use dsp.FastTransversalFilter instead.

Syntax

```
ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs,
states)
```

Description

`ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs, states)` constructs a fast transversal least squares adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ftf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/`l`, 1]. `lambda` defaults to 1.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`gamma`	Conversion factor. `gamma` defaults to one specifying soft-constrained initialization.

Input Argument	Description
gstates	States of the Kalman gain updates. gstates defaults to a zero vector of length l.
coeffs	Length l vector of initial filter coefficients. coeffs defaults to a length l vector of zeros.
states	Vector of initial filter States. states defaults to a zero vector of length (l-1).

Properties

Since your adaptfilt.ftf filter is an object, it has properties that define its operating behavior. Note that many of the properties are also input arguments for creating adaptfilt.ftf objects. To show you the properties that apply, this table lists and describes each property for the fast transversal least squares filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPrediction		Returns the predicted samples generated during adaptation. See “References — Adaptive Filters” for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor		Conversion factor. Called gamma when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
`ForgettingFactor`		RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/`l`, 1]. `lambda` defaults to 1.
`FwdPrediction`		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`KalmanGain`		Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

System Identification of a 32-coefficient FIR filter by running the identification process for 500 iterations.

```
x  = randn(1,500);    % Input to the filter
b  = fir1(31,0.5);    % FIR system to be identified
n  = 0.1*randn(1,500);% Observation noise signal
d  = filter(b,1,x)+n; % Desired signal
```

```
N   = 31;               % Adaptive filter order
lam = 0.99;             % RLS forgetting factor
del = 0.1;              % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('coefficient #'); ylabel('Coefficient Value');
```

For this example of identifying an unknown system, the figure shows that the adaptation process identifies the filter coefficients for the unknown FIR filter within the first 150 iterations.

Introduced in R2011a

adaptfilt.gal

FIR adaptive filter that uses gradient lattice

Compatibility

`adaptfilt.gal` has been removed. Use dsp.AdaptiveLatticeFilter instead.

Syntax

```
ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta,
lambda,...rcoeffs,coeffs,states)
```

Description

`ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta, lambda,...rcoeffs,coeffs,states)` constructs a gradient adaptive lattice FIR filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.gal`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the reflection coefficients plus one. `l` defaults to 10.
`step`	Joint process step size of the adaptive filter. This scalar should be a value between zero and one. `step` defaults to 0.
`leakage`	Leakage factor of the adaptive filter. It must be a scalar between 0 and 1. Setting leakage less than one implements a leaky algorithm to estimate both the reflection and the joint process coefficients. `leakage` defaults to 1 (no leakage).

Input Argument	Description
offset	Specifies an optional offset for the denominator of the step size normalization term. It must be a scalar greater or equal to zero. A non-zero offset is useful to avoid divide-by-near-zero conditions when the input signal amplitude becomes very small. offset defaults to 1.
rstep	Reflection process step size of the adaptive filter. This scalar should be a value between zero and one. rstep defaults to step.
delta	Initial common value of the forward and backward prediction error powers. It should be a positive value. 0.1 is the default value for delta.
lambda	Specifies the averaging factor used to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. lambda should lie in the range (0, 1]. lambda defaults to the value (1 - step).
rcoeffs	Vector of initial reflection coefficients. It should be a length (l-1) vector. rcoeffs defaults to a zero vector of length (l-1).
coeffs	Vector of initial joint process filter coefficients. It must be a length l vector. coeffs defaults to a length l vector of zeros.
states	Vector of the backward prediction error states of the adaptive filter. states defaults to a zero vector of length (l-1).

Properties

Since your adaptfilt.gal filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.gal objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed forward and backward prediction error

Name	Range	Description
		powers for the coefficient updates. Same as the input argument `lambda`.
`BkwdPredErrorPower`		Returns the minimum mean-squared prediction error. See "References — Adaptive Filters" for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`FwdPredErrorPower`		Returns the minimum mean-squared prediction error in the forward direction. See "References — Adaptive Filters" for details about linear prediction.
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky GAL algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.
`Offset`		Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small. `offset` defaults to one.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
ReflectionCoeffs		Coefficients determined for the reflection portion of the filter during adaptation.
ReflectionCoeffsStep		Size of the steps used to determine the reflection coefficients.
States	Vector of elements	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
StepSize	0 to 1	Specifies the step size taken between filter coefficient updates

Examples

Perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter over 1000 iterations.

```
D  = 16;                     % Number of delay samples
b  = exp(1j*pi/4)*[-0.7 1];   % Numerator coefficients
a  = [1 -0.7];               % Denominator coefficients
ntr= 1000;                   % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;        % Received signal
x  = r(1+D:ntr+D);           % Input signal (received signal)
d  = s(1:ntr);               % Desired signal (delayed QPSK signal)
L = 32;                      % filter length
mu = 0.007;                  % Step size
ha = adaptfilt.gal(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

To see the results, look at this figure.

Introduced in R2011a

adaptfilt.hrls

FIR adaptive filter that uses householder (RLS)

Compatibility

`adaptfilt.hrls` has been removed. Use dsp.RLSFilter instead.

Syntax

```
ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)
```

Description

`ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)` constructs an FIR householder RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1 meaning the adaptation process retains infinite memory.
`sqrtinvcov`	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

Input Argument	Description
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to being a length `l` vector of zeros.
`states`	Vector of initial filter states. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties

Since your `adaptfilt.hrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.hrls` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument `lambda`. It defaults to 1 meaning the adaptation process retains infinite memory.
`KalmanGain`	Vector of size (`l`,1)	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when

Name	Range	Description
		you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
SqrtInvCov	Matrix of doubles	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l - 1).

Examples

Use 500 iterations of an adaptive filter object to identify a 32-coefficient FIR filter system. Both the example code and the resulting figure show the successful filter identification through adaptive filter processing.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.hrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
 xlabel('Coefficient #'); ylabel('Coefficient Value');
```

adaptfilt.hswrls | adaptfilt.qrdrls | adaptfilt.rls

Introduced in R2011a

adaptfilt.hswrls

FIR adaptive filter that uses householder sliding window RLS

Compatibility

`adaptfilt.hswrls` has been removed in a future release. Use dsp.RLSFilter instead.

Syntax

```
ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen,
dstates,coeffs,states)
```

Description

`ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen, dstates,coeffs,states)` constructs an FIR householder sliding window recursive-least-square adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hswrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	Recursive least square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1 meaning the adaptation process retains infinite memory.

Input Argument	Description
sqrtinvcov	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
swblocklen	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.
dstates	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (swblocklen - 1).
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to being a length l vector of zeros.
states	Vector of initial filter states. It must be a length (l + swblocklen - 2) vector. states defaults to a length (l + swblocklen - 2) vector of zeros.

Properties

Since your adaptfilt.hswrls filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.hswrls objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
DesiredSignalStates	Vector	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (swblocklen - 1).
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
ForgettingFactor	Scalar	Root-least-square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument lambda. It defaults to 1 meaning the adaptation process retains infinite memory.
KalmanGain	(l,1) vector	Empty when you construct the object, this gets populated after you run the filter.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. Defaults to false.
SqrtInvCov	l-by-l Matrix	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Examples

System Identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
```

```
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % block length
ha = adaptfilt.hswrls(32,lam,G0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

In the pair of plots shown in the figure you see the comparison of the desired and actual output for the adapting filter and the coefficients of both filters, the unknown and the adapted.

`adaptfilt.hrls` | `adaptfilt.qrdrls` | `adaptfilt.rls`

Introduced in R2011a

adaptfilt.lms

FIR adaptive filter that uses LMS

Compatibility

`adaptfilt.lms` has been removed. Use dsp.LMSFilter instead.

Syntax

```
ha = adaptfilt.lms(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.lms(l,step,leakage,coeffs,states)` constructs an FIR LMS adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a

Input Argument	Description
	leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the `adaptfilt.lms` object, their default values, and a brief description of the property.

Property	Range	Property Description
`Algorithm`	None	Reports the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to a length `l` vector of zeros when you do not provide the vector as an input argument.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	LMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values

Property	Range	Property Description
		in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0 to 1	LMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. `step` defaults to 0.1.

Examples

Use 500 iterations of an adapting filter system to identify and unknown 32nd-order FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Using LMS filters in an adaptive filter architecture is a time honored means for identifying an unknown filter. By running the example code provided you can demonstrate one process to identify an unknown FIR filter.

Introduced in R2011a

adaptfilt.lsl

Least squares lattice adaptive filter

Compatibility

`adaptfilt.lsl` has been removed. Use dsp.AdaptiveLatticeFilter instead.

Syntax

```
ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)
```

Description

`ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)` constructs a least squares lattice adaptive filter ha.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lsl`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
`lambda`	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1. `lambda` = 1 denotes infinite memory while adapting to find the new filter.
`delta`	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. `delta` defaults to 1.
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of all zeros.

Input Argument	Description
states	Vector of the backward prediction error states of the adaptive filter. states defaults to a length l vector of all zeros, specifying soft-constrained initialization for the algorithm.

Properties

Since your adaptfilt.lsl filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.lsl objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
BkwdPrediction		Returns the predicted samples generated during adaptation. See "References — Adaptive Filters" for details about linear prediction.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
ForgettingFactor		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.
FwdPrediction		Contains the predicted values for samples during adaptation. Compare

Name	Range	Description
		these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`.

Examples

Demonstrate Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter running for 1000 iterations. After you review the example code, the figure shows the results of running the example to use QPSK adaptive equalization with a 32nd-order FIR filter. The error between the in-phase and quadrature components, as shown by the errors plotted in the upper plots, falls to near zero. Also, the equalized signal shows the clear quadrature nature.

```
D  = 16;                      % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];    % Numerator coefficients of channel
a  = [1 -0.7];                % Denominator coefficients of channel
ntr= 1000;                    % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;         % Received signal
x  = r(1+D:ntr+D);            % Input signal (received signal)
```

```
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
lam = 0.995;                    % Forgetting factor
del = 1;                        % initialization factor
ha = adaptfilt.lsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');  grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

adaptfilt.qrdlsl | adaptfilt.gal | adaptfilt.ftf | adaptfilt.rls

Introduced in R2011a

adaptfilt.nlms

Normalized least mean squares adaptive filter

Compatibility

`adaptfilt.nlms` has been removed. Use dsp.LMSFilter instead.

Syntax

```
ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)
```

Description

`ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)` constructs a normalized least-mean squares (NLMS) FIR adaptive filter object named `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.nlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	NLMS step size. It must be a scalar between 0 and 2. Setting this step size value to one provides the fastest convergence. `step` defaults to 1.
`leakage`	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`offset`	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar

Input Argument	Description
	greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.
`coeffs`	Vector composed of your initial filter coefficients. Enter a length `l` vector. `coeffs` defaults to a vector of zeros with length equal to the filter order.
`states`	Your initial adaptive filter states appear in the `states` vector. It must be a vector of length `l`-1. `states` defaults to a length `l`-1 vector with zeros for all of the elements.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for normalized LMS objects, their default values, and a brief description of the property.

Property	Range	Property Description
`Algorithm`	None	Reports the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).

Property	Range	Property Description
`Offset`	0 or greater	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0 to 1	NLMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. `step` defaults to one.

Examples

To help you compare this algorithm's performance to other LMS-based algorithms, such as BLMS or LMS, this example demonstrates the NLMS adaptive filter in use to identify the coefficients of an unknown FIR filter of order equal to 32 — an example used in other adaptive filter examples.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 1;                % NLMS step size
offset = 50;           % NLMS offset
ha = adaptfilt.nlms(32,mu,1,offset);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:500,[d;y;e]);
legend('Desired','Output','Error');
title('System Identification of FIR Filter');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2);
stem([b', ha.coefficients']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As you see from the figure, the `nlms` variant again closely matches the actual filter coefficients in the unknown FIR filter.

Introduced in R2011a

adaptfilt.pbfdaf

Partitioned block frequency-domain FIR adaptive filter

Compatibility

`adaptfilt.pbfdaf` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

Description

`ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen,offset,coeffs,states)` constructs a partitioned block frequency-domain FIR adaptive filter `ha` that uses bin step size normalization during adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbfdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.

Input Argument	Description
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1— no leakage.
delta	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
lambda	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
offset	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a vector of length l. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
states	Specifies the filter initial conditions. states defaults to a zero vector of length l.

Properties

Since your adaptfilt.pbfdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.pbfdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.

Name	Range	Description
AvgFactor		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. AvgFactor should lie in the range (0,1]. AvgFactor defaults to 0.9. Called lambda as an input argument.
BlockLength		Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
FFTCoefficients		Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates		States for the FFT operation.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power		A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

Examples

An example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr = 1000;                     % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));     % Noise signal
r  = filter(b,a,s)+n;    % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
del = 1;                         % Initial FFT input powers
mu  = 0.1;                       % Step size
lam = 0.9;                       % Averaging factor
N   = 8;                         % Block size
ha = adaptfilt.pbfdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
 title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;subplot(2,2,4); plot(y(ntr-100:ntr),'.');  ax
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

In the figure shown, the four subplots provide the details of the results of the QPSK process used in the equalization for this example.

`adaptfilt.fdaf` | `adaptfilt.pbufdaf` | `adaptfilt.blmsfft`

Introduced in R2011a

adaptfilt.pbufdaf

Partitioned block unconstrained frequency-domain adaptive filter

Compatibility

`adaptfilt.pbufdaf` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda,
blocklen,...offset,coeffs,states)
```

Description

`ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda, blocklen,...offset,coeffs,states)` constructs a partitioned block unconstrained frequency-domain FIR adaptive filter `ha` with bin step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.

Input Argument	Description
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. leakage defaults to 1 — no leakage.
delta	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.
lambda	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer such that (l/blocklen) is also an integer. For faster execution, blocklen should be a power of two. blocklen defaults to two.
offset	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. offset defaults to zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a vector of length l. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
states	Specifies the filter initial conditions. states defaults to a zero vector of length l.

Properties

Since your adaptfilt.pbufdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.pbufdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation

Name	Range	Description
`AvgFactor`		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `AvgFactor` should lie in the range (0,1]. `AvgFactor` defaults to 0.9. Called `lambda` as an input argument.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1 — no leakage.
`Offset`		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small.v`offset` defaults to zero.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. step defaults to 1.

Examples

Demonstrating Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. To perform the equalization, this example runs for 1000 iterations.

```
D  = 16;      % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a  = [1 -0.7];             % Denominator coefficients of channel
ntr= 1000;                 % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;          % Received signal
x  = r(1+D:ntr+D);             % Input signal (received signal)
d  = s(1:ntr);                 % Desired signal (delayed QPSK signal)
del = 1;                       % Initial FFT input powers
mu  = 0.1;                     % Step size
lam = 0.9;                     % Averaging factor
N   = 8;                       % Block size
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

You can compare this algorithm to another, such as the `pbfdaf` version. Use the same example of QPSK adaptation. The following figure shows the results.

`adaptfilt.ufdaf` | `adaptfilt.pbfdaf` | `adaptfilt.blmsfft`

Introduced in R2011a

adaptfilt.qrdlsl

QR-decomposition-based least-squares lattice adaptive filter

Compatibility

`adaptfilt.qrdlsl` has been removed. Use dsp.AdaptiveLatticeFilter instead.

Syntax

```
ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)
```

Description

`ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)` returns a QR-decomposition-based least squares lattice adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdlsl`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
`lambda`	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1. `lambda` = 1 denotes infinite memory while adapting to find the new filter.
`delta`	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. `delta` defaults to 1.

Input Argument	Description
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of all zeros.
`states`	Vector of the angle normalized backward prediction error states of the adaptive filter

Properties

Since your `adaptfilt.qrdlsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdlsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`BkwdPrediction`		Returns the predicted samples generated during adaptation. See “References — Adaptive Filters” for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor =` 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.

Name	Range	Description
`FwdPrediction`		Returns the predicted samples generated during adaptation in the forward direction. See "References — Adaptive Filters" for details about linear prediction.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l -1`

Examples

Implement Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. To see the results of the equalization process in this example, look at the figure that follows the example code.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband  QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;       % Received signal
x  = r(1+D:ntr+D);          % Input signal (received signal)
d  = s(1:ntr);              % Desired signal (delayed QPSK signal)
```

```
lam = 0.995;              % Forgetting factor
del = 1;                  % Soft-constrained initialization factor
ha = adaptfilt.qrdlsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

adaptfilt.qrdrls | adaptfilt.gal | adaptfilt.ftf | adaptfilt.lsl

Introduced in R2011a

adaptfilt.qrdrls

FIR adaptive filter that uses QR-decomposition-based RLS

Compatibility

`adaptfilt.qrdrls` has been removed. Use dsp.RLSFilter instead.

Syntax

```
ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)
```

Description

`ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)` constructs an FIR QR-decomposition-based recursive-least squares (RLS) adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer.`l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. `lambda` defaults to 1.
`sqrtcov`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector whose elements are zeros.

Input Argument	Description
`states`	Vector of initial filter states. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties

Since your `adaptfilt.qrdrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of length `l`	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you

Name	Range	Description
		constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`SqrtCov`	Square matrix with each dimension equal to the filter length `l`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

System Identification of a 32-coefficient FIR filter (500 iterations).

```
x  = randn(1,500);       % Input to the filter
b  = fir1(31,0.5);       % FIR system to be identified
n  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+n;    % Desired signal
G0 = sqrt(.1)*eye(32);   % Initial sqrt correlation matrix
lam = 0.99;              % RLS forgetting factor
ha = adaptfilt.qrdrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using this variant of the RLS algorithm successfully identifies the unknown FIR filter, as shown here.

`adaptfilt.rls` | `adaptfilt.hrls` | `adaptfilt.hswrls` | `adaptfilt.swrls`

Introduced in R2011a

adaptfilt.rls

Recursive least-squares FIR adaptive filter

Compatibility

`adaptfilt.rls` has been removed. Use dsp.RLSFilter instead.

Syntax

```
ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)
```

Description

`ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)` constructs an FIR direct form RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.rls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1.
`invcov`	Inverse of the input signal covariance matrix. For best performance, you should initialize this matrix to be a positive definite matrix.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.

Input Argument	Description
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties

Since your adaptfilt.rls filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.rls objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
Coefficients	Vector containing l elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps. Remember that filter length is filter order + 1.
ForgettingFactor	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting forgetting factor = 1 denotes infinite memory while adapting to find the new filter. Note that this is the lambda input argument.
InvCov	Matrix of size l-by-l	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
KalmanGain	Vector of size (l,1)	Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
`States`	Double array	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

System Identification of a 32-coefficient FIR filter over 500 adaptation iterations.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.rls(32,lam,P0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient valUe');  grid on;
```

In this example of adaptive filtering using the RLS algorithm to update the filter coefficients for each iteration, the figure shown reveals the fidelity of the derived filter after adaptation.

`adaptfilt.hrls` | `adaptfilt.hswrls` | `adaptfilt.qrdrls`

Introduced in R2011a

adaptfilt.sd

Sign-data FIR adaptive filter

Compatibility

`adaptfilt.sd` has been removed. Use dsp.LMSFilter instead.

Syntax

```
ha = adaptfilt.sd(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.sd(l,step,leakage,coeffs,states)` constructs an FIR sign-data adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.sd`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SD step size. It must be a nonnegative scalar. `step` defaults to 0.1
`leakage`	Your SD leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.sd` implements a leaky SD algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

Input Argument	Description
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for sign-data objects, their default values, and a brief description of the property.

Property	Default Value	Description
Al gorithm	Sign-data	Defines the adaptive filter algorithm the object uses during adaptation.
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need l entries in coefficients.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps.
Leakage	0	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to 0.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting

Property	Default Value	Description
		values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	`zeros(l-1,1)`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0.1	Sets the SD algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Adaptive line enhancement using a 32-coefficient FIR filter to perform the enhancement. This example runs for 5000 iterations, as you see in property `iter`.

```
d  = 1;                         % Number of samples of delay
ntr= 5000;                      % Number of iterations
v  = sin(2*pi*0.05*[1:ntr+d]);  % Sinusoidal signal
n  = randn(1,ntr+d);            % Noise signal
x  = v(1:ntr)+n(1:ntr);         % Input signal
d  = v(1+d:ntr+d)+n(1+d:ntr+d); % Desired signal
mu = 0.0001;                    % Sign-data step size.
ha = adaptfilt.sd(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of a Noisy Sinusoidal Signal');
legend('Observed','Enhanced','Original');
 xlabel('Time Index'); ylabel('Signal Value');
[pxx,om] = pwelch(x(ntr-1000:ntr));
 pyy = pwelch(y(ntr-1000:ntr));
subplot(2,1,2);
plot(om/pi,10*log10([pxx/max(pxx),pyy/max(pyy)]));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Each of the variants — sign-data, sign-error, and sign-sign — uses the same example. You can compare the results by viewing the figure shown for each adaptive filter method — `adaptfilt.sd`, `adaptfilt.se`, and `adaptfilt.ss`.

`adaptfilt.lms` | `adaptfilt.se` | `adaptfilt.ss`

Introduced in R2011a

adaptfilt.se

FIR adaptive filter that uses sign-error algorithm

Compatibility

`adaptfilt.se` has been removed. Use dsp.LMSFilter instead.

Syntax

```
ha = adaptfilt.se(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.se(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.se`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SE step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1
`leakage`	Your SE leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.se` implements a leaky SE algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

Input Argument	Description
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l-1 vector. states defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the adaptfilt object, the input options are properties of the object you create. This table lists the properties for the sign-error SD object, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-error	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to one if omitted.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation.

Property	Default Value	Description
		The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	`zeros(l-1,1)`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` -1).
`StepSize`	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Use `inspect(ha)` to view or change the object properties graphically using the MATLAB Property Inspector.

Examples

Adaptive line enhancement using a 32-coefficient FIR filter running over 5000 iterations.

```
d = 1;                        % Number of samples of delay
ntr= 5000;                    % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);           % Noise signal
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                    % Sign-error step size
ha = adaptfilt.se(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
HWelch = spectrum.welch;
InputPsd = psd(HWelch,x(ntr-1000:ntr));
OutputPsd = psd(HWelch,y(ntr-1000:ntr));
CompPsdEst = [InputPsd.Data/max(InputPsd.Data), OutputPsd.Data/max(OutputPsd.Data)];
subplot(2,1,2); plot(InputPsd.Frequencies/pi,10*log10(CompPsdEst));
```

```
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Compare the figure shown here to the ones for `adaptfilt.sd` and `adaptfilt.ss` to see how the variants perform on the same example.

See Also

`adaptfilt.sd` | `adaptfilt.ss` | `adaptfilt.lms`

Introduced in R2011a

adaptfilt.ss

FIR adaptive filter that uses sign-sign algorithm

Compatibility

`adaptfilt.ss` has been removed. Use dsp.LMSFilter instead.

Syntax

```
ha = adaptfilt.ss(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.ss(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ss`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SS step size. It must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	Your SS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky SS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

Input Argument	Description
coeffs	Vector of initial filter coefficients. it must be a length l vector. coeffs defaults to length l vector with elements equal to zero.
states	Vector of initial filter states for the adaptive filter. It must be a length l -1 vector. states defaults to a length l-1 vector of zeros.

adaptfilt.ss can be called for a block of data, when x and d are vectors, or in "sample by sample mode" using a For-loop with the method filter:

```
for n = 1:length(x)
ha = adaptfilt.ss(25,0.9);
[y(n),e(n)] = filter(ha,(x(n),d(n),s));
end
```

Properties

In the syntax for creating the adaptfilt object, most of the input options are properties of the object you create. This table lists the properties for sign-sign objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-sign	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps
Leakage	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even

Property	Default Value	Description
		after it reaches a minimum value. Ranges between 0 and 1. 1 is the default value.
PersistentMemory	false or true	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.
States	zeros(l-1,1)	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l-1).
StepSize	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Demonstrating adaptive line enhancement using a 32-coefficient FIR filter provides a good introduction to the sign-sign algorithm.

```
d = 1;                        % Number of samples of delay
ntr= 5000;                    % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);           % Noise signal
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                    % Sign-error step size
ha = adaptfilt.ss(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
```

```
[InputPsd,wi] = pwelch(x(ntr-1000:ntr));
[OutputPsd,wo] = pwelch(y(ntr-1000:ntr));
CompPsdEst = [InputPsd/max(InputPsd), OutputPsd/max(OutputPsd)];
subplot(2,1,2); plot(wi/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

This example is the same as the ones used for the sign-data and sign-error examples. Comparing the figures shown for each of the others lets you assess the performance of each for the same task.

adaptfilt.se | adaptfilt.sd | adaptfilt.lms

Introduced in R2011a

adaptfilt.swftf

FIR adaptive filter that uses sliding window fast transversal least squares

Compatibility

`adaptfilt.swftf` has been removed. Use dsp.FastTransversalFilter instead.

Syntax

```
ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates,
dstates,...coeffs,states)
```

Description

`ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates, dstates,...coeffs,states)` constructs a sliding window fast transversal least squares adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swftf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to maintain stability. `delta` defaults to 1.
`blocklen`	Block length of the sliding window. This must be an integer at least as large as the filter length `l`, which is the default value.
`gamma`	Conversion factor. `gamma` defaults to the matrix [1 -1] that specifies soft-constrained initialization.

Input Argument	Description
gstates	States of the Kalman gain updates. gstates defaults to a zero vector of length (l + blocklen - 1).
dstates	Desired signal states of the adaptive filter. dstates defaults to a zero vector of length equal to (blocklen - 1). For a default object, dstates is (l-1).
coeffs	Vector of initial filter coefficients. It must be a length l vector. coeffs defaults to length l vector of all zeros.
states	Vector of initial filter states. states defaults to a zero vector of length equal to (l + blocklen - 2).

Properties

Since your adaptfilt.swftf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.swftf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
BkwdPredictions		Returns the predicted samples generated during adaptation. See “References — Adaptive Filters” for details about linear prediction.
BlockLength		Block length of the sliding window. This must be an integer at least as large as the filter length l, which is the default value.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.

Name	Range	Description
`ConversionFactor`		Conversion factor. Called `gamma` when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
`DesiredSignal States`		Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`blocklen` - 1).
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`FwdPrediction`		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`KalmanGain`		Empty when you construct the object, this gets populated after you run the filter.
`KalmanGainStates`		Contains the states of the Kalman gains for the adaptive algorithm. Initialized to a vector of double data type entries.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

Over 500 iterations, perform a system identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
L  = 32;               % Adaptive filter length
del = 0.1;             % Soft-constrained initialization factor
N  = 64;               % block length
ha = adaptfilt.swftf(L,del,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Review the figure for the results of the example. When you evaluate the example you should get the same results, within the differences in the random noise signal you use.

`adaptfilt.ftf` | `adaptfilt.swrls` | `adaptfilt.ap` | `adaptfilt.apru`

Introduced in R2011a

adaptfilt.swrls

FIR adaptive filter that uses window recursive least squares (RLS)

Compatibility

`adaptfilt.swrls` has been removed. Use dsp.RLSFilter instead.

Syntax

```
ha = adaptfilt.swrls(l,lambda,invcov,swblocklen,
dstates,...coeffs,states)
```

Description

`ha = adaptfilt.swrls(l,lambda,invcov,swblocklen, dstates,...coeffs,states)` constructs an FIR sliding window RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. `lambda` defaults to 1.
`invcov`	Inverse of the input signal covariance matrix. You should initialize `invcov` to a positive definite matrix.

Input Argument	Description
`swblocklen`	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector of all zeros.
`states`	Vector of initial filter states. `states` defaults to a zero vector of length equal to (l + `swblocklen` - 2).

Properties

Since your `adaptfilt.swrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Any vector of `l` elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`DesiredSignalStates`	Vector	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1.

Name	Range	Description
		Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`InvCov`	Matrix	Square matrix with each dimension equal to the filter length `l`.
`KalmanGain`	Vector with dimensions (`l`,1)	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `swblocklen` - 2)
`SwBlockLength`	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.

Examples

System Identification of a 32-coefficient FIR filter. Use 500 iterations to adapt to the unknown filter. After the example code, you see a figure that plots the results of the running the code.

```
x  = randn(1,500);     % Input to the filter
```

```
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32);       % Initial correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % Block length
ha = adaptfilt.swrls(32,lam,P0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
 title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

In the figure you see clearly that the adaptive filter process successfully identified the coefficients of the unknown FIR filter. You knew it had to or many things that you take for granted, such as modems on computers, would not work.

adaptfilt.rls | adaptfilt.qrdrls | adaptfilt.hswrls

Introduced in R2011a

adaptfilt.tdafdct

Adaptive filter that uses discrete cosine transform

Compatibility

`adaptfilt.tdafdct` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda,
coeffs,states)
```

Description

`ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda, coeffs,states)` constructs a transform-domain adaptive filter ha object that uses the discrete cosine transform to perform filter adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdct`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.

Input Argument	Description
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDCT algorithm. leakage defaults to 1 — no leakage.
offset	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
delta	Initial common value of all of the transform domain powers. Its initial value should be positive. delta defaults to 5.
lambda	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. lambda should lie between zero and one. For default filter objects, lambda equals (1 - step).
coeffs	Initial time domain coefficients of the adaptive filter. Set it to be a length l vector. coeffs defaults to a zero vector of length l.
states	Initial conditions of the adaptive filter. states defaults to a zero vector with length equal to (l - 1).

Properties

Since your adaptfilt.tdafdct filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.tdafdct objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation.
AvgFactor		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. AvgFactor should lie between zero and one. For

Name	Range	Description
		default filter objects, AvgFactor equals (1 - step). lambda is the input argument that represent AvgFactor.
Coefficients	Vector of elements	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
FilterLength	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
Leakage	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.
Offset		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.

Name	Range	Description
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`StepSize`	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.

For checking the values of properties for an adaptive filter object, use `get(ha)` or enter the object name, without a trailing semicolon, at the MATLAB prompt.

Examples

Using 1000 iterations, perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;           % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
L  = 32;                        % filter length
mu = 0.01;                      % Step size
ha = adaptfilt.tdafdct(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1);
plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
```

```
title('Equalized Signal Scatter Plot'); grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

Compare the plots shown in this figure to those in the other time domain filter variations. The comparison should help you select and understand how the variants differ.

`adaptfilt.tdafdft` | `adaptfilt.fdaf` | `adaptfilt.blms`

Introduced in R2011a

adaptfilt.tdafdft

Adaptive filter that uses discrete Fourier transform

Compatibility

`adaptfilt.tdafdft` has been removed. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FastTransversalFilter, dsp.AffineProjectionFilter, dsp.AdaptiveLatticeFilter, dsp.FilteredXLMSFilter, dsp.FrequencyDomainAdaptiveFilter, or dsp.AffineProjectionFilter instead.

Syntax

```
ha = adaptfilt.tdafdft(l,step,leakage,offset,
delta,lambda,...coeffs,states)
```

Description

`ha = adaptfilt.tdafdft(l,step,leakage,offset, delta,lambda,...coeffs,states)` constructs a transform-domain adaptive filter object `ha` using a discrete Fourier transform.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdft`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.

Input Argument	Description
leakage	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. leakage defaults to 1 — no leakage.
offset	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. offset defaults to zero.
delta	Initial common value of all of the transform domain powers. Its initial value should be positive. delta defaults to 5.
lambda	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. lambda should lie between zero and one. For default filter objects, LAMBDA equals (1 - step).
coeffs	Initial time domain coefficients of the adaptive filter. Set it to be a length l vector. coeffs defaults to a zero vector of length l.
states	Initial conditions of the adaptive filter. states defaults to a zero vector with length equal to (l - 1).

Properties

Since your adaptfilt.tdafdft filter is an object, it has properties that define its behavior in operation. StepSize	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. step defaults to 0.

Examples

Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter (1000 iterations).

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;            % Received signal
x  = r(1+D:ntr+D);               % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
L  = 32;                        % filter length
mu = 0.01;                      % Step size
ha = adaptfilt.tdafdft(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
 axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

All of the time domain adaptive filter reference pages use this QPSK example. By comparing the results for each variation you get an idea of the differences in the way each one performs.

This figure demonstrates the results of running the example code shown.

`adaptfilt.tdafdct` | `adaptfilt.fdaf` | `adaptfilt.blms`

Introduced in R2011a

adaptfilt.ufdaf

FIR adaptive filter that uses unconstrained frequency-domain with quantized step size normalization

Compatibility

`adaptfilt.ufdaf` has been removed. Use dsp.FrequencyDomainAdaptiveFilter instead.

Syntax

```
ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

Description

`ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen, offset,coeffs,states)` constructs an unconstrained frequency-domain FIR adaptive filter `ha` with quantized step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.

Input Argument	Description
delta	Initial common value of all of the FFT input signal powers. the initial value of delta should be positive, and it defaults to 1.
lambda	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. lambda should lie in the range (0,1]. For default UFDAF filter objects, lambda defaults to 0.9.
blocklen	Block length for the coefficient updates. This must be a positive integer. For faster execution, (blocklen l) should be a power of two. blocklen defaults to l.
offset	Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
coeffs	Initial time-domain coefficients of the adaptive filter. It should be a length l vector. The filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by blocklen.
states	Adaptive filter states. states defaults to a zero vector with length equal to l.

Properties

Since your adaptfilt.ufdaf filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating adaptfilt.ufdaf objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
Algorithm	None	Defines the adaptive filter algorithm the object uses during adaptation
AvgFactor		Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the

Name	Range	Description
		coefficient updates. `AvgFactor` should lie in the range (0,1]. For default UFDAF filter objects, `AvgFactor` defaults to 0.9. Note that AvgFactor and lambda are the same thing — lambda is an input argument and AvgFactor a property of the object.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer. For faster execution, (`blocklen` + `1`) should be a power of two. `blocklen` defaults to `1`.
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.
`Offset`		Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.

Name	Range	Description
PersistentMemory	false or true	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to false.
Power	2*l element vector	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
StepSize	0 to 1	Adaptive filter step size. It must be a nonnegative scalar. You can use maxstep to determine a reasonable range of step size values for the signals being processed. step defaults to 0.

Examples

Show an example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. For fidelity, use 1024 iterations. The figure that follows the code provides the information you need to assess the performance of the equalization process.

```
D  = 16;                         % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];       % Numerator coefficients of channel
a  = [1 -0.7];                   % Denominator coefficients of channel
ntr= 1024;                       % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));
r  = filter(b,a,s)+n;% Received signal
x  = r(1+D:ntr+D);   % Input signal (received signal)
d  = s(1:ntr);       % Desired signal (delayed QPSK signal)
del = 1;            %Initial FFT input powers
mu  = 0.1;           % Step size
lam = 0.9;          % Averaging factor
ha = adaptfilt.ufdaf(32,mu,1,del,lam);

allpass2wdf

Allpass to Wave Digital Filter coefficient transformation

Syntax

```
w = allpass2wdf(a)
W = allpass2wdf(A)
```

Description

`w = allpass2wdf(a)` accepts a vector of real allpass polynomial filter coefficients `a`, and returns the transformed coefficient `w`. `w` can be used with allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with Structure set to `'Wave Digital Filter'`.

`W = allpass2wdf(A)` accepts the cell array of allpass polynomial coefficient vectors `A`. Each cell of `A` holds the coefficients of a section of a cascade allpass filter. `W` is also a cell array, and each cell of `W` contains the transformed version of the coefficients in the corresponding cell of `A`. W can be used with allpass filter objects such as dsp.AllpassFilter and dsp.CoupledAllpassFilter, with structure set to `'Wave Digital Filter'`.

Examples

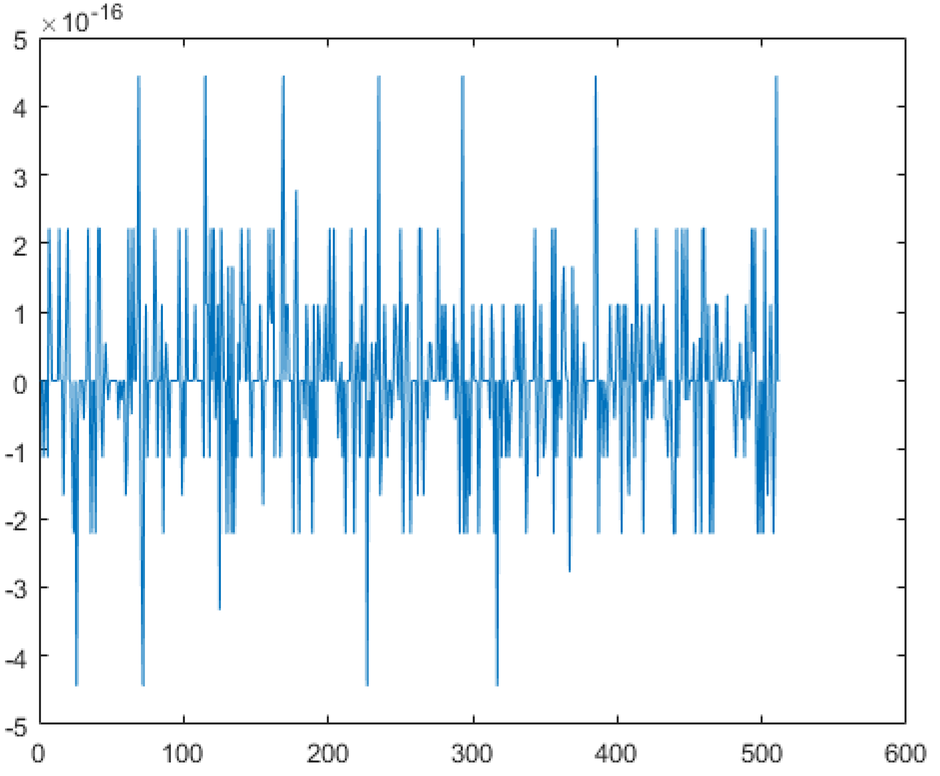
Convert Allpass coefficients to Wave Digital Filter Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a second order allpass filter with coefficients a = [0 0.5]. Convert these coefficients into wave digital filter form using `allpass2wdf`. Assign the transformed coefficients to an allpass filter using the wave digital filter structure. Pass a random input to both these filters and compare the outputs.

```
a = [0 0.5];
allpass = dsp.AllpassFilter('AllpassCoefficients', a);
w = allpass2wdf(a);
```

```
allpasswdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...
    'WDFCoefficients', w);
in = randn(512, 1);
outputAllpass = allpass(in);
outputAllpasswdf = allpasswdf(in);
plot(outputAllpass-outputAllpasswdf)
```



The difference between the two outputs is very small.

Input Arguments

a — allpass filter coefficients

(default) | vector of real numbers

Numeric vector of allpass filter coefficients, specified as real numbers. `a` can have length only equal to 1,2, and 4. When the length is 4, the first and third components must both be zero. `a` can be a row or a column vector.

Example: `0.7`

Data Types: `double` | `single`

A — allpass filter coefficients
(default) | vector of cells

Cascade of allpass filter coefficients, specified as a cell vector. Every cell of `A` must contain a real vector of length 1,2, or 4. When the length is 4, the first and third components must both be zero. `A` can be a row or column vector of cells.

Example: `{0.7, [0.1, 0.2]}`

Data Types: `double` | `single`

Output Arguments

w — transformed version of the coefficients a
(default) | vector of real numbers

Numeric vector of transformed coefficients, determined as a real number, to use with single-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. `w` is always returned as a numeric row vector.

Example: `0.7`

Data Types: `double` | `single`

W — transformed version of the coefficients cell array A
(default) | vector of cell

Cascade of transformed allpass filter coefficients, determined as a cell array, to use with multi-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. `W` is always returned as a column of cells.

Example: `{0.7;[0.2,-0.0833]}`

Data Types: `double` | `single`

Algorithms

In the more general case, the input coefficients A define a cascade or multisection allpass filter. `allpass2wdf` applies separately to each section of the same transformation used in the single-section case. In the single-section case, the numeric coefficients vector a contains a standard polynomial representation of an allpass filter of order 1, 2, or 4. For example, in the first order case,

$$a = [a_1]$$

represents the first order transfer function:

$$H_1(z) = \frac{z^{-1} + a_1}{1 + a_1 z^{-1}}$$

and in the second order case,

$$a = [a_1, a_2]$$

represents the second order transfer function:

$$H_2(z) = \frac{z^{-2} + a_1 z^{-1} + a_2}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

.

The allpass transfer functions H_1 and H_2 can also have the following alternative representations, using decoupled coefficients in vector w_1 or w_2 respectively.

$$\tilde{H}1(z) = \frac{z^{-1} + w_1}{1 + w_1 z^{-1}}$$

$$\tilde{H}2(z) = \frac{z^{-2} + w_2(1 + w_1)z^{-1} + w_1}{1 + w_2(1 + w_1)z^{-1} + w_1 z^{-2}}$$

For allpass coefficients, w is often used to derive adaptor multipliers for Wave Digital Filter structures, and it is required by a number of allpass based filters in DSP System Toolbox when `Structure` is set to `'Wave Digital Filter'` (e.g. dsp.AllpassFilter, and dsp.CoupledAllpassFilter).

For a given vector of section coefficients a, `allpass2wdf` computes the corresponding vector w such that

$$when\ i = 1,\ 2\ or\ 4$$

$$\tilde{H}_i(z) = H_i(z)$$

This results in using the following formulas:

$$\begin{aligned}
&\textit{for order } 1: \\
&w_1 = a_1 \\
&\textit{for order } 2: \\
&w_1 = a_2 \\
&w_2 = \frac{a_1}{1+a_2} \\
&\textit{for order } 4: \\
&w_1 = a_4 \\
&w_3 = \frac{a_2}{1+a_4} \\
&w_2 = w_4 = 0
\end{aligned}$$

allpassbpc2bpc

Allpass filter for complex bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a complex bandpass to complex bandpass frequency transformation. This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations W_{t1} and W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

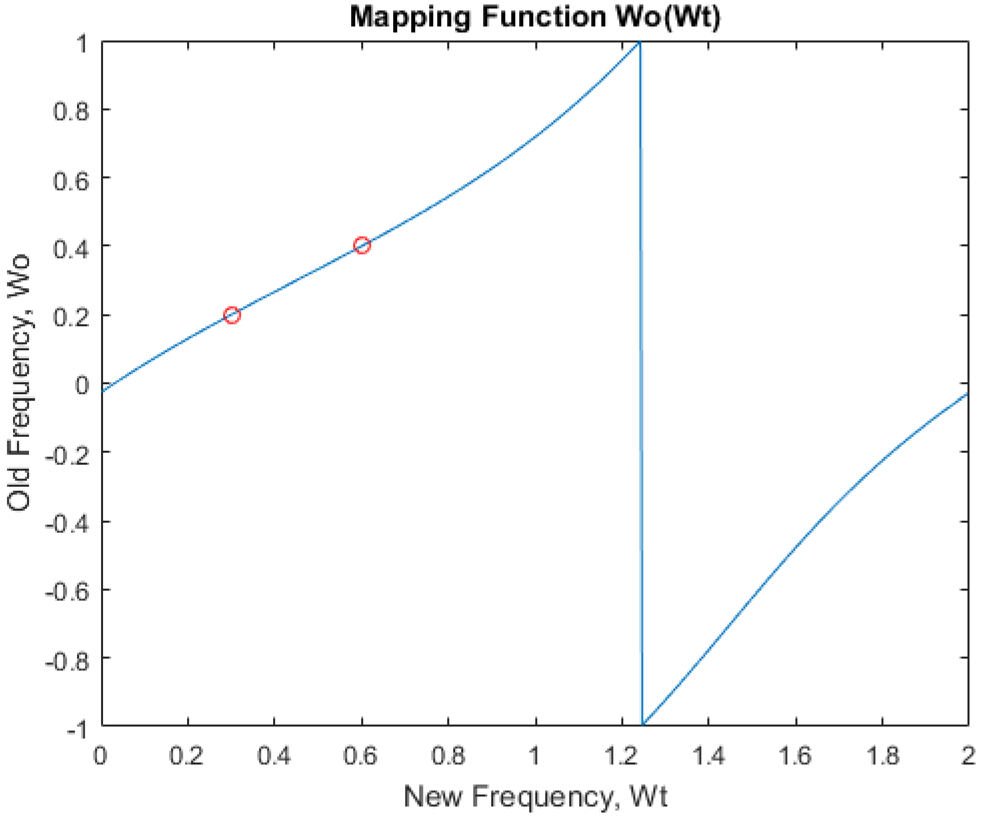
This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle. This is very attractive for adaptive systems.

Examples

Design of the allpass mapping filter

This example shows how to design allpass mapping filter, changing the complex bandpass filter with the band edges at $W_{o1} = 0.2$ and $W_{o2} = 0.4$ to the new band edges of $W_{t1} = 0.3$ and $W_{t2} = 0.6$. Find the frequency response of the allpass mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);
[ha, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi,-angle(ha)/pi, Wt, Wo, 'ro'); title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

allpasslp2bp

Allpass filter for lowpass to bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "DC mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

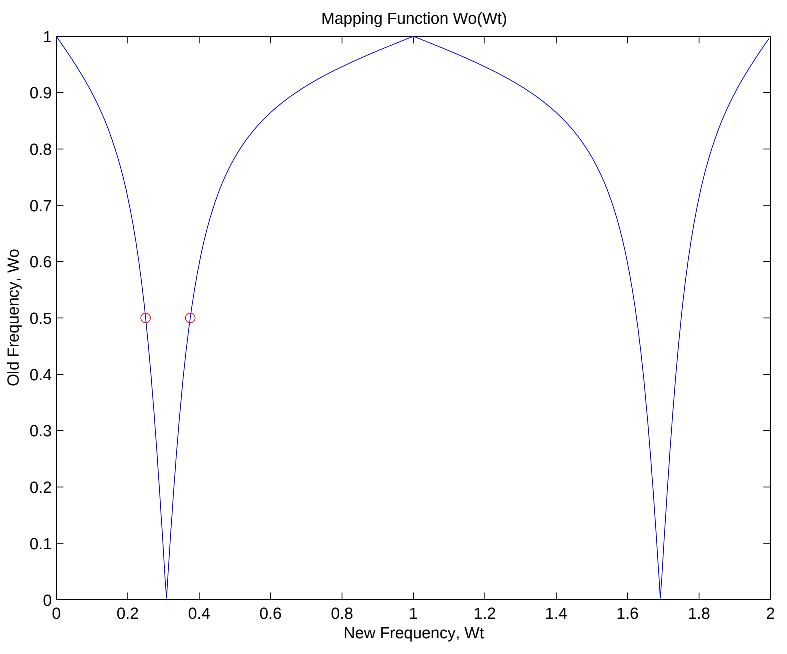
Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

Examples

Design the allpass mapping filter changing the lowpass filter with cutoff frequency at W_o=`0.5` to the real–valued bandpass filter with cutoff frequencies at W_{t1}=`0.25` and W_{t2}=`0.375`.

Compute the frequency response and plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2bpc

Allpass filter for lowpass to complex bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

Examples

Design the allpass mapping filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex bandpass filter with band edges of W_{t1}=`0.2` and

W_{t2}=0.4 precisely defined. Calculate the frequency response of the mapping filter in the full range:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bpc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

allpasslp2bs

Allpass filter for lowpass to bandstop transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

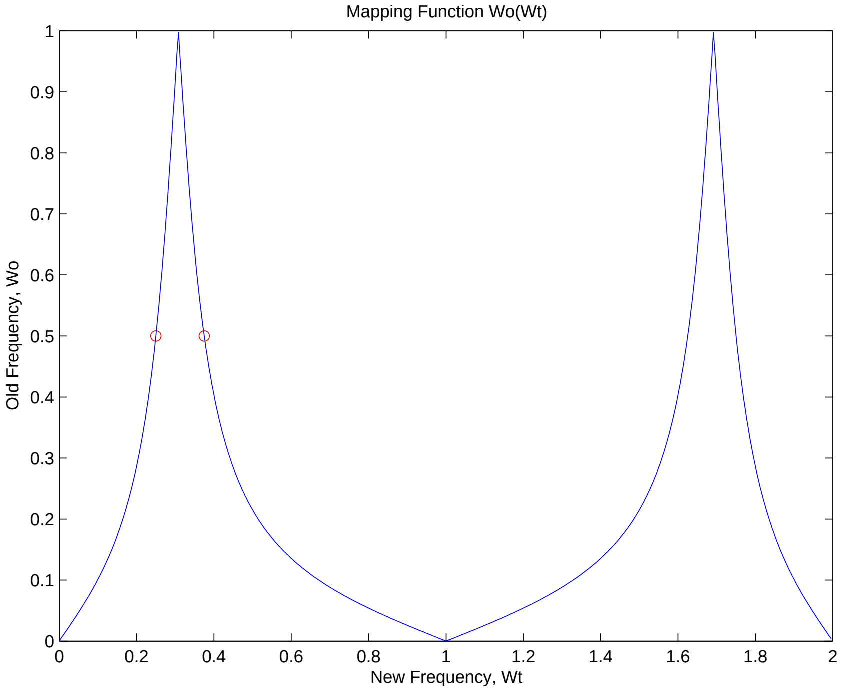
Examples

Design the allpass filter changing the lowpass filter with cutoff frequency at W_o=`0.5` to the real bandstop filter with cutoff frequencies at W_{t1}=`0.25` and W_{t2}=`0.375`:

```
Wo = 0.5; Wt = [0.25, 0.375];
```

```
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to π:



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter

Variable	Description
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2bsc

Allpass filter for lowpass to complex bandstop transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/ resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=0.5 into a complex bandstop filter with band edges of W_{t1}=0.2 and W_{t2}=0.4 precisely defined:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bsc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

allpasslp2hp

Allpass filter for lowpass to highpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency, W_o, at the required target frequency location, W_t, at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

Examples

Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from $W_o = 0.5$ to $W_t = 0.25$.

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2lp

Allpass filter for lowpass to lowpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real lowpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency W_o, at the required target frequency location, W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

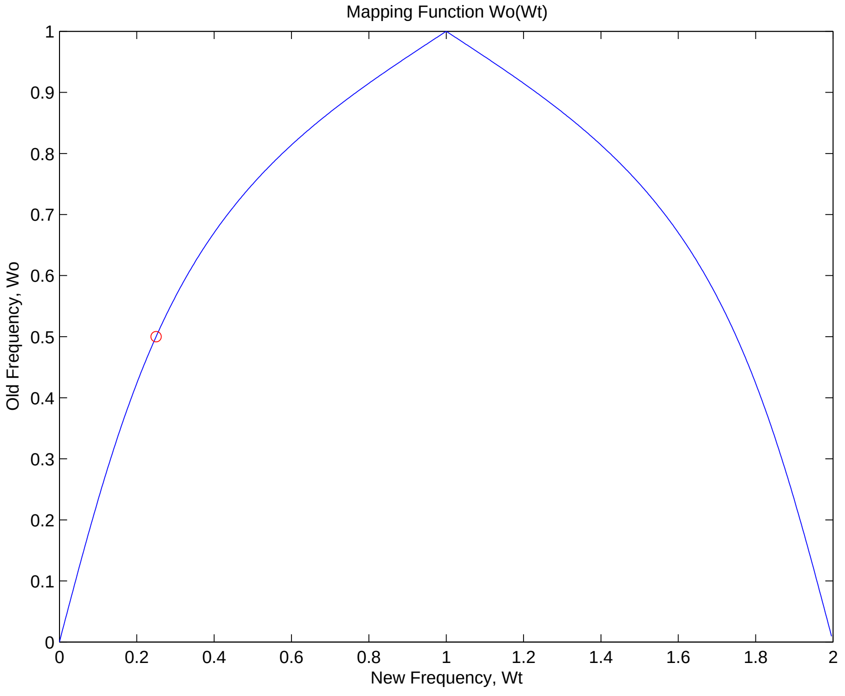
Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband and so on.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by applying the lowpass to lowpass transformation.

Examples

Design the allpass filter changing the lowpass filter cutoff frequency originally at W_o=`0.5` to W_t=`0.25`. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



As shown in the figure, `allpasslp2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}. By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

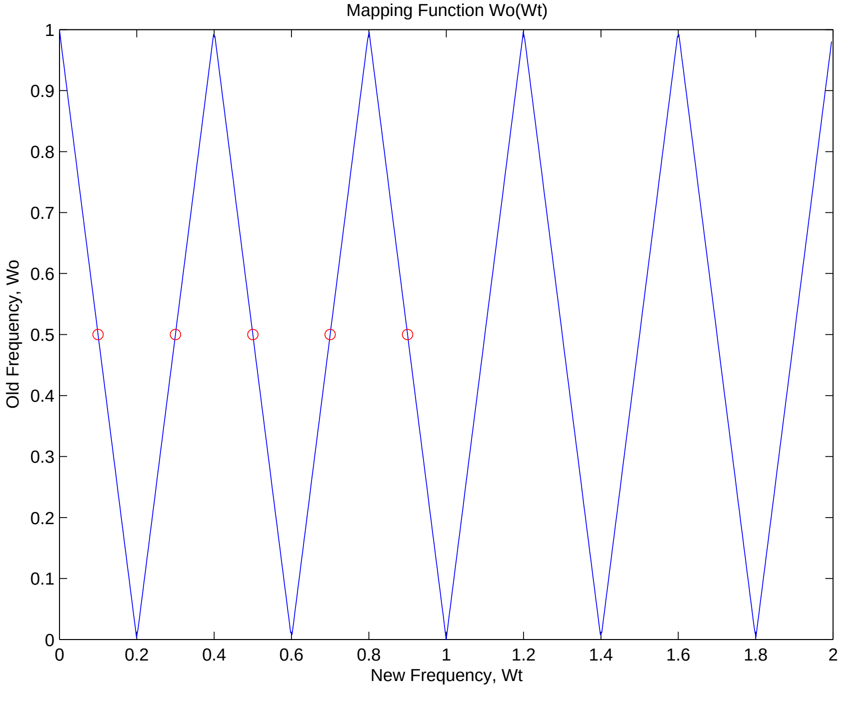
Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=0.5 into a real multiband filter with band edges of W_t=[1:2:9]/10 precisely defined. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2mbc

Allpass filter for lowpass to complex M-band transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to complex multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need to design them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex multiband filter with band edges of W_t=`[-3+1:2:9]/10` precisely defined:

```
Wo = 0.5; Wt = [-3+1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
```

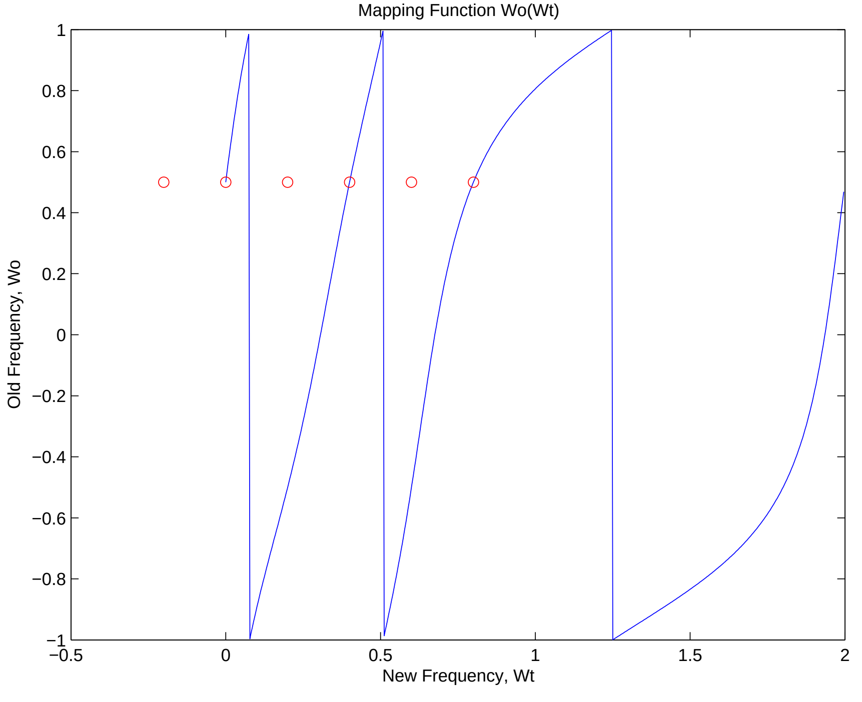
Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
 title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Introduced in R2011a

allpasslp2xc

Allpass filter for lowpass to complex N-point transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter, where `N` is the allpass filter order, for performing a real lowpass to complex multipoint frequency transformation. Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of the, original filter located at frequencies W_{o1},...,W_{oN}, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter moving four features of an original complex filter given in W_o to the new independent frequency locations W_t. Please note that the transformation creates N replicas of an original filter around the unit circle, where N is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

allpasslp2xn

Allpass filter for lowpass to N-point transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter, where `N` is the allpass filter order, for performing a real lowpass to real multipoint frequency transformation. Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies W_{o1},...,W_{oN}, at the required target frequency locations, W_{t1},...,W_{tM}. By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need of designing them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpassrateup

Allpass filter for integer upsample transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassrateup(N)
```

Description

`[AllpassNum,AllpassDen] = allpassrateup(N)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter for performing the rateup frequency transformation, which creates `N` equal replicas of the prototype filter frequency response.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

Design the allpass filter creating the effect of upsampling the digital filter four times:

Choose any feature from an original filter, say at W_o=`0.2`:

```
N = 4;
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
N	Frequency replication ratio (upsampling ratio)

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Introduced in R2011a

allpassshift

Allpass filter for real shift transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real frequency shift transformation. This transformation places one selected feature of an original filter, located at frequency W_o, at the required target frequency location, W_t. This transformation implements the "DC mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be moved to a different frequency by applying a shift transformation. In such a way you can avoid designing the filter from the beginning.

Examples

Design the allpass filter precisely shifting one feature of the lowpass filter originally at W_o=`0.5` to the new frequencies of W_t=`0.25`:

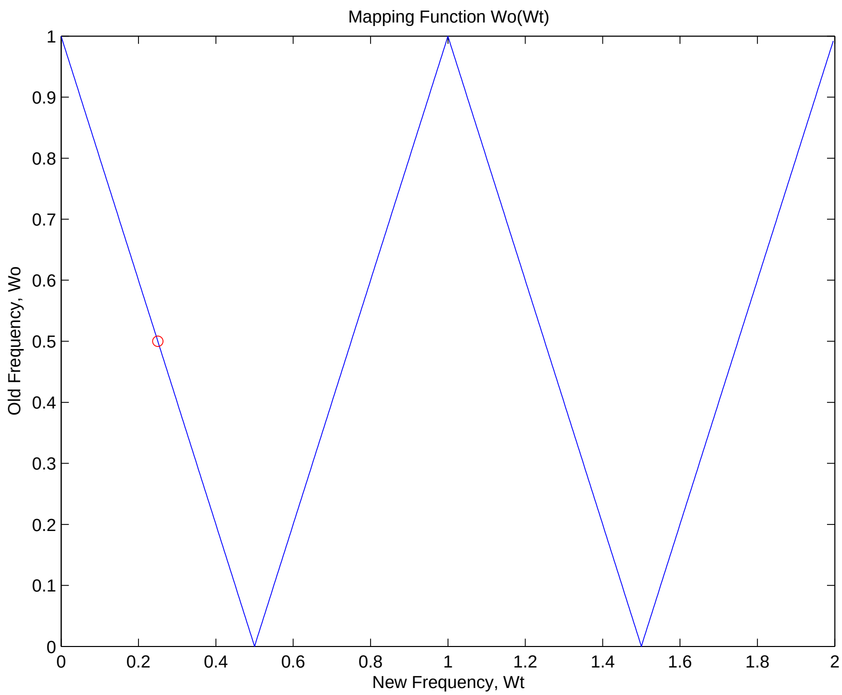
```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshift(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function `Wo(Wt)`. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter

Variable	Description
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpassshiftc

Allpass filter for complex shift transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)
[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)
[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)
```

Description

`[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)` returns the numerator, `AllpassNum`, and denominator, `AllpassDen`, vectors of the allpass mapping filter for performing a complex frequency shift of the frequency response of the digital filter by an arbitrary amount.

`[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)` calculates the allpass filter for doing the Hilbert transformation, a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design the allpass filter precisely rotating the whole filter by the amount defined by the location of the selected feature from an original filter, W_o=`0.5`, and its required position in the target filter, W_t=`0.25`:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshiftc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

`iirshiftc` | `zpkshiftc`

Introduced in R2011a

autoscale

Automatic dynamic range scaling

Syntax

```
autoscale(hd,x)
hnew = autoscale(hd,x)
```

Description

`autoscale(hd,x)` provides dynamic range scaling for each node of the filter `hd`. This method runs signal `x` through `hd` in floating-point to simulate filtering. `autoscale` uses the maximum and minimum data obtained from that simulation at each filter node to set fraction lengths to cover the simulation full range and maximize the precision. Word lengths are not changed during autoscaling.

`hnew = autoscale(hd,x)` If you request an output, `autoscale` returns a new filter with the scaled fraction lengths. The original filter is not changed.

For an introductory example of the automatic scale process, see “Floating-Point to Fixed-Point Conversion of IIR Filters”.

Examples

Dynamic Range Scaling in a Lattice ARMA Filter

```
hd = design(fdesign.bandpass,'ellip');
hd = convert(hd,'latticearma');
hd.arithmetic = 'fixed';
rng(4); x = rand(100,10); % Training input data.
hd(2) = autoscale(hd,x);
hfvt = fvtool(hd,'Analysis','magestimate','ShowReference','off');
legend(hfvt, 'Before Autoscaling', 'After Autoscaling')
```

`qreport`

Introduced in R2011a

block

Generate block from a digital filter

Syntax

```
block(hd)
block(hd,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2,...)
```

Description

`block(hd)` generates a DSP System Toolbox block equivalent to the digital filter, `hd`.

`block(hd,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2,...)` generates a DSP System Toolbox block using the options specified in the property name/ property value pairs. The valid properties and their values are

Property Name	Property Values	Description and Values
`Destination`	`'current'` (default), `'new'`, or *`Subsystemname`*.	Determine which Simulink model gets the block. Enter `'current'`, `'new'`, or specify the name of an existing subsystem with *`subsystemname`*. `'current'` adds the block to your current Simulink model. Specifying `'new'` opens a new model and adds the block. Specifying `'new'` opens a new model and adds the block. If you provide the name of a subsystem in *`subsystemname`*, `block` adds the new block to your specified subsystem.
`Blockname`	`'filter'` (default)	Specify the name of the generated block. The name appears below the block in the model. When you do not specify a block name, the default is `filter`.
`OverwriteBl`	`'off'` (default), or `'on'`.	Tell `block` whether to overwrite an existing block of the same name, or create a new

Property Name	Property Values	Description and Values
		block. `'off'` is the default setting—`block` does not overwrite existing blocks with matching names. Switching from `'off'` to `'on'` directs `block` to overwrite existing blocks.
`MapStates`	`'off'` (default), or `'on'`.	Specify whether to apply the current filter states to the new block. This lets you save states from a filter object you may have used or configured in a specific way. The default setting of `'off'` means the states are not transferred to the block. Choosing `'on'` preserves the current filter states in the block.
`Link2Obj`	`'off'` (default), or `'on'`.	Specify how to set the **Coefficient source** in the block mask. The default setting is `'off'` and the **Coefficient source** is set to **Dialog parameters**. Setting `Link2Obj` to `'on'` sets the **Coefficient source** to **Discrete-time filter object (DFILT)**. The `Link2Obj` and `MapCoeffstoPorts` cannot be simultaneously `'on'`.
`MapCoeffstc`	`'off'` (default) or `'on'`	Specify whether to map the coefficients of the filter to the ports of the block. The `Link2Obj` and `MapCoeffstoPorts` cannot be simultaneously `'on'`.
`CoeffNames`	`{'Num'}` (default FIR) `{'Num','Den'}` (default direct form IIR) `{'Num','Den','g'}` (default IIR SOS), `{'K'}` (default form lattice)	Specify the coefficient variable names as a cell array of character vectors. `MapCoeffsToPorts` must be set to `'on'` for this property to apply.

Property Name	Property Values	Description and Values
InputProces	'columns as channels' (default), 'elements as channels'	Specify sample-based (elements as channels) or frame-based (columns as channels) processing.
RateOption	'enforce single rate' (default) or 'allow multirate'	Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.

Using block to Realize a Fixed-Point Digital Filter

When the source filter hd is fixed-point, the input word and fraction lengths for the block are derived from the block input signal. The realization process issues a warning and ignores the input word and input fraction lengths that are part of the source filter object, choosing to inherit the settings from the input data. Other fixed-point properties map directly to settings for word and fraction length in the realized block.

Examples

Create a Block from a Lowpass Filter

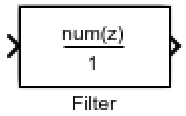
Create a lowpass filter specification object. Specify the passband frequency to be 0.15? rad/sample and the stopband frequency to be 0.25? rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

In the first example, use block with the default syntax, letting the function determine the block name and configuration.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
hd = design(d);
```

Now use the default syntax to create a block.

```
block(hd);
```



In this second example, define the block name to meet your needs by using the property name/property value pair input arguments.

```
block(hd, 'blockname', 'FIR Filter');
```

The figure shows the blocks in a Simulink model. When you try these examples, you see that the second block writes over the first block location. You can avoid this by moving the first block before you generate the second, always naming your block with the blockname property, or setting the Destination property to new which puts the filter block in a new Simulink model.

butter

Butterworth IIR filter design using specification object

Syntax

```
butterFilter = design(d,'butter','SystemObject',true)
butterFilter =
design(d,'butter',designoption,value,'SystemObject',true)
```

Description

`butterFilter = design(d,'butter','SystemObject',true)` designs a Butterworth IIR digital filter using the specifications supplied in the object `d`.

`butterFilter =`
`design(d,'butter',designoption,value,'SystemObject',true)` returns a Butterworth IIR filter where you specify a design option and value.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `butter`, refer to the command line help system. For example, to get specific information about using `butter` with `d`, the specification object, enter the following at the MATLAB prompt.

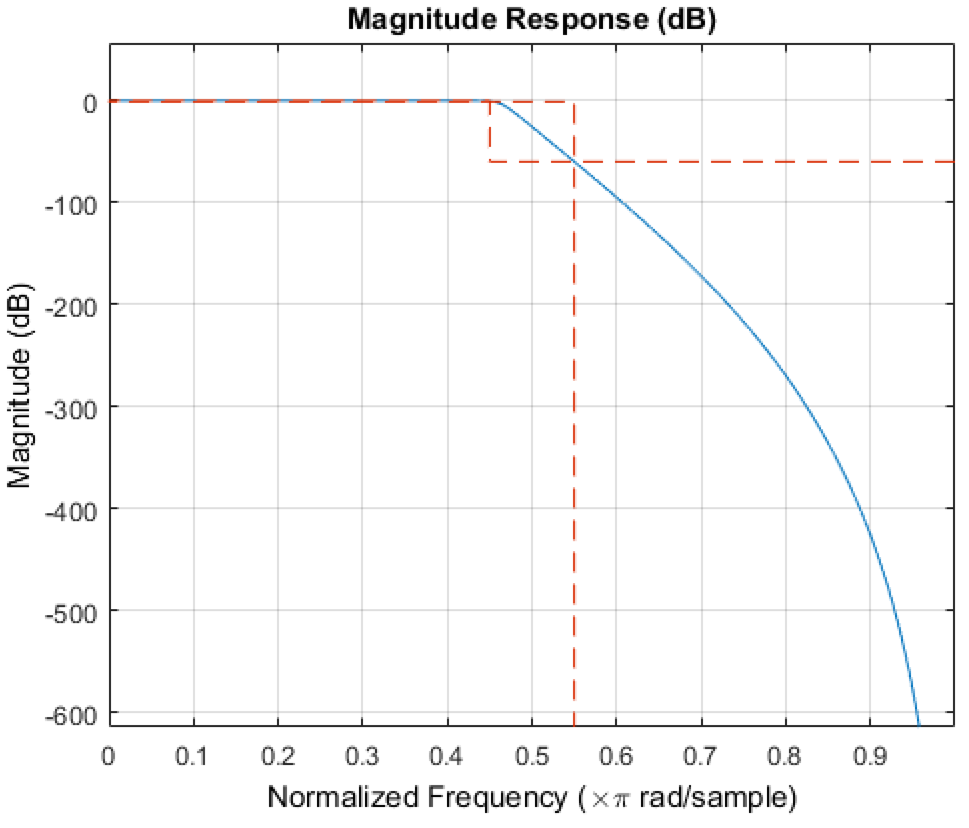
```
help(d,'butter')
```

Examples

Design a Butterworth Filter

Construct a default lowpass filter specification object and design a Butterworth filter.

```
d = fdesign.lowpass;
Lowpass = design(d,'butter','matchexactly','stopband','SystemObject',true);
fvtool(Lowpass);
```



Construct a highpass filter specification object and design a Butterworth filter. Specify the order to be 8 and 3 dB frequency to be 0.6*pi radians/sample.

```
d = fdesign.highpass('N,F3dB',8,.6);
Highpass = design(d,'butter','SystemObject',true);
fvtool(Highpass)
```

ca2tf

Convert coupled allpass filter to transfer function form

Syntax

```
[b,a]=ca2tf(d1,d2)
[b,a]=ca2tf(d1,d2,beta)
[b,a,bp]=ca2tf(d1,d2)
[b,a,bp]=ca2tf(d1,d2,beta)
```

Description

`[b,a]=ca2tf(d1,d2)` returns the vector of coefficients `b` and the vector of coefficients `a` corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\left[H1(z) + H2(z)\right]$$

`d1` and `d2` are real vectors corresponding to the denominators of the allpass filters `H1(z)` and `H2(z)`.

`[b,a]=ca2tf(d1,d2,beta)` where `d1`, `d2` and `beta` are complex, returns the vector of coefficients `b` and the vector of coefficients `a` corresponding to the numerator and the denominator of the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\right]$$

`[b,a,bp]=ca2tf(d1,d2)`, where `d1` and `d2` are real, returns the vector `bp` of real coefficients corresponding to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z) / A(z) = \frac{1}{2}\left[H1(z) - H2(z)\right]$$

`[b,a,bp]=ca2tf(d1,d2,beta)`, where `d1`, `d2` and `beta` are complex, returns the vector of coefficients `bp` of real or complex coefficients that correspond to the numerator of the power complementary filter G(z)

$$G(z) = Bp(z) / A(z) = \frac{1}{2_j}\left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\right]$$

Examples

Create a filter, convert the filter to coupled allpass form, and convert the result back to the original structure (create the power complementary filter as well).

```
[b,a]=cheby1(10,.5,.4);
[d1,d2,beta]=tf2ca(b,a);        % tf2ca returns the denominators
                                of the allpasses
[num,den,numpc]=ca2tf(d1,       % Reconstruct the original filter
d2,beta);                       plus the power complementary one
[h,w,s]=freqz(num,den);
hpc = freqz(numpc,den);
s.plot = 'mag';
s.yunits = 'sq';
freqzplot([h hpc],w,s);         % Plot the mag response of the
                                original filter and the power
                                complementary one
```

Examples

Convert Coupled Allpass to Transfer Function Form

Create a filter, convert the filter to coupled allpass form, and convert the result back to the original structure (create the power complementary filter as well).

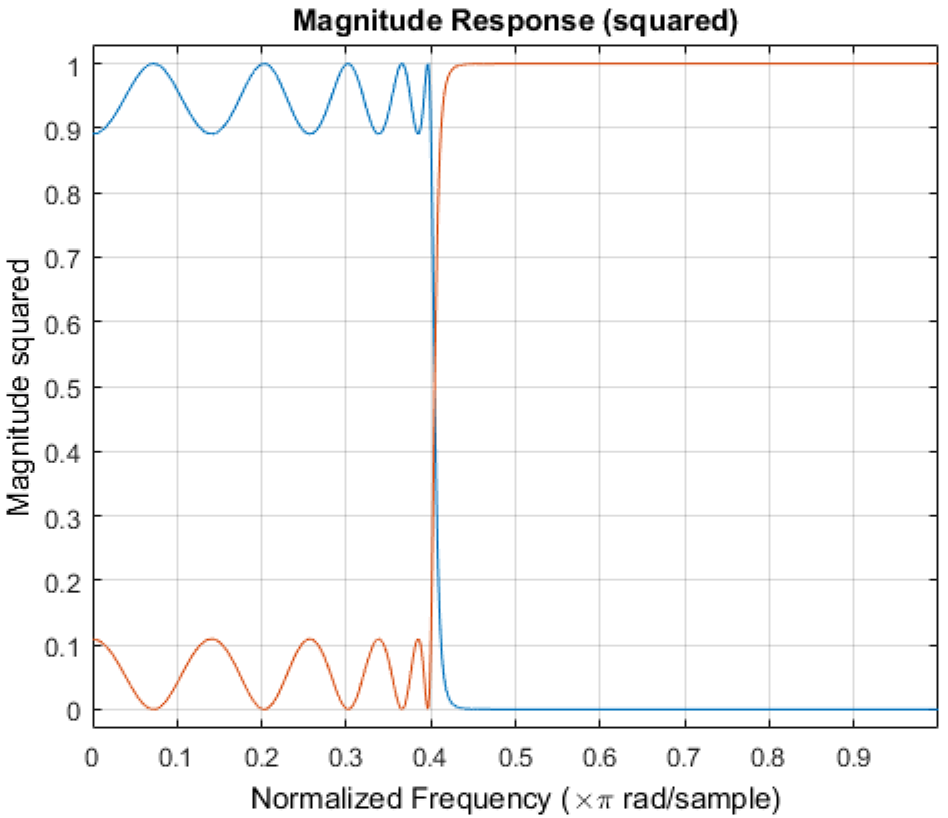
```
[b,a]=cheby1(10,.5,.4);
 [d1,d2,beta]=tf2ca(b,a);
```

tf2ca returns the denominators of the allpasses

```
[num,den,numpc]=ca2tf(d1, d2,beta);
```

Plot the mag response of the original filter and the power complementary one .

```
fvtool(num,den,numpc,den,'Analysis','magnitude','MagnitudeDisplay',...
    'Magnitude Squared')
```



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

Introduced in R2011a

cascade

Cascade of filter system objects

Syntax

```
FC = cascade(obj1,obj2,...objn)
```

Description

`FC = cascade(obj1,obj2,...objn)` returns an object, `FC`, of type dsp.FilterCascade. `FC` is a cascaded version of the input System objects `obj1`, `obj2`,`....objn`. You can input multiple System objects to the function. The input System objects must be supported by the cascade method. For the list of supported System objects, see "Input Arguments" on page 5-200.

Examples

Design Two-Stage Decimator

Design a two-stage decimator by cascading `dsp.CICDecimator` and `dsp.CICCompensationDecimator` System objects.

Construct the objects

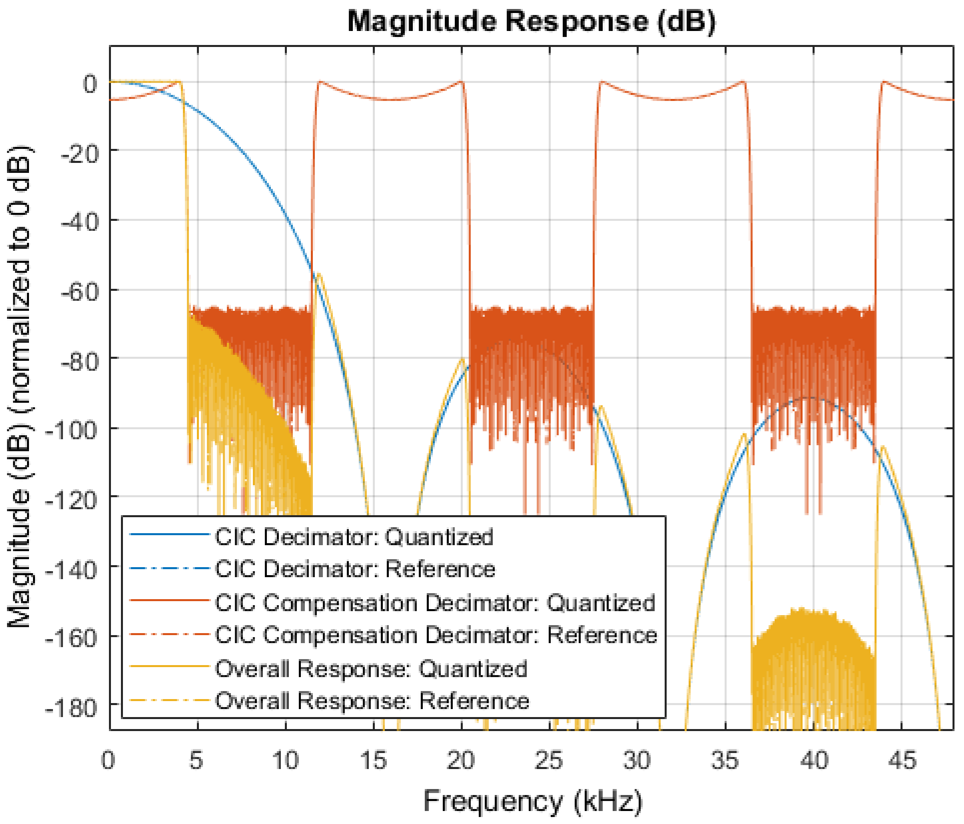
```
CICDecim = dsp.CICDecimator('DecimationFactor', 6, ...
                            'NumSections', 6);
fs = 16e3;     % Sampling frequency of input of compensation decimator
fPass = 4e3;   % Passband frequency
fStop = 4.5e3; % Stopband frequency
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
                              'DecimationFactor', 2, ...
                              'PassbandFrequency', fPass, ...
                              'StopbandFrequency', fStop, ...
                              'SampleRate', fs);
```

Create a cascade of the two objects using the `cascade` method

```
 FC = cascade(CICDecim, CICCompDecim);
```

Visualize the frequency response of the cascade

```
f = fvtool(CICDecim, CICCompDecim, FC, 'Fs', [fs*6, fs, fs*6],...
       'Arithmetic', 'fixed');
set(f, 'NormalizeMagnitudeto1', 'on');
legend(f,'CIC Decimator','CIC Compensation Decimator', ...
            'Overall Response');
```



Input Arguments

`obj1` — Filter to be cascaded
filter System object

`obj1`, `obj2`,`....objn` are filters to be cascaded. To see the list of System objects you can pass to the cascade method, type

`dsp.FilterCascade.helpSupportedSystemObjects`
in the MATLAB command prompt.

Output Arguments

`FC` — cascaded filter

`dsp.FilterCascade` System object

Cascaded filter, returned as a System object of type `dsp.FilterCascade`. For information on the properties of the filter in each stage, type `info(FC)` in the MATLAB command prompt.

dsp.FilterCascade

Introduced in R2016a

cheby1

Chebyshev Type I filter using specification object

Syntax

```
chebOneFilter = design(d,'cheby1','SystemObject',true)
chebOneFilter = design(d,'cheby1',designoption,value,designoption,
value,'SystemObject',true)
```

Description

`chebOneFilter = design(d,'cheby1','SystemObject',true)` designs a type I Chebyshev IIR digital filter using the specifications supplied in the object `d`. Depending on the filter specification object, `cheby1` may or may not be a valid design. Use `designmethods` with the filter specification object to determine if a Chebyshev type I filter design is possible.

`chebOneFilter = design(d,'cheby1',designoption,value,designoption, value,'SystemObject',true)` returns a type I Chebyshev IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby1`, refer to the command line help system. For example, to get specific information about using `cheby1` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby1')
```

Examples

Design a Chebyshev Type I Filter

Construct a default lowpass filter specification object and design a Chebyshev Type I filter.

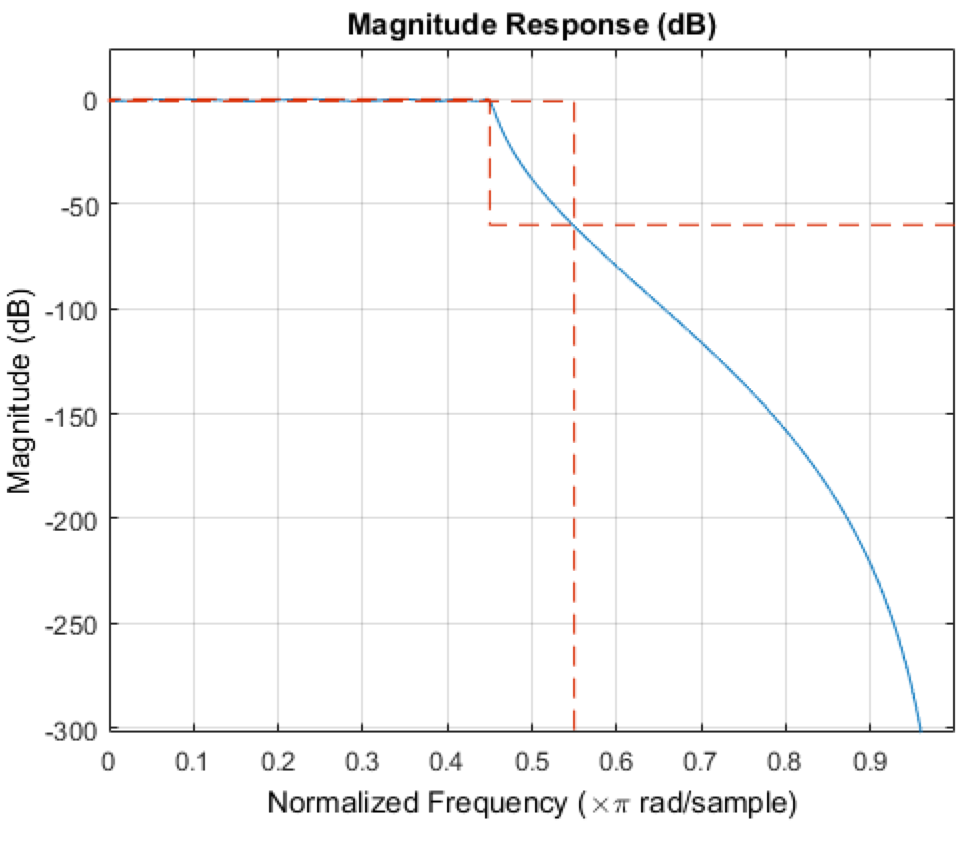
```
d = fdesign.lowpass; designopts(d,'cheby1');
```

Use `matchexactly` option to ensure the performance of the filter in the passband.

```
LowpassCheb1 = design(d,'cheby1','matchexactly','passband',...
    'SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(LowpassCheb1)
```

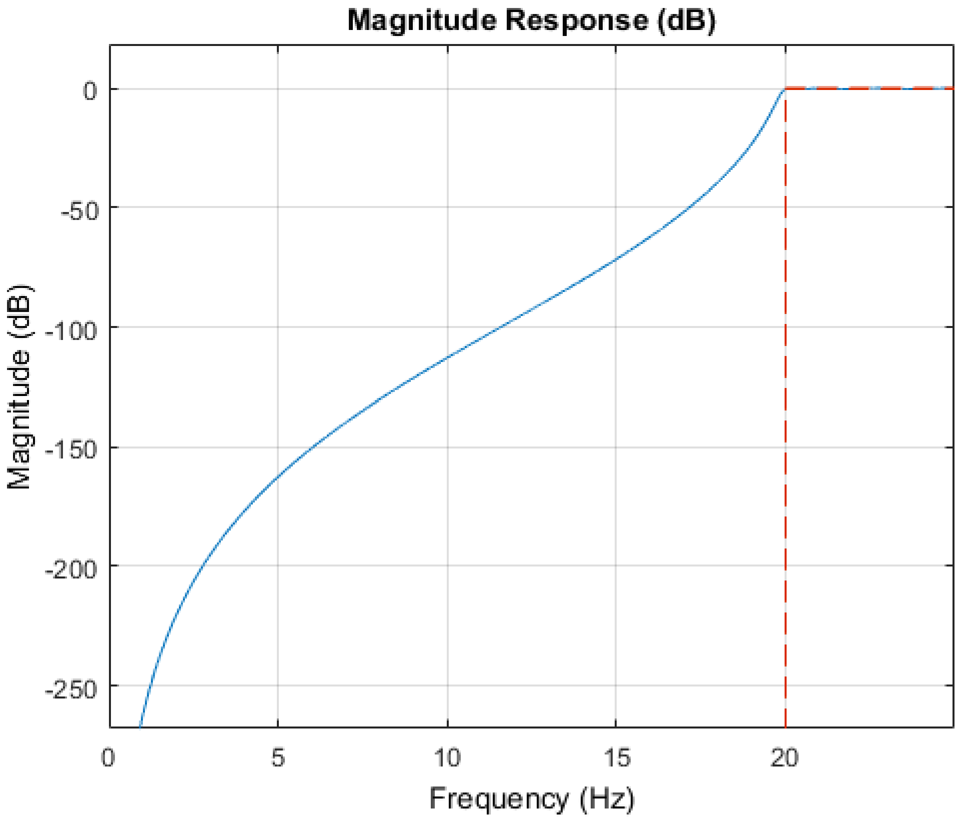


Construct a highpass filter specification object and design a Chebyshev Type I filter. Specify the filter order, passband edge frequency, and the passband ripple to get the filter exactly as required.

```
d = fdesign.highpass('n,fp,ap',7,20,.4,50);
HighpassCheb1 = design(d,'cheby1','SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(HighpassCheb1)
```



By design, `cheby1` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

`design` | `designmethods` | `fdesign`

Introduced in R2011a

cheby2

Chebyshev Type II filter using specification object

Syntax

```
chebTwoFilter= design(d,'cheby2','SystemObject',true)
chebTwoFilter = design(d,'cheby2',designoption,value,designoption,
value,'SystemObject',true)
```

Description

`chebTwoFilter= design(d,'cheby2','SystemObject',true)` designs a Chebyshev II IIR digital filter using the specifications supplied in the object `d`.

`chebTwoFilter = design(d,'cheby2',designoption,value,designoption, value,'SystemObject',true)` returns a Chebyshev II IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `cheby2`, refer to the command line help system. For example, to get specific information about using `cheby2` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'cheby2')
```

Examples

Design a Chebyshev Type II Filter

Construct a default lowpass filter specification object and design a Chebyshev Type II filter.

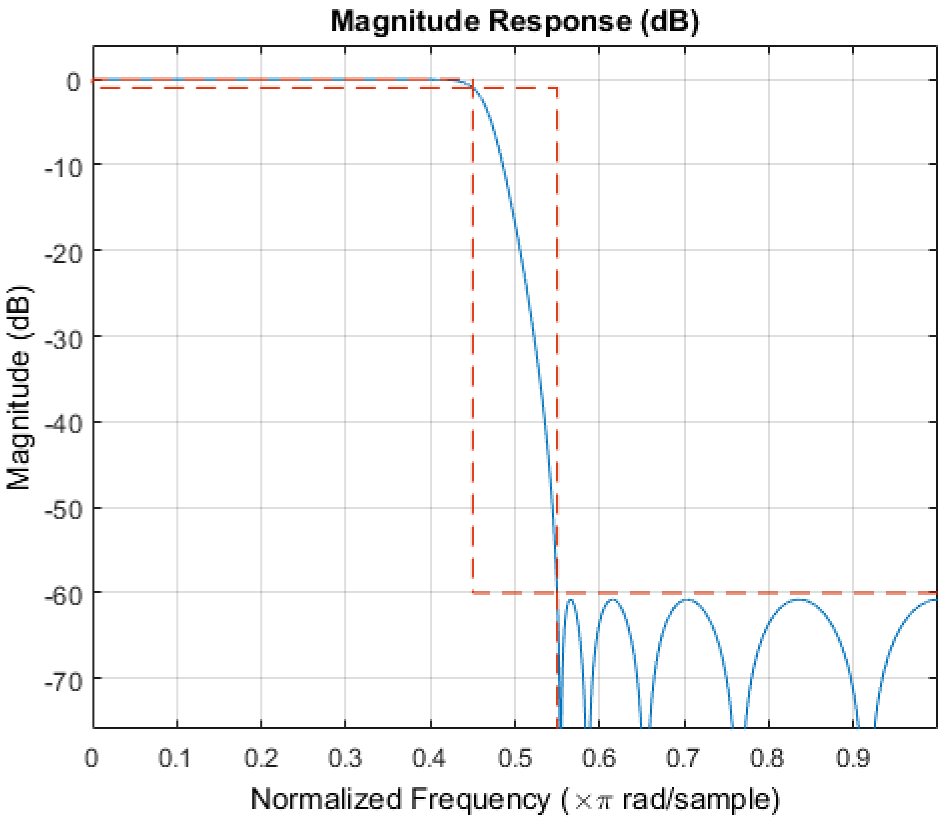
```
d = fdesign.lowpass;
```

Use `matchexactly` option to ensure the performance of the filter in the passband.

```
LowpassCheb2 = design(d,'cheby2','matchexactly','passband',...
    'SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(LowpassCheb2)
```



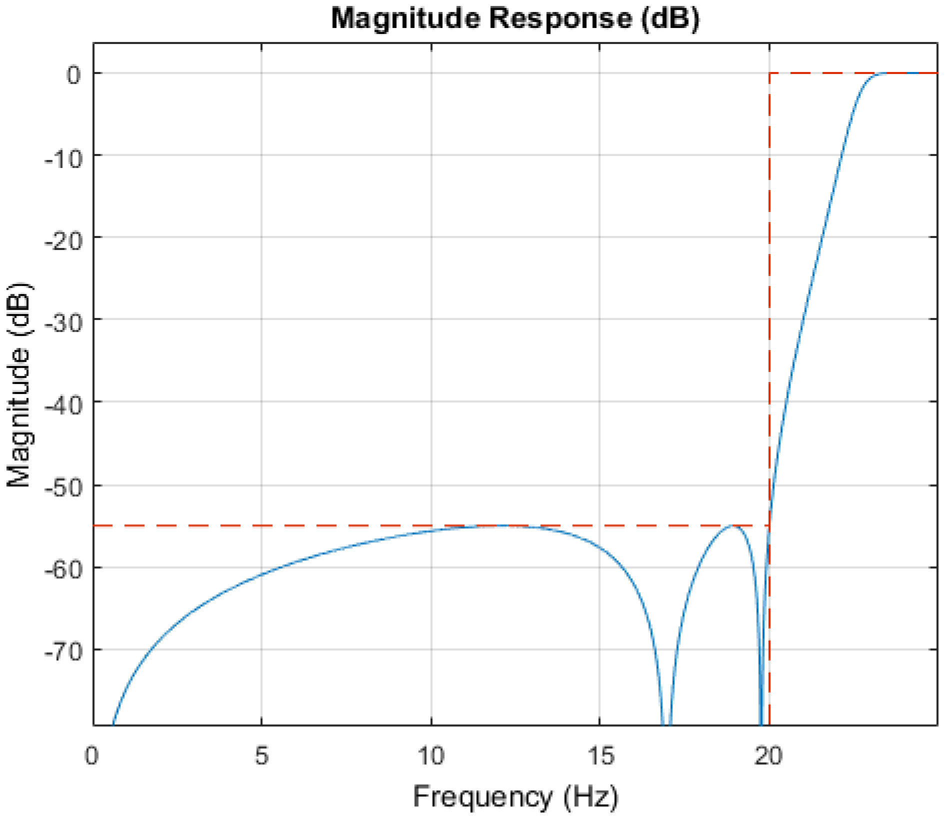
Construct a highpass filter specification object and design a Chebyshev Type II filter. Specify the filter order, stopband edge frequency, and the stopband attenuation to get the filter exactly as required.

```
d = fdesign.highpass('n,fst,ast',5,20,55,50);
```

```
HighpassCheb2 = design(d,'cheby2','SystemObject',true);
```

Use `fvtool` to view the resulting filter

```
fvtool(HighpassCheb2)
```



By design, `cheby2` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

Introduced in R2011a

cl2tf

Convert coupled allpass lattice to transfer function form

Syntax

```
[b,a] = cl2tf(k1,k2)
[b,a] = cl2tf(k1,k2,beta)
[b,a,bp] = cl2tf(k1,k2)
[b,a,bp] = cl2tf(k1,k2,beta)
```

Description

`[b,a] = cl2tf(k1,k2)` returns the numerator and denominator vectors of coefficients `b` and `a` corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\left[H1(z) + H2(z)\right]$$

where *H1(z)* and *H2(z)* are the transfer functions of the allpass filters determined by `k1` and `k2`, and `k1` and `k2` are real vectors of reflection coefficients corresponding to allpass lattice structures.

`[b,a] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the numerator and denominator vectors of coefficients b and a corresponding to the transfer function

$$H(z) = B(z) / A(z) = \frac{1}{2}\left[-(\bar{\beta})\cdot H1(z) + \beta \cdot H2(z)\right]$$

`[b,a,bp] = cl2tf(k1,k2)` where `k1` and `k2` are real, returns the vector `bp` of real coefficients corresponding to the numerator of the power complementary filter *G(z)*

$$G(z) = Bp(z) / A(z) = \frac{1}{2}\left[H1(z) - H2(z)\right]$$

`[b,a,bp] = cl2tf(k1,k2,beta)` where `k1`, `k2` and `beta` are complex, returns the vector of coefficients `bp` of possibly complex coefficients corresponding to the numerator of the power complementary filter *G(z)*

$$G(z) = Bp(z)\,/\,A(z) = \frac{1}{2_j}\left[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)\right]$$

Examples

Convert Coupled Allpass Lattice to Transfer Function

`tf2cl` returns the reflection coeffs

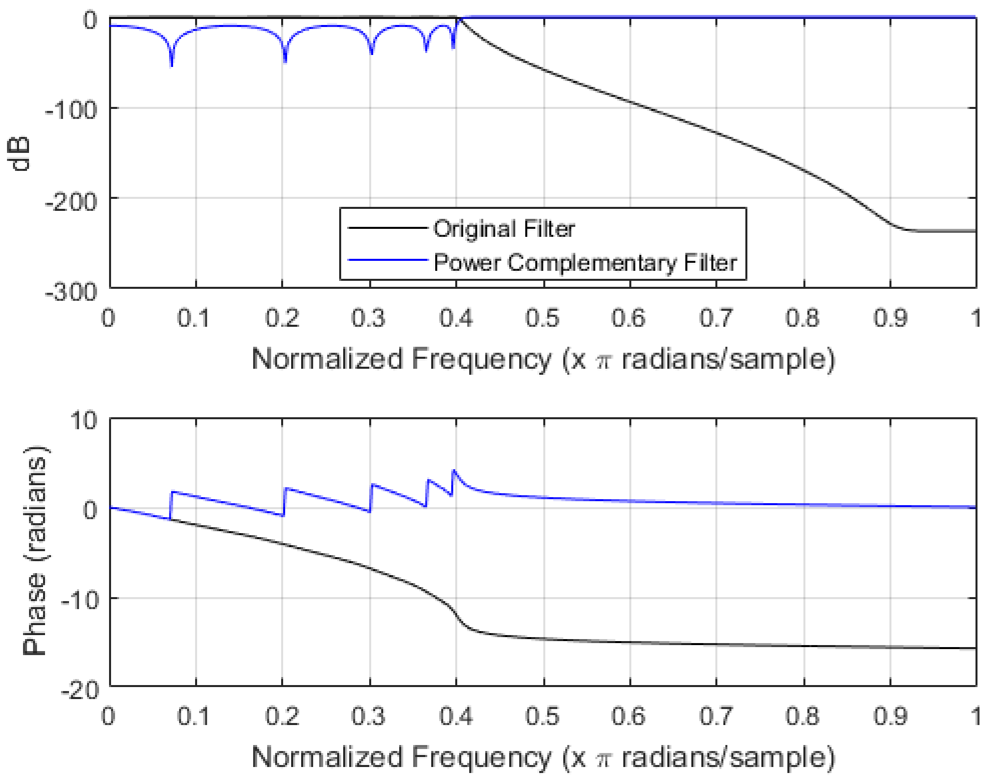
```
[b,a]=cheby1(10,.5,.4);
[k1,k2,beta]=tf2cl(b,a);
```

Construct the original and the power complementary filter.

```
[num,den,numpc]=cl2tf(k1,k2,beta);
[h,w]=freqz(num,den); hpc = freqz(numpc,den);
```

Show the frequency response

```
subplot(211);
plot(w./pi,20*log10(abs(h)),'k'); hold on; grid on;
plot(w./pi,20*log10(abs(hpc)),'b');
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('dB');
legend('Original Filter','Power Complementary Filter',...
    'Location','best');
subplot(212);
plot(w./pi,unwrap(angle(h)),'k'); hold on; grid on;
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('Phase (radians)');
plot(w./pi,unwrap(angle(hpc)),'b');
```



Extended Capabilities

Introduced in R2011a

coeffs

Filter coefficients

Syntax

```
s = coeffs(sysobj)
s = coeffs(sysobj,Name,Value)
```

Description

`s = coeffs(sysobj)` returns the coefficients of filter System object, `sysobj`, in the structure `s`.

`s = coeffs(sysobj,Name,Value)` returns filter coefficients for the filter System object `sysobj` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter

Filter System objects
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — The types of values:
`‘double’ | 'single' | 'fixed'`

Specify the arithmetic used during analysis. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The `coeffs` method returns the quantized filter coefficients when the arithmetic is set to `'single'` or `'fixed'`. When you specify `'fixed'`, the arithmetic changes depend on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

`s`

Structure with a single field, `Numerator`, containing filter coefficients.

Examples

Coefficients of an FIR Halfband Interpolator

```
FIRHalfbandInterp = dsp.FIRHalfbandInterpolator('Specification',...
    'Filter order and transition width','FilterOrder',26);
C = coeffs(FIRHalfbandInterp);
C.Numerator

% Impulse response of the filter
fvtool(FIRHalfbandInterp,'impulse')
```

```
ans =

  Columns 1 through 7

    0.0525         0   -0.0379         0    0.0537         0   -0.0771

  Columns 8 through 14

         0    0.1172         0   -0.2060         0    0.6345    1.0000

  Columns 15 through 21

    0.6345         0   -0.2060         0    0.1172         0   -0.0771

  Columns 22 through 27

         0    0.0537         0   -0.0379         0    0.0525

Introduced in R2011a

coeread

Read Xilinx COE file

Syntax

```
hd = coeread(filename)
```

Description

`hd = coeread(filename)` extracts the Distributed Arithmetic FIR filter coefficients defined in the XILINX CORE Generator .COE file specified by `filename`. It returns a `dfilt` object, the fixed-point filter `hd`. If you do not provide the file type extension `.coe` with the `filename`, the function assumes the `.coe` extension.

See Also

`coewrite` | `dfilt` | `dfilt.dffir`

Introduced in R2011a

coewrite

Write Xilinx COE file

Syntax

```
coewrite(hd)
coewrite(hd,radix)
coewrite(...,filename)
```

Description

`coewrite(hd)` writes a XILINX Distributed Arithmetic FIR filter coefficient .COE file which can be loaded into the XILINX CORE Generator. The coefficients are extracted from the fixed-point `dfilt` object `hd`. Your fixed-point filter must be a direct form FIR structure `dfilt` object with one section and whose `Arithmetic` property is set to `fixed`. You cannot export single-precision, double-precision, or floating-point filters as `.coe` files, nor multiple-section filters. To enable you to provide a name for the file, `coewrite` displays a dialog box where you fill in the file name. If you do not specify the name of the output file, the default file name is `untitled.coe`.

`coewrite(hd,radix)` indicates the radix (number base) used to specify the FIR filter coefficients. Valid `radix` values are `2` for binary, `10` for decimal, and `16` for hexadecimal (default).

`coewrite(...,filename)` writes a XILINX.COE file to `filename`. If you omit the file extension, `coewrite` adds the `.coe` extension to the name of the file.

The `coewrite` function always generates the XILINX.COE file in your current folder. To use this function, you must have write permission in your current folder.

Examples

`coewrite` generates an ASCII text file that contains the filter coefficients in a format the XILINX CORE Generator can read and load. In this example, you create a 30th-order fixed-point filter and generate the `.coe` file that includes the filter coefficients as well as associated information about the filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); hq = dfilt.dffir(b);
set(hq,'arithmetic','fixed'); coewrite(hq,10,'mycoefile');
```

The `coewrite` function generates the output file, `mycoefile.coe`, in your current folder. The `.coe` file contains the radix, coefficient width, and filter coefficients. The file reports the filter coefficients in column-major order. The radix, coefficient width, and filter coefficients are the minimum set of data needed in a `.coe` file.

`coeread` | `dfilt` | `dfilt.dffir`

Introduced in R2011a

constraincoeffwl

Constrain coefficient wordlength

Syntax

```
Hq = constraincoeffwl(Hd,wordlength)
Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)
Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)
Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)
Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)
```

Description

`Hq = constraincoeffwl(Hd,wordlength)` returns a fixed-point filter `Hq` meeting the design specifications of the single-stage or multistage FIR filter object `Hd` with a wordlength of at most `wordlength` bits. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `Hd` must be generated using `fdesign` and `design`. `constraincoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use. `Hq` is first filter among the trials to meet the specifications in `Hd` with a wordlength of at most `wordlength`.

`Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the constraint of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` constrains the wordlength without using noise-shaping.

`Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`

You must have the Fixed-Point Designer software installed to use this function.

Examples

Design Fixed-Point Filter

Design fixed-point filter with a wordlength of at most 11 bits using `constraincoeffwl`

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',.4,.5,1,60);
Hd = design(Hf,'equiripple'); % 43 coefficients
Hq = constraincoeffwl(Hd,11); % 45 11-bit coefficients
hfvt = fvtool(Hd,Hq);
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

convert

Convert filter structure of discrete-time filter

Syntax

```
hq = convert(hq,newstruct)
```

Description

Discrete-Time Filters

`hq = convert(hq,newstruct)` returns a quantized filter whose structure has been transformed to the filter structure specified by `newstruct`. You can enter any one of the following quantized filter structures:

- `'antisymmetricfir'`: Antisymmetric finite impulse response (FIR)
- `'df1'`: Direct form I
- `'df1t'`: Direct form I transposed
- `'df1sos'`: Direct-Form I, Second-Order Sections
- `'df1tsos'`: Direct-Form I Transposed, Second-Order Sections
- `'df2'`: Direct form II
- `'df2t'`: Direct form II transposed. Default filter structure
- `'df2sos'`: Direct-Form II, Second-Order Sections
- `'df2tsos'`: Direct-Form II Transposed, Second-Order Sections
- `'dffir'`: FIR
- `'dffirt'`: Direct form FIR transposed
- `'latcallpass'`: Lattice allpass
- `'latticeca'`: Lattice coupled-allpass
- `'latticecapc'`: Lattice coupled-allpass power-complementary
- `'latticear'`: Lattice autoregressive (AR)
- `'latticemamax'`: Lattice moving average (MA) maximum phase

- `'latticemamin'`: Lattice moving average (MA) minimum phase
- `'latticearma'`: Lattice ARMA
- `'statespace'`: Single-input/single-output state-space
- `'symmetricfir'`: Symmetric FIR. Even and odd forms

All filters can be converted to the following structures:

- `'df1'`: Direct form I
- `'df1t'`: Direct form I transposed
- `'df1sos'`: Direct-Form I, Second-Order Sections
- `'df1tsos'`: Direct-Form I Transposed, Second-Order Sections
- `'df2'`: Direct form II
- `'df2t'`: Direct form II transposed. Default filter structure
- `'df2sos'`: Direct-Form II, Second-Order Sections
- `'df2tsos'`: Direct-Form II Transposed, Second-Order Sections
- `'statespace'`: Single-input/single-output state-space
- `'symmetricfir'`: Symmetric FIR. Even and odd forms

For the following filter classes, you can specify other conversions as well:

- Minimum phase FIR filters can be converted to `latticemamin`
- Maximum phase FIR filters can be converted to `latticemamax`
- Allpass filters can be converted to `latcallpass`

`convert` generates an error when you specify a conversion that is not possible.

Examples

Convert Direct-Form II Transposed Structure to Direct-Form I

```
[b,a]=ellip(5,3,40,.7); hq = dfilt.df2t(b,a)
hq2 = convert(hq,'df1')
```

```
hq =
```

```
     FilterStructure: 'Direct-Form II Transposed'
          Arithmetic: 'double'
           Numerator: [1x6 double]
         Denominator: [1x6 double]
    PersistentMemory: false

hq2 =

     FilterStructure: 'Direct-Form I'
          Arithmetic: 'double'
           Numerator: [1x6 double]
         Denominator: [1x6 double]
    PersistentMemory: false
```

See Also

mfilt | dfilt

Introduced in R2011a

cost

Estimate cost for implementing filter System objects

Syntax

```
c = cost(sysobj)
c = cost(sysobj,Name,Value)
```

Description

`c = cost(sysobj)` returns a cost estimate `c` for the filter System object `sysobj`.

`c = cost(sysobj,Name,Value)` returns a cost estimate `c` for the filter System object `sysobj` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`sysobj`

Filter System object.

All filter system objects support analysis methods. For more information on analysis methods, see “Analysis Methods for Filter System Objects” on page 3-2. For a list of analysis methods supported by a particular filter System object, for example `dsp.FIRHalfbandDecimator`, enter `dsp.FIRHalfbandDecimator.helpFilterAnalysis` at the MATLAB Command prompt.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

Specify the arithmetic used during analysis. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

c

Cost estimate, `c` contains the following fields:

Estimated Value	Description
`NumCoefficients`	Number of filter coefficients (excluding coefficients with values 0, 1 or -1)
`NumStates`	Number of filter states
`MultiplicationsPerInputSample`	Number of multiplication operations performed for each input sample
`AdditionsPerInputSample`	Number of addition operations performed for each input sample

Examples

Cost of FIR Filter

This example shows how to compute the cost of implementing an FIR Filter created using `dsp.FIRFilter` object.

```
Fs = 8000; Fcutoff = 2000;
firFilt = dsp.FIRFilter('Numerator', fir1(130,Fcutoff/(Fs/2)));
cost(firFilt)
```

```
ans =

cumsec

Cumulative second-order section of `BiquadFilter` System object

Syntax

```
sect = cumsec(biquad)
sections = cumsec(biquad,indices)
sections = cumsec(biquad,indices,secondary)
cumsec(biquad,...)
sections = cumsec(biquad,Name,Value)
```

Description

`sect = cumsec(biquad)` returns a cell array, `sect`, which contains cumulative sections of the `dsp.BiquadFilter` filter System object, `biquad`. Each element in `sect` is a filter with the structure of the original filter. The first element is the first filter section of `biquad`. The second element of `sect` is a filter that represents the combination of the first and second sections of `biquad`. The third element of `sections` is a filter which combines sections 1, 2, and 3 of `biquad`. This pattern continues until the final element of `sections` contains all the sections of `biquad` and should be identical to `biquad`.

`sections = cumsec(biquad,indices)` returns the cumulative sections of the `dsp.BiquadFilter` filter System object `biquad` whose indices in the original filter are in the vector `indices`.

`sections = cumsec(biquad,indices,secondary)` uses the secondary scaling points `secondary` in the sections to determine where the sections should be split when `secondary` is `true`. `secondary` is `false` by default. This option only applies for `dsp.BiquadFilter` objects with `'Direct form II'` and `'Direct form I transposed'` structures. For these structures, the secondary scaling points refer to the location between the recursive and the nonrecursive part, that is the 'middle' of the section.

`cumsec(biquad,...)` plots the magnitude response of the cumulative sections using `fvtool`.

`sections = cumsec(biquad,Name,Value)` returns the cumulative sections of the filter System object `biquad` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`biquad`

`dsp.BiquadFilter` filter System object with one of the following filter structures:

Structure	Description
`df1sos`	Direct-form I filter object with second-order sections.
`df1tsos`	Direct-Form I transposed filter with second-order sections.
`df2sos`	Direct-form II filter object with second-order sections.
`df2tsos`	Direct-Form II transposed filter with second-order sections.

`indices`

Filter indices. Use `indices` to specify the filter sections `cumsec` uses to compute the cumulative responses.

`secondary`

This option applies only when `biquad` has the `df2sos` and `df1tsos` structures. For these second-order section structures, the secondary scaling points refer to the scaling locations between the recursive and the nonrecursive parts of the section (the "middle" of the section). Argument `secondary` accepts either `true` or `false`. By default, `secondary` is `false`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value types:
'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

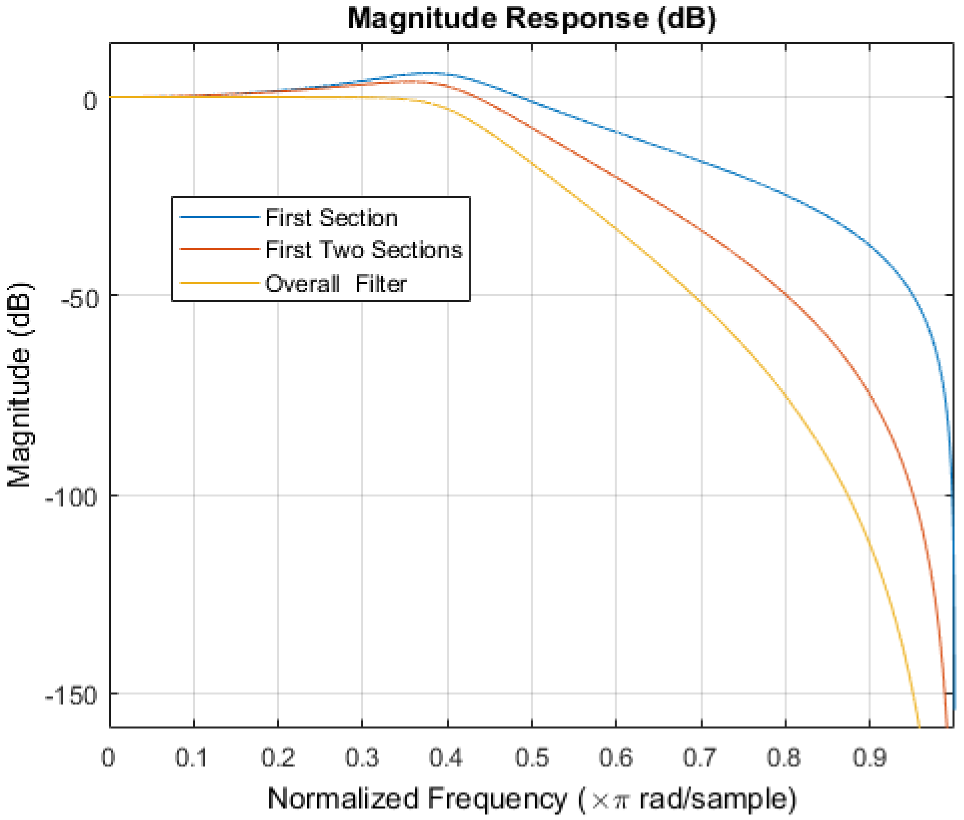
When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Examples

Frequency Response of SOS Filter

This example plots the relative responses of the sections of a sixth-order filter with three sections. Each curve adds one more section to form the filter response.

```
Lowpass = fdesign.lowpass('n,fc',6,.4); ButterLowpass = butter(Lowpass,'SystemObject',t
CumSections = cumsec(ButterLowpass); hfvt = fvtool(CumSections{1},CumSections{2},CumSec
legend(hfvt,'First Section','First Two Sections','Overall  Filter');
```



See Also

`scale` | `scalecheck`

Introduced in R2011a

denormalize

Undo filter coefficient and gain changes caused by normalize

Syntax

```
denormalize(hq)
```

Description

`denormalize(hq)` reverses the coefficient changes you make when you use `normalize` with `hq`. The filter coefficients do not change if you call `denormalize(hq)` before you use `normalize(hq)`. Calling `denormalize` more than once on a filter does not change the coefficients after the first `denormalize` call.

Examples

Denormalize Filter Coefficients

Construct a quantized filter `hd`.

```
d=fdesign.highpass('n,F3dB',14,0.45);
hd =design(d,'butter');
hd.arithmetic='fixed';
```

Normalize the filter coefficients

```
normalize(hd)
NormSOSMatrix = hd.sosMatrix;
```

After normalizing the filter coefficients, restore them to their original values by reversing the effects of the `normalize` function.

```
denormalize(hd)
eqSOSMatrices = isequal(NormSOSMatrix,hd.sosMatrix)
```

```
eqSOSMatrices =
```

```
logical

 0
```

normalize

Introduced in R2011a

design

Apply design method to filter specification object

Syntax

```
filt = design(D,'Systemobject',true)
filt = design(D,METHOD,'Systemobject',true)
filt =
design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...,'Systemobject',true)
filt = design(D,METHOD,OPTS,'Systemobject',true)
```

Description

`filt = design(D,'Systemobject',true)` uses the filter specifications object `D` to generate a filter System object, `filt`. When you do not provide a design method as an input argument, `design` uses the default design method. Use `designmethods(D,'default')` to see the default design method for your filter specifications object.

`filt = design(D,METHOD,'Systemobject',true)` uses the design method specified by `METHOD`. `METHOD` must be one of the options returned by `designmethods`. Use `designmethods(D,'default')` to determine which algorithm is used by default.

The design method you provide as the `designmethod` input argument must be one of the methods returned by

```
designmethods(D,'Systemobject',true)
```

To help you design filters more quickly, the input argument `METHOD` accepts a variety of special keywords that force `design` to behave in different ways. The following table presents the keywords you can use for `METHOD` and how `design` responds to the keyword.

Design Method Keyword	Description of the Design Response
`'FIR'`	Forces `design` to produce an FIR filter. When no FIR design method exists for object `D`, `design` returns an error.

Design Method Keyword	Description of the Design Response
`'IIR'`	Forces `design` to produce an IIR filter. When no IIR design method exists for object `D`, `design` returns an error.
`'ALLFIR'`	Produces filters from every applicable FIR design method for the specifications in `D`, one filter for each design method. As a result, `design` returns multiple filters in the output object.
`'ALLIIR'`	Produces filters from every applicable IIR design method for the specifications in `D`, one filter for each design method. As a result, `design` returns multiple filters in the output object.
`'ALL'`	Designs filters using all applicable design methods for the specifications object `D`. As a result, `design` returns multiple filters, one for each design method. `design` uses the design methods in the order that `designmethods(D,'Systemobject',true)` returns them.

Keywords are not case sensitive.

When `design` returns multiple filters in the output object, use indexing to see the individual filters. For example, to see the third filter in `filt`, enter:

```
filt(3)
```

`filt = design(D,METHOD,PARAM1,VALUE1,PARAM2,VALUE2,...,'Systemobject',true)` specifies design-method options. Use `help(D,METHOD)` for complete information on which design-method-specific options are available. You can also use `designopts(D,METHOD)` for a less-detailed listing of the design-method-specific options.

`filt = design(D,METHOD,OPTS,'Systemobject',true)` specifies design-method options using the structure `OPTS`. `OPTS` is usually obtained from `designopts` and then specified as an input to `design`. Use `help(D,METHOD)` for more information on optional inputs.

If you are specifying design-method-specific options using `OPTS`, you can also set `OPTS.SystemObject` to `true` instead of calling `design` with the `'SystemObject', true` syntax.

Examples

Design of Lowpass Filters

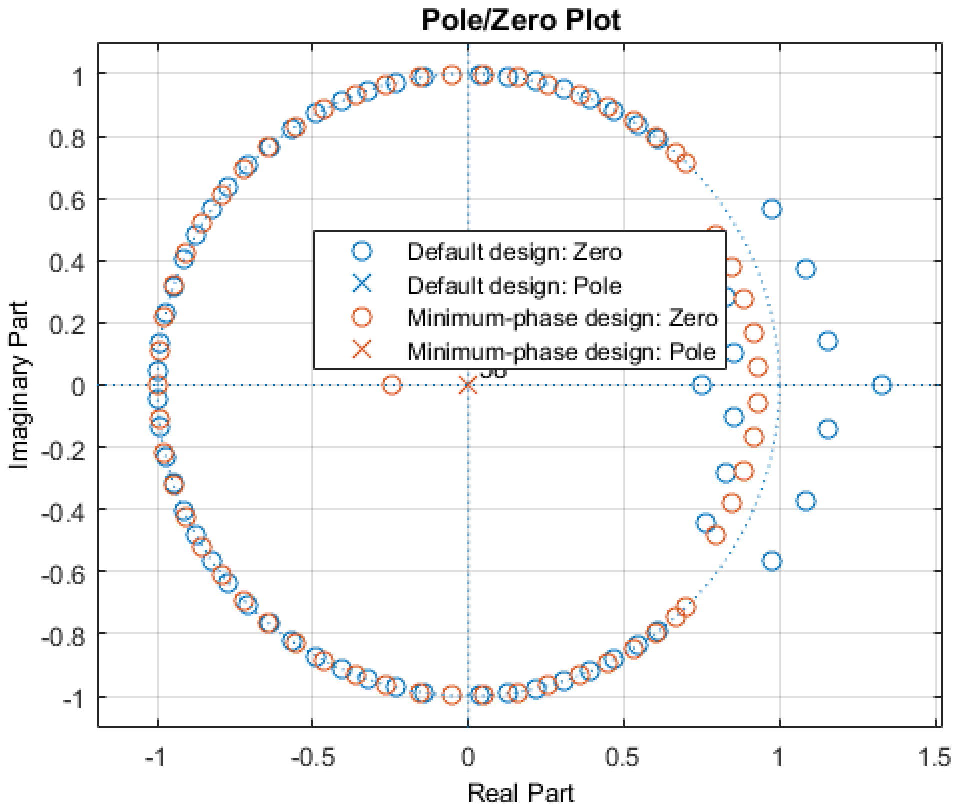
Design an FIR equiripple lowpass filter. Specify a passband edge frequency of 0.2π rad/sample and a stopband edge frequency of 0.25π rad/sample. Set the passband ripple to 0.5 dB and the stopband attenuation to 40 dB. Use the default equiripple method.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40);
filt = design(D,'SystemObject',true);
```

Design a minimum-phase FIR equiripple filter. Display pole-zero plots of the default and minimum-phase designs.

```
filtMin = design(D,'equiripple','MinPhase',true,'SystemObject',true);

fvt = fvtool(filt,filtMin,'Analysis','polezero');
legend(fvt,'Default design','Minimum-phase design')
```



Redesign the filter using the elliptic method. Match the passband exactly.

```
filt = design(D,'ellip','MatchExactly','passband','SystemObject',true);
```

You can specify the P-th norm scaling on the second-order sections. Use L-infinity norm scaling in the time domain.

```
filtL = design(D,'ellip','MatchExactly','passband','SOSScaleNorm','linf', ...
    'SystemObject',true);
```

Display the frequency responses of the Butterworth filters.

```
fvt = fvtool(filt,filtL);
legend(fvt,'Default scaling','L-infinity norm scaling')
```

Introduced in R2009a

designMultirateFIR

Multirate FIR filter design

Syntax

`B = designMultirateFIR(L,M)`

`B = designMultirateFIR(L,M,P)`

`B = designMultirateFIR(L,M,P,Astop)`

Description

`B = designMultirateFIR(L,M)` designs a multirate FIR filter with interpolation factor `L` and decimation factor `M`. The output `B` is the vector of designed FIR coefficients. To design a pure interpolator, set *M* to 1. To design a pure decimator, set *L* to 1.

`B = designMultirateFIR(L,M,P)` designs a multirate FIR filter with half-polyphase length `P`. By default, the half-polyphase length is `12`.

`B = designMultirateFIR(L,M,P,Astop)` designs a multirate FIR filter with stopband attenuation `Astop`. By default, the stopband attenuation is 80 dB.

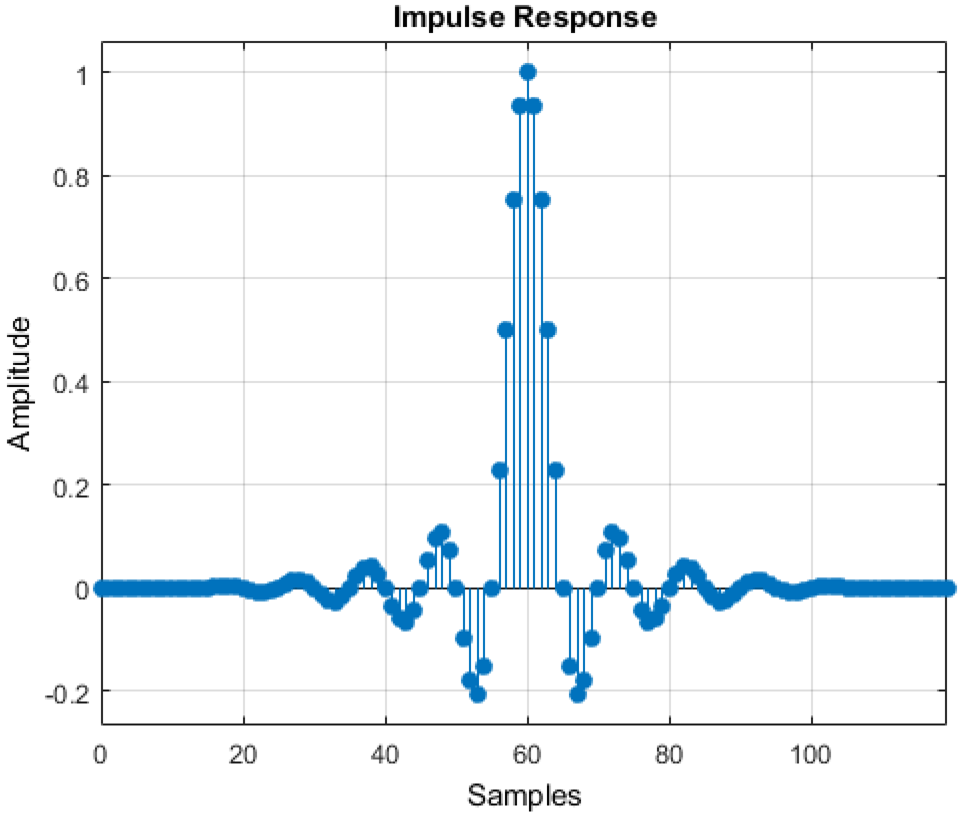
Examples

Design an FIR Interpolator

To design an FIR Interpolator using the `designMultirateFIR` function, you must specify the interpolation factor of interest (usually greater than 1) and a decimation factor equal to 1. You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values.

Design an FIR interpolator with interpolation factor set to 5. Use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB.

```
b = designMultirateFIR(5,1);
fvtool(b,'impulse')
```

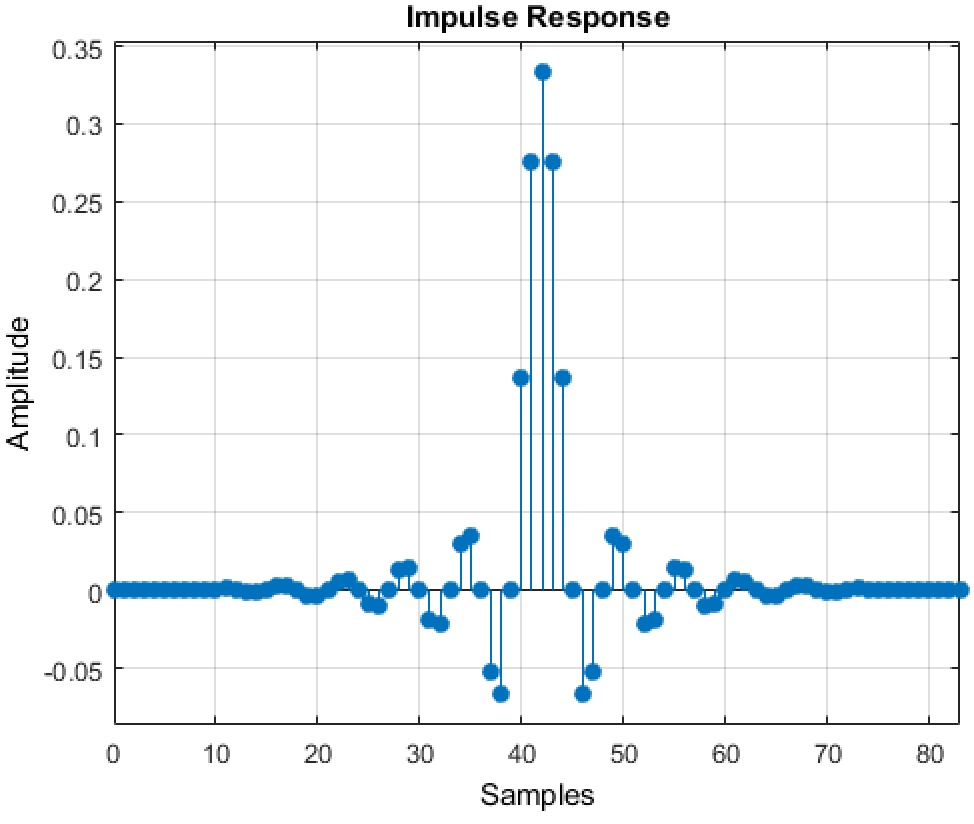


Design an FIR Decimator

To design an FIR Decimator using the `designMultirateFIR` function, you must specify the decimation factor of interest (usually greater than 1) and an interpolation factor equal to 1. You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values. Design an FIR decimator with decimation factor set to 3, and half-polyphase length set to 14. Use the default stopband attenuation of 80 dB.

```
b = designMultirateFIR(1,3,14);
```

```
fvtool(b,'impulse');
```



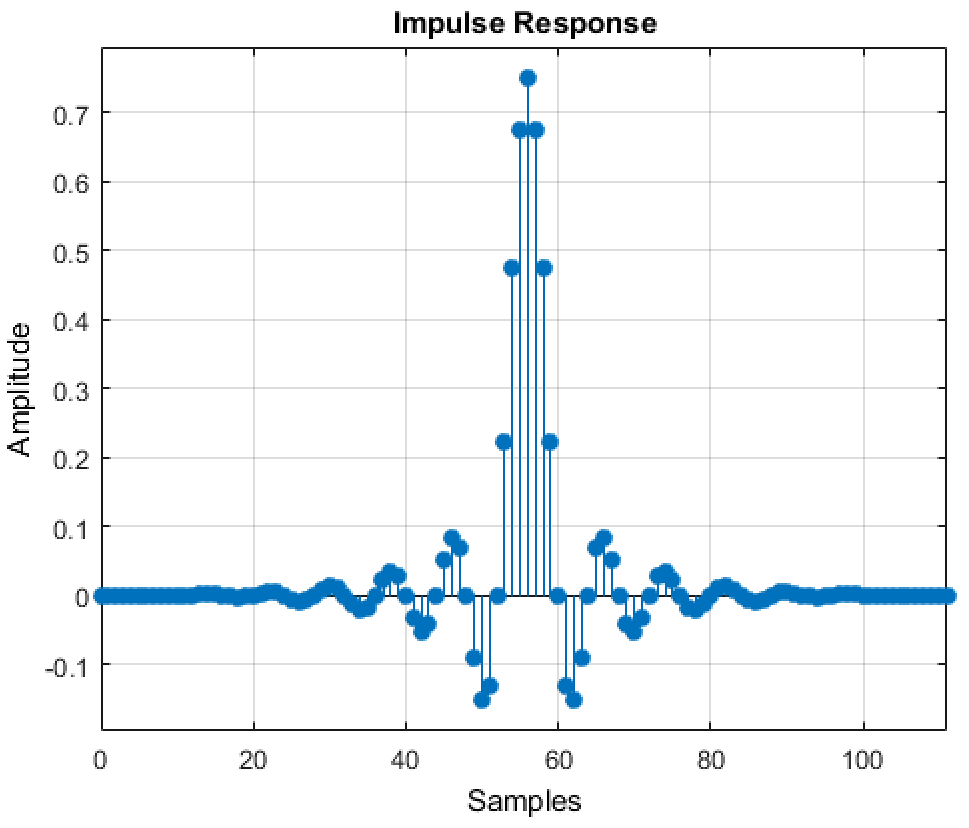
Design an FIR Rate Converter

To design an FIR Rate Comverter using the `designMultirateFIR` function, you must specify an interpolation factor and decimation factor of interest (usually greater than 1). You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values.

Design an FIR rate converter with interpolation factor set to 3, decimation factor set to 4, half-polyphase length set to 14, and stopband attenuation set to 90 dB.

```
b = designMultirateFIR(3,4,14,90);
```

```
fvtool(b,'impulse');
```



Input Arguments

L — Interpolation factor

positive scalar integer

Interpolation factor, specified as a positive scalar integer. To design a decimator only, set L to 1.

Example: 2

Data Types: `single` | `double`

`M` — Decimation factor
positive scalar integer

Decimation factor, specified as a positive scalar integer. To design an interpolator only, set M to `1`.

Example: `2`

Data Types: `single` | `double`

`P` — Half-polyphase length
12 (default) | positive scalar integer

Half-polyphase length, specified as a positive scalar integer.

Example: `12`

Example: `20`

Data Types: `single` | `double`

`Astop` — Stopband attenuation
90 (default) | nonnegative scalar

Stopband attenuation in dB, specified as a nonnegative real scalar greater than or equal to `0`.

Example: `0.0`

Example: `80.5`

Data Types: `single` | `double`

Output Arguments

`B` — Coefficients
real-valued vector

Multirate FIR filter coefficients, returned as a real-valued $N + 1$ length vector, where $N = 2*P*R$, where P is the half-polyphase length, R is defined as max(L,M). For more details, see the “More About” on page 5-249 section.

More About

`designMultirateFIR` designs an Nth order, Rth band Nyquist FIR filter using the N + 1 length Kaiser window vector to window the truncated impulse response of the FIR filter.

Filter order N is defined as $N = 2*P*R$ and R is defined as max(L,M).

The truncated impulse response $d(n)$ is delayed by $N/2$ samples to make it causal. The truncated and delayed impulse response is given by:

$$d(n-N/2)=\frac{\sin(w_c(n-N/2))}{\pi(n-N/2)},\quad n=0,\cdots,\frac{N}{2},\cdots,N$$

where $w_c = \pi/R$.

For every Rth band, the impulse response of the Nyquist filters is exactly zero. Because of this property, when Nyquist filters are used for pure interpolation, the input samples remain unaltered after interpolating.

A Kaiser window is used because of its near-optimum performance while providing a robust way of designing a Nyquist filter. The window depends on two parameters: length $N + 1$ and shape parameter β.

The Kaiser window is defined by:

$$w(n)=\frac{I_0\left(\beta\sqrt{1-\left(\frac{n-N/2}{N/2}\right)^2}\right)}{I_0(\beta)},\qquad 0\le n\le N,$$

where I_0 is the zeroth-order modified Bessel function of the first kind.

The shape parameter β is calculated from:

$$\beta=\begin{cases}0.1102(A_{stop}-8.7) & \text{if } A_{stop}\ge 50\\ 0.5842(A_{stop}-\ 21)^{0.4}+0.07886(A_{stop}-\ 21) & \text{if } 21<A_{stop}<50\\ 0 & \text{if } A_{stop}\le 21,\end{cases}$$

where A_{stop} is the stopband attenuation in dB.

The windowed impulse response is given by

$$h(n) = w(n)d(n - N/2) = w(n)\frac{\sin(w_c(n - N/2))}{\pi(n - N/2)}, \quad n = 0, \cdots, \frac{N}{2}, \cdots, N$$

h(n) for *n = 0,..,N/2,...N* are the coefficients of the multirate filter. These coefficients are defined by the interpolation factor, *L*, and decimation factor, *M*.

designmethods

Methods available for designing filter from specification object

Syntax

```
M = designmethods(D,'SystemObject',true)
M = designmethods(D,'default')
M = designmethods(D,TYPE,'SystemObject',true)
M = designmethods(D,'full','SystemObject',true)
```

Description

`M = designmethods(D,'SystemObject',true)` returns the available design methods for designing filter System objects for the filter specification object, `D`.

`M = designmethods(D,'default')` returns the default design method for the filter specification object `D`.

`M = designmethods(D,TYPE,'SystemObject',true)` returns the `TYPE` design methods for the filter specification object, `D`. `TYPE` can be either `'FIR'` or `'IIR'`.

`M = designmethods(D,'full','SystemObject',true)` returns the full name for each of the available design methods. For example, `designmethods` with the `'full'` argument returns `Butterworth` for the `butter` method.

Examples

Valid Design Methods for Lowpass Filter

Construct a lowpass filter specification object and determine the valid design methods.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',500,600,0.5,60,1e4);
M = designmethods(D,'SystemObject',true)
```

```
M =

  8×1 cell array
```

```
'butter'
'cheby1'
'cheby2'
'ellip'
'equiripple'
'ifir'
'kaiserwin'
'multistage'
```

Obtain detailed command line help on the Chebyshev type I design method.

```
help(D,M{2})
```

```
 DESIGN Design a Chebyshev type I iir filter.
    HD = DESIGN(D, 'cheby1') designs a Chebyshev type I filter specified by the
    FDESIGN object D, and returns the DFILT/MFILT object HD.

    HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD,
    using a System object instead of a DFILT/MFILT object.

    HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
    structure STRUCTURE.  STRUCTURE is 'df2sos' by default and can be any of
    the following:

    'df1sos'
    'df2sos'
    'df1tsos'
    'df2tsos'
    'cascadeallpass'
    'cascadewdfallpass'

    Some of the listed structures may not be supported by System object
    filters. Type validstructures(D, 'cheby1', 'SystemObject', true) to
    get a list of structures supported by System objects.

    HD = DESIGN(..., 'MatchExactly', MATCH) designs a Chebyshev type I
    filter and matches the frequency and magnitude specification for the
    band MATCH exactly.  The other band will exceed the specification.  MATCH
    can be 'stopband' or 'passband' and is 'passband' by default.

    HD = DESIGN(..., 'SOSScaleNorm', NORM) designs an SOS filter and scales
    the coefficients using the P-Norm NORM. NORM can be either a
    discrete-time-domain norm or a frequency-domain norm. Valid time-domain
```

```
norms are 'l1','l2', and 'linf'. Valid frequency-domain norms are
'L1','L2', and 'Linf'. Note that L2-norm is equal to l2-norm
(Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are
as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'.
Using the most stringent scaling, 'l1', the filter is the least prone
to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is
the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting
SOSScaleNorm = ''.

HD = DESIGN(..., 'SOSScaleOpts', OPTS) designs an SOS filter and scales
the coefficients using an FDOPTS.SOSSCALING object OPTS.  Scaling options
are:
Property                Default     Description/Valid values
---------               -------     ------------------------
'sosReorder'            'auto'      Reorder section prior to scaling.
                                    {'auto','none','up','down','lowpass',
                                     'highpass','bandpass','bandstop'}
'MaxNumerator'          2           Maximum value for numerator coefficients
'NumeratorConstraint'   'none'      {'none', 'unit', 'normalize','po2'}
'OverflowMode'          'wrap'      {'wrap','saturate'}
'ScaleValueConstraint'  'unit'      {'unit','none','po2'}
'MaxScaleValue'         'Not used'  Maximum value for scale values

When sosReorder is set to 'auto', the sections will be automatically
reordered depending on the response type of the design (lowpass,
highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint'
is set to something other than 'unit'. If 'MaxScaleValue' is set to a
number, the 'ScaleValueConstraint' will be changed to 'none'. Further,
if SOSScaleNorm is off (as it is by default), then all the SOSScaleOpts
will be ignored.

For more information about P-Norm and scaling options see help for DFILT\SCALE.

% Example #1 - Compare passband and stopband MatchExactly.
   h     = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
   Hd    = design(h, 'cheby1', 'MatchExactly', 'passband');
   Hd(2) = design(h, 'cheby1', 'MatchExactly', 'stopband');
```

```
% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);

design | designopts | fdesign

Introduced in R2009a

designopts

Valid input arguments and values for specification object and method

Syntax

```
OPTS = designopts(D,METHOD)
```

Description

`OPTS = designopts(D,METHOD)` returns a structure array with the default design parameters used by the design method `METHOD`. `METHOD` must be one of the options returned by `designmethods`.

Use `help(D,METHOD)` to get a description of the design parameters.

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property if at least one of the structures available for that design method is supported by System objects. However, not all structures for that design method are supported by System objects.

Examples

Butterworth Filter Design Options

Create a lowpass filter with a numerator and denominator order of 10 and a 3-dB frequency of 0.2π rad/sample. Obtain the default design parameters for a Butterworth design. Test whether the filter structure is a direct-form II biquad.

```
D = fdesign.lowpass('Nb,Na,F3dB',10,10,0.2);
OPTS = designopts(D,'butter')
if (OPTS.FilterStructure == 'df2sos')
    fprintf('The default filter structure is Direct-Form II\n');
    fprintf('with second-order sections.\n');
end
```

```
OPTS =

  struct with fields:

    FilterStructure: 'df2sos'
       SOSScaleNorm: ''
       SOSScaleOpts: [1×1 fdopts.sosscaling]
       SystemObject: 0

The default filter structure is Direct-Form II
with second-order sections.
```

dfilt

Discrete-time filter

Syntax

```
hd = dfilt.structure(input1,...)
hd = [dfilt.structure(input1,...), dfilt.structure(input1,...),...]
hd = design(d,'designmethod')
```

Description

`hd = dfilt.`*`structure`*`(input1,...)` returns a discrete-time filter, `hd`, of type *`structure`*. Each structure takes one or more inputs. When you specify a `dfilt.`*`structure`* with no inputs, a default filter is created.

Note You must use a *`structure`* with `dfilt`.

`hd = [dfilt.`*`structure`*`(input1,...), dfilt.`*`structure`*`(input1,...),...]` returns a vector containing `dfilt` filters.

Structures

Structures for `dfilt.structure` specify the type of filter structure. Available types of structures for `dfilt` are shown below.

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
`dfilt.allpass`	Allpass filter	Supported
`dfilt.cascadeallpas`	Cascade of allpass filter sections	Supported
`dfilt.cascadewdfall`	Cascade of allpass wave digital filters	Supported
`dfilt.delay`	Delay	Not supported
`dfilt.df1`	Direct-form I	Supported

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
`dfilt.df1sos`	Direct-form I, second-order sections	Supported
`dfilt.df1t`	Direct-form I transposed	Supported
`dfilt.df1tsos`	Direct-form I transposed, second-order sections	Supported
`dfilt.df2`	Direct-form II	Supported
`dfilt.df2sos`	Direct-form II, second-order sections	Supported
`dfilt.df2t`	Direct-form II transposed	Supported
`dfilt.df2tsos`	Direct-form II transposed, second-order sections	Supported
`dfilt.dffir`	Direct-form FIR	Supported
`dfilt.dffirt`	Direct-form FIR transposed	Supported
`dfilt.dfsymfir`	Direct-form symmetric FIR	Supported
`dfilt.dfasymfir`	Direct-form antisymmetric FIR	Supported
`dfilt.farrowfd`	Generic fractional delay Farrow filter	Supported
`dfilt.farrowlinearf`	Linear fractional delay Farrow filter	Not supported
`dfilt.fftfir`	Overlap-add FIR	Not supported
`dfilt.latticeallpas`	Lattice allpass	Supported
`dfilt.latticear`	Lattice autoregressive (AR)	Supported
`dfilt.latticearma`	Lattice autoregressive moving-average (ARMA)	Supported
`dfilt.latticemamax`	Lattice moving-average (MA) for maximum phase	Supported
`dfilt.latticemamin`	Lattice moving-average (MA) for minimum phase	Supported
`dfilt.calattice`	Coupled, allpass lattice	Supported

dfilt.structure	Description	Coefficient Mapping Support in realizemdl
`dfilt.calatticepc`	Coupled, allpass lattice with power complementary output	Supported
`dfilt.statespace`	State-space	Supported
`dfilt.scalar`	Scalar gain object	Supported
`dfilt.wdfallpass`	Allpass wave digital filter object	Supported
`dfilt.cascade`	Filters arranged in series	Supported
`dfilt.parallel`	Filters arranged in parallel	Supported

For more information on each structure, refer to its reference page.

`hd = design(d,'designmethod')` returns the `dfilt` object `hd` resulting from the filter specification object `d` and the design method you specify in *`designmethod`*. When you omit the `designmethod` argument, `design` uses the default design method to construct a filter from the object `d`.

With this syntax, you design filters by:

1. Specifying the filter specifications, such as the response shape (perhaps highpass) and details (passband edges and attenuation).
2. Selecting a method (such as `equiripple`) to design the filter.
3. Applying the method to the specifications object with `design(d,'designmethod')`.

Using the specification-based technique can be more effective than the coefficient-based filter design techniques.

Design Methods for Design Syntax

When you use the `hd = design(d,'`*`designmethod`*`')` syntax, you have a range of design methods available depending on `d`, the filter specification object. The next table lists all of the design methods in the toolbox.

Design Method String	Filter Design Result
`butter`	Butterworth IIR

Design Method String	Filter Design Result
cheby1	Chebyshev Type I IIR
cheby2	Chebyshev Type II IIR
ellip	Elliptic IIR
equiripple	Equiripple with the same ripple in the pass and stopbands
firls	Least-squares FIR
freqsamp	Frequency-Sampled FIR
ifir	Interpolated FIR
iirlpnorm	Least Pth norm IIR
iirls	Least-Squares IIR
kaiserwin	Kaiser-windowed FIR
lagrange	Fractional delay filter
multistage	Multistage FIR
window	Windowed FIR

As the specifications object `d` changes, the available methods for designing filters from `d` also change. For instance, if `d` is a lowpass filter with the default specification `'Fp,Fst,Ap,Ast'`, the applicable methods are:

```
% Create an object to design a lowpass filter.
d=fdesign.lowpass;
designmethods(d) % What design methods apply to object d?
```

If you change the specification string to `'N,F3dB'`, the available design methods change:

```
d=fdesign.lowpass('N,F3dB');
designmethods(d)
```

Analysis Methods

Methods provide ways of performing functions directly on your `dfilt` object without having to specify the filter parameters again. You can apply these methods directly on the variable you assigned to your `dfilt` object.

For example, if you create a `dfilt` object, `hd`, you can check whether it has linear phase with `islinphase(hd)`, view its frequency response plot with `fvtool(hd)`, or obtain its frequency response values with `h = freqz(hd)`. You can use all of the methods described here in this way.

Note If your variable `hd` is a 1-D array of `dfilt` filters, the method is applied to each object in the array. Only `freqz`, `grpdelay`, `impz`, `is*`, `order`, and `stepz` methods can be applied to arrays. The `zplane` method can be applied to an array only if `zplane` is used without outputs.

Some of the methods listed here have the same name as functions in Signal Processing Toolbox software. They behave similarly.

Method	Description
`addstage`	Adds a stage to a `cascade` or `parallel` object, where a stage is a separate, modular filter. Refer to `dfilt.cascade` and `dfilt.parallel`.
`block`	`block(hd)` creates a block of the `dfilt` object. The `block` method can specify these properties and values: `'Destination'` indicates where to place the block. `'Current'` places the block in the current Simulink model. `'New'` creates a new model. Default value is `'Current'`. `'Blockname'` assigns the entered string to the block name. Default name is `'Filter'`. `'OverwriteBlock'`indicates whether to overwrite the block generated by the block method (`'on'`) and defined by `Blockame`. Default is `'off'`. `'MapStates'` specifies initial conditions in the block (`'on'`). Default is `'off'`. Refer to "Using Filter States" in Signal Processing Toolbox documentation.
`cascade`	Returns the series combination of two `dfilt` objects. Refer to `dfilt.cascade`.
`coeffs`	Returns the filter coefficients in a structure containing fields that use the same property names as those in the original `dfilt`.

Method	Description
convert	Converts a dfilt object from one filter structure, to another filter structure.
fcfwrite	Writes a filter coefficient ASCII file. The file can contain a single filter or a vector of objects. The default file name is untitled.fcf. fcfwrite(hd,filename) writes to a disk file named filename in the current working folder. The .fcf extension is added automatically. fcfwrite(...,fmt) writes the coefficients in the format fmt, where valid fmt strings are: 'hex' for hexadecimal 'dec' for decimal 'bin' for binary representation
fftcoeffs	Returns the frequency-domain coefficients used when filtering with a dfilt.fftfir
filter	Performs filtering using the dfilt object.
firtype	Returns the type (1-4) of a linear phase FIR filter.
freqz	Plots the frequency response in fvtool. Unlike the freqz function, this dfilt freqz method has a default length of 8192.
grpdelay	Plots the group delay in fvtool.
impz	Plots the impulse response in fvtool.
impzlength	Returns the length of the impulse response.
info	Displays dfilt information, such as filter structure, length, stability, linear phase, and, when appropriate, lattice and ladder length.
isallpass	Returns a logical 1 (i.e., true) if the dfilt object in an allpass filter or a logical 0 (i.e., false) if it is not.

Method	Description
iscascade	Returns a logical 1 if the dfilt object is cascaded or a logical 0 if it is not.
isfir	Returns a logical 1 if the dfilt object has finite impulse response (FIR) or a logical 0 if it does not.
islinphase	Returns a logical 1 if the dfilt object is linear phase or a logical 0 if it is not.
ismaxphase	Returns a logical 1 if the dfilt object is maximum-phase or a logical 0 if it is not.
isminphase	Returns a logical 1 if the dfilt object is minimum-phase or a logical 0 if it is not.
isparallel	Returns a logical 1 if the dfilt object has parallel stages or a logical 0 if it does not.
isreal	Returns a logical 1 if the dfilt object has real-valued coefficients or a logical 0 if it does not.
isscalar	Returns a logical 1 if the dfilt object is a scalar or a logical 0 if it is not scalar.
issos	Returns a logical 1 if the dfilt object has second-order sections or a logical 0 if it does not.
isstable	Returns a logical 1 if the dfilt object is stable or a logical 0 if it are not.
nsections	Returns the number of sections in a second-order sections filter. If a multistage filter contains stages with multiple sections, using nsections returns the total number of sections in all the stages (a stage with a single section returns 1).
nstages	Returns the number of stages of the filter, where a stage is a separate, modular filter.
nstates	Returns the number of states for an object.
order	Returns the filter order. If hd is a single-stage filter, the order is given by the number of delays needed for a minimum realization of the filter. If hd has multiple stages, the order is given by the number of delays needed for a minimum realization of the overall filter.

Method	Description
`parallel`	Returns the parallel combination of two `dfilt` filters. Refer to `dfilt.parallel`.
`phasez`	Plots the phase response in `fvtool`.

Method	Description
`realizemdl`	(Available only with Simulink.) `realizemdl(hd)` creates a Simulink model containing a subsystem block realization of your `dfilt`. `realizemdl(hd,p1,v1,p2,v2,...)` creates the block using the properties `p1`, `p2`,... and values `v1`, `v2`,... specified. The following properties are available: `'Blockname'` specifies the name of the block. The default value is `'Filter'`. `'Destination'` specifies whether to add the block to a current Simulink model or create a new model. Valid values are `'Current'` and `'New'`. `'OverwriteBlock'` specifies whether to overwrite an existing block that was created by `realizemdl` or create a new block. Valid values are `'on'` and `'off'`. Only blocks created by `realizemdl` are overwritten. The following properties optimize the block structure. Specifying `'on'` turns the optimization on and `'off'` creates the block without optimization. The default for each block is `'off'`. `'OptimizeZeros'` removes zero-gain blocks. `'OptimizeOnes'` replaces unity-gain blocks with a direct connection. `'OptimizeNegOnes'` replaces negative unity-gain blocks with a sign change at the nearest summation block. `'OptimizeDelayChains'` replaces delay chains made up of *n* unit delays with a single delay by *n*.

Method	Description
removestage	Removes a stage from a cascade or parallel dfilt. Refer to dfilt.cascade and dfilt.parallel.
setstage	Overwrites a stage of a cascade or parallel dfilt. Refer to dfilt.cascade and dfilt.parallel.
sos	Converts the dfilt to a second-order sections dfilt. If hd has a single section, the returned filter has the same class. sos(hd,flag) specifies the ordering of the second-order sections. If flag='UP', the first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle. If flag='down', the sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them. sos(hd,flag,scale) specifies the scaling of the gain and the numerator coefficients of all second-order sections. scale can be 'none', 'inf' (infinity-norm), or 'two' (2-norm). Using infinity-norm scaling with up ordering minimizes the probability of overflow in the realization. Using 2-norm scaling with down ordering minimizes the peak roundoff noise.
ss	Converts the dfilt to state-space. To see the separate A,B,C,D matrices for the state-space model, use [A,B,C,D]=ss(hd).
stepz	Plots the step response in fvtool stepz(hd,n) computes the first n samples of the step response. stepz(hd,n,Fs) separates the time samples by T = 1/Fs, where Fs is assumed to be in hertz.
sysobj	Converts the dfilt to a filter System object. See the reference page for a list of supported objects.
tf	Converts the dfilt to a transfer function.
zerophase	Plots the zero-phase response in fvtool.

Method	Description
`zpk`	Converts the `dfilt` to zeros-pole-gain form.
`zplane`	Plots a pole-zero plot in `fvtool`.

Viewing Properties

As with any object, use `get` to view a `dfilt` properties. To see a specific property, use

```
get(hd,'property')
```

To see all properties for an object, use

```
get(hd)
```

Note `dfilt` objects include an `arithmetic` property. You can change the internal arithmetic of the filter from double- precision to single-precision using: `hd.arithmetic = 'single'`.

If you have Fixed-Point Designer software, you can change the `arithmetic` property to fixed-point using: `hd.arithmetic = 'fixed'`

Changing Properties

To set specific properties, use

```
set(hd,'property1',value,'property2',value,...)
```

You must use single quotation marks around the property name. Use single quotation marks around the `value` argument when the value is a string, such as `specifyall` or `fixed`.

Copying an Object

To create a copy of an object, use the `copy` method.

```
h2 = copy(hd)
```

Note Using the syntax `H2 = hd` copies only the object handle and does not create a new, independent object.

Converting Between Filter Structures

To change the filter structure of a dfilt object hd, use

```
hd2 = convert(hd,'structure_string');
```

where structure_string is any valid structure name in single quotation marks. If hd is a cascade or parallel structure, each stage is converted to the new structure.

Using Filter States

Two properties control the filter states:

- states — Stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions. For df1, df1t, df1sos and df1tsos structures, states returns a filtstates object.
- PersistentMemory — Controls whether filter states are saved. The default value is 'false', which causes the initial conditions to be reset to zero before filtering and turns off the display of states information. Setting PersistentMemory to 'true' allows the filter to use your initial conditions or to reuse the final conditions from a previous filtering operation as the initial conditions of the next filtering operation. The true setting also displays information about the filter states.

Note If you set the states and want to use them for filtering, you must set PersistentMemory to 'true' before you use the filter.

Examples

Create a direct-form I filter, and use a method to see if it is stable.

```
[b,a] = butter(8,0.25);
hd = dfilt.df1(b,a);
isstable(hd)
```

If a dfilt's numerator values do not fit on a single line, a description of the vector is displayed. To see the specific numerator values for this example, use

```
B = get(hd,'numerator');
```

```
% or
B1 = hd.numerator;
```

Create an array containing two `dfilt` objects, apply a method and verify that the method acts on both objects. Use a method to test whether the objects are FIR objects.

```
b = fir1(5,.5);
hd = dfilt.dffir(b);         % Create an FIR filter object
[b,a] = butter(5,.5);        % Create IIR filter
hd(2) = dfilt.df2t(b,a);      % Create DF2T object and place
                              % in the second column of hd.
[h,w] = freqz(hd);
test_fir = isfir(hd)
% hd(1) is FIR and hd(2) is not.
```

Refer to the reference pages for each structure for more examples.

Introduced in R2011a

dfilt.allpass

Allpass filter

Syntax

```
hd = dfilt.allpass(c)
```

Description

`hd = dfilt.allpass(c)` constructs an allpass filter with the minimum number of multipliers from the elements in vector `c`. To be valid, `c` must contain one, two, three, or four real elements. The number of elements in `c` determines the order of the filter. For example, `c` with two elements creates a second-order filter and `c` with four elements creates a fourth-order filter.

The transfer function for the allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}$$

given the coefficients in `c`.

To construct a cascade of allpass filter objects, use `dfilt.cascadeallpass`. For more information about creating cascades of allpass filters, refer to `dfilt.cascadeallpass`.

Properties

The following table provides a list of all the properties associated with an allpass `dfilt` object.

Property Name	Brief Description
`AllpassCoefficients`	Contains the coefficients for the allpass filter object

Property Name	Brief Description
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Examples

This example constructs and displays the information about a second-order allpass filter that uses the minimum number of multipliers.

```
c = [1.5, 0.7];
% Create a second-order dfilt object.
hd = dfilt.allpass(c);
```

dfilt.calattice

Coupled-allpass, lattice filter

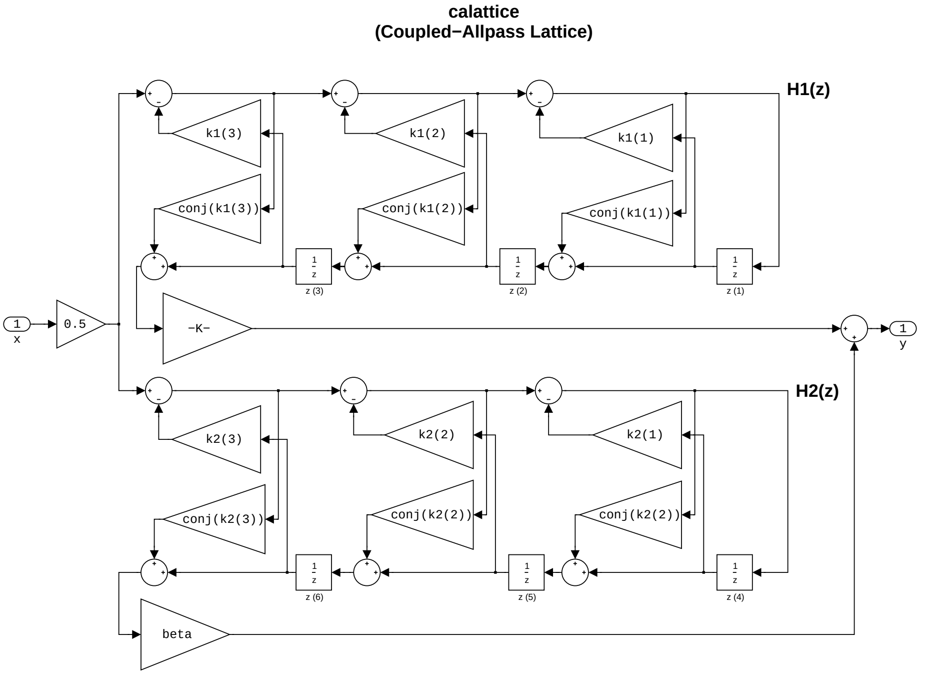
Syntax

```
hd = dfilt.calattice(k1,k2,beta)
hd = dfilt.calattice
```

Description

`hd = dfilt.calattice(k1,k2,beta)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, which is two allpass, lattice filter structures coupled together. The lattice coefficients for each structure are vectors `k1` and `k2`. Input argument `beta` is shown in the diagram below.

`hd = dfilt.calattice` returns a default, discrete-time coupled-allpass, lattice filter object, `hd`. The default values are `k1` = `k2` = [], which is the default value for `dfilt.latticeallpass`, and `beta` = 1. This filter passes the input through to the output unchanged.



Examples

Specify a third-order lattice coupled-allpass filter structure for a `dfilt` filter, `hd` with the following code.

```
k1 = [0.9511 + 1j*0.3088; 0.7511 + 1j*0.1158];
k2 = 0.7502 - 1j*0.1218;
beta = 0.1385 + 1j*0.9904;
hd = dfilt.calattice(k1,k2,beta);
```

The `Allpass1` and `Allpass2` properties store vectors of coefficients.

Introduced in R2011a

dfilt.calatticepc

Coupled-allpass, power-complementary lattice filter

Syntax

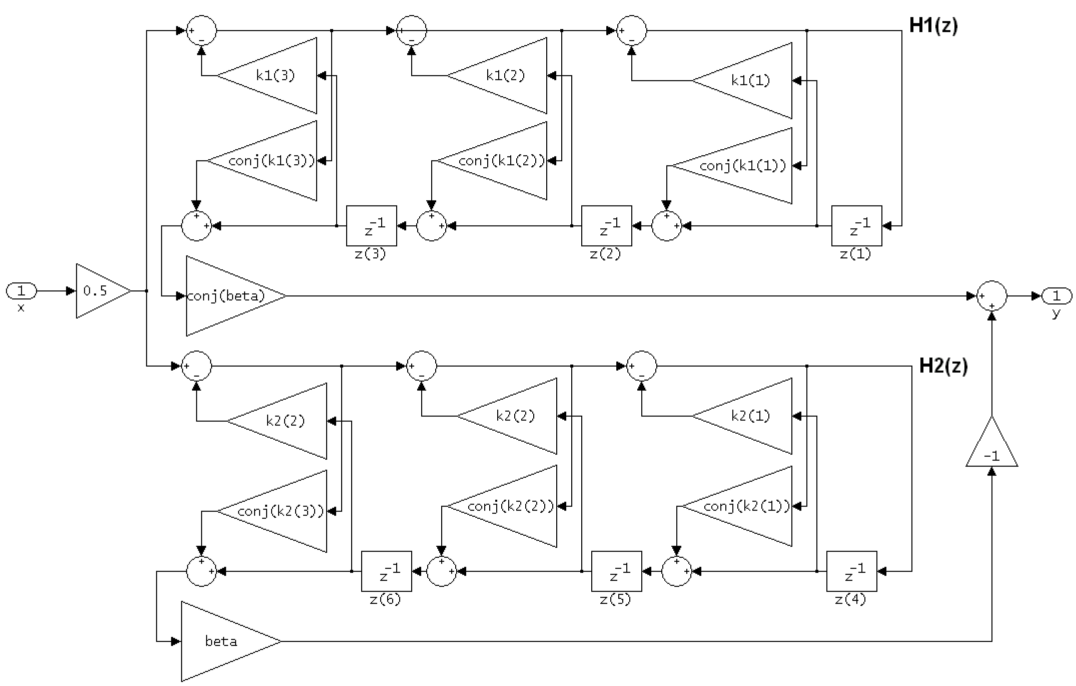
```
hd = dfilt.calatticepc(k1,k2)
hd = dfilt.calatticepc
```

Description

`hd = dfilt.calatticepc(k1,k2)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. This object is two allpass lattice filter structures coupled together to produce complementary output. The lattice coefficients for each structure are vectors, `k1` and `k2`, respectively. `beta` is shown in the following diagram.

`hd = dfilt.calatticepc` returns a default, discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. The default values are `k1` = `k2` = [], which is the default value for the `dfilt.latticeallpass`. The default for `beta` = 1. This filter passes the input through to the output unchanged.

calatticepc
(Coupled Allpass Lattice, Power Complementary output)



Examples

Specify a third-order lattice coupled-allpass power complementary filter structure for a filter `hd` with the following code. You see from the returned properties that `Allpass1` and `Allpass2` contain vectors of coefficients for the constituent filters.

```
k1 = [0.9511 + 0.3088i; 0.7511 + 0.1158i];
k2 = 0.7502 - 0.1218i;
beta = 0.1385 + 0.9904i;
hd = dfilt.calatticepc(k1,k2,beta);
```

To see the coefficients for `Allpass1`, check the property values.

```
get(hd,'Allpass1')
```

dfilt.cascade

Cascade of discrete-time filters

Syntax

Refer to `dfilt.cascade` in Signal Processing Toolbox documentation for more information.

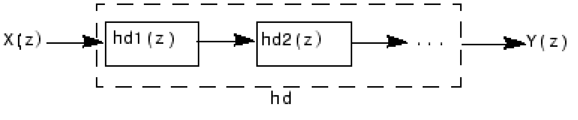
Description

`hd = dfilt.cascade(filterobject1,filterobject2,...)` returns a discrete-time filter object `hd` of type `cascade`, which is a serial interconnection of two or more filter objects `filterobject1`, `filterobject2`, and so on. `dfilt.cascade` accepts any combination of `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

You can use the standard notation to cascade one or more filters:

```
cascade(hd1,hd2,...)
```

where `hd1`, `hd2`, and so on can be mixed types, such as `dfilt` objects and other filtering objects.



`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the cascade must be the same arithmetic format — `double`, `single`, or `fixed`. `hd`, the filter object returned, inherits the format of the cascaded filters.

Examples

Cascade a lowpass filter and a highpass filter to produce a bandpass filter.

```
[b1,a1]=butter(8,0.6);    % Lowpass
```

```
[b2,a2]=butter(8,0.4,'high');  % Highpass
h1=dfilt.df2t(b1,a1);
h2=dfilt.df2t(b2,a2);
hcas=dfilt.cascade(h1,h2);   % Bandpass with passband 0.4-0.6
% View stage 1 with hcas.Stage(1)
```

Introduced in R2011a

dfilt.cascadeallpass

Cascade of allpass discrete-time filters

Syntax

```
hd = dfilt.cascadeallpass(c1,c2,...)
```

Description

`hd = dfilt.cascadeallpass(c1,c2,...)` constructs a cascade of allpass filters, each of which uses the minimum number of multipliers, given the filter coefficients provided in `c1`, `c2`, and so on.

Each vector `c` represents one section in the cascade filter. `c` vectors must contain one, two, three, or four elements as the filter coefficients for each section. As a result of the design algorithm, each section is a `dfilt.allpass` structure whose coefficients are given in the matching `c` vector, such as the `c1` vector contains the coefficients for the first stage.

States for each section are shared between sections.

Vectors `c` do not have to be the same length. You can combine various length vectors in the input arguments. For example, you can cascade fourth-order sections with second-order sections, or first-order sections.

For more information about the vectors `ci` and about the transfer function of each section, refer to `dfilt.allpass`.

Generally, you do not construct these allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadeallpass` to design an IIR filter.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples

Two examples show how dfilt.cascadeallpass works in very different applications — designing a halfband IIR filter and constructing an allpass cascade of dfilt objects.

First, design the IIR halfband filter using cascaded allpass filters. Each branch of the parallel cascade construction is a cascadeallpass filter object.

```
tw = 100;  % Transition width of filter to be designed, 100 Hz.
ast = 80;  % Stopband attenuation of filter to be designed, 80dB.
fs = 2000; % Sampling frequency of signal to be filtered.
% Store halfband design specs in the specifications object d.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual filter design. hd contains two dfilt.cascadeallpass objects.

```
hd = design(d,'ellip','filterstructure','cascadeallpass');
% Get summary information about one dfilt.cascadeallpass stage.
StageInfo = hd.Stage(1).Stage(1);
```

This second example constructs a `dfilt.cascadeallpass` filter object directly given allpass coefficients for the input vectors.

```
section1 = 0.8;
section2 = [1.2,0.7];
section3 = [1.3,0.9];
hd = dfilt.cascadeallpass(section1,section2,section3);
% Get information about the filter
% return informatio in character array
S = info(hd);
```

`dfilt` | `dfilt.allpass` | `dfilt.cascadewdfallpass` | dsp.IIRHalfbandDecimator | dsp.IIRHalfbandDecimator

Introduced in R2011a

dfilt.cascadewdfallpass

Cascade allpass WDF filters to construct allpass WDF

Syntax

```
hd = dfilt.cascadewdfallpass(c1,c2,...)
```

Description

`hd = dfilt.cascadewdfallpass(c1,c2,...)` constructs a cascade of allpass wave digital filters given the allpass coefficients in the vectors `c1`, `c2`, and so on.

Each `c` vector contains the coefficients for one section of the cascaded filter. `C` vectors must have one, two, or four elements (coefficients). Three element vectors are not supported.

When the `c` vector has four elements, the first and third elements of the vector must be 0. Each section of the cascade is an allpass wave digital filter, from `dfilt.wdfallpass`, with the coefficients given by the corresponding c vector. That is, the first section has coefficients from vector `c1`, the second section coefficients come from `c2`, and on until all of the `c` vectors are used.

You can mix the lengths of the `c` vectors. They do not need to be the same length. For example, you can cascade several fourth-order sections (`length(c)` = 4) with first or second-order sections.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Generally, you do not construct these WDF allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadewdfallpass` to design an IIR filter.

For more information about the `c` vectors and the transfer function for the allpass filters, refer to `dfilt.wdfallpass`.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Examples

To demonstrate two approaches to using `dfilt.cascadewdfallpass` to design a filter, these examples show both direct construction and construction as part of another filter.

The first design shown creates an IIR halfband filter that uses lattice wave digital filters. Each branch of the parallel connection in the lattice is an allpass cascade wave digital filter.

```
tw = 100;  % Transition width of filter, 100 Hz.
ast = 80;  % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency of signal to filter.
% Store halfband specs.
```

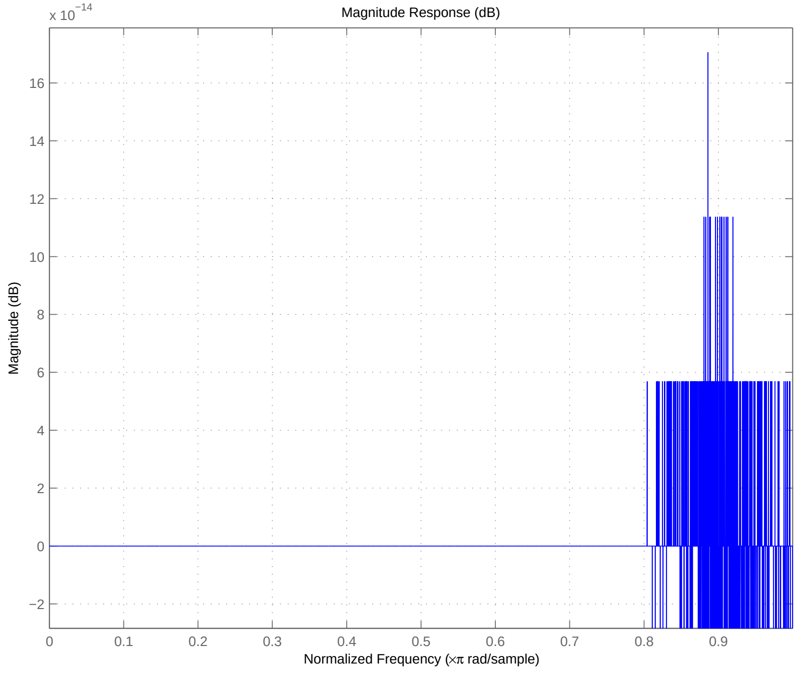
```
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual halfband design process. `hd` contains two `dfilt.cascadewdfallpass` filters.

```
hd = design(d,'ellip','filterstructure','cascadewdfallpass');
% Summary info on dfilt.cascadewdfallpass.
StageSummary = hd.stage(1).stage(2);
```

This example demonstrates direct construction of a `dfilt.cascadewdfallpass` filter with allpass coefficients.

```
section1 = 0.8;
section2 = [1.5,0.7];
section3 = [1.8,0.9];
hd = dfilt.cascadewdfallpass(section1,section2,section3);
```



See Also

`dfilt` | `dfilt.wdfallpass`

Introduced in R2011a

dfilt.delay

Delay filter

Syntax

```
Hd = dfilt.delay
Hd = dfilt.delay(latency)
```

Description

`Hd = dfilt.delay` returns a discrete-time filter, `Hd`, of type `delay`, which adds a single delay to any signal filtered with `Hd`. The filtered signal has its values shifted by one sample.

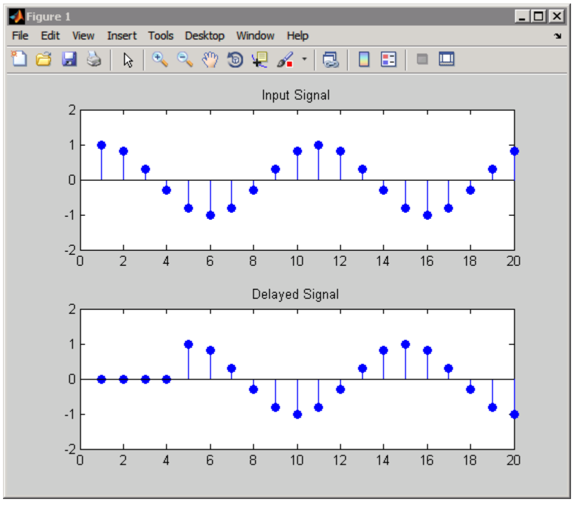
`Hd = dfilt.delay(latency)` returns a discrete-time filter, `Hd`, of type `delay`, which adds the number of delay units specified in `latency` to any signal filtered with `Hd`. The filtered signal has its values shifted by the `latency` number of samples. The values that appear before the shifted signal are the filter states.

Examples

Create a `delay` filter with a `latency` of 4 and filter a simple signal to view the impact of applying a delay.

```
h = dfilt.delay(4);
Fs = 1000;
t = 0:1/Fs:1;
sig = cos(2*pi*100*t);
y = filter(h,sig);
subplot(211);
stem(sig,'markerfacecolor',[0 0 1]);
axis([0 20 -2 2]);
title('Input Signal');
subplot(212);
stem(y,'markerfacecolor',[0 0 1]);
axis([0 20 -2 2]);
```

```
title('Delayed Signal');
```



See Also

dfilt

Introduced in R2011a

dfilt.df1

Discrete-time, direct-form I filter

Syntax

Refer to `dfilt.df1` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1` returns a default discrete-time, direct-form I filter object that uses double-precision arithmetic. By default, the numerator and denominator coefficients b and a are set to 1. With these coefficients the filter passes the input to the output without changes.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

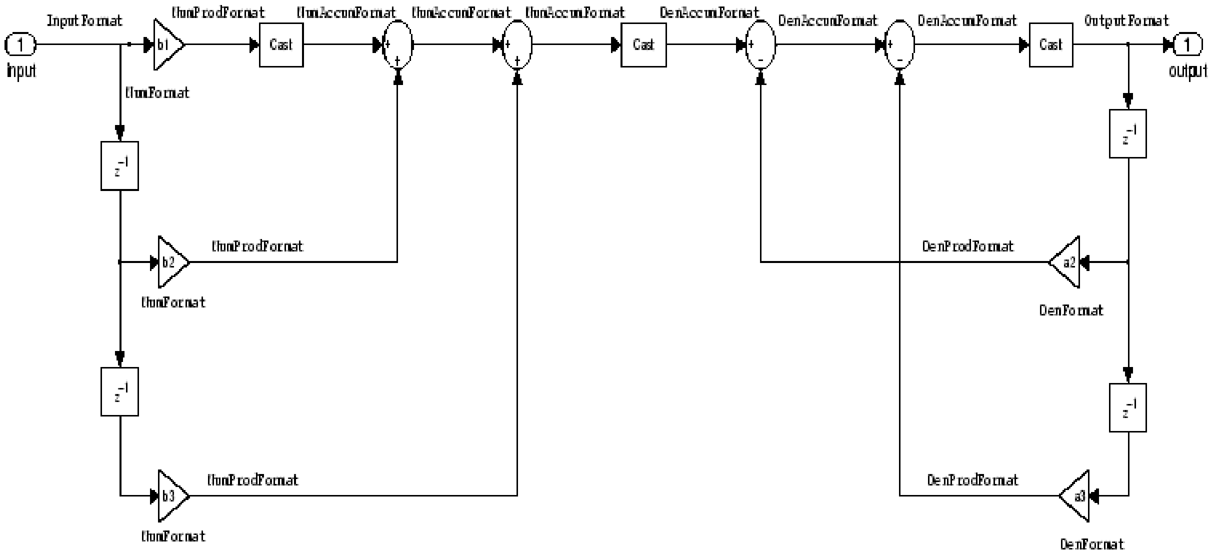
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

Note `a(1)`, the leading denominator coefficient, cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented by `dfilt.df1`. To help you see how the filter processes the coefficients, input, output, and states of the filter, as well as numerical operations, the figure includes the locations of the arithmetic and data type format elements within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFormat	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenFormat	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale` , `SignedDenominator`
DenProdFormat	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
InputFormat	`InputWordLength`	`InputFracLength`	None
NumAccumFormat	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFormat	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
NumProdFormat	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFormat, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFormat refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with df1 implementations of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use `get(hd)` where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length the filter algorithm uses to interpret the results of product operations involving denominator coefficients. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
`DenFracLength`	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Stores the denominator coefficients for the IIR filter.

Property Name	Brief Description
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`ProductMode`	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
`ProductWordLength`	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.

Examples

Specify a second-order direct-form I structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1(b,a);
% Convert hd to fixed-point filter
set(hd,'arithmetic','fixed')
```

See Also

dfilt | dfilt.df1t | dfilt.df2 | dfilt.df2t

Introduced in R2011a

dfilt.df1sos

Discrete-time, SOS direct-form I filter

Syntax

Refer to `dfilt.df1sos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1sos(s)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.df1sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, and so on.

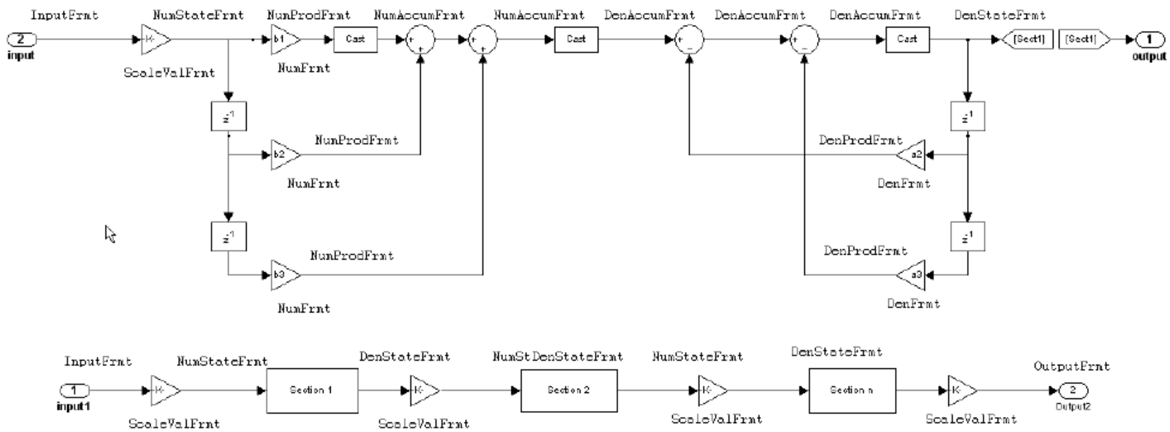
`hd = dfilt.df1sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. When you do not specify `g`, all gains default to one.

`hd = dfilt.df1sos` returns a default, discrete-time, second-order section, direct-form I filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented in second-order sections by `dfilt.df1sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt“ means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Similarly consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	ProductWordLength	DenProdFracLength	ProductMode
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	ProductWordLength	NumProdFracLength	ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValueFracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProductWordLength`, `DenProdFracLength` and `ProductMode` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with SOS implementation of direct-form I `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations.

Property Name	Brief Description
	You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
`DenFracLength`	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`DenProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set `ProductMode` to `SpecifyPrecision`.
`DenStateFracLength`	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
`DenStateWordLength`	Specifies the word length used to represent the states associated with denominator coefficients in the filter.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`NumAccumFracLength`	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set `AccumMode` to `SpecifyPrecision`.
`NumFracLength`	Sets the fraction length used to interpret the value of numerator coefficients.
`NumStateFracLength`	Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
`NumWordFracLength`	Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.

Property Name	Brief Description
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length applied for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a fixed-point, second-order section, direct-form I dfilt object with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1sos(b,a);
% Convert to fixed-point filter
hd.arithmetic = 'fixed';
```

See Also

dfilt | dfilt.df2tsos

Introduced in R2011a

dfilt.df1t

Discrete-time, direct-form I transposed filter

Syntax

Refer to `dfilt.df1t` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1t(b,a)` returns a discrete-time, direct-form I transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

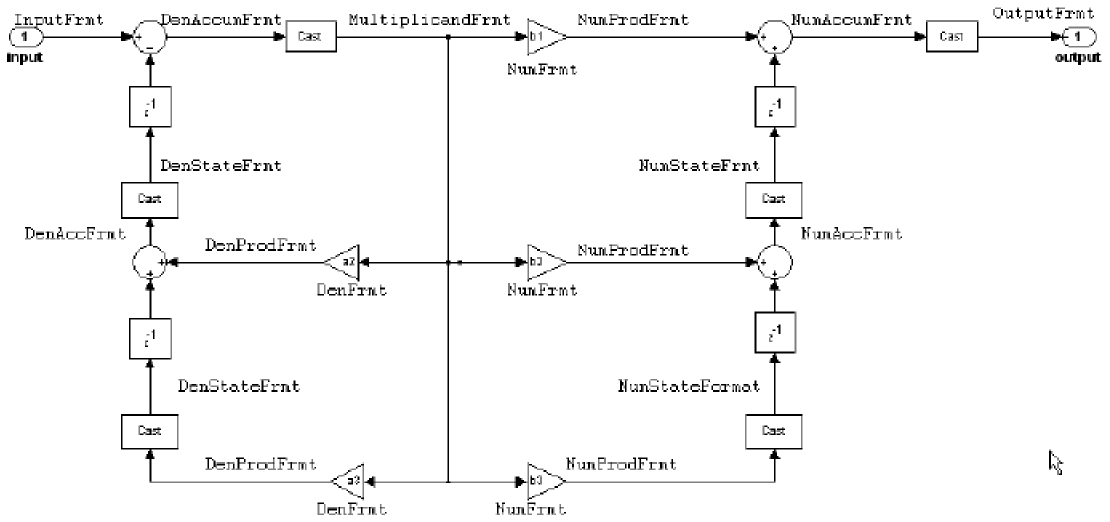
For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.df1t` returns a default, discrete-time, direct-form I transposed filter object `hd`, with `b`=1 and `a`=1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the transposed direct-form I filter implemented by `dfilt.df1t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale`, , `Signed`, `Denominator`
DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
DenStateFrmt	`DenStateWordLength`	`DenStateFracLength`	`CastBeforeSum`, `States`
InputFrmt	`InputWordLength`	`InputFracLength`	None
Multiplicandfrmt	`Multiplicand-WordLength`	`Multiplicand-FracLength`	`CastBeforeSum`
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
NumStateFrmt	`NumStateWordLength`	`NumStateFracLength`	`States`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with df1t implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this

Property Name	Brief Description
	off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
`DenFracLength`	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Holds the denominator coefficients for the filter.
`DenProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set `ProductMode` to `SpecifyPrecision`.
`DenStateFracLength`	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`MultiplicandFracLength`	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
`MultiplicandWordLength`	Sets the word length applied to the values input to a multiply operation (the multiplicands).

Property Name	Brief Description
`NumAccumFracLength`	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set `AccumMode` to `SpecifyPrecision`.
`Numerator`	Holds the numerator coefficient values for the filter.
`NumFracLength`	Sets the fraction length used to interpret the value of numerator coefficients.
`NumProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set `ProductMode` to `SpecifyPrecision`.
`NumStateFracLength`	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`StateAutoScale`	Setting autoscaling for filter states to `true` reduces the possibility of overflows occurring during fixed-point operations. Set to `false`, `StateAutoScale` lets the filter select the fraction length to limit the overflow potential.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Specify a second-order direct-form I transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1t(b,a);
% Convert filter to single-precision arithmetic
set(hd,'arithmetic','single')
```

Introduced in R2011a

dfilt.df1tsos

Discrete-time, SOS direct-form I transposed filter

Syntax

Refer to `dfilt.df1tsos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df1tsos(s)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to .

`hd = dfilt.df1tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

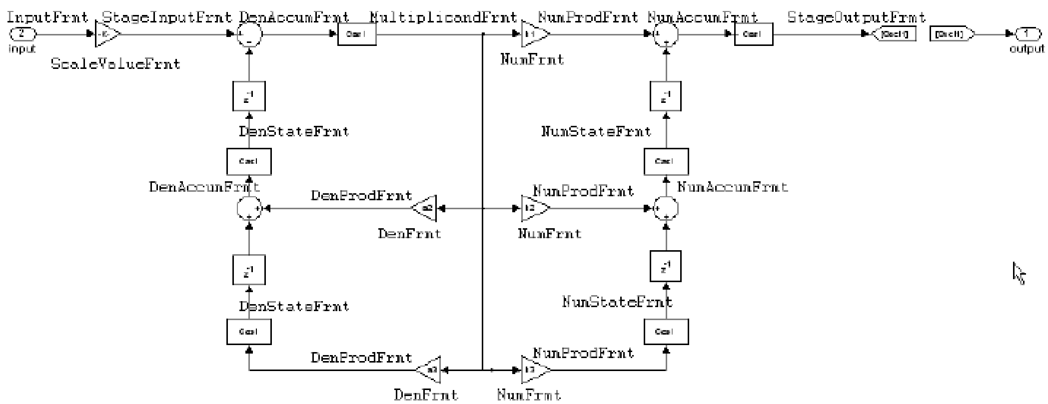
`hd = dfilt.df1tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

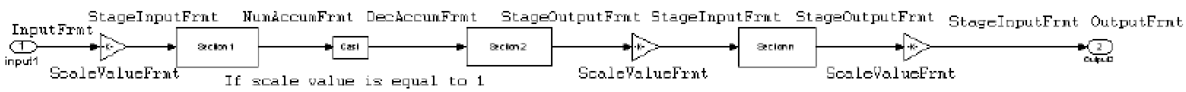
`hd = dfilt.df1tsos` returns a default, discrete-time, second-order section, direct-form I, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I transposed filter implemented using second-order sections by `dfilt.df1tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.





Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
DenStateFrmt	DenStateWordLength	DenStateFracLength	CastBeforeSum, States
InputFrmt	InputWordLength	InputFracLength	None
MultiplicandFrmt	Multiplicand-WordLength	Multiplicand-FracLength	CastBeforeSum
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
NumStateFrmt	NumStateWordLength	NumStateFracLength	States
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmt	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with SOS implementation of transposed direct-form I dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.

Property Name	Brief Description
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set `ProductMode` to `SpecifyPrecision`.
DenStateFracLength	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.

Property Name	Brief Description
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
MultiplicandFracLength	Sets the fraction length for values (multiplicands) used in multiply operations in the filter.
MultiplicandWordLength	Sets the word length applied to the values input to a multiply operation (the multiplicands)
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
NumStateFracLength	For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.
NumStateWordLength	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.

Property Name	Brief Description
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Property Name	Brief Description
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/sectiondatatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

With the following code, this example specifies a second-order section, direct-form I transposed dfilt object for a filter. Then convert the filter to fixed-point operation.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1tsos(b,a);
set(hd,'arithmetic','fixed')
```

dfilt | dfilt.df1sos | dfilt.df2sos | dfilt.df2tsos

Introduced in R2011a

dfilt.df2

Discrete-time, direct-form II filter

Syntax

Refer to `dfilt.df2` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2(b,a)` returns a discrete-time, direct-form II filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

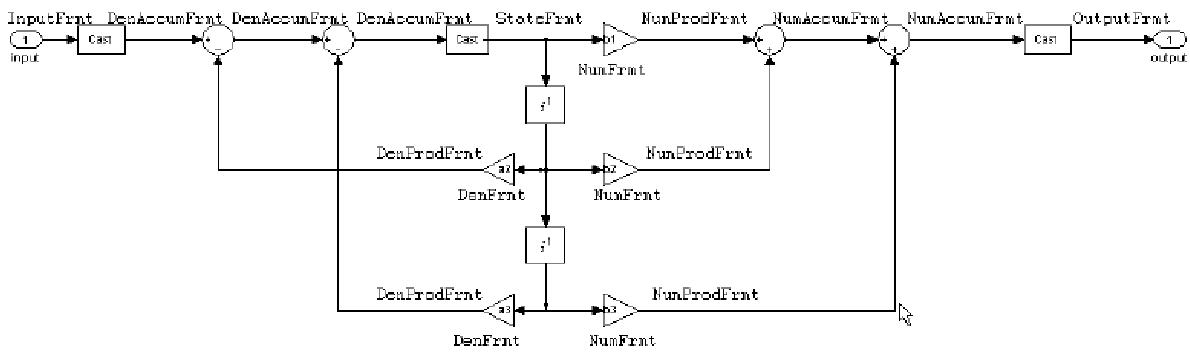
For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.df2` returns a default, discrete-time, direct-form II filter object `hd`, with `b` = 1 and `a` = 1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II filter implemented by `dfilt.df2`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters“frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale`, `Signed`, `Denominator`
DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with the df2 implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.

Property Name	Brief Description
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
Denominator	Holds the denominator coefficients for IIR filters.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
Numerator	Holds the numerator coefficient values for the filter.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.

Property Name	Brief Description
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a second-order direct-form II filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2(b,a);
% Change filter to fixed-point
set(hd,'arithmetic','fixed')
```

See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2t`

Introduced in R2011a

dfilt.df2sos

Discrete-time, SOS, direct-form II filter

Syntax

Refer to `dfilt.df2sos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2sos(s)` returns a discrete-time, second-order section, direct-form II filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.df2sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II object, `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

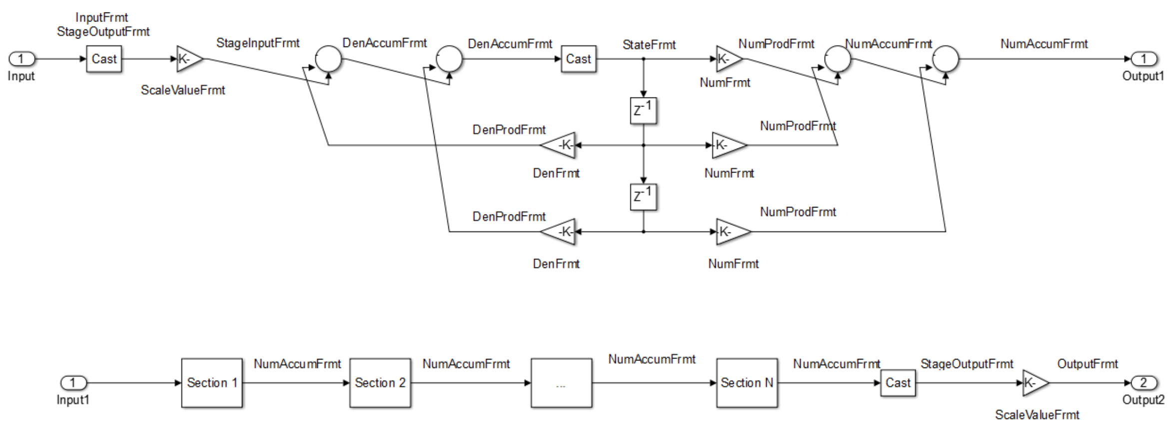
`hd = dfilt.df2sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2sos` returns a default, discrete-time, second-order section, direct-form II filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The figure below shows the signal flow for the direct-form II filter implemented with second-order sections by `dfilt.df2sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The frmt properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale, Signed, sosMatrix
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength, sosMatrix
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, sosMatrix
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	OutputMode
ScaleValueFrmat	CoeffWordLength	ScaleValue-FracLength	CoeffAutoScale, ScaleValues
SectionInputFormt	SectionInput-WordLength	SectionInput-FracLength	SectionInput-AutoScale
SectionOutputFrmt	SectionOutput-WordLength	SectionOutput-FracLength	SectionOutput-AutoScale
StateFrmt	StateWordLength	StateFracLength	CastBeforeSum, States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with second-order section implementation of direct-form II `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.

Property Name	Brief Description
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.

Property Name	Brief Description
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
SectionInputAutoScale	Tells the filter whether to set the stage input data format to minimize the occurrence of overflow conditions.
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.

Property Name	Brief Description
SectionOutputAutoScale	Tells the filter whether to set the section output data format to minimize the occurrence of overflow conditions.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set `SectionOutputAutoScale` to `off`.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set `SectionOutputAutoScale` to `false`.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A `[15x6 double]` SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type `double` to represent the coefficients.
StateFracLength	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a second-order section, direct-form II `dfilt` object for a Butterworth filter converted to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(s,g);
% Convert filter to fixed-point
hd.arithmetic='fixed';
```

Introduced in R2011a

dfilt.df2t

Discrete-time, direct-form II transposed filter

Syntax

Refer to `dfilt.df2t` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2t(b,a)` returns a discrete-time, direct-form II transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

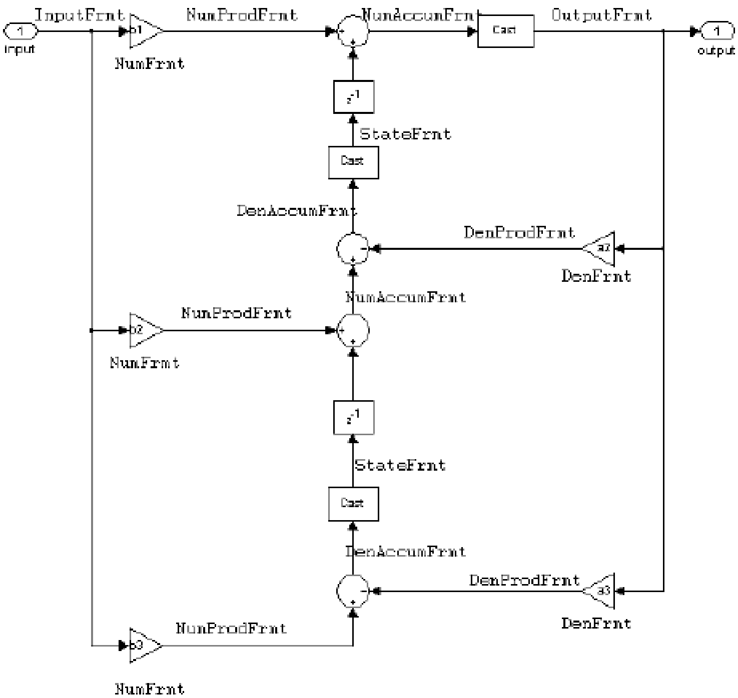
For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.df2t` returns a default, discrete-time, direct-form II transposed filter object `hd`, with `b` = 1 and `a` = 1. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II transposed filter implemented by `dfilt.df2t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt." In this use, "frmt" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	AccumWordLength	DenAccumFracLength	AccumMode, CastBeforeSum
DenFrmt	CoeffWordLength	DenFracLength	CoeffAutoScale,Signed, Denominator
DenProdFrmt	CoeffWordLength	DenProdFracLength	ProductMode, ProductWordLength
InputFrmt	InputWordLength	InputFracLength	None
NumAccumFrmt	AccumWordLength	NumAccumFracLength	AccumMode, CastBeforeSum
NumFrmt	CoeffWordLength	NumFracLength	CoeffAutoScale, Signed, Numerator
NumProdFrmt	CoeffWordLength	NumProdFracLength	ProductWordLength, ProductMode
OutputFrmt	OutputWordLength	OutputFracLength	None
StateFrmt	StateWordLength	StateFracLength	States

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with df2t implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where hd is a filter.

For further information about the properties of this filter or any dfilt object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value

Property Name	Brief Description
	to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set `AccumMode` to `SpecifyPrecision`.
`DenFracLength`	Set the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Holds the denominator coefficients for IIR filters.
`DenProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set `ProductMode` to `SpecifyPrecision`.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`NumAccumFracLength`	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set `AccumMode` to `SpecifyPrecision`.
`Numerator`	Holds the numerator coefficient values for the filter.
`NumFracLength`	Sets the fraction length used to interpret the value of numerator coefficients.
`NumProdFracLength`	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set `ProductMode` to `SpecifyPrecision`.

Property Name	Brief Description
OutputFracLength	Determines how the filter interprets the filter output data.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
`RoundMode`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`StateAutoScale`	Setting autoscaling for filter states to `true` reduces the possibility of overflows occurring during fixed-point operations. Set to `false`, `StateAutoScale` lets the filter select the fraction length to limit the overflow potential.
`StateFracLength`	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Create a fixed-point filter by specifying a second-order direct-form II transposed filter structure for a `dfilt` object, and then converting the double-precision arithmetic setting to fixed-point.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2t(b,a);
% Convert filter to fixed-point
set(hd,'arithmetic','fixed')
```

See Also

`dfilt` | `dfilt.df1` | `dfilt.df1t` | `dfilt.df2`

Introduced in R2011a

dfilt.df2tsos

Discrete-time, SOS direct-form II transposed filter

Syntax

Refer to `dfilt.df2tsos` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.df2tsos(s)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients given in the matrix `s`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.df2tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

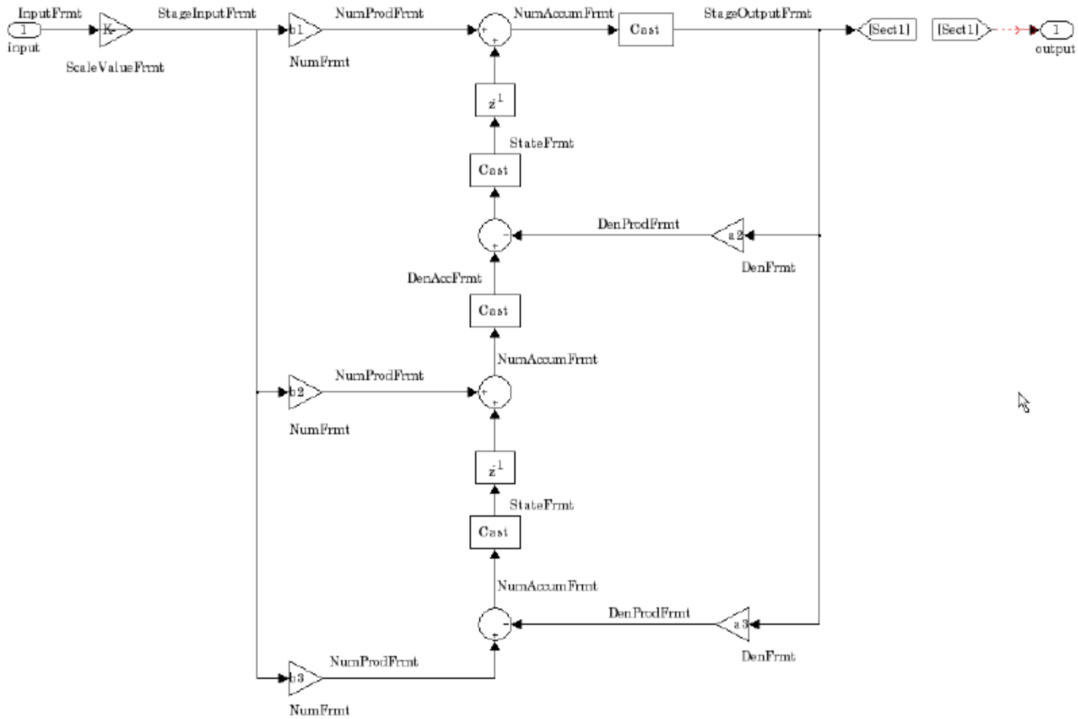
`hd = dfilt.df2tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

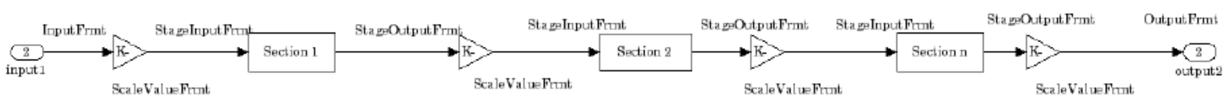
`hd = dfilt.df2tsos` returns a default, discrete-time, second-order section, direct-form II, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

Note The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

Fixed-Point Filter Structure

The figure below shows the signal flow for the second-order section transposed direct-form II filter implemented by `dfilt.dftsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.





Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters "frmt" (format). In this use, "frmt" indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
DenAccumFrmt	`AccumWordLength`	`DenAccumFracLength`	`AccumMode`, `CastBeforeSum`
DenFrmt	`CoeffWordLength`	`DenFracLength`	`CoeffAutoScale`, `Signed`, `Denominator`
DenProdFrmt	`CoeffWordLength`	`DenProdFracLength`	`ProductMode`, `ProductWordLength`
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumAccumFrmt	`AccumWordLength`	`NumAccumFracLength`	`AccumMode`, `CastBeforeSum`
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `SignedNumerator`
NumProdFrmt	`CoeffWordLength`	`NumProdFracLength`	`ProductWordLength`, `ProductMode`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ScaleValueFrmt	`CoeffWordLength`	`ScaleValueFracLengt`	`CoeffAutoScale`, `ScaleValues`
SectionInputFormt	`SectionInput-WordLength`	`SectionInput-FracLength`	
SectionOutputFrmt	`SectionOutput-WordLength`	`SectionOutput-FracLength`	
StateFrmt	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties `ProdWordLength`, `ProductMode` and `DenProdFracLength` that fully define the denominator format after multiply (or product) operations.

Properties

In this table you see the properties associated with second-order section implementation of transposed direct-form II `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to “Fixed-Point Filter Properties” on page 6-2.

Property Name	Brief Description
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.

Property Name	Brief Description
AccumWordLength	Sets the word length used to store data in the accumulator/ buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength and DenFracLength properties to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
DenAccumFracLength	Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision.
DenFracLength	Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.
DenProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
NumAccumFracLength	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.
NumFracLength	Sets the fraction length used to interpret the value of numerator coefficients.
NumProdFracLength	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.
OptimizeScaleValues	When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.

Property Name	Brief Description
`OverflowMode`	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`ProductMode`	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
`ProductWordLength`	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
`PersistentMemory`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
ScaleValueFracLength	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable AutoScaleMode by setting it to false.
ScaleValues	Scaling for the filter objects in SOS filters.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
SosMatrix	Holds the filter coefficients as property values — you use set and get to modify them. Displays the matrix in the format [sections x coefficients/section data type]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type double to represent the coefficients.

Property Name	Brief Description
SectionInputFracLength	Lets you set the fraction length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionInputWordLength	Lets you set the word length for section inputs in SOS filters, if you set SectionInputAutoScale to false.
SectionOutputFracLength	Lets you set the fraction length for section outputs in SOS filters, if you set SectionOutputAutoScale to off.
SectionOutputWordLength	Lets you set the word length for section outputs in SOS filters, if you set SectionOutputAutoScale to false.
StateAutoScale	Setting autoscaling for filter states to true reduces the possibility of overflows occurring during fixed-point operations. Set to false, StateAutoScale lets the filter select the fraction length to limit the overflow potential.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Construct a second-order section Butterworth filter for fixed-point filtering. Start by specifying a Butterworth filter, and then convert the filter to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2tsos(s,g);
% convert filter to fixed-point
hd.arithmetic='fixed';
```

See Also

dfilt | dfilt.df1sos | dfilt.df1tsos | dfilt.df2sos

Introduced in R2011a

dfilt.dfasymfir

Discrete-time, direct-form antisymmetric FIR filter

Syntax

Refer to `dfilt.dfasymfir` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dfasymfir(b)` returns a discrete-time, direct-form, antisymmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

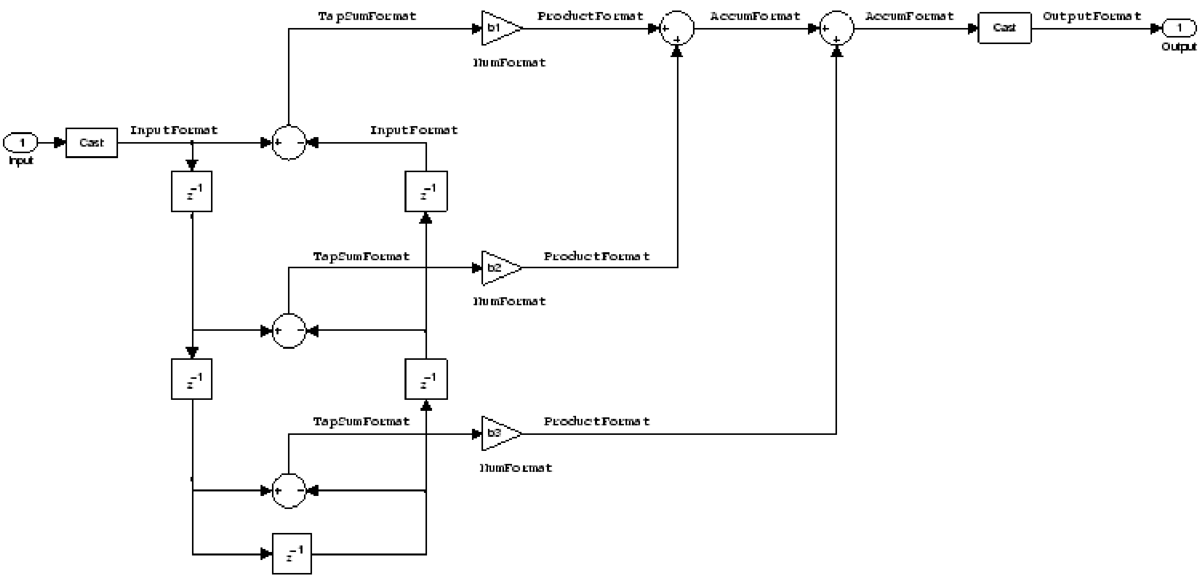
For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.dfasymfir` returns a default, discrete-time, direct-form, antisymmetric FIR filter object `hd`, with `b`=1. This filter passes the input through to the output unchanged.

Note Only the coefficients in the first half of vector `b` are used because `dfilt.dfasymfir` assumes the coefficients in the second half are antisymmetric to those in the first half. For example, in the figure coefficients, b(4) = -b(3), b(5) = -b(2), and b(6) = -b(1).

Fixed-Point Filter Structure

The following figure shows the signal flow for the odd-order antisymmetric FIR filter implemented by `dfilt.dfasymfir`. The even-order filter uses similar flow. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	AccumWordLength	AccumFracLength	None
InputFormat	InputWordLength	InputFracLength	None
NumFormat	CoeffWordLength	NumFracLength	CoeffAutoScale, , Signed, Numerator
OutputFormat	OutputWordLength	OutputFracLength	None
ProductFormat	ProductWordLength	ProductFracLength	None
TapSumFormat	InputWordLength	InputFracLength	InputFormat

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with an antisymmetric FIR implementation of dfilt objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits [27]	Specifies the fraction length used to interpret data output by the accumulator.
`AccumWordLength`	Any integer number of bits[33]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data. Also controls `TapSumFracLength`.

Name	Values	Description
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data. Also determines TapSumWordLength.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilerInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [27]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [33]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Odd Order

Specify a fifth-order direct-form antisymmetric FIR filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hd = dfilt.dfasymfir(b);
```

Even Order

Specify a fourth-order direct-form antisymmetric FIR filter structure for `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hd = dfilt.dfasymfir(b);
hd.arithmetic='fixed';
FilterCoefs = get(hd,'numerator');
% or equivalently
FilterCoefs = hd.numerator;
```

Refer to `dfilt.dffir` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dffir(b)` returns a discrete-time, direct-form finite impulse response (FIR) filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

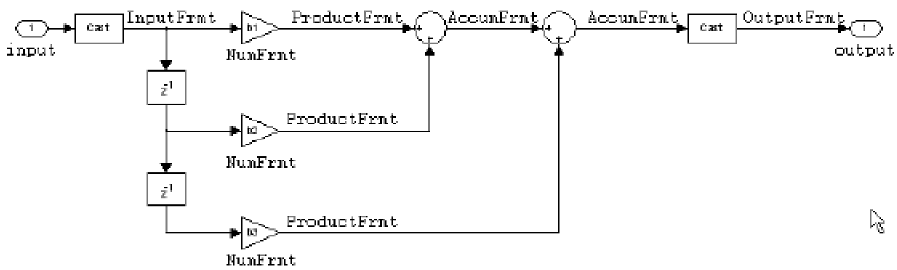
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.dffir` returns a default, discrete-time, direct-form FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form FIR filter implemented by `dfilt.dffir`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters“frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	`AccumWordLength`	`AccumFracLength`	None
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
ProductFrmt	`ProductWordLength`	`ProductFracLength`	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with direct-form FIR implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits [30]	Specifies the fraction length used to interpret data output by the accumulator.
`AccumWordLength`	Any integer number of bits[34]	Sets the word length used to store data in the accumulator.

Name	Values	Description
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
`OutputFracLength`	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilerInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.

Name	Values	Description
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [30]	Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductWordLength	Any integer number of bits [32]	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	fi object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Specify a second-order direct-form FIR filter structure for a `dfilt` object `hd`, with the following code that constructs the filter in double-precision format and then converts the filter to fixed-point operation:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
% Create fixed-point filter
hd.arithmetic='fixed';
% Change FilterInternals property to
% SpecifyPrecision enabling other properites
hd.FilterInternals='SpecifyPrecision';
```

dfilt.dffirt

Discrete-time, direct-form FIR transposed filter

Syntax

Refer to `dfilt.dffirt` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dffirt(b)` returns a discrete-time, direct-form FIR transposed filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

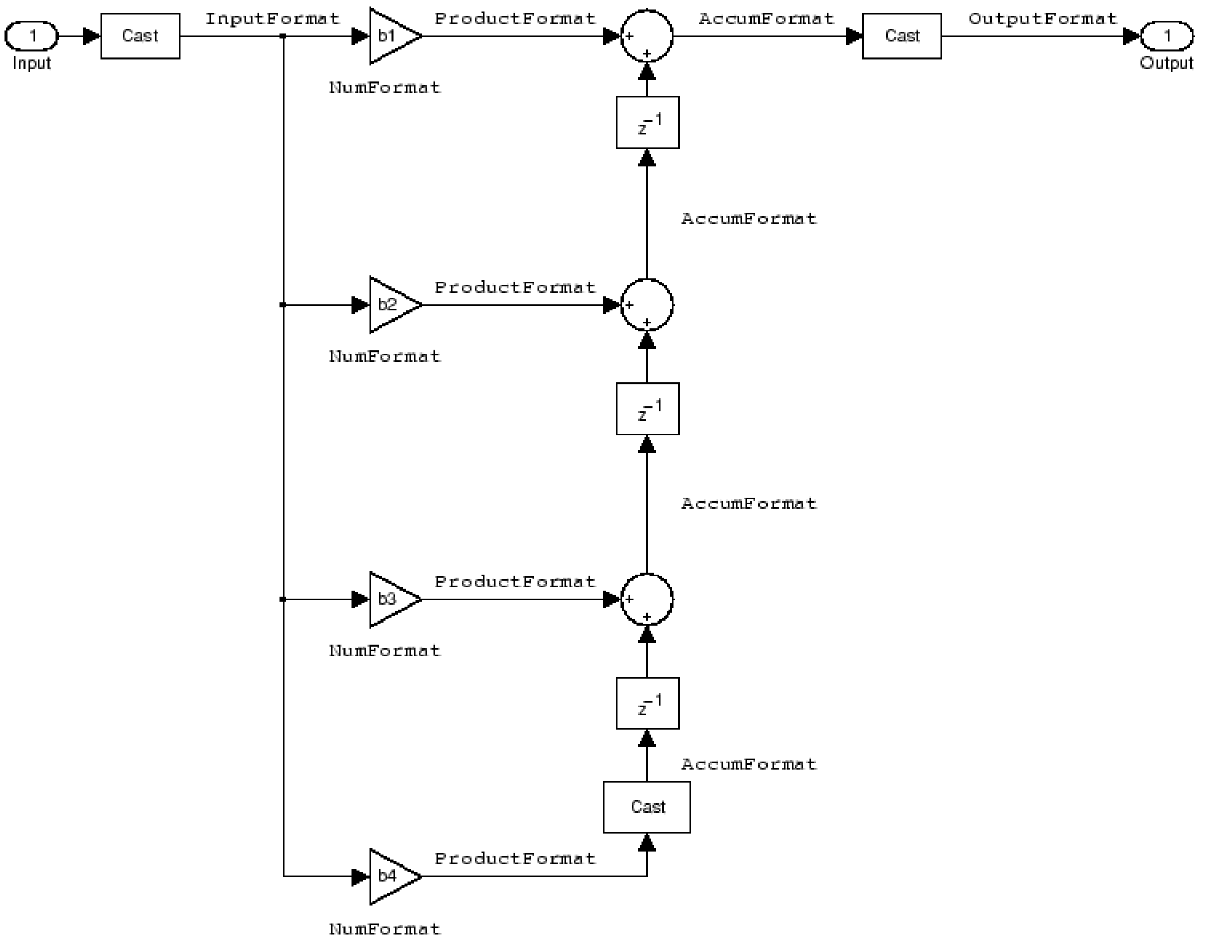
```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.dffirt` returns a default, discrete-time, direct-form FIR transposed filter object `hd`, with `b` = 1. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the transposed direct-form FIR filter implemented by `dfilt.dffirt`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	None
InputFormat	`InputWordLength`	`InputFracLength`	None
NumFormat	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
OutputFormat	`OutputWordLength`	`OutputFracLength`	None
ProductFormat	`ProductWordLength`	`ProductFracLength`	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties

`dfilt` | `dfilt.dffir` | `dfilt.dfasymfir` | `dfilt.dfsymfir`

Introduced in R2011a

dfilt.dfsymfir

Discrete-time, direct-form symmetric FIR filter

Syntax

Refer to `dfilt.dfsymfir` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.dfsymfir(b)` returns a discrete-time, direct-form symmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

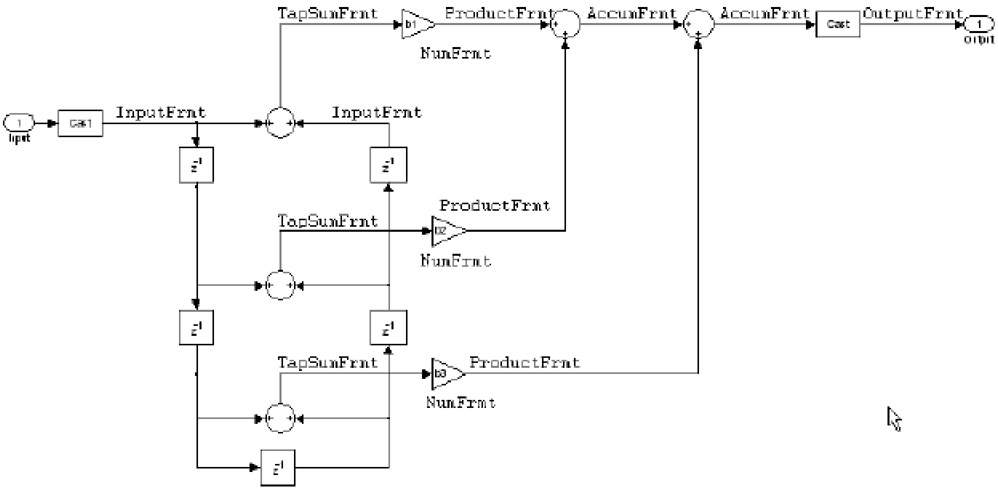
For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.dfsymfir` returns a default, discrete-time, direct-form symmetric FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

Note Only the coefficients in the first half of vector `b` are used because `dfilt.dfsymfir` assumes the coefficients in the second half are symmetric to those in the first half. In the following figure, for example, b(3) = 0, b(4) = b(2) and b(5) = b(1).

Fixed-Point Filter Structure

In the following figure you see the signal flow diagram for the symmetric FIR filter that `dfilt.dfsymfir` implements.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters“frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFrmt	`AccumWordLength`	`AccumFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFrmt	`InputWordLength`	`InputFracLength`	None
NumFrmt	`CoeffWordLength`	`NumFracLength`	`CoeffAutoScale`, `Signed`, `Numerator`
OutputFrmt	`OutputWordLength`	`OutputFracLength`	None
ProductFrmt	`ProductWordLength`	`ProductFracLength`	None
TapSumFrmt	`InputWordLength`	`InputFracLength`	None

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties `ProductFracLength` and `ProductWordLength` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the symmetric FIR implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object to match the filter arithmetic setting	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Examples

Odd Order

Specify a fifth-order direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd = dfilt.dfsymfir(b);
% Create fixed-point filter
set(hd,'arithmetic','fixed')
% Change FilterInternals property to
% SpecifyPrecision
hd.Filterinternals='SpecifyPrecision';
```

Even Order

Specify a fourth-order, fixed-point, direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.01 0.1 0.8 0.1 -0.01];
hd = dfilt.dfsymfir(b);
set(hd,'arithmetic','fixed');
```

Introduced in R2011a

dfilt.farrowfd

Fractional Delay Farrow filter

Syntax

```
Hd = dfilt.farrowfd(D, COEFFS)
```

Description

`Hd = dfilt.farrowfd(D, COEFFS)` Constructs a discrete-time fractional delay Farrow filter with COEFFS coefficients and D delay.

Examples

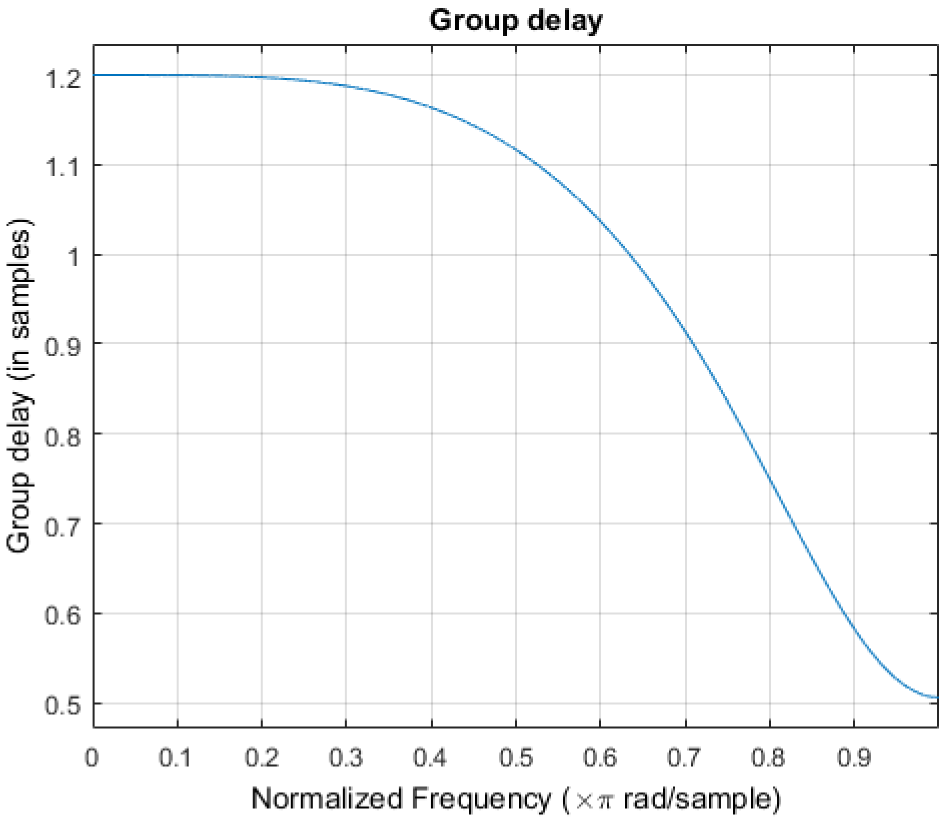
Design a Fractional Delay Farrow Filter

Farrow filters can be designed with the `dfilt.farrowfd` filter designer.

```
coeffs = [-1/6 1/2 -1/3 0;1/2 -1 -1/2 1;
-1/2 1/2 1 0;1/6 0 -1/6 0];
farrow = dfilt.farrowfd(0.5, coeffs);
```

Design a cubic fractional delay filter with the Lagrange method.

```
fdelay = .2; % Fractional delay
d = fdesign.fracdelay(fdelay,'N',3);
cubicfarrow = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
fvtool(cubicfarrow, 'Analysis', 'grpdelay');
```



For more information about fractional delay filter implementations, see the "Fractional Delay Filters Using Farrow Structures" example, `farrowdemo`.

dfilt.farrowlinearfd

Farrow Linear Fractional Delay filter

Syntax

```
Hd = dfilt.farrowlinearfd(D)
```

Description

`Hd = dfilt.farrowlinearfd(D)` Constructs a discrete-time linear fractional delay Farrow filter with the delay D.

Examples

Farrow linear fractional delay filter with 1/2 sample delay:

```
 Hd = dfilt.farrowlinearfd(0.5);
x = cos(pi/10*(0:159));
y = filter(Hd,x);
stem(x(1:40));
axis([0 40 -2 2]);
hold on;
stem(y(1:40),'color',[1 0 0],'markerfacecolor',[1 0 0 ]);
legend('Original Signal','Filtered Signal','Location','best');
```

For more information about fractional delay filter implementations, see the “Fractional Delay Filters Using Farrow Structures” example, farrowdemo.

Topics

dfilt

Introduced in R2011a

dfilt.fftfir

Discrete-time, overlap-add, FIR filter

Syntax

```
Hd = dfilt.fftfir(b,len)
Hd = dfilt.fftfir(b)
Hd = dfilt.fftfir
```

Description

This object uses the overlap-add method of block FIR filtering, which is very efficient for streaming data.

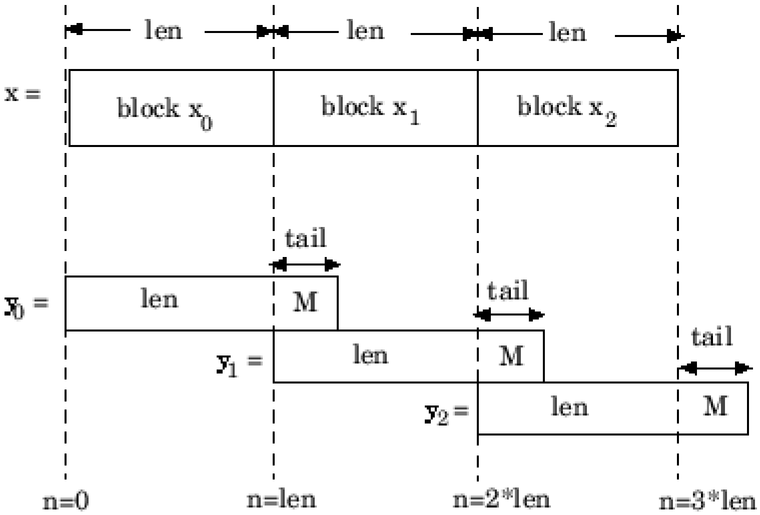
`Hd = dfilt.fftfir(b,len)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len`. The block length is the number of input points to use for each overlap-add computation.

`Hd = dfilt.fftfir(b)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len`=100.

`Hd = dfilt.fftfir` returns a default, discrete-time, FFT, FIR filter, `Hd`, with the numerator `b=1` and block length, `len`=100. This filter passes the input through to the output unchanged.

Note When you use a `dfilt.fftfir` object to filter, the input signal length must be an integer multiple of the object's block length, `len`. The resulting number of FFT points = (filter length + the block length - 1). The filter is most efficient if the number of FFT points is a power of 2.

The `fftfir` uses an overlap-add block processing algorithm, which is represented as follows,



where `len` is the block length and `M` is the length of the numerator-1, (`length(b)-1`), which is also the number of states. The output of each convolution is a block that is longer than the input block by a tail of (`length(b)-1`) samples. These tails overlap the next block and are added to it. The states reported by `dfilt.fftfir` are the tails of the final convolution.

Examples

Create an FFT FIR discrete-time filter with coefficients from a 30^{th} order lowpass equiripple design:

```
b = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);
Hd = dfilt.fftfir(b);
% To obtain frequency domain coefficients
% used in filtering
Coeffs = fftcoeffs(Hd);
```

`dfilt` | `dfilt.dffir` | `dfilt.dfasymfir` | `dfilt.dffirt` | `dfilt.dfsymfir`

Introduced in R2011a

dfilt.latticeallpass

Discrete-time, lattice allpass filter

Syntax

Refer to `dfilt.latticeallpass` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticeallpass(k)` returns a discrete-time, lattice allpass filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

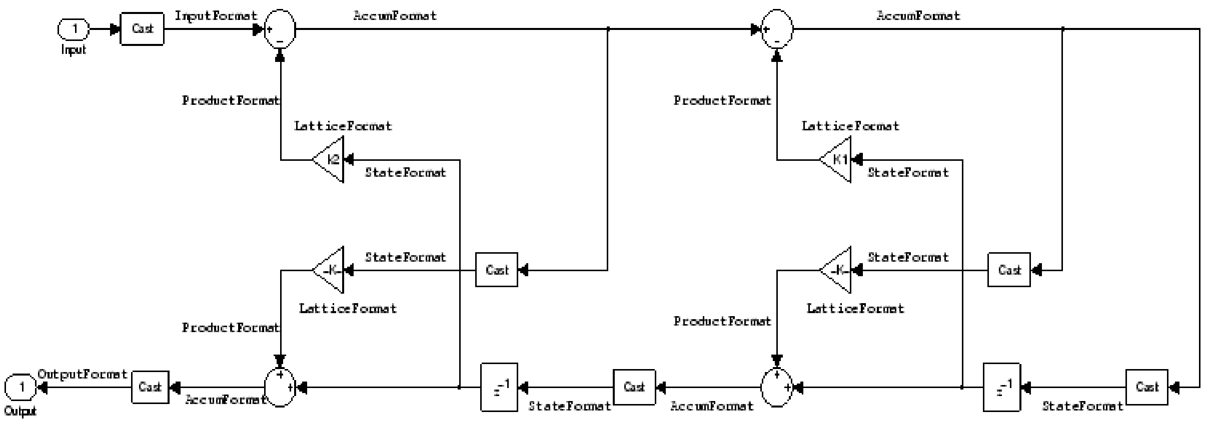
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`hd = dfilt.latticeallpass` returns a default, discrete-time, lattice allpass filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the allpass lattice filter implemented by `dfilt.latticeallpass`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the allpass lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumFracLength`	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties

Property Name	Brief Description
	—DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/ buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property value to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.
Lattice	Any lattice structure coefficients. No default value.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.

Property Name	Brief Description
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.

Property Name	Brief Description
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a third-order lattice allpass filter structure for a `dfilt` object `hd`, with the following code:

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
% convert to fixed-point arithmetic
hd.arithmetic = 'fixed';
```

Introduced in R2011a

dfilt.latticear

Discrete-time, lattice, autoregressive filter

Syntax

Refer to `dfilt.latticear` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticear(k)` returns a discrete-time, lattice autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

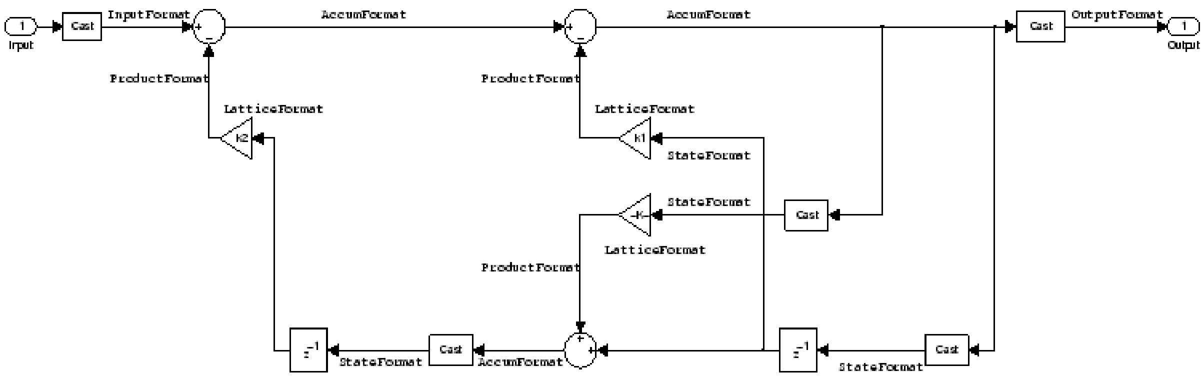
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd = dfilt.latticear` returns a default, discrete-time, lattice autoregressive filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticear`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the autoregressive lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

dfilt | dfilt.latticeallpass | dfilt.latticearma | dfilt.latticemamax | dfilt.latticemamin

Introduced in R2011a

dfilt.latticearma

Discrete-time, lattice, autoregressive, moving-average filter

Syntax

Refer to `dfilt.latticearma` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticearma(k)` returns a discrete-time, lattice moving-average autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

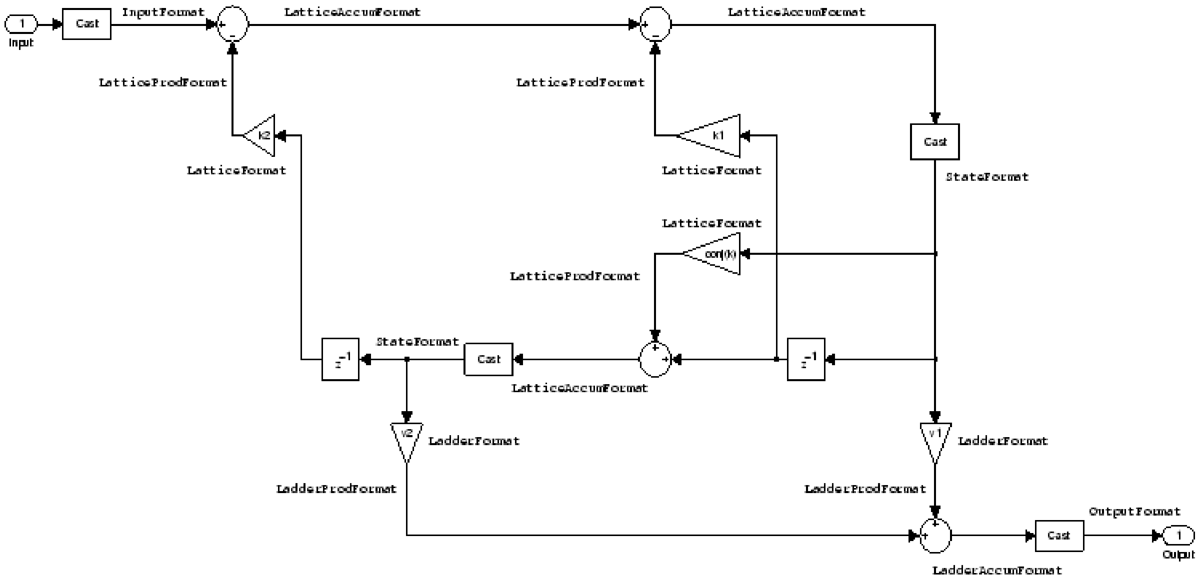
  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

`hd dfilt.latticearma` returns a default, discrete-time, lattice moving-average, autoregressive filter object `hd`, with `k` = [ ]. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticearma`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFormat	`InputWordLength`	`InputFracLength`	None

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
LadderAccumFormat	`AccumWordLength`	`LadderAccumFracLength`	`AccumMode`
LadderFormat	`CoeffWordLength`	`LadderFracLength`	`CoeffAutoScale`
LadderProdFormat	`ProductWordLength`	`LadderProdFracLength`	`ProductMode`
LatticeAccumFormat	`AccumWordLength`	`LatticeAccum-FracLength`	`AccumMode`
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
LatticeProdFormat	`ProductWordLength`	`LatticeProdFracLength`	`ProductMode`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label LatticeProdFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that lattice coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the LatticeProdFormat refers to the properties `ProductWordLength`, `LatticeProdFracLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the autoregressive moving-average lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`AccumFracLength`	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
`AccumMode`	Determines how the accumulator outputs stored values. Choose from full precision (`FullPrecision`), or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set `AccumMode` to `SpecifyPrecision`.
`AccumWordLength`	Sets the word length used to store data in the accumulator/buffer.
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `LatticeFracLength` property to specify the precision used.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations

Property Name	Brief Description
	during filtering—gains, delays, sums, products, and input/output.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`Ladder`	Stores the ladder coefficients for lattice ARMA (`dfilt.latticearma`) filters.
`LadderAccumFracLength`	Sets the fraction length used to interpret the output from sum operations that include the ladder coefficients. You can change this property value after you set `AccumMode` to `SpecifyPrecision`.
`LadderFracLength`	Determines the precision used to represent the ladder coefficients in ARMA lattice filters.
`Lattice`	Stores the lattice structure coefficients.
`LatticeFracLength`	Sets the fraction length applied to the lattice coefficients.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the word and fraction lengths used by the output data from filtering.
`OutputWordLength`	Determines the word length used for the output data.

Property Name	Brief Description
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (`FullPrecision`), or whether to keep the most significant bit (`KeepMSB`) or least significant bit (`KeepLSB`) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set `ProductMode` to `SpecifyPrecision`.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set `ProductMode` to `SpecifyPrecision`.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `False` is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Introduced in R2011a

dfilt.latticemamax

Discrete-time, lattice, moving-average filter with maximum phase

Syntax

Refer to `dfilt.latticemamax` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticemamax(k)` returns a discrete-time, lattice, moving-average filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

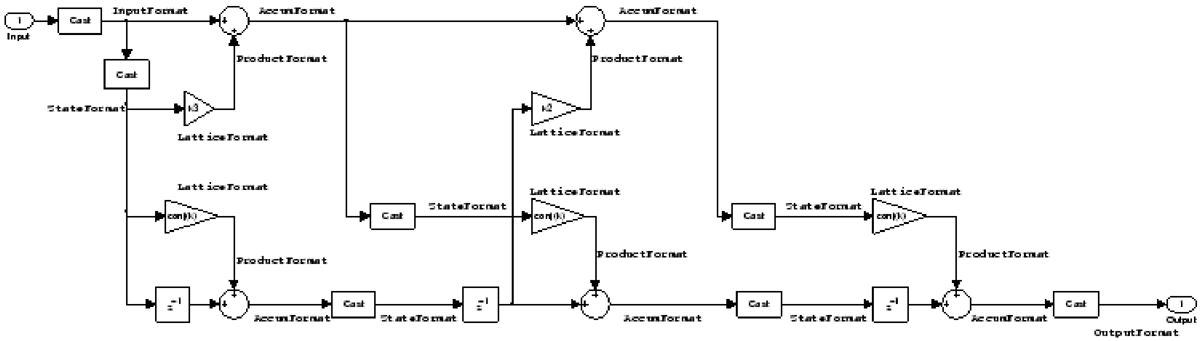
For more information about the property `Arithmetic`, refer to "Arithmetic" on page 6-18.

Note When the `k` coefficients define a maximum phase filter, the resulting filter in this structure is maximum phase. When your coefficients do not define a maximum phase filter, placing them in this structure does not produce a maximum phase filter.

`hd = dfilt.latticemamax` returns a default discrete-time, lattice, moving-average filter object `hd`, with `k` = [ ]. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the maximum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamax`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word "format." In this use, "format" means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the maximum phase, moving average lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering —gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
StateFracLength	When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.
StateWordLength	Sets the word length used to represent the filter states.

Examples

Specify a fourth-order lattice, moving-average, maximum phase filter structure for a dfilt object, hd, with the following code:

```
k = [.66 .7 .44 .33];
hd = dfilt.latticemamax(k);
```

Introduced in R2011a

dfilt.latticemamin

Discrete-time, lattice, moving-average filter with minimum phase

Syntax

Refer to `dfilt.latticemamin` in Signal Processing Toolbox documentation.

Description

`hd = dfilt.latticemamin(k)` returns a discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```

- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

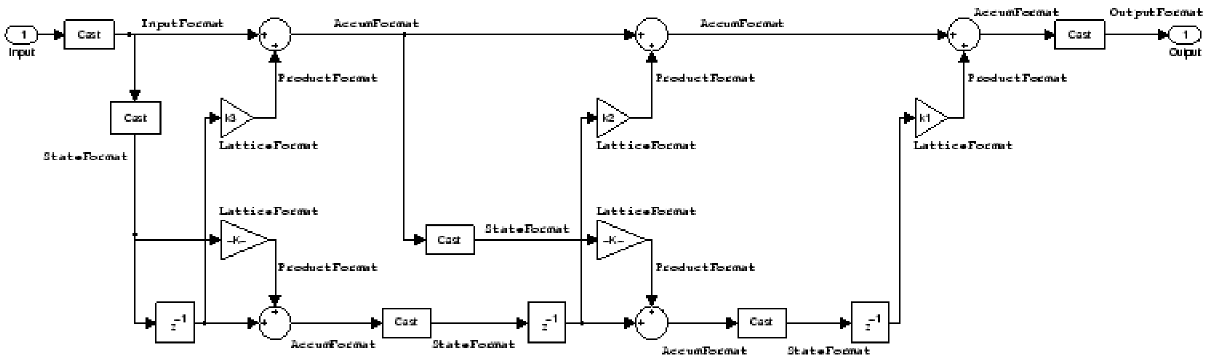
For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

Note When the `k` coefficients define a minimum phase filter, the resulting filter in this structure is minimum phase. When your coefficients do not define a minimum phase filter, placing them in this structure does not produce a minimum phase filter.

`hd = dfilt.latticemamin` returns a default discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

Fixed-Point Filter Structure

The following figure shows the signal flow for the minimum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamin`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.



Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties `InputWordLength` and `InputFracLength` (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (`CoeffWordLength`, `NumFracLength`) associated with representing filter numerator coefficients.

Signal Flow Label	Corresponding Word Length Property	Corresponding Fraction Length Property	Related Properties
AccumFormat	`AccumWordLength`	`AccumFracLength`	`AccumMode`
InputFormat	`InputWordLength`	`InputFracLength`	None
LatticeFormat	`CoeffWordLength`	`LatticeFracLength`	`CoeffAutoScale`
OutputFormat	`OutputWordLength`	`OutputFracLength`	`OutputMode`
ProductFormat	`ProductWordLength`	`ProductFracLength`	`ProductMode`
StateFormat	`StateWordLength`	`StateFracLength`	`States`

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties `ProductFracLength`, `ProductWordLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

Properties

In this table you see the properties associated with the minimum phase, moving average lattice implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
AccumFracLength	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumMode	Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.
AccumWordLength	Sets the word length used to store data in the accumulator/buffer.
Arithmetic	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.
CastBeforeSum	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
CoeffAutoScale	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.
CoeffWordLength	Specifies the word length to apply to filter coefficients.
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
InputFracLength	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Specifies the word length applied to interpret input data.

Property Name	Brief Description
Lattice	Any lattice structure coefficients.
LatticeFracLength	Sets the fraction length applied to the lattice coefficients.
OutputFracLength	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.
OutputMode	Sets the mode the filter uses to scale the filtered data for output. You have the following choices: • AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
ProductFracLength	For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.

Property Name	Brief Description
ProductMode	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Brief Description
`Signed`	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`StateFracLength`	When you set `StateAutoScale` to `false`, you enable the `StateFracLength` property that lets you set the fraction length applied to interpret the filter states.
`States`	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Sets the word length used to represent the filter states.

Examples

Specify a third-order lattice, moving-average, minimum phase, filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44];
hd = dfilt.latticemamin(k);
```

Introduced in R2011a

dfilt.parallel

Discrete-time, parallel structure filter

Syntax

Refer to `dfilt.parallel` in Signal Processing Toolbox documentation.

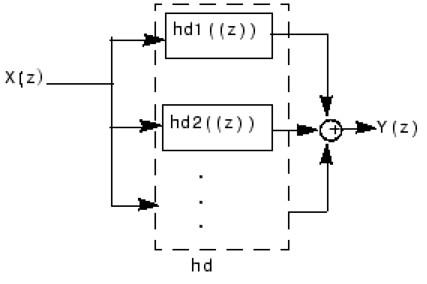
Description

`hd = dfilt.parallel(hd1,hd2,...)` returns a discrete-time filter object `hd`, which is a structure of two or more `dfilt` filter objects, `hd1`, `hd2`, and so on arranged in parallel.

You can also use the standard notation to combine filters into a parallel structure.

```
parallel(hd1,hd2,...)
```

In this syntax, `hd1`, `hd2`, and so on can be a mix of `dfilt` objects and other filtering objects.



`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the parallel structure must be the same arithmetic format — double, single, or fixed. `hd`, the filter returned, inherits the format of the individual filters.

See Also

`dfilt` | `dfilt.cascade` | `dfilt.cascade` | `dfilt.parallel`

Introduced in R2011a

dfilt.scalar

Discrete-time, scalar filter

Syntax

Refer to `dfilt.scalar` in Signal Processing Toolbox documentation.

Description

`dfilt.scalar(g)` returns a discrete-time, scalar filter object with gain `g`, where `g` is a scalar.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

  ```
  set(hd,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hd,'arithmetic','fixed');
  ```

For more information about the property `Arithmetic`, refer to “Arithmetic” on page 6-18.

`dfilt.scalar` returns a default, discrete-time scalar gain filter object `hd`, with gain `1`.

Properties

In this table you see the properties associated with the scalar implementation of `dfilt` objects.

Note The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

For further information about the properties of this filter or any `dfilt` object, refer to "Fixed-Point Filter Properties" on page 6-2.

Property Name	Brief Description
`Arithmetic`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `CoeffFracLength` property to specify the precision used.
`CoeffFracLength`	Set the fraction length the filter uses to interpret coefficients. `CoeffFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`CoeffWordLength`	Specifies the word length to apply to filter coefficients.
`FilterStructure`	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`Gain`	Returns the gain for the scalar filter. Scalar filters do not alter the input data except by adding gain.
`InputFracLength`	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Specifies the word length applied to interpret input data.
`OutputFracLength`	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	Sets the mode the filter uses to scale the filtered data for output. You have the following choices:

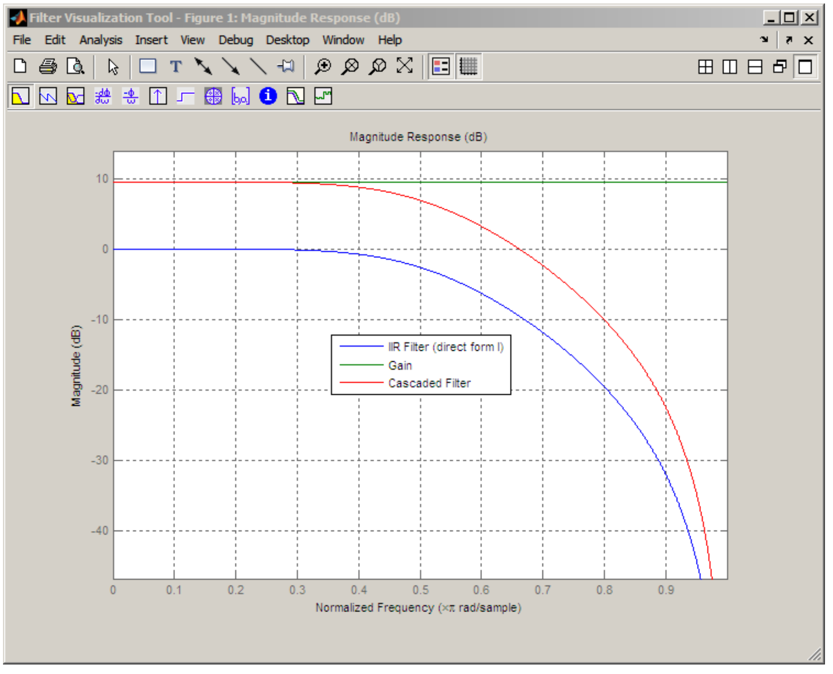
Property Name	Brief Description
	• AvoidOverflow — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow. • BestPrecision — directs the filter to set the output data word length and fraction length to maximize the precision in the output data. • SpecifyPrecision — lets you set the word and fraction lengths used by the output data from filtering.
OutputWordLength	Determines the word length used for the output data.
OverflowMode	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.

Property Name	Brief Description
RoundMode	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Examples

Create a direct-form I filter object hd_filt and a scalar object with a gain of 3 hd_gain and cascade them together.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd_filt = dfilt.df1(b,a);
hd_gain = dfilt.scalar(3);
hd_cascade=cascade(hd_gain,hd_filt);
fvtool_handle = fvtool(hd_filt,hd_gain,hd_cascade);
legend(fvtool_handle,'IIR Filter (direct form I)',...
'Gain','Cascaded Filter');
```



To view the stages of the cascaded filter, use

```
hd.Stage(1)
```

and

```
hd.Stage(2)
```

See Also

dfilt | dfilt.cascade

Introduced in R2011a

dfilt.wdfallpass

Wave digital allpass filter

Syntax

```
hd = dfilt.wdfallpass(c)
```

Description

`hd = dfilt.wdfallpass(c)` constructs an allpass wave digital filter structure given the allpass coefficients in vector `c`.

Vector `c` must have, one, two, or four elements (filter coefficients). Filters with three coefficients are not supported. When you use `c` with four coefficients, the first and third coefficients must be 0.

Given the coefficients in `c`, the transfer function for the wave digital allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \ldots + z^{-n}}{1 + c(1)z^{-1} + \ldots + c(n)z^{-n}}$$

Internally, the allpass coefficients are converted to wave digital filters for filtering. Note that `dfilt.wdfallpass` allows only stable filters. Also note that the leading coefficient in the denominator, a 1, does not need to be included in vector `c`.

Use the constructor `dfilt.cascadewdfallpass` to cascade `wdfallpass` filters.

To compare these filters to other similar filters, `dfilt.wdfallpass` and `dfilt.cascadewdfallpass` filters have the same number of multipliers as the non-wave digital filters `dfilt.allpass` and `dfilt.cascadeallpass`. However, the wave digital filters use fewer states and they may require more adders in the filter structure.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Properties

In the next table, the row entries are the filter properties and a brief description of each property.

Property Name	Brief Description
AllpassCoefficients	Contains the coefficients for the allpass wave digital filter object
FilterStructure	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. False is the default setting.
States	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system.

Filter Structure

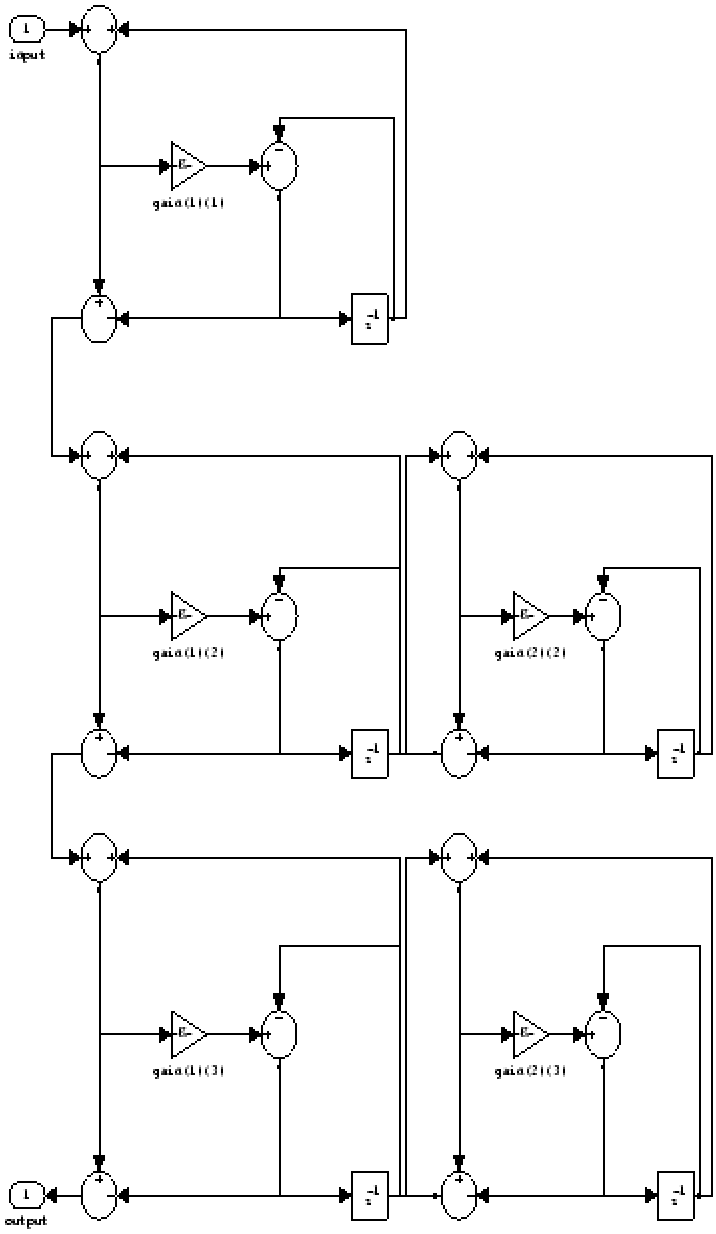
When you change the order of the wave digital filters in the cascade, the filter structure changes as well.

As shown in this example, realizemdl lets you see the filter structure used for your filter, if you have Simulink installed.

```
section11=0.8;
section12=[1.5,0.7];
section13=[1.8,0.9];
hd1=dfilt.cascadewdfallpass(section11,section12,section13);
```

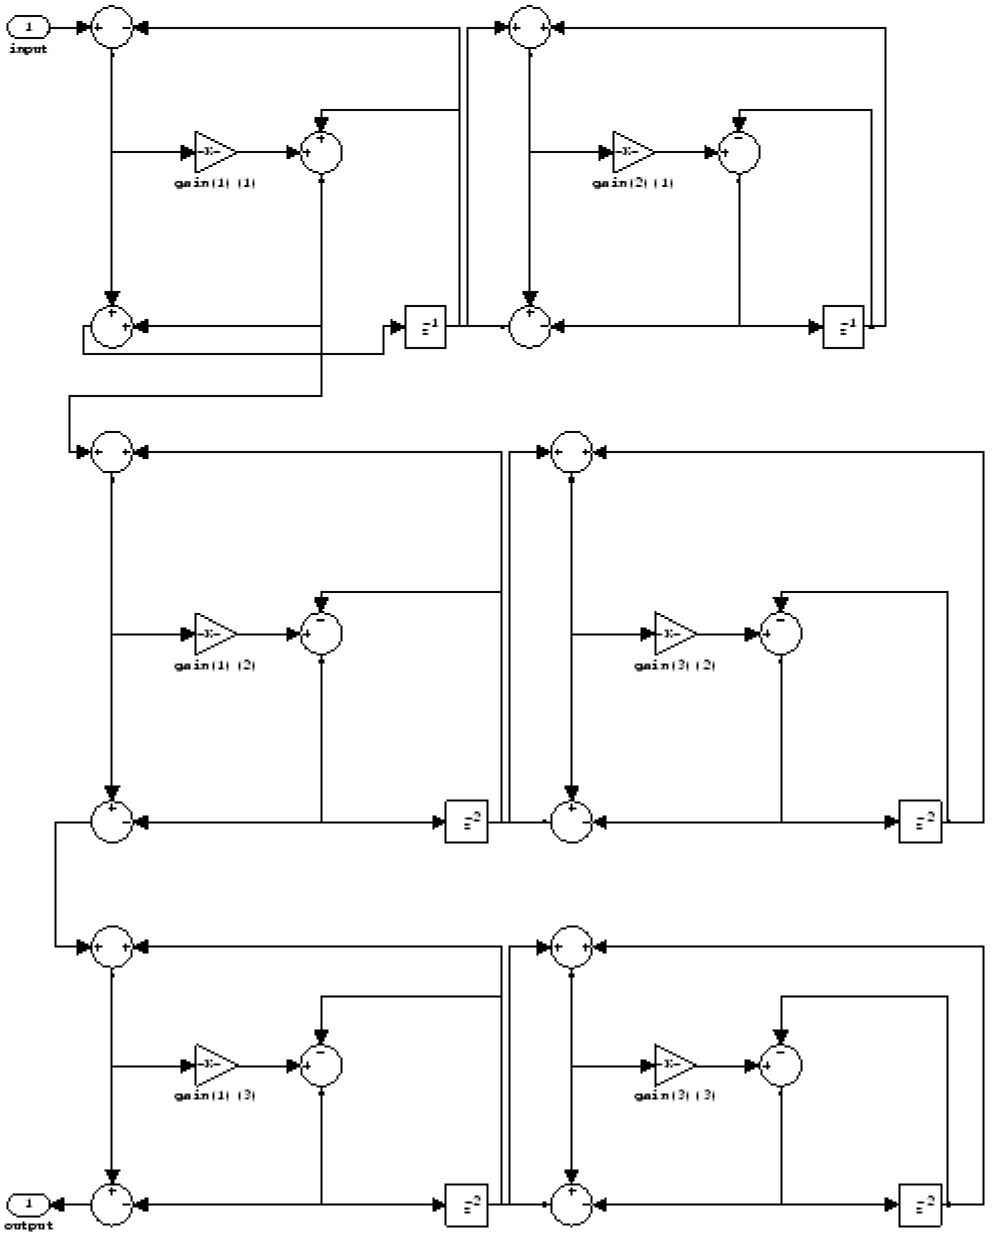
```
section21=[0.8,0.4];
section22=[0,1.5,0,0.7];
section23=[0,1.8,0,0.9];
hd2=dfilt.cascadewdfallpass(section21,section22,section23);
% If you have Simulink
realizemdl(hd2)
```

hd1 has this filter structure with three sections.



input
gain(1)(1)
gain(1)(2)
gain(2)(2)
gain(1)(3)
gain(2)(3)
output

The filter structure for hd2 is somewhat different, with the different orders and interconnections between the three sections.



1
input
gain(1)(1)
gain(2)(1)
gain(1)(2)
gain(3)(2)
gain(1)(3)
gain(3)(3)
1
output

Examples

Construct a second-order wave digital allpass filter with two coefficients. Note that to use `realizemdl`, you must have Simulink.

```
c = [1.5,0.7];
hd = dfilt.wdfallpass(c);
```

With Simulink installed, `realizemdl` returns this structure for `hd`.

Introduced in R2011a

disp

Filter properties and values

Syntax

```
disp(h)
```

Description

`disp(h)` lists the property names and property values of a filter object. In all ways, it is the same as leaving the semicolon off an on the command line, except that `disp` does not display the variable name.

Examples

Display the Properties of a Filter Object

```
FIRFilt = dsp.FIRFilter;
disp(FIRFilt);
```

```
  dsp.FIRFilter with properties:

            Structure: 'Direct form'
      NumeratorSource: 'Property'
            Numerator: [0.5000 0.5000]
    InitialConditions: 0

  Use get to show all properties
```

See Also

`set`

Introduced in R2011a

double

Cast fixed-point filter to use double-precision arithmetic

Syntax

```
hd = double(h)
```

Description

`hd = double(h)` returns a new filter `hd` that has the same structure and coefficients as `h`, but whose arithmetic property is set to `double` to use double-precision arithmetic for filtering. `double(h)` is not the same as the `reffilter(h)` function:

- `hd`, the filter returned by `double` has the quantized coefficients of `h` represented in double-precision floating-point format
- The reference filter returned by `reffilter` has double-precision, floating-point coefficients that have not been quantized.

You might find `double(h)` useful to isolate the effects of quantizing the coefficients of a filter by using `double` to create a filter `hd` that operates in double-precision but uses the quantized filter coefficients.

Examples

Compare Fixed-point Output with Floating-Point Output

Construct a Lowpass Filter

```
h = dfilt.dffir(firgr(27,[0 .4 .6 1],...
[1 1 0 0]));
```

Set h to use fixed-point arithmetic to filter. Quantize the coeffs.

```
h.arithmetic = 'fixed';
```

Cast h to double-precision

```
hd = double(h);
```

Set up an input signal.

```
n = 0:99; x = sin(0.7*pi*n(:));
```

Fixed-point output.

```
y = filter(h,x);
```

Floating-point output.

```
yd = filter(hd,x);
```

Compare the Fixed-point output with Floating-point output

```
FixedFloatNormDiff=norm(yd-double(y),inf)
```

```
FixedFloatNormDiff =

   2.1234e-05
```

Introduced in R2011a

dsp.util.getLogsArray

Package: dsp.util

Return logged signal as MATLAB array

Syntax

```
Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalPath',PATH)
Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalName',NAME)
```

Description

`Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalPath',PATH)` returns a MATLAB array that contains a signal in `LogObject`. You must specify the `PATH` to the signal in `LogObject` using the `Name,Value` pair argument.

`Array = dsp.util.getLogsArray(LogObject,Format2D,'SignalName',NAME)` returns a MATLAB array that contains a signal in `LogObject`. You must specify the `NAME` of the signal in `LogObject` using the `Name,Value` pair argument.

Input Arguments

`LogObject`

Specify the name of the object that contains your logged signals. Valid classes for `LogObject` depend on the syntax you use:

- When you specify `PATH` as a dsp.util.SignalPath object, `LogObject` can be either a Simulink.SimulationData.Dataset or `Simulink.SimulationData.Signal` object.
- When you specify `PATH` as the full path to a block in a Simulink model, `LogObject` must be a `Simulink.SimulationData.Dataset` object.
- When you specify the `NAME` of a signal in `LogObject`, `LogObject` can be an object of class timeseries, `Simulink.SimulationData.Dataset`, or `Simulink.SimulationData.Signal`.

`Format2D`

Specify a logical value to determine whether the function formats 3-D logged signals as a 2-D or 3-D MATLAB array. When you set this property to `true`, the function uses the following formula to format the 3-D logged signal into a 2-D MATLAB array:

```
dim = size(signal);
ntimes = dim(1)*dim(3);
Array = reshape(permute(signal,[1 3 2]),[ntimes dim(2)]);
```

When you set this property to `false`, the function returns the logged signal without any reformatting.

`PATH`

Specify the path to the logged signal in `LogObject`. You can specify the path using a dsp.util.SignalPath object, or you can provide the full path to a block in your Simulink model. To get the full path to a block in your Simulink model, use the `gcb` command.

`NAME`

Specify the name of the signal in `LogObject`.

Output Arguments

`Array`

The output `Array` is a MATLAB array that contains the specified logged signal. When the input is a 3-D logged signal, the dimensions of `Array` depend on the value you specify for `Format2D`:

- When `Format2D` is `true`, `Array` is a 2-D MATLAB array.
- When `Format2D` is `false`, `Array` is a 3-D MATLAB array.

When the input is not a 3-D signal, the dimensions of the output `Array` match those of the input.

Examples

Note: To run the following examples, you must first load ex_logsout.mat which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the ex_log_utils Simulink model. Doing so will log signals and generate the necessary `ex_logsout` object.

Extract a unique signal named Signal3x4 from ex_logsout.

```
dsp.util.getLogsArray(ex_logsout, true, 'SignalName','Signal3x4')
```

Extract a unique signal named Signal3x4 from ex_logsout as a 3-D array.

```
dsp.util.getLogsArray(ex_logsout, false, 'SignalName','Signal3x4')
```

Find and extract a specific signal from multiple signals that have the same name.

Because `ex_logsout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logsout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', paths(2))
```

Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logsout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to the
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus1'.
% Now that you have the path to the signal, call dsp.util.getLogsArray
```

```
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', buspaths(1))
```

Introduced in R2011b

dsp.util.getSignalPath

Package: dsp.util

Paths to logged signals

Syntax

```
Path = dsp.util.getSignalPath(LogObject, SignalName)
```

Description

`Path = dsp.util.getSignalPath(LogObject, SignalName)` returns all paths to signals in `LogObject` with name `SignalName`. The output `Path` is a dsp.util.SignalPath object or an array of `dsp.util.SignalPath` objects.

Input Arguments

`LogObject`

Specify the name of the object that contains your logged signals. `LogObject` must be a Simulink.SimulationData.Dataset or `Simulink.SimulationData.Signal` object.

`SignalName`

Specify the name of a logged signal in `LogObject`.

Output Arguments

`Path`

The output `Path` contains the path to all signals named `SignalName` in `LogObject`.

- If `LogObject` contains a unique signal with name `SignalName`, the function returns a single dsp.util.SignalPath object.

- If `LogObject` contains more than one signal with the specified name, the function returns an array of dsp.util.SignalPath objects.

Examples

Note: To run the following examples, you must first load ex_logsout.mat which contains a `Simulink.SimulationData.Dataset` object. Alternatively, you can open and simulate the ex_log_utils Simulink model. Doing so will log signals and generate the necessary `ex_logsout` object.

Find and extract a specific signal from multiple signals that have the same name.

Because `ex_logsout` contains multiple signals named `Signal2x4`, you must use the `dsp.util.getSignalPath` function to find the paths to each of those signals.

```
paths = dsp.util.getSignalPath(ex_logsout, 'Signal2x4')
% paths is a 2x1 array of dsp.util.SignalPath objects. Next, examine
% the BlockPath property of each paths object.
paths.BlockPath
% Find the signal path that corresponds to the logged signal you are
% interested in. For example paths(2). You can then use the
% dsp.util.getLogsArray function and provide the 'SignalPath' name-value
% pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', paths(2))
```

Find and extract a signal from a bus.

Use the `dsp.util.getSignalPath` function to get paths to all the signals in the bus named `Bus1`.

```
buspaths = dsp.util.getSignalPath(ex_logsout, 'Bus1')
% buspaths is a 2x1 array of dsp.util.SignalPath objects. Examine the
% BusElement property of each buspaths object.
buspaths.BusElement
% Select a signal path. For example buspaths(1). This is the path to the
% signal named 'Signal3x4' in bus 'Bus' that is contained in bus 'Bus1'.
% Now that you have the path to the signal, call dsp.util.getLogsArray
% using the 'SignalPath' name-value pair argument.
dsp.util.getLogsArray(ex_logsout, true, 'SignalPath', buspaths(1))
```

Tips

- To return the path to an unnamed signal in `LogObject`, set `SignalName` to the empty string (`''`).

Introduced in R2011b

dsp.util.SignalPath class

Package: dsp.util

Properties of paths to signals

Description

`dsp.util.SignalPath` objects contain path information for signals in Simulink.SimulationData.Dataset objects. You get `Simulink.SimulationData.Dataset` objects when you use `Dataset` logging to log signals from a Simulink model.

Construction

`dsp.util.SignalPath` objects are returned by the `dsp.util.getSignalPath` function and can be used as input to the `dsp.util.getLogsArray` function.

Properties

`SignalName`

Contains the name of the signal output by the block at the specified `BlockPath`.

`BlockPath`

Provides the `Simulink.SimulationData.BlockPath` to the block in the Simulink model from which the signal originates.

`PortIndex`

Provides the output port index of the block from which the logged signal `SignalName` originates.

`BusElement`

Provides a string description of a signal in a logged bus. When `SignalPath` is not a logged bus, this property will be an empty string.

If the `SignalPath` object is a logged bus signal, the `BusElement` string will be formatted as follows:

- When the bus contains a nonbus signal, `BusElement` is the name of that signal.
- When the bus contains a nested bus that contains a nonbus signal, `BusElement` will be a dot-separated string consisting of the name of the nested bus followed by the name of the non-bus signal. For example: `nestbus.signal1`
- When the bus contains nested busses within nested busses to any depth, `BusElement` will be a dot-separated string. This string contains each of the nested bus names, and ends with the nonbus signal name. For example: `outernestedbus.innernestedbus.signal1`

dsp_links

Identify whether blocks in model are current, deprecated, or obsolete

Syntax

```
dsp_links
dsp_links('modelname')
```

Description

`dsp_links` returns a structure with three elements that identify whether the DSP System Toolbox blocks in the current model are current, deprecated, or obsolete. Each element is one of the three block categories and contains a cell array of character vectors. Each character vector is the name of a library block in the current model.

`dsp_links('modelname')` returns the three-element structure for the specified model.

Examples

Name of the First Current Block

Display block support information for the specified model, and then find the name of the first current block.

```
sys = 'dspcochlear';
```

Load the dspcochlear model

```
load_system(sys)
```

Run dsp_links on the model

```
links = dsp_links(sys)
```

```
links =
```

```
  struct with fields:

      obsolete: {}
    deprecated: {}
       current: {1×23 cell}
```

Find the name of the first current block

```
links.current{1}
```

```
ans =

    'dspcochlear/Filter bank signal processing/Subsystem3/IIR Filter Bank/Digital Filte
```

Definitions

Obsolete Blocks

Obsolete blocks are blocks that the toolbox no longer supports. In some cases, these blocks no longer function properly.

Deprecated Blocks

Deprecated blocks are blocks that the toolbox still supports but are likely to become obsolete in a future release. Refer to the block reference page for suggested replacements.

Current Blocks

Current blocks are blocks that the toolbox supports and that represent the latest block functionality.

`liblinks`

Introduced before R2006a

dsplib

Open top-level DSP System Toolbox library

Syntax

```
dsplib
```

Description

`dsplib` opens the top-level DSP System Toolbox block library model.

Examples

View and gain access to the DSP System Toolbox blocks:

```
dsplib
```

Alternatives

To view and gain access to the DSP System Toolbox blocks using the Simulink library browser:

- Type `simulink` at the MATLAB command line, and then expand the DSP System Toolbox node in the library browser.
- Click the Simulink icon 
from the MATLAB Toolstrip.

Introduced before R2006a

dspstartup

Configure Simulink environment for signal processing systems

Note: `dspstartup` will be removed in a future release. Use DSP Simulink model templates instead. For more information on DSP Simulink model templates, see Configure the Simulink Environment for Signal Processing Models.

Syntax

`dspstartup`

Description

`dspstartup` configures Simulink environment parameters with settings appropriate for a typical signal processing project. You can use the `dspstartup` function in the following ways:

- At the MATLAB command line. Doing so configures the Simulink environment in your current session for signal processing projects.
- By adding a call to the `dspstartup` function from your `startup.m` file. When you do so, MATLAB configures your Simulink environment for typical signal processing projects each time you launch MATLAB.

When the function successfully configures your Simulink environment, MATLAB displays the following message in the command window.

```
Changed default Simulink settings for signal processing
systems (dspstartup.m).
```

The `dspstartup.m` file executes the following commands.

```
set_param(0, ...
          'SingleTaskRateTransMsg','error', ...
          'multiTaskRateTransMsg', 'error', ...
          'Solver',                'fixedstepdiscrete', ...
```

```
'EnableMultiTasking',    'Off', ...
'StartTime',             '0.0', ...
'StopTime',              'inf', ...
'FixedStep',             'auto', ...
'SaveTime',              'off', ...
'SaveOutput',            'off', ...
'AlgebraicLoopMsg',      'error', ...
'SignalLogging',         'off');
```

Examples

Add a call to the `dspstartup` function from your `startup.m` file:

1. To find out if there is a `startup.m` file on your MATLAB path, run the following code at the MATLAB command line:

   ```
   which startup.m
   ```

2. If MATLAB returns `'startup.m' not found`, see "Specify Startup Options" (MATLAB) to learn more about the `startup.m` file.

   If MATLAB returns a path to your `startup.m` file, open that file for editing.

   ```
   edit startup.m
   ```

3. Add a call to the `dspstartup` function. Your `startup.m` file now resembles the following code sample:

   ```
   %STARTUP   Startup file
   %   This file is executed when MATLAB starts up, if it exists
   %   anywhere on the path.  In this case, the startup.m file
   %   runs the dspstartup.m file to configure the Simulink
   %   environment with settings appropriate for typical
   %   signal processing projects.

   dspstartup;
   ```

dspunfold

Generates a multi-threaded MEX file from a MATLAB function

Syntax

```
dspunfold file
dspunfold options file
```

Description

`dspunfold file` generates a multi-threaded MEX file from the entry-point MATLAB function specified by `file`, using the DSP unfolding technology. DSP unfolding is a technique to improve throughput through parallelization. The multi-threaded MEX file leverages the multicore CPU architecture of the host computer and can improve speed significantly. In addition to the multi-threaded MEX file, the function generates a single-threaded MEX file, a self-diagnostic analyzer function, and the corresponding help files.

`dspunfold options file` generates a multi-threaded MEX file from the entry-point MATLAB function specified by `file`, using the function arguments specified by `options`.

Note: This function requires a MATLAB Coder license.

Examples

- "Multi-Threaded MEX File Generation Using DSP Unfolding"

Input Arguments

`options` — Function parameters

option value pairs

Option	Values	Description	Examples
`-args arguments`	Cell array	Argument types for the entry-point	The number of elements in the cell array must be the same as

Option	Values	Description	Examples
		MATLAB function, specified as a cell array. The cell array accepts numeric elements, the `coder.typeof` function, and the `coder.Constant` function. The generated multi-threaded MEX file is specialized to the size, class, and complexity of `arguments`.	the number of arguments that the entry-point MATLAB function expects. • `dspunfold fcn -args {ones(10,1), 5}` `dspunfold` extracts the type (size, class, and complexity) information from the elements in the `arguments` cell array. `fcn` is the entry-point MATLAB function. • `dspunfold fcn -args {coder.typeof(ones(10,1)), coder.typeof(5)}` `coder.typeof` is used to specify the types of the `fcn` arguments. • `dspunfold fcn -args {coder.Constant(ones(10,1)), coder.Constant(5)}` • `dspunfold fcn -args {}` By default, `arguments` is `{}`. An empty cell array `{}` indicates that `fcn` accepts no input arguments.

Option	Values	Description	Examples

`-o output`	Charact vector	Name of the output multi-threaded MEX file, specified as a character vector. If no `output` name is specified, the name of the generated multi-threaded MEX file is inherited from the input MATLAB function with an `'_mt'` suffix. `dspunfold` also adds a platform-specific extension to this name. In addition, `dspunfold` generates a single-threaded MEX file with an `'_st'` suffix, and a test bench file with an `'_analyzer'` suffix.	• No `output` name specified
			`dspunfold fcn`
			Files generated: `fcn_mt.mexw64`, `fcn_st.mexw64`, `fcn_analyzer.p`
			• `output` name specified
			`dspunfold fcn -o foo`
			Files generated: `foo.mexw64`, `foo_st.mexw64`, `foo_analyzer.p`

Option	Values	Description	Examples
`-s statelength`	Scalar integer greater than or equal to zero `auto`	State length of the algorithm in the entry-point MATLAB function, specified as a scalar integer greater than or equal to zero, or `auto`. By default, the `statelength` is `zero` frames, indicating that the algorithm is stateless. If at least one entry of `frameinputs` is `true`, `statelength` is considered in samples. For information on frames and samples, see "Sample- and Frame-Based Concepts" `-s auto` triggers automatic state length detection. In this mode, you must provide numeric inputs to the `arguments` cell array. These inputs detect the	• `dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [false, false, false]` State length is `three` frames. • `dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [true, false, false]` State length is `three` samples. State length is considered in samples, because at least one entry of the `-f` option is `true`. • `dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s auto` Automatic state length detection is invoked. • `dspunfold fcn -args {coder.typeof (randn(10,1)), coder.typeof(randn(10,1)), coder.typeof(randn(10,1))} -s auto` generates this error message: `The input argument 1 is of type coder.PrimitiveType which is not supported when using -s auto`

Option	Values	Description	Examples
		state length of the algorithm. You can input `coder.Constant` but not `coder.typeof`. When automatic state length detection is invoked, it is recommended that you provide random inputs to the `arguments` array. See "Automatic State Length Detection" on page 5-478	

Option	Values	Description	Examples
`-f frameinputs`	scalar logical vector of logical values	Frame status of input arguments for the entry-point MATLAB function, specified as one of `true` or `false`. • `true` — Input is in frames and can be subdivided into samples without changing the system behavior. • `false` — Input cannot be subdivided into samples without changing the system behavior. For example, you cannot subdivide the coefficients of a filter without changing the characteristics of the filter. By default, `frameinputs` is `false`.	• `dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f true` All the inputs are marked as frames. State length is `three` samples. • `dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [true, false, false]` State length is `three` samples. • `dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3` The default value of `frameinputs` is `false`. State length is `three` frames.

Option	Values	Description	Examples
		`frameinputs` set to a scalar logical value sets the frame status of all the inputs simultaneously. To specify `statelength` in samples, set at least one entry of `frameinputs` to `true`. If `frameinputs` is not specified, the unit of `statelength` is frames.	
`-r repetition`	Positive integer	Repetition factor used to generate the multi-threaded MEX file, specified as a positive integer. The default value of `repetition` is `1`. See “Repetition Factor” on page 5-478.	`dspunfold fcn -args {randn(10,2), randn(20,2), randn(30,3)} -r 2`

Option	Values	Description	Examples
`-t threads`	Positive integer	Number of threads used by the multi-threaded MEX file, specified as a positive integer. The default value of `threads` is the number of physical CPU cores present on your machine. See "Threads" on page 5-478.	`dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -t 4`
`-v verbose`	Scalar logical	Option to show verbose output during code generation, specified as `true` or `false`. The default is `true`.	• `dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -v true` • `dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -v false`

`file` — entry-point MATLAB function
character vector

Entry-point MATLAB function from which `dspunfold` generates the multi-threaded MEX file. The function must support code generation.

Example: `dspunfold fcn -args {randn(10,1),randn(10,2),randn(20,1)}`

`fcn` is the entry-point MATLAB function and `{randn(10,1),randn(10,2),randn(20,1)}` are its input arguments.

Output Files

When you invoke `dspunfold` on an entry-point MATLAB function, `dspunfold` generates the following files.

File	Value	Description	Examples
Multi-threaded MEX file	MEX file	Multi-threaded MEX file generated from the entry-point MATLAB function. The MEX file inherits the output name. If no output name is specified, the name of this file is inherited from the MATLAB function with an '_mt' suffix. A platform-specific extension is also added to the name.	• dspunfold fcn -o foo generates foo.mexw64 • dspunfold fcn generates fcn_mt.mexw64
Help file for the multi-threaded MEX file	MATLA file	MATLAB help file for the multi-threaded MEX file. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type help <MEX filename> at the MATLAB command prompt. This help file displays information on how to invoke the MEX file, its syntax, latency, and types (size, class, and complexity) of the inputs to the MEX file. In addition, the help file documents the parameters used by dspunfold — Threads, Repetition, and State length. This information is useful when you are invoking the MEX file. The syntax to invoke the MEX file should be the same as the syntax shown in the help file.	• help foo • help fcn_mt

File	Value	Description	Examples
Single-threaded MEX file	MEX file	Single-threaded MEX file generated from the entry-point MATLAB function. The MEX file inherits the `output` name with an `'_st'` suffix. If no `output` name is specified, the name of this file is inherited from the MATLAB function with an `'_st'` suffix. A platform-specific extension is also added to the name. Use this file as a benchmark to compare against the speed of the multi-threaded MEX file.	• `dspunfold fcn -o foo` generates `foo_st.mexw64` • `dspunfold fcn` generates `fcn_st.mexw64`
Help file for the single-threaded MEX file	MATLAB file	MATLAB help file for the single-threaded MEX file. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type `help <MEX filename>` at the MATLAB command prompt. The help file displays information on how to invoke the MEX file, its syntax, and types (size, class, and complexity) of the inputs to the MEX file. The syntax to invoke the MEX file should be the same as the syntax shown in the help file.	• `help foo_st` • `help fcn_st`

File	Value	Description	Examples
Self-diagnostic analyzer function	P-coded file	`report = function_analyzer (input 1, input 2,...input n)` measures the difference in speed between the multi-threaded MEX file and the single-threaded MEX file. This file verifies that the output values match. `report = function_analyzer('late` reports the latency of the multi-threaded MEX file introduced by DSP unfolding. `report` contains the following fields: • Latency — The value of the latency (in frames) • Speedup — The speedup difference between the multi-threaded MEX file and single-threaded MEX file. If you specified `latency` option, the value of this field is empty `[]`. • Pass — Logical value that shows if the outputs match between the generated multi-threaded MEX file and the single-threaded MEX file. If you specified `latency` option,	• Multiple frames with different values are specified along the first dimension Example 1: `report = foo_analyzer(randn(10*2,1), randn(20*2,2), randn(30*3,3))` Example 2: `report = foo_analyzer([randn(10,1);randn [randn(20,1);randn(20,1)], [randn(30,1);randn(30,1);randn` • `report = foo_analyzer('latency')`

File	Value	Description	Examples
		the value of this field is empty `[]`. The first dimension of the analyzer inputs must be a multiple of the first dimension of the corresponding inputs, given to the `-args` option. The other dimensions must match exactly. The analyzer inherits the `output` name with an `'_analyzer'` suffix. If no `output` name is specified, the name of this file is inherited from the MATLAB function with an `'_analyzer'` suffix.	

File	Value	Description	Examples
Help file for the self-diagnostic analyzer function	MATLA file	Help file for the self-diagnostic analyzer function. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type `help <function_analyzer>` in MATLAB. The help file for the self-diagnostic analyzer function displays information on how to invoke the analyzer function, its syntax, and types (size, class, and complexity) of the inputs to the analyzer function. The syntax to invoke the analyzer function should be the same as the syntax shown in the help file.	`help foo_analyzer`

Limitations

General Limitations:

- On Windows and Linux, you must use a compiler that supports the Open Multiprocessing (OpenMP) application interface. See `http://www.mathworks.com/support/compilers/current_release/`.
- If the input MATLAB function has runtime errors, the errors are not caught when you run the multi-threaded MEX file. Before you use the `dspunfold` function, call `codegen` on the MATLAB function and make sure that the MEX file is generated successfully.
- If the generated code uses a large amount of memory to store the local variables, around `4 MB` on Windows platform, the generated multi-threaded MEX file can have unexpected behavior. This limit varies with each platform. As a workaround, reduce

the size of the input signals or restructure the MATLAB function to use less local memory.

- `dspunfold` does not support:

  - `varargin` and `varargout` inside the MATLAB function
  - variable-size inputs and outputs
  - P-coded entry-point MATLAB functions
  - cell arrays as inputs and outputs

Analyzer Limitations:

The following limitations apply to the analyzer function generated by the `dspunfold` function. For more information on the analyzer function, see 'Self-Diagnostic Analyzer' in the 'More About' section of `dspunfold`.

- If multiple frames of the analyzer input are identical, the analyzer might throw false positive pass results. It is recommended that you provide at least two different frames for each input of the analyzer.
- If the algorithm in the entry-point MATLAB function chooses its state length based on the input values, the analyzer might provide different *pass* results for different input values. For an example, see the `FIR_Mean` function in “Why Does the Analyzer Choose the Wrong State Length?”.
- If the input to the entry-point MATLAB function does affect the output immediately, the analyzer might throw false positive *pass* results. For an example, see the `Input_Output` function in “Why Does the Analyzer Choose a Zero State Length?”.
- If the output results of the multi-threaded MEX file and single-threaded MEX file match statistically but do not match numerically, the analyzer does not pass. Consider the `FilterNoise` function that follows, which filters a random noise signal with an FIR filter. The function calls `randn` from within itself to generate random noise. Hence, the output results of the `FilterNoise` function match statistically but not match numerically.

  ```
  function Output = FilterNoise(x)

  persistent FIRFilter
  if isempty(FIRFilter)
      FIRFilter = dsp.FIRFilter('Numerator',fir1(12,0.4));
  end
  Output = FIRFilter(x+randn(1000,1));
  ```

```
end
```

When you run the automatic state length detection tool run on `FilterNoise`, the tool detects an infinite state length. Because the tool cannot find a numerical match for a finite state length, it chooses an infinite state length.

```
dspunfold FilterNoise -args {randn(1000,1)} -s auto
```

```
Analyzing input MATLAB function FilterNoise

> In coder.internal.warning (line 8)
  In FilterNoise_analyzer
ans =
    Latency: 8
    Speedup: 0.4970
       Pass: 0
```

The analyzer looks for a numerical match and fails the verification, even though the generated multi-threaded MEX file is valid.

Speedup Limitations:

- If the entry-point MATLAB function contains code with low complexity, MATLAB overhead or multi-threaded MEX overhead overshadow any performance gains. In such cases, do not use `dspunfold`.
- If the number of operations in the input MATLAB function is small compared to the size of the input or output data, the multi-threaded MEX file does not provide any speedup gain. Sometimes, it can result in a speedup loss, even if the repetition value is increased. In such cases, do not use `dspunfold`.

More About

State Length

State length of the algorithm.

Most of the time, the state length used by `dspunfold` matches the state length of the algorithm in the entry-point MATLAB function. If the algorithm is simple, state length is easy to determine. For example, the state length of an FIR filter is the number of taps in the filter – `1`. In some scenarios, to optimize speedup, `dspunfold` chooses a state length that is different from the algorithm state length or the state length specified using the `-s` option. For example, when the state length is greater than ($threads - 1$) × *repetition* frames, `dspunfold` considers the state length to be infinite. Also, multi-threading gets disabled due to performance considerations.

Automatic State Length Detection

You can automatically detect the minimum state length for which the outputs of the multi-threaded MEX and single-threaded MEX match.

In complex algorithms, it is not easy to determine the state length analytically. In such scenarios, use the analyzer to compute the state length. When you set `-s` to `auto`, `dspunfold` invokes the analyzer. The analyzer computes the outputs for different state lengths and detects the minimum state length for which the outputs of the multi-threaded MEX file and single-threaded MEX file match. The analyzer uses the numeric value of the inputs given to `-args`. To detect the most efficient state length, provide random inputs to `-args`. In this mode, you cannot input `coder.typeof` to `arguments`. Due to the extra analysis this tool requires, the time to generate the MEX file increases.

When you use automatic state length detection on an algorithm with code paths that depend on the input values, use inputs that choose the code path with the longest state length. Also, the inputs must have an immediate effect on the output. If inputs choose a code path that triggers runtime errors, automatic state length detection stops, and so does the analyzer. Make sure that the MATLAB function supports code generation and does not have run-time errors for the inputs under test. Before invoking `dspunfold`, call `codegen` on the entry-point MATLAB function. In addition, simulate the entry-point MATLAB function to make sure it has no run-time errors.

Threads

The `-t` option specifies the number of threads used by the multi-threaded MEX file.

Increasing this value can improve the multi-threaded MEX speedup, at the cost of a larger latency. Decreasing this value reduces the latency and potentially decreases the multi-threaded MEX speedup.

Repetition Factor

Repetition factor is the number of consecutive frames processed by each thread in one processing step.

Increasing this value reduces the overhead per frame of data, potentially improving the speedup at the cost of larger latency. Decreasing this value reduces the latency, and potentially decreases the multi-threaded MEX speedup.

Self-Diagnostic Analyzer

The self-diagnostic analyzer function is a help tool that is generated with the MEX file. This function measures the speedup gain of the multi-threaded MEX file compared to the single-threaded MEX file. The analyzer function also verifies that the outputs of the multi-threaded MEX file and single-threaded MEX file match.

If you specify an incorrect state length value, the outputs usually do not match. To check for the numerical match between the multi-threaded MEX file and the single-threaded MEX file, provide at least two different frames for each input argument of the analyzer. The frames are appended along the first dimension. The analyzer alternates between these frames while verifying that the outputs match. Failure to provide multiple frames for each input can decrease the effectiveness of the analyzer and can lead to false positive verification results. In other words, the analyzer might produce *pass* `= 1` results even when an incorrect state length value is specified. The analyzer alternates through a maximum of 3 × (2 × *threads* × *repetition*) frames. If your algorithm requires more than 3 × (2 × *threads* × *repetition*) frames to verify the results, then the analyzer cannot verify accurately.

Tips

General

- Do not display plots, scopes, or execute other user interface operations from within the multi-threaded MEX file. The generated MEX file can have unexpected behavior.
- Do not use `coder.extrinsic` inside the input MATLAB function. The generated MEX file can have unexpected behavior.

When the state length is less than or equal to (*threads* `- 1`) × *repetition* frames:

- Do not use a random number inside the MATLAB function. The outputs of the single-threaded MEX file and the multi-threaded MEX file might not match. Also, the outputs of the consecutive executions of the multi-threaded MEX file might not match. The analyzer might not pass the numerical match verification.

  It is recommended that you generate the random number outside the entry-point MATLAB function and pass it as an argument to the function.
- Do not use global or persistent variables anywhere other than in the entry-point MATLAB function. For example, avoid using persistent variables in subfunctions. The

generated MEX file can produce inaccurate results. In general, global variables are not recommended.

- Do not access I/O resources from within the multi-threaded MEX file. The generated MEX file can have unexpected behavior. These resources include file writers and readers, UDP sockets, and audio players and recorders.
- Do not use functions with interactive inputs (for example, the keyboard) inside the multi-threaded MEX file. The generated MEX file can have unexpected behavior.

Workflow

- To generate a valid multi-threaded MEX file with the required speedup and latency, follow the "Workflow for Generating a Multi-Threaded MEX File using dspunfold".
- Before using `dspunfold`, call `codegen` on the entry-point MATLAB function and make sure that the function generates a MEX file successfully.
- After generating the multi-threaded MEX file using `dspunfold`, run the analyzer function. Make sure that the analyzer function passes. The exception to this rule is when the algorithm produces results that match statistically, but not numerically. In this exception, the analyzer function does not `pass`, even though the `dspunfold` function generates a valid multi-threaded MEX file. See 'Analyzer Limitations' for an example.
- For help on using the MEX file and analyzer, at the MATLAB command prompt, enter `help <mexfile name>` and `help <analyzer name>`.

State Length

- If you choose a state length that is greater than or equal to the value of the exact state length, the analyzer passes. If the analyzer fails, increase the state length, regenerate the MEX file, and verify again.
- If the state length is greater than `0`, the inputs marked as frames (through `-f` option) must all have the same dimensions.
- When generating the MEX file and running the analyzer, use inputs that invoke the same state length.

Automatic State Length Detection

When you set `-s` to `auto`:

- If the algorithm in the entry-point MATLAB function chooses a code path based on the input values, use inputs that choose the code path with the longest state length.
- Provide random inputs to `-args`.

- Choose inputs that have an immediate effect on the output. See "Why Does the Analyzer Choose a Zero State Length?".

Analyzer

- Make sure the outputs of the multi-threaded MEX file and the single-threaded MEX file do not contain `NaN` or an `Inf`. The analyzer cannot do numeric checks and returns `pass` as `false`. The automatic state length detection tool detects infinite state length and displays a warning

> **Warning:** The output results of the multi-threaded MEX file do not match the output results of the single-threaded MEX file even for Infinite state length. A possible reason is that input MATLAB function generates different output results between consecutive runs even for the same input values.

- Provide multiple frames with different values for each input of the analyzer.
  To improve the analyzer effectiveness, append successive frames along the first dimension.
- Provide inputs to the analyzer that lead to efficient code coverage.

Speedup

- To improve the speedup of the multi-threaded MEX file, specify the exact state length in samples. You can specify the state length in samples by setting at least one entry of `frameinputs` to `true`. The use of samples reduces the overhead and increases the speedup.
- To increase the speedup at the cost of larger latency, you can:
  - Increase the repetition factor. Use the `-r` option.
  - Increase the number of threads. Use the `-t` option.
- For each input that can be divided into samples without altering the algorithm behavior, set frame status to `true` using the `-f` option. The input is then considered in samples, which can increase the speedup of the generated multi-threaded MEX file.

Algorithms

The multi-threaded MEX file buffers multiple-input signal frames into a buffer of 2 × *threads* × *repetition* frames, where *threads* is the number of threads, and *repetition* is the repetition factor. The MEX file processes these frames simultaneously, using multiple cores. This process introduces some deterministic latency, where *latency* = 2 × *threads* × *repetition*. Latency is traded off with the speedup you might gain by increasing the number of threads or the repetition factor.

Introduced in R2015b

ellip

Elliptic filter using specification object

Syntax

```
ellipFilter = design(d,'ellip','SystemObject',true)
ellipFilter = design(d,'ellip',designoption,value,designoption,...
value,...,'SystemObject',true)
```

Description

`ellipFilter = design(d,'ellip','SystemObject',true)` designs an elliptical IIR digital filter using the specifications supplied in the object `d`.

`ellipFilter = design(d,'ellip',designoption,value,designoption,... value,...,'SystemObject',true)` returns an elliptical or Cauer FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `ellip`, refer to the command line help system. For example, to get specific information about using `ellip` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'ellip')
```

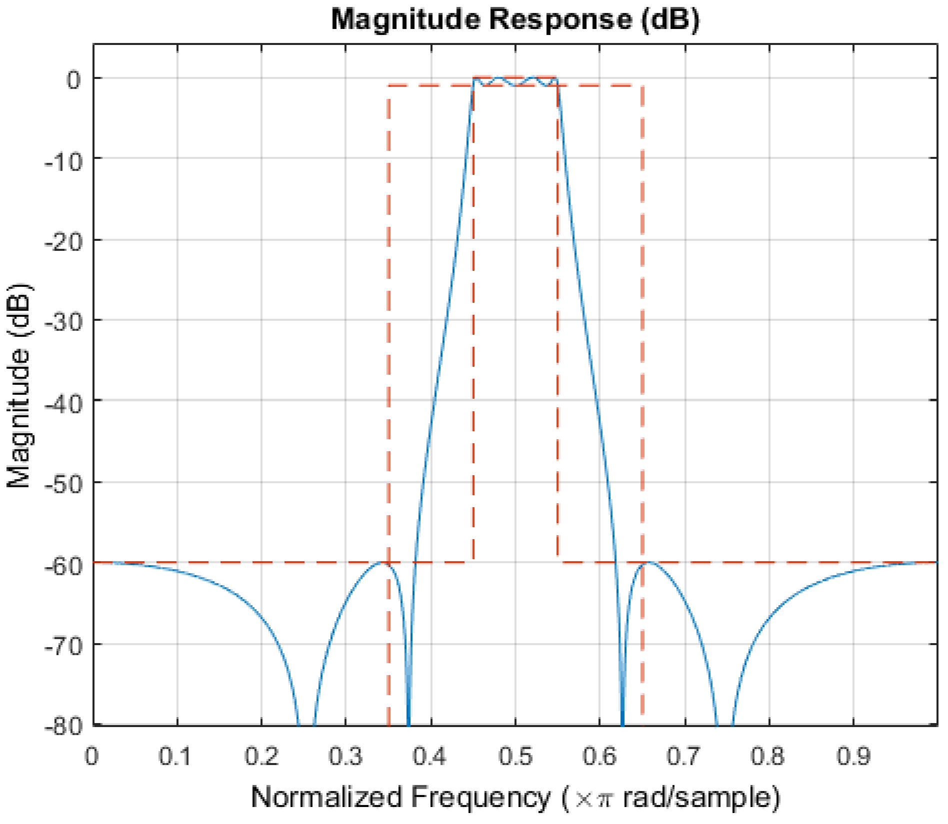
Examples

These examples demonstrate how to use `ellip` to design filters based on filter specification objects.

Design a Bandpass Filter

Construct the default bandpass filter specification object and design an elliptic filter.

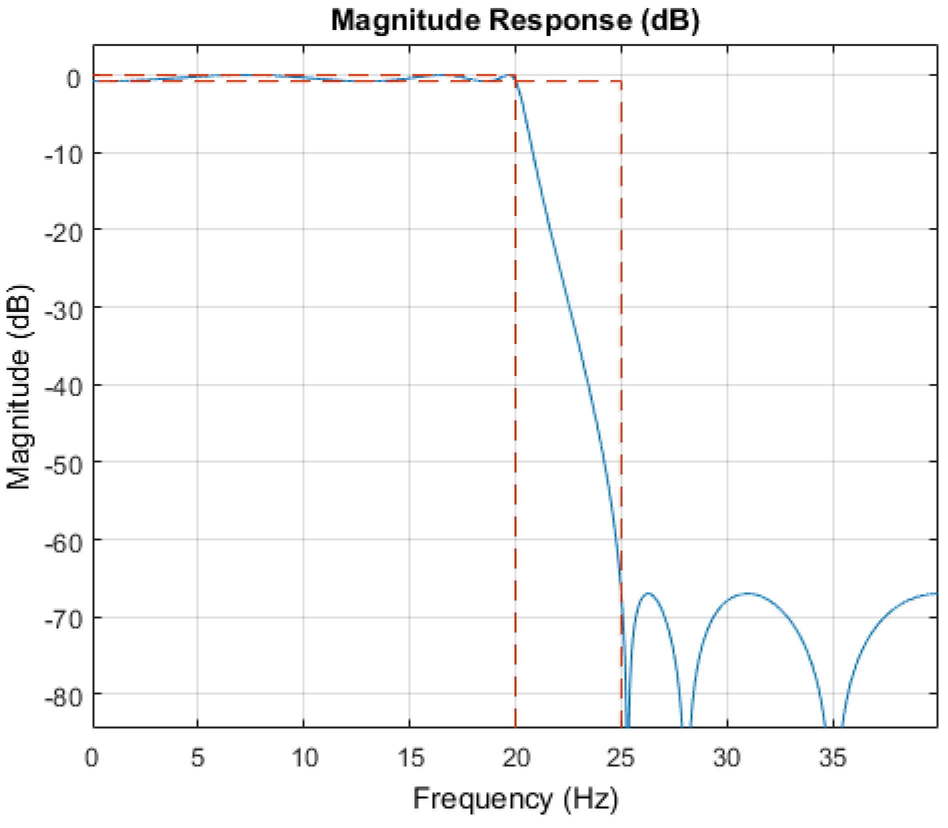
```
d = fdesign.bandpass;
bandpass = design(d,'ellip','matchexactly','both','SystemObject',true);
fvtool(bandpass);
```



Design Lowpass Filter

Construct a lowpass object with order, passband-edge frequency, stopband-edge frequency, and passband ripple specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,fst,ap',6,20,25,.8,80);
design(d,'ellip','SystemObject',true); % Starts fvtool to display the filter.
```



Construct a lowpass object with filter order, passband edge frequency, passband ripple, and stopband attenuation specifications, and then design an elliptic filter.

```
d = fdesign.lowpass('n,fp,ap,ast',6,20,.8,60,80);
design(d,'ellip','SystemObject',true); % Starts fvtool to display the filter.
```

Introduced in R2011a

euclidfactors

Euclid factors for multirate filter

Compatibility

`mfilt` will be removed in a future release. See dsp.CICDecimator, dsp.CICInterpolator, dsp.FIRDecimator, dsp.FIRInterpolator, dsp.FilterCascade, dsp.FarrowRateConverter, dsp.FIRRateConverter, dsp.IIRHalfbandDecimator, or dsp.IIRHalfbandInterpolator instead.

Syntax

```
[lo,mo] = euclidfactors(hm)
```

Description

`[lo,mo] = euclidfactors(hm)` returns integer factors `lo` and `mo` such that (`lo`*L)-(`mo`*M) = -1. L and M are relatively prime and represent the interpolation and decimation factors of the multirate filter `hm`.

`euclidfactors` works with the multirate filter `mfilt.firsc`. You cannot return `lo` and `mo` for decimators or interpolators.

Examples

Use an FIR fractional decimator, with L = 5 and M = 7, to show what `euclidfactors` does.

Indeed, (`lo`*L)-(`mo`*M) = (4*5)-(3*7) = -1.

equiripple

Equiripple single-rate FIR filter from specification object

Syntax

```
equiFilt = design(d,'equiripple','SystemObject',true)
equiFilt =
design(d,'equiripple',designoption,value,...,'SystemObject',true)
```

Description

`equiFilt = design(d,'equiripple','SystemObject',true)` designs an equiripple FIR digital filter using the specifications supplied in the object `d`. Equiripple filter designs minimize the maximum ripple in the passbands and stopbands.

When you use `equiripple` with Nyquist filter specification objects, you might encounter design cases where the filter design does not converge. Convergence errors occur mostly at large filter orders, or small transition widths, or large stopband attenuations. These specifications, alone or combined, can cause design failures. For more information, refer to `fdesign.nyquist` in the online Help system.

`equiFilt =`
`design(d,'equiripple',designoption,value,...,'SystemObject',true)` returns an equiripple FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `equiripple`, refer to the command line help system. For example, to get specific information about using `equiripple` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'equiripple')
```

Examples

Design a Single-Rate Equiripple Filter

Design a single-rate equiripple filter from a halfband filter specification object. Notice the help command used to learn about the options for the specification object and method.

```
d = fdesign.halfband('tw,ast',0.1,80);
designmethods(d,'Systemobject',true)

Design Methods that support System objects for class fdesign.halfband (TW,Ast):

ellip
iirlinphase
equiripple
kaiserwin

help(d,'equiripple')

 DESIGN Design a Equiripple FIR filter.
    HD = DESIGN(D, 'equiripple') designs a Equiripple filter specified by the
    FDESIGN object D, and returns the DFILT/MFILT object HD.

    HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD,
    using a System object instead of a DFILT/MFILT object.

    HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
    structure STRUCTURE.  STRUCTURE is 'dffir' by default and can be any of
    the following:

    'dffir'
    'dffirt'
    'dfsymfir'
    'fftfir'

    Some of the listed structures may not be supported by System object
    filters. Type validstructures(D, 'equiripple', 'SystemObject', true) to
    get a list of structures supported by System objects.
```

```
    HD = DESIGN(..., 'MinPhase', MPHASE) designs a minimum-phase filter
    when MPHASE is TRUE.  MPHASE is FALSE by default.

    HD = DESIGN(..., 'StopbandShape', SHAPE) designs a filter whose stopband
    has the shape defined by SHAPE.  SHAPE can be 'flat', '1/f', or 'linear'.
    SHAPE is 'flat' by default.

    HD = DESIGN(..., 'StopbandDecay', DECAY) specifies the decay to use when
    'StopbandShape' is not set to 'flat'.  When the shape is '1/f' this
    specifies the power that 1/f is raised.  When shaped is 'linear' this
    specifies the slope of the stopband in dB/rad/s.

    % Example #1 - Design a halfband lowpass equiripple filter with increased stopband
       TW = 0.1; % Transition Width
       Ast = 80; % Stopband Attenuation (dB)
       h  = fdesign.halfband('Type','Lowpass','TW,Ast',TW,Ast);
       Hd = design(h, 'equiripple', 'StopbandShape','linear','StopbandDecay',50);
       fvtool(Hd)
```

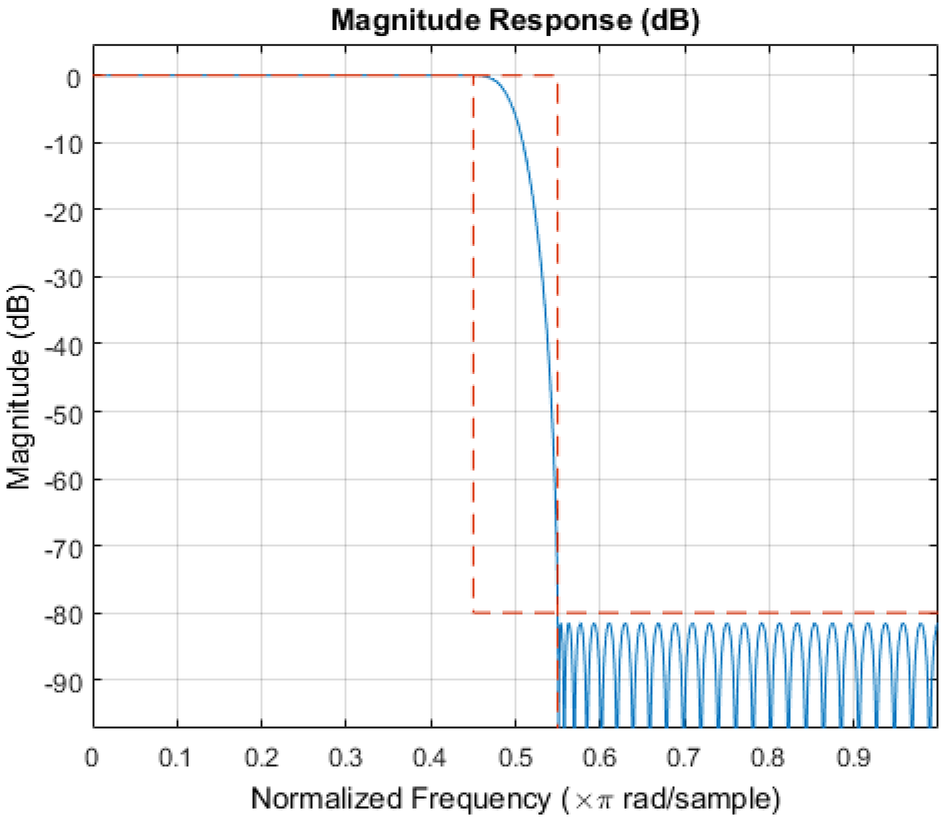
```
designopts(d,'equiripple')
```

```
ans =

  struct with fields:

    FilterStructure: 'dffir'
           MinPhase: 0
      StopbandShape: 'flat'
      StopbandDecay: 0
       SystemObject: 0
```

```
equiFilt = design(d,'equiripple','stopbandshape','flat','SystemObject',true);
fvtool(equiFilt);
```



The `fvtool` shows the equiripple nature of the filter.

Design an Equiripple FIR Filter with a Direct-Form Transposed Structure

This example designs an equiripple filter with a direct-form transposed structure by specifying the 'FilterStructure' argument. To set the design options for the filter, use the `designopts` method and options object `opts`.

```
d = fdesign.lowpass('fp,fst,ap,ast');
opts = designopts(d,'equiripple');
opts.FilterStructure='dffirt';
opts.DensityFactor=20
```

```
opts = 

  struct with fields:

    FilterStructure: 'dffirt'
      DensityFactor: 20
           MinPhase: 0
           MaxPhase: 0
           MinOrder: 'any'
      StopbandShape: 'flat'
      StopbandDecay: 0
        UniformGrid: 1
       SystemObject: 0
```

```
firFilt = design(d,'equiripple','SystemObject',true,opts)
```

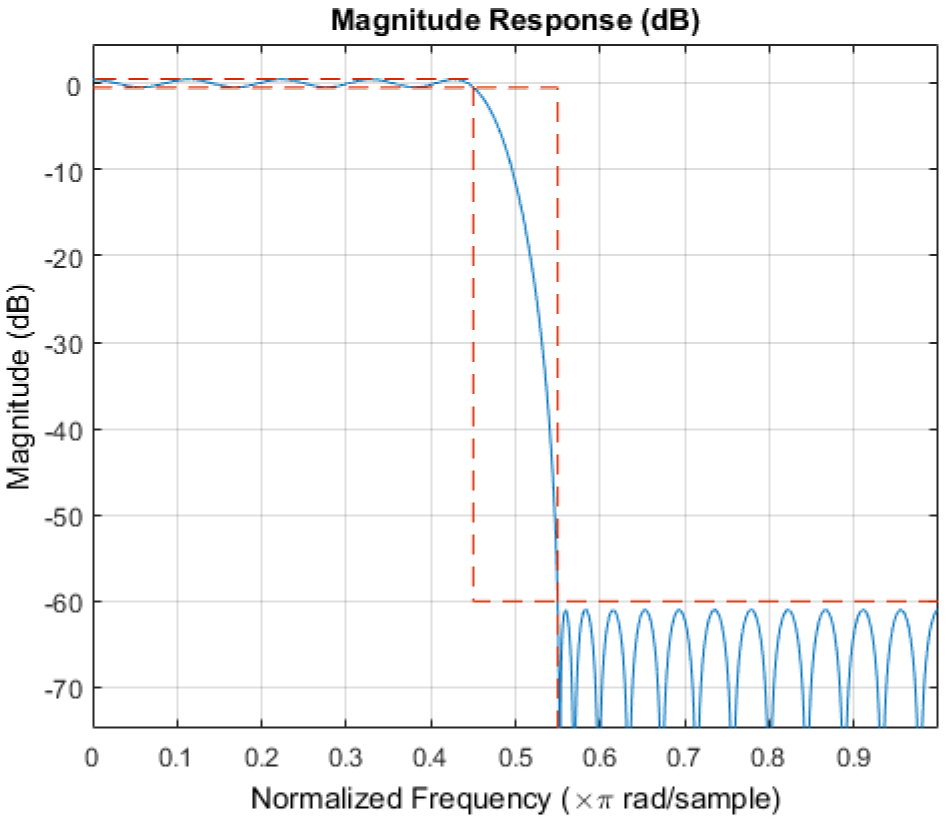
```
firFilt = 

  dsp.FIRFilter with properties:

            Structure: 'Direct form transposed'
      NumeratorSource: 'Property'
            Numerator: [1×43 double]
    InitialConditions: 0

  Use get to show all properties
```

```
fvtool(firFilt);
```



The MaxPhase design option for equripple FIR filters is currently only available for lowpass, highpass, bandpass, and bandstop filters.

fcfwrite

Write file containing filter coefficients

Syntax

```
fcfwrite(h)
fcfwrite(h,filename)
fcfwrite(...,'fmt')
```

Description

`fcfwrite(h)` writes a filter coefficient ASCII file in a folder you choose, or your current MATLAB working folder. `h` can be a single filter object or a vector of filter objects. On execution, `fcfwrite` opens the **Export Filter Coefficients to .FCF File** dialog box to let you assign a file name for the output file. You can choose the destination folder within this dialog as well.

The default file name is `untitled.fcf`. When you have DSP System Toolbox software, you can use `fcfwrite(h)` to write filter coefficient files for multirate filters, adaptive filters, and discrete-time filters.

`fcfwrite(h,filename)` writes the filter coefficients and general information to a text file called `filename` in your present MATLAB working folder and opens the file in the MATLAB editor for you to review or modify.

If you do not include a file extension in `filename`, `fcfwrite` adds the extension `fcf` to `filename`.

`fcfwrite(...,'fmt')` writes the filter coefficients in the format specified by the input argument `fmt`. Valid `fmt` values are `hex` for hexadecimal, `dec` for decimal, or `bin` for binary representation of the filter coefficients.

Examples

To demonstrate `fcfwrite`, create a fixed-point IIR filter at the command line, and then write the filter coefficients to a file named `iirfilter.fcf`.

```
d=fdesign.lowpass;
hd=design(d,'butter');
set(hd,'arithmetic','fixed');
fcfwrite(hd,'iirfilter.fcf');
```

Here is the output from `fcfwrite` as it appears in the MATLAB editor. Not shown here is the filename — `iirfilter.fcf` as specified and some comments at the top of the file.

```

`dfilt`

Introduced in R2011a

filterDesigner

Open Filter Designer app

Syntax

`filterDesigner`

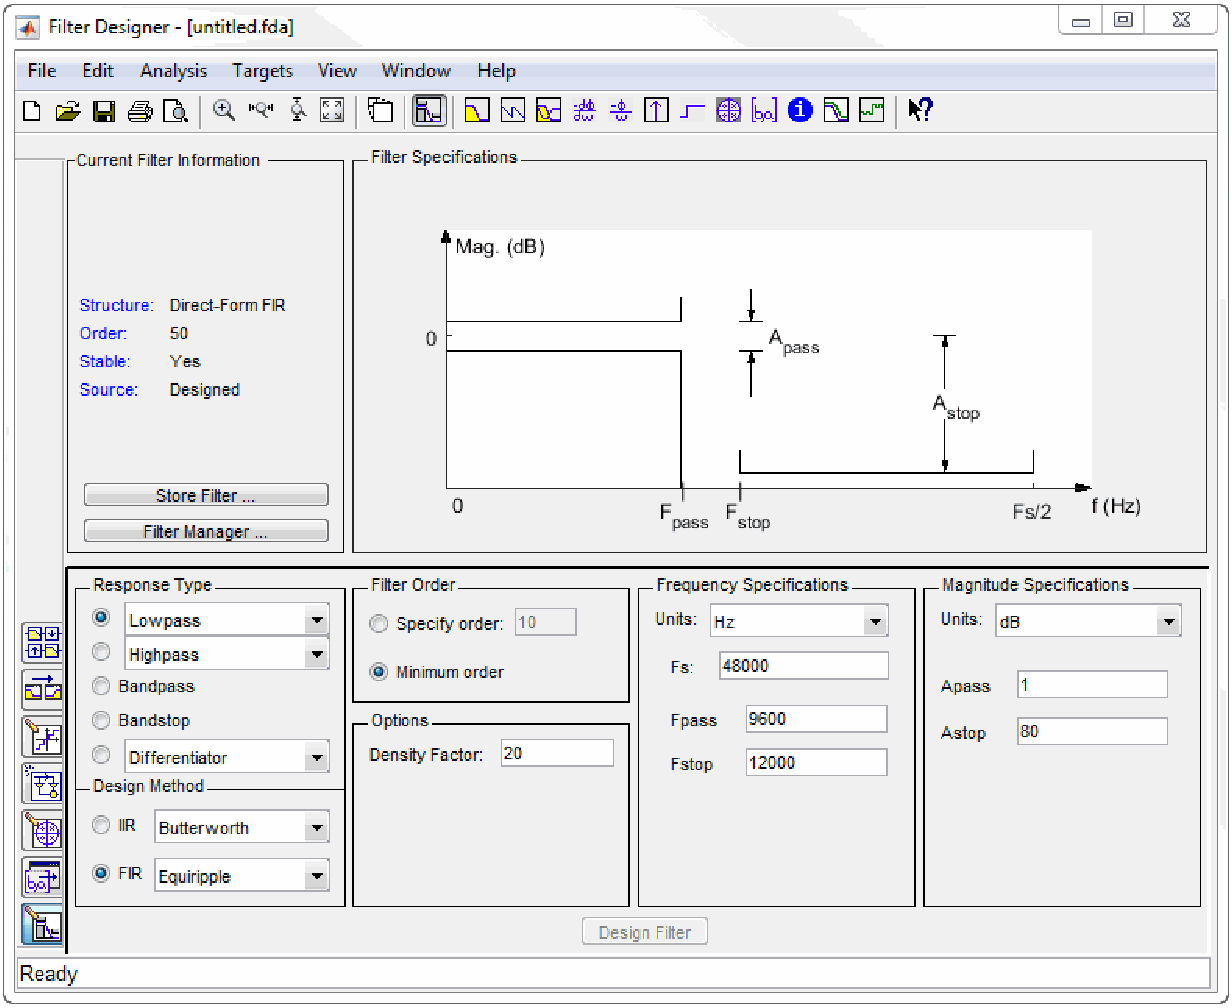
Description

`filterDesigner` opens the Filter Designer app. Use this tool to:

- Design filters
- Quantize filters (with DSP System Toolbox software installed)
- Analyze filters
- Modify existing filter designs
- Create multirate filters (with DSP System Toolbox software installed)
- Realize Simulink models of quantized, direct-form, FIR filters (with DSP System Toolbox software installed)
- Perform digital frequency transformations of filters (with DSP System Toolbox software installed)

Refer to "Use Filter Designer with DSP System Toolbox Software" for more information about using the analysis, design, and quantization features of filter designer. For general information about using filter designer, refer to "Using Filter Designer".

When you open the filter designer app and you have DSP System Toolbox software installed, filter designer incorporates features that are added by DSP System Toolbox software. With DSP System Toolbox software installed, filter designer lets you design and analyze quantized filters, as well as convert quantized filters to various filter structures, transform filters, design multirate filters, and realize models of filters.



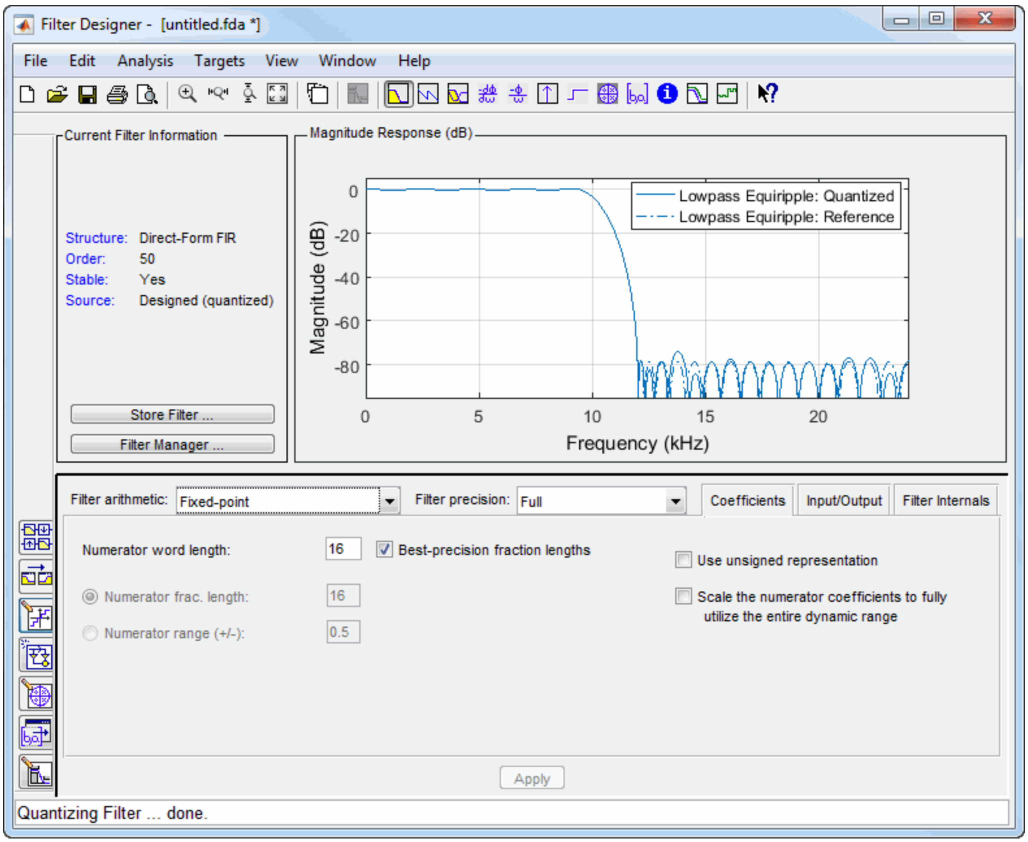
Use the buttons on the sidebar to configure the design area to use various tools in the filter designer app.

Set Quantization Parameters — provides access to the properties of the quantizers that compose a quantized filter. When you click **Set Quantization Parameters**, you see filter designer displaying the quantization options at the bottom of the dialog box (the design area), as shown in the figure.

Transform Filter — clicking this button opens the *Frequency Transformations* pane so you can use digital frequency transformations to change the magnitude response of your filter.

Create a multirate filter — clicking this button switches filter designer to multirate filter design mode so you can design interpolators, decimators, and fractional rate change filters.

Realize Model — starting from your quantized, direct-form, FIR filter, clicking this button creates a Simulink model of your filter structure in new model window.



Other options in the menu bar let you convert the filter structure to a new structure, change the order of second-order sections in a filter, or change the scaling applied to the filter, among many possibilities.

Examples

- "Use Filter Designer with DSP System Toolbox Software"

Tips

By incorporating many advanced filter design methods from DSP System Toolbox software, filter designer provides more design methods than the SPTool Filter Designer.

fdesign

Filter specification object

Syntax

```
filtSpecs = fdesign.response
filtSpecs = fdesign.response(spec)
filtSpecs = fdesign.response(...,Fs)
filtSpecs = fdesign.response(...,magunits)
```

Description

Filter Specification Objects

`filtSpecs = fdesign.`*`response`* returns a filter specification object, `filtSpecs`, of filter response *`response`*. To create filters from `filtSpecs`, use one of the design methods listed in "Using Filter Design Methods with Specification Objects" on page 5-509.

Note: Several of the filter response types described below are only available if your installation includes the DSP System Toolbox. The DSP System Toolbox significantly expands the functionality available for the specification, design, and analysis of filters.

Here is how you design filters using `fdesign`.

1. Use `fdesign.`*`response`* to construct a filter specification object.
2. Use `designmethods` to determine which filter design methods work for your new filter specification object.
3. Use `design` to apply your filter design method from step 2 to your filter specification object to construct a filter object.
4. Use FVTool to inspect and analyze your filter object.

Note `fdesign` does not create filters. `fdesign` returns a filter specification object that contains the specifications for a filter, such as the passband cutoff or attenuation in the stopband. To design a filter from a filter specification object `filtSpecs`, use `filtSpecs` with a filter design method such as `butter` — `IIRbutter = design(filtSpecs,'butter','SystemObject',true)`.

`response` can be one of the entries in the following table that specify the filter response desired, such as a bandstop filter or an interpolator.

fdesign Response Method	Description
`arbgrpdelay`	`fdesign.arbgrpdelay` creates an object to specify allpass arbitrary group delay filters. Requires the DSP System Toolbox
`arbmag`	`fdesign.arbmag` creates an object to specify IIR filters that have arbitrary magnitude responses defined by the input arguments.
`arbmagnphase`	`fdesign.arbmagnphase` creates an object to specify IIR filters that have arbitrary magnitude and phase responses defined by the input arguments. Requires the DSP System Toolbox.
`audioweighting`	`fdesign.audioweighting` creates a filter specification object for audio weighting filters. The supported audio weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. Requires the DSP System Toolbox
`bandpass`	`fdesign.bandpass` creates an object to specify bandpass filters.
`bandstop`	`fdesign.bandstop` creates an object to specify bandstop filters.
`ciccomp`	`fdesign.ciccomp` creates an object to specify filters that compensate for the CIC decimator or interpolator response curves. Requires the DSP System Toolbox.
`comb`	`fdesign.comb` creates an object to specify a notching or peaking comb filter. Requires the DSP System Toolbox.
`decimator`	`fdesign.decimator` creates an object to specify decimators. Requires the DSP System Toolbox

fdesign Response Method	Description
`differentiator`	`fdesign.differentiator` creates an object to specify an FIR differentiator filter.
`fracdelay`	`fdesign.fracdelay` creates an object to specify fractional delay filters. Requires the DSP System Toolbox.
`halfband`	`fdesign.halfband` creates an object to specify halfband filters. Requires the DSP System Toolbox.
`highpass`	`fdesign.highpass` creates an object to specify highpass filters.
`hilbert`	`fdesign.hilbert` creates an object to specify an FIR Hilbert transformer.
`interpolator`	`fdesign.interpolator` creates an object to specify interpolators. Requires the DSP System Toolbox.
`isinchp`	`fdesign.isinchp` creates an object to specify an inverse sinc highpass filter. Requires the DSP System Toolbox.
`isinclp`	`fdesign.isinclp` creates an object to specify an inverse sinc lowpass filters. Requires the DSP System Toolbox.
`lowpass`	`fdesign.lowpass` creates an object to specify lowpass filters.
`notch`	`fdesign.notch` creates an object to specify notch filters. Requires the DSP System Toolbox.
`nyquist`	`fdesign.nyquist` creates an object to specify Nyquist filters. Requires the DSP System Toolbox.
`octave`	`fdesign.octave` creates an object to specify octave and fractional octave filters. Requires the DSP System Toolbox.
`parameq`	`fdesign.parameq` creates an object to specify parametric equalizer filters. Requires the DSP System Toolbox.
`peak`	`fdesign.peak` creates an object to specify peak filters. Requires the DSP System Toolbox.
`polysrc`	`fdesign.polysrc` creates an object to specify polynomial sample-rate converter filters. Requires the DSP System Toolbox.

fdesign Response Method	Description
`rsrc`	`fdesign.rsrc` creates an object to specify rational-factor sample-rate convertors. Requires the DSP System Toolbox.

Use the `doc fdesign.`*`response`* syntax at the MATLAB prompt to get help on a specific structure. Using `doc` in a syntax like

```
doc fdesign.lowpass
doc fdesign.bandstop
```

gets more information about the lowpass or bandstop structure objects.

Each `response` has a property `Specification` that defines the specifications to use to design your filter. You can use defaults or specify the `Specification` property when you construct the specifications object.

Using the `Specification` property, you can provide filter constraints such as the filter order or the passband attenuation to use when you construct your filter from the specification object.

Properties

`fdesign` returns a filter specification object. Every filter specification object has the following properties.

Property Name	Default Value	Description
`Response`	Depends on the chosen type	Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.
`Specification`	Depends on the chosen type	Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency `Fc` or the filter order `N`.
`Description`	Depends on the filter type you choose	Contains descriptions of the filter specifications used to define the object, and the filter specifications

Property Name	Default Value	Description
		you use when you create a filter from the object. This is a read-only value.
`NormalizedFrequency`	Logical `true`	Determines whether the filter calculation uses normalized frequency from 0 to 1, or the frequency band from 0 to $F_s/2$, the sampling frequency. Accepts either `true` or `false` without single quotation marks. Audio weighting filters do not support normalized frequency.

In addition to these properties, filter specification objects may have other properties as well, depending on whether they design single-rate filters or multirate filters.

Added Properties for Multirate Filters	Description
`DecimationFactor`	Specifies the amount to decrease the sampling rate. Always a positive integer.
`InterpolationFactor`	Specifies the amount to increase the sampling rate. Always a positive integer.
`PolyphaseLength`	Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change factor filters. Total filter length is the product of `pl` and the rate change factors. `pl` must be an even integer.

`filtSpecs = fdesign.`*`response`*`(spec)`. In `spec`, you specify the variables to use that define your filter design, such as the passband frequency or the stopband attenuation. The specifications are applied to the filter design method you choose to design your filter.

For example, when you create a default lowpass filter specification object, `fdesign.lowpass` sets the passband frequency `Fp`, the stopband frequency `Fst`, the stopband attenuation `Ast`, and the passband ripple `Ap`:

```
filtSpecs = fdesign.lowpass
```

Use without a terminating semicolon to display the filter specifications.

The default specification `'Fp,Fst,Ap,Ast'` is only one of the possible specifications for `fdesign.lowpass`. To see all available specifications:

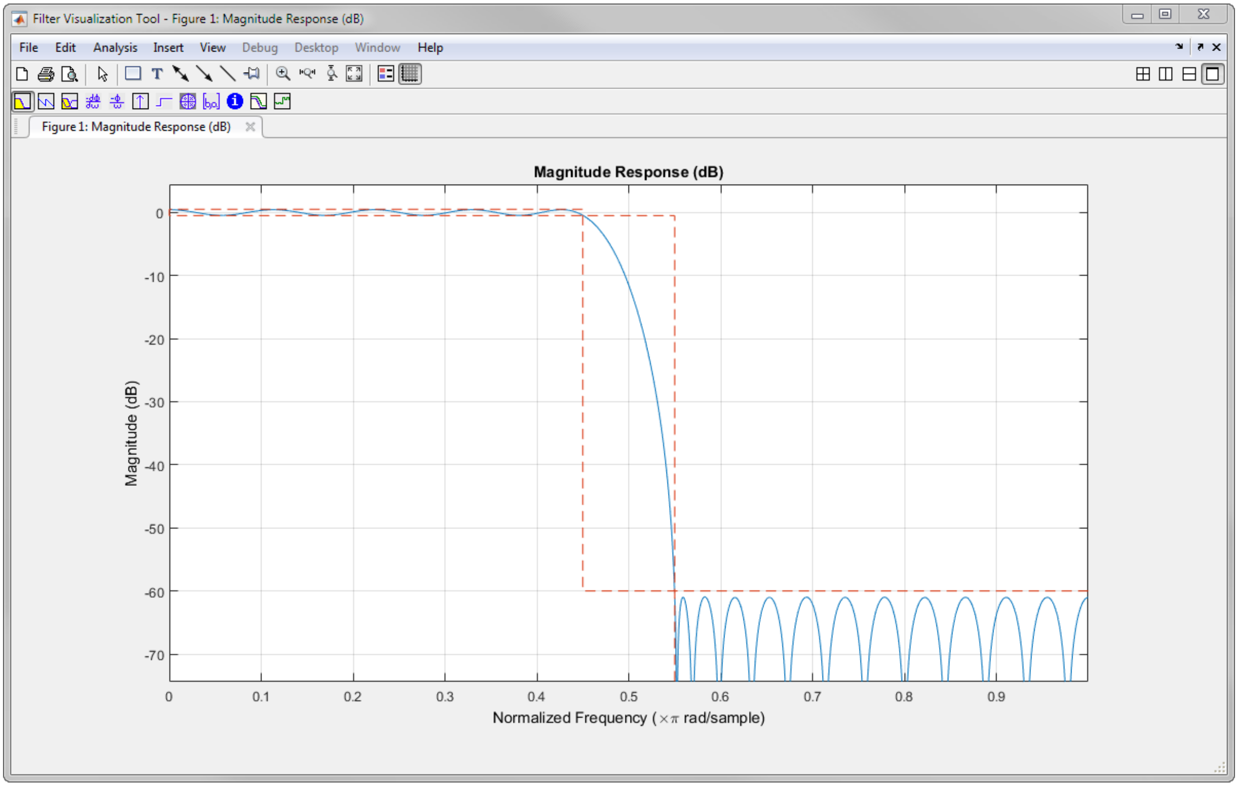
```
filtSpecs = fdesign.lowpass;
set(filtSpecs,'Specification')
```

The DSP System Toolbox software supports all available specification options. The Signal Processing Toolbox supports a subset of the specification options. See the reference pages for the filter specification object to determine which specification option your installation supports.

One important note is that the specification option you choose determines which design methods apply to the filter specifications object.

Specifications that do not contain the filter order result in minimum order designs when you invoke the `design` method:

```
filtSpecs = fdesign.lowpass;      % Specification is 'Fp,Fst,Ap,Ast'
FIReq = design(filtSpecs,'equiripple','SystemObject',true);
length(FIReq.Numerator)           % Returns 43. The filter order is 42
fvtool(FIReq)                     % View magnitude
```



`filtSpecs = fdesign.`*`response`*`(...,Fs)` specifies the sampling frequency in Hz to use in the filter specifications. The sampling frequency is a scalar trailing all other input arguments. If you specify a sampling frequency, all frequency specifications are in Hz.

`filtSpecs = fdesign.`*`response`*`(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of the following options:

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in decibels
- `'squared'` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Using Filter Design Methods with Specification Objects

After you create a filter specification object, you use a filter design method to implement your filter with a selected algorithm. Use `designmethods` to determine valid design methods for your filter specification object.

```
filtSpecs = fdesign.lowpass('N,Fc,Ap,Ast',10,0.2,0.5,40);
designmethods(filtSpecs)
% Design FIR equiripple filter
FIReq = design(filtSpecs,'equiripple','SystemObject',true);
```

When you use any of the design methods without providing an output argument, the resulting filter design appears in FVTool by default.

Along with filter design methods, `fdesign` works with supporting methods that help you create filter specification objects or determine which design methods work for a given specifications object.

Supporting Function	Description
`setspecs`	Set all of the specifications simultaneously.
`designmethods`	Return the design methods.
`designopts`	Return the input arguments and default values that apply to a specifications object and method

You can set filter specification values by passing them after the `Specification` argument, or by passing the values without the `Specification`.

Filter object constructors take the input arguments in the same order as `setspecs` and `Specification`. Enter `doc setspecs` at the prompt for more information about using `setspecs`.

When the first input to `fdesign` is not a valid `Specification` option like `'N,Fc'`, `fdesign` assumes that the input argument is a filter specification and applies it using the default `Specification` option — `'Fp,Fst,Ap,Ast'` for a lowpass object, for example.

Examples

Design of Lowpass Filter

This example requires the DSP System Toolbox product.

Design a lowpass filter to be used on a signal sampled at 96 kHz. The passband of the filter extends up to 20 kHz. The stopband of the filter starts at 24 kHz. Specify a passband ripple of 0.01 dB and a stopband attenuation of 80 dB. Determine automatically the order required to meet the specifications.

Set up the filter design specifications and determine the available design algorithms.

```
Fs = 96e3;
Fpass = 20e3;
Fstop = 24e3;
Apass = 0.01;
Astop = 80;

filtSpecs = fdesign.lowpass(Fpass,Fstop,Apass,Astop,Fs);
designmethods(filtSpecs)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Design an equiripple FIR filter and an elliptic IIR filter that meet the specifications. Measure the designs to verify that the filters satisfy the constraints.

```
lpFIR = design(filtSpecs,'equiripple','SystemObject',true);
lpIIR = design(filtSpecs,'ellip','SystemObject',true);

FIRmeas = measure(lpFIR)
IIRmeas = measure(lpIIR)
```

```
FIRmeas =

Sample Rate      : 96 kHz
Passband Edge    : 20 kHz
```

```
3-dB Point       : 21.4297 kHz
6-dB Point       : 21.8447 kHz
Stopband Edge    : 24 kHz
Passband Ripple  : 0.0092309 dB
Stopband Atten.  : 80.6014 dB
Transition Width : 4 kHz

IIRmeas =

Sample Rate      : 96 kHz
Passband Edge    : 20 kHz
3-dB Point       : 20.5524 kHz
6-dB Point       : 20.7138 kHz
Stopband Edge    : 24 kHz
Passband Ripple  : 0.01 dB
Stopband Atten.  : 80 dB
Transition Width : 4 kHz
```

Estimate and display the computational cost of each filter. The equiripple FIR filter requires many more coefficients than the elliptic IIR filter.

```
FIRcost = cost(lpFIR)
IIRcost = cost(lpIIR)
```

```
FIRcost =

  struct with fields:

                  NumCoefficients: 101
                        NumStates: 100
    MultiplicationsPerInputSample: 101
          AdditionsPerInputSample: 100

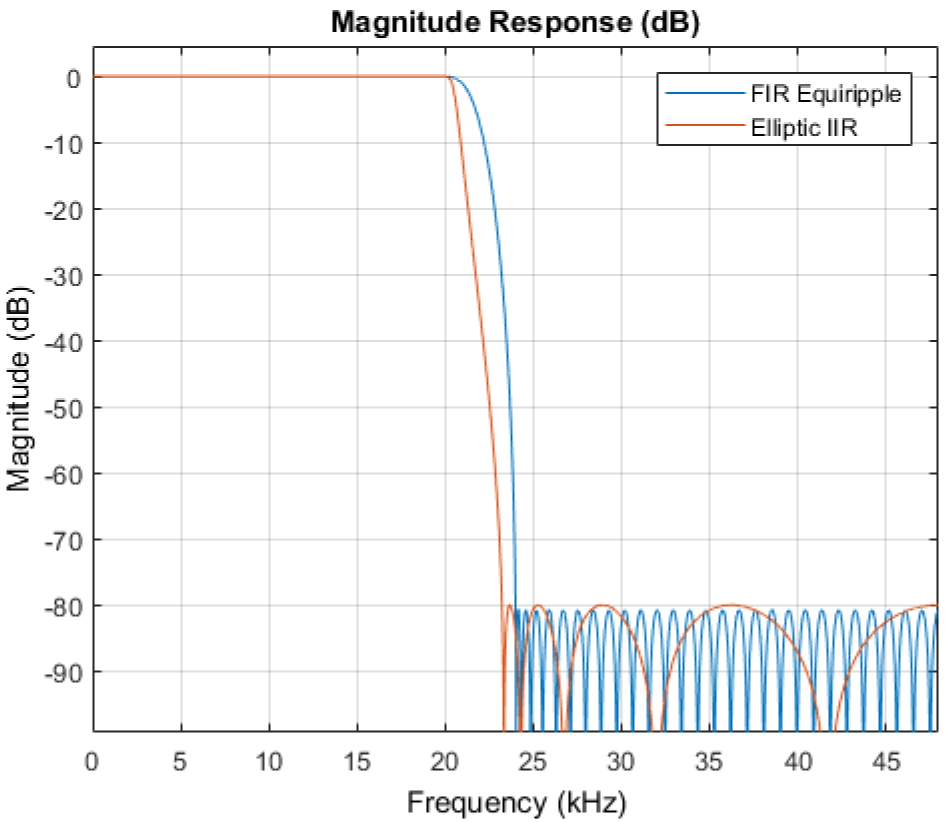
IIRcost =

  struct with fields:

                  NumCoefficients: 20
                        NumStates: 10
    MultiplicationsPerInputSample: 20
          AdditionsPerInputSample: 20
```

Visualize the resulting designs with FVTool to compare their properties.

```
fvtool(lpFIR,lpIIR,'Fs',Fs);
legend('FIR Equiripple','Elliptic IIR')
```



Design of Lowpass Decimator

This example requires the DSP System Toolbox product.

Design a 100-tap FIR lowpass decimator filter that reduces the sample rate of a signal from 60 kHz to 20 kHz. The passband of the filter extends up to 6 kHz. Specify a passband ripple of 0.01 dB and a stopband attenuation of 100 dB.

```
Fs = 60e3;
N = 99;
Fpass = 6e3;
Apass = 0.01;
Astop = 100;
M = Fs/20e3;

filtSpecs = fdesign.decimator(M,'lowpass','N,Fp,Ap,Ast',N,Fpass,Apass,Astop,Fs);
```

Design the filter and display information about it.

```
decimFIR = design(filtSpecs,'equiripple','SystemObject',true);
info(decimFIR)
```

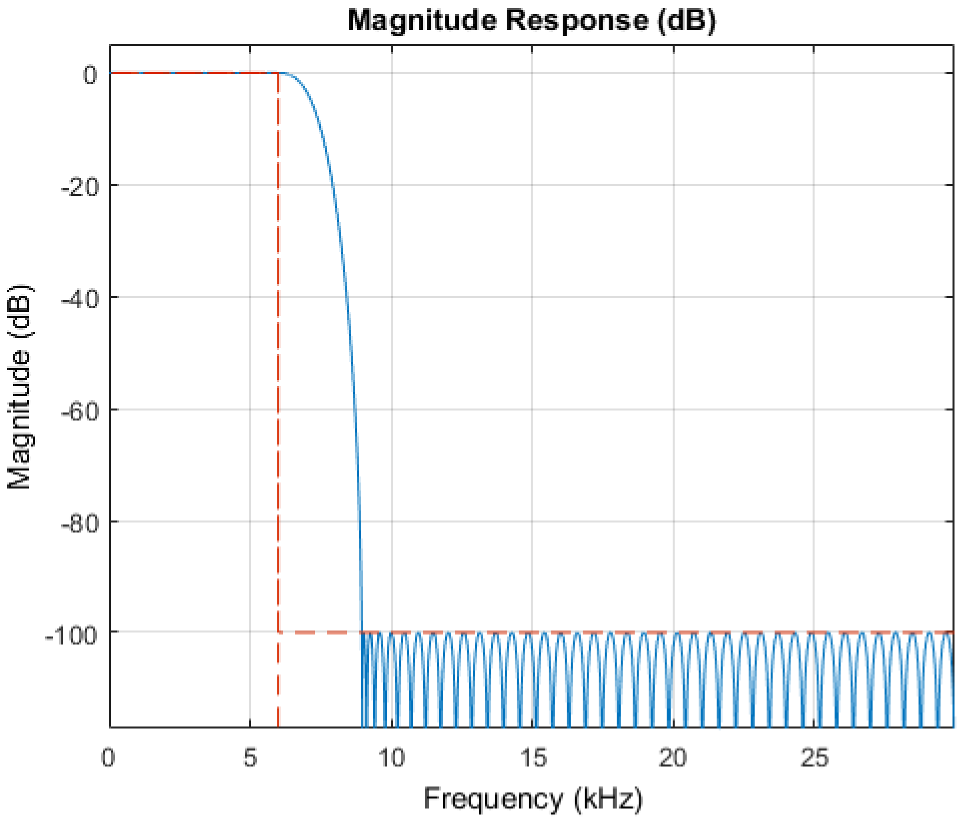
```
ans =

  10×56 char array

    'Discrete-Time FIR Multirate Filter (real)               '
    '-----------------------------------------               '
    'Filter Structure   : Direct-Form FIR Polyphase Decimator'
    'Decimation Factor  : 3                                  '
    'Polyphase Length   : 34                                 '
    'Filter Length      : 100                                '
    'Stable             : Yes                                '
    'Linear Phase       : Yes (Type 2)                       '
    '                                                        '
    'Arithmetic         : double                             '
```

Visualize the magnitude response of the filter.

```
fvtool(decimFIR,'Fs',Fs)
```



Lowpass Butterworth Filter Specification and Design

Use a filter specification object to construct a lowpass Butterworth filter with the default specification, `'Fp,Fst,Ap,Ast'`. Specify a passband edge frequency of 0.4π rad/sample, a stopband frequency of 0.5π rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 80 dB.

```
filtSpecs = fdesign.lowpass(0.4,0.5,1,80);
```

Determine which design methods apply to `filtSpecs`.

```
designmethods(filtSpecs)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

You can use `filtSpecs` and the `butter` design method to design a Butterworth filter. Determine the available design options.

```
designoptions(filtSpecs,'butter')
```

```
ans =

  struct with fields:

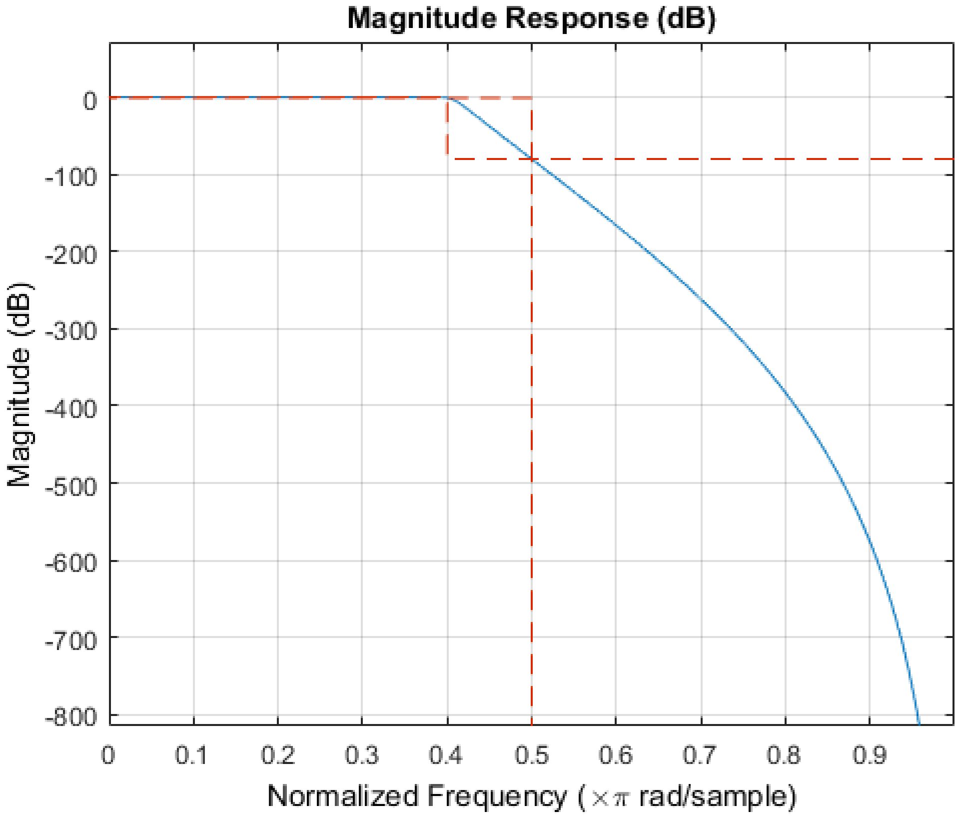
           FilterStructure: {1×6 cell}
              SOSScaleNorm: 'ustring'
              SOSScaleOpts: 'fdopts.sosscaling'
              MatchExactly: {'passband'  'stopband'}
              SystemObject: 'bool'
    DefaultFilterStructure: 'df2sos'
       DefaultMatchExactly: 'stopband'
       DefaultSOSScaleNorm: ''
       DefaultSOSScaleOpts: [1×1 fdopts.sosscaling]
       DefaultSystemObject: 0
```

The filter order necessary to meet a set of design constraints must also be rounded up to an integer value. This loosens some of the constraints, and, as a consequence, some design specifications are met while others are exceeded. The `'MatchExactly'` option allows you to match the passband or stopband exactly while exceeding the specification for the other band. Design the filter so that it matches the passband exactly.

```
IIRbutter = design(filtSpecs,'butter','MatchExactly','passband', ...
    'SystemObject',true);
```

Use FVTool to visualize the magnitude response of the filter.

```
fvtool(IIRbutter)
```



If you have the DSP System Toolbox software installed, the preceding figure appears with the filter specification mask.

Introduced in R2009a

fdesign.arbgrpdelay

Arbitrary group delay filter specification object

Syntax

```
D = fdesign.arbgrpdelay(SPEC)
D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)
D = fdesign.arbgrpdelay(N,F,Gd)
D = fdesign.arbgrpdelay(...,Fs)
```

Description

Arbitrary group delay filters are allpass filters you can use for correcting phase distortion introduced by other filters. `fdesign.arbgrpdelay` uses an iterative least *p*-th norm optimization procedure to minimize the phase response error [1].

`D = fdesign.arbgrpdelay(SPEC)` specifies an allpass arbitrary group delay filter with the `Specification` property set to `SPEC`. See "Input Arguments" on page 5-519 for a description of supported specifications.

`D = fdesign.arbgrpdelay(SPEC,SPEC1,SPEC2,...)` initializes the allpass arbitrary group delay filter specification object with specifications `SPEC1,SPEC2,...`. See SPEC for a description of supported specifications.

`D = fdesign.arbgrpdelay(N,F,Gd)` specifies an allpass arbitrary group delay filter. The filter order is equal to `N`, frequency vector equal to `F`, and group delay vector equal to `Gd`. See SPEC for a description of the filter order, frequency vector, and group delay vector inputs. See the example "Design an Allpass Filter With an Arbitrary Group Delay" on page 5-523 for an example using this syntax.

`D = fdesign.arbgrpdelay(...,Fs)` specifies the sampling frequency in hertz as a trailing scalar. If you do not specify a sampling frequency, all frequencies are normalized frequencies and group delay values are in samples. If you specify a sampling frequency, group delay values are in seconds.

Tips

If your arbitrary group delay design produces the error `Poorly conditioned Hessian matrix`, attempt one or more of the following:

- Set the `MaxPoleRadius` IIR lp norm design option to some number less than 1. Set this option when you `design` your filter with the syntax:

  ```
  design(d,'iirlpnorm','MaxPoleRadius',0.95)
  ```
  See the "Design an Arbitrary Group Delay Filter" on page 5-521 and "Multiband Delay Equalization" on page 5-524 examples for the use of the `MaxPoleRadius` design option.
- Reduce the order of your filter design.

Input Arguments

SPEC

Filter specification. `SPEC` is one of the following two options. The entries are not case sensitive.

- `'N,F,Gd'`
- `'N,B,F,Gd'`

The filter specifications are defined as follows:

- `N` — Filter order. This value must be an even positive integer. The numerator and denominator orders are both equal to `N`. "Allpass Systems" on page 5-527 explains why the numerator and denominator filter orders are equal and the order must be even in `fdesign.arbgrpdelay`.
- `F` — Frequency vector for the group delay specifications. The elements of the frequency vector must increase monotonically. If you do not specify a sampling frequency, `Fs`, in hertz, the frequencies are normalized frequencies. For a single-band design, the first element of the normalized frequency vector must be zero and the last element must be 1. These correspond to 0 and π radians/sample respectively. For multiband designs, the union of the frequency vectors must range from [0,1].

  If you specify a sampling frequency, `Fs`, the first element of the frequency vector in a single-band design must be 0. The last element must be the Nyquist frequency, Fs/2. For multiband designs, the union of the frequency vectors must range from [0,Fs/2].

- `Gd` — Group delay vector. A vector with nonnegative elements equal in length to the frequency vector, `F`. The elements of `Gd` specify the nonnegative group delay at the corresponding element of the frequency vector, `F`.

  If you do not specify a sampling frequency, `Fs`, in Hertz, the group delays are in samples. If you specify a sampling frequency, the group delays are in seconds.
- `B` — Number of frequency bands. If you use this specification, you must specify a frequency and group delay vector for each band. The union of the frequency vectors must range from [0,1] in normalized frequency, or [0,Fs/2] when a sampling frequency is specified. The elements in the union of the frequency bands must be monotonically increasing.

  For example:

  ```
  filtorder = 14;
  freqband1 = [0 0.1 0.4]; grpdelay1 = [1 2 3];
  freqband2 = [0.5 0.8 1]; grpdelay2 = [3 2 1];
  D = fdesign.arbgrpdelay('N,B,F,Gd',filtorder,2,freqband1,grpdelay1,freqband2,grpdela
  ```

Default: `'N,F,Gd'`

`Fs`

Sampling frequency. Specify the sampling frequency as a trailing positive scalar after all other input arguments. Specifying a sampling frequency forces the group delay units to be in seconds. If you specify a sampling frequency, the first element of the frequency vector must be 0. The last element must be the Nyquist frequency, Fs/2.

Output Arguments

`D`

Filter specification object. An allpass arbitrary group delay filter specification object containing the following modifiable properties: `Specification`, `NormalizedFrequency`, `FilterOrder`, `Frequencies`, and `GroupDelay`.

Use the `normalizefreq` method to change the `NormalizedFrequency` property after construction.

Examples

Design an Arbitrary Group Delay Filter

Construct a signal consisting of two discrete-time windowed sinusoids (wave packets) with disjoint time support to illustrate frequency dispersion. One discrete-time sinusoid has a frequency of pi/2 radians/sample and the other has a frequency of pi/4 radians/sample. There are 9 periods of the higher-frequency sinusoid that precede 5 periods of the lower-frequency signal.

Create the signal.

```
x = zeros(300,1);
x(1:36) = cos(pi/2*(0:35)).*hamming(36)';
x(40:40+39) = cos(pi/4*(0:39)).*hamming(40)';
```

Create an arbitrary group delay filter that delays the higher-frequency wave packet by approximately 100 samples.

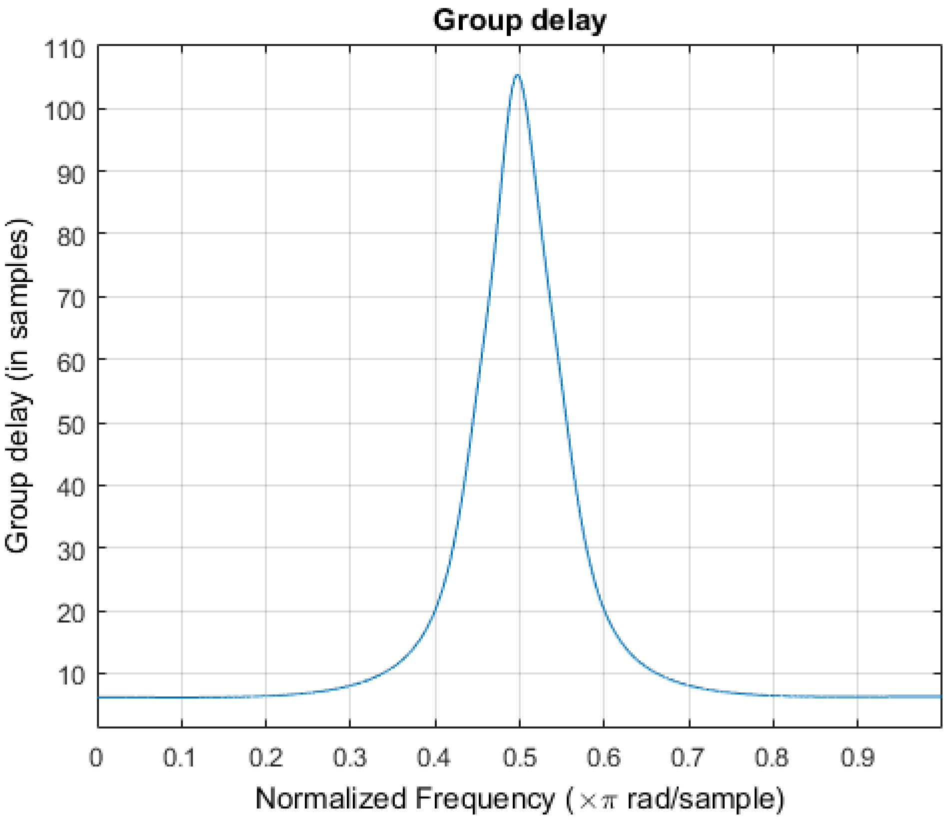
```
N = 18;
f = 0:.1:1;
gd = ones(size(f));
```

Delay pi/2 radians/sample by 100 samples

```
gd(6) = 100;
d = fdesign.arbgrpdelay(N,f,gd);
Hd = design(d,'iirlpnorm','MaxPoleRadius',0.9,'SystemObject',true);
```

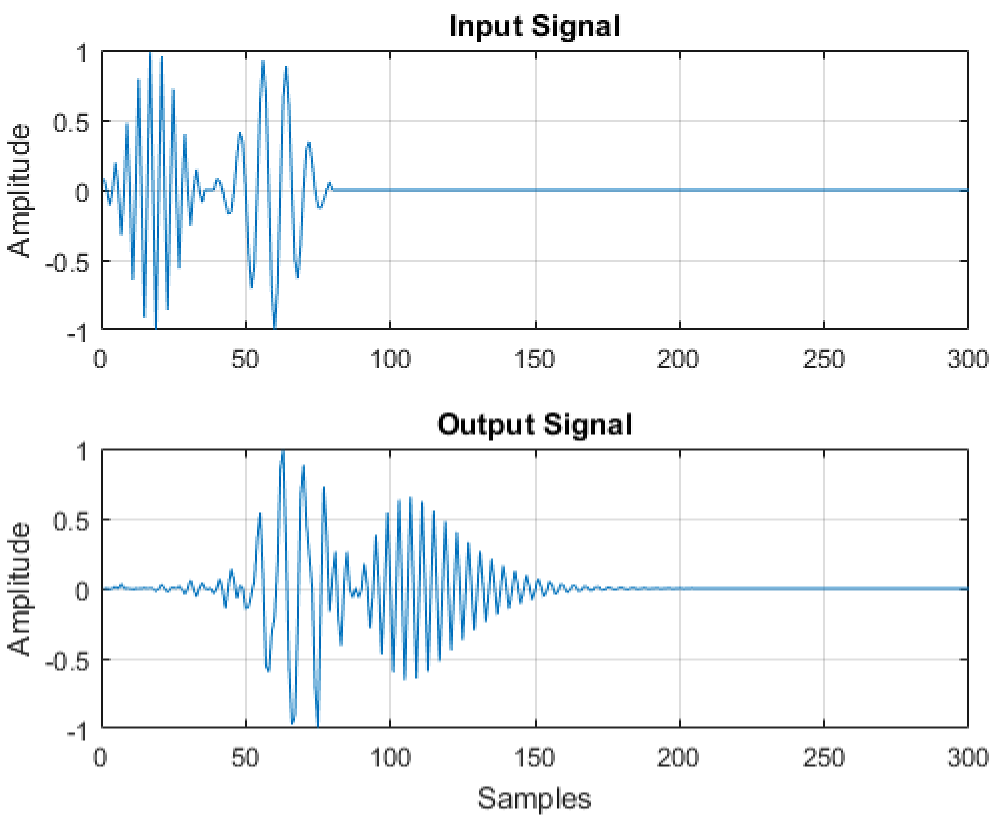
Visualize the group delay

```
fvtool(Hd,'analysis','grpdelay');
```



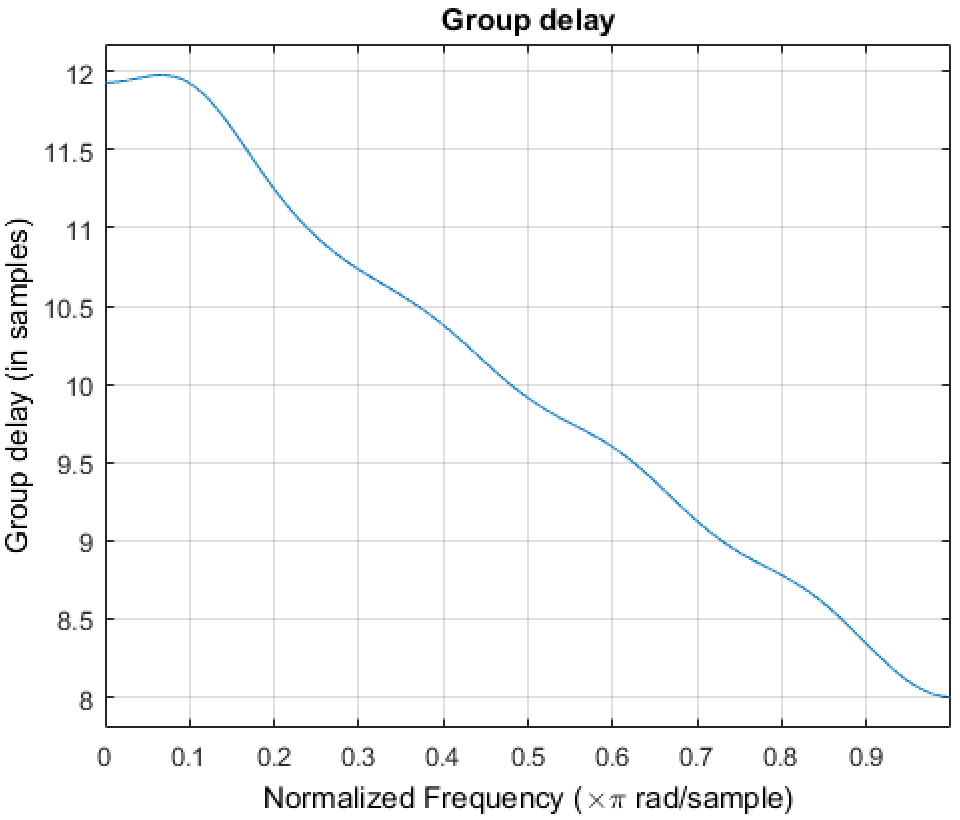
Filter the input signal with the arbitrary group delay filter and illustrate the frequency dispersion. The high-frequency wave packet, which initially preceded the low-frequency wave packet, now occurs later because of the nonconstant group delay.

```
y = Hd(x);
subplot(211)
plot(x); title('Input Signal');
grid on; ylabel('Amplitude');
subplot(212);
plot(y); title('Output Signal'); grid on;
xlabel('Samples'); ylabel('Amplitude');
```



Design an Allpass Filter With an Arbitrary Group Delay

```
N = 10;
f = [0 0.02 0.04 0.06 0.08 0.1 0.25 0.5 0.75 1];
g = [5 5 5 5 5 5 4 3 2 1];
w = [2 2 2 2 2 2 1 1 1 1];
hgd = fdesign.arbgrpdelay(N,f,g);
Hgd = design(hgd,'iirlpnorm','Weights',w,'MaxPoleRadius',0.95,...
    'SystemObject',true);
fvtool(Hgd,'Analysis','grpdelay') ;
```

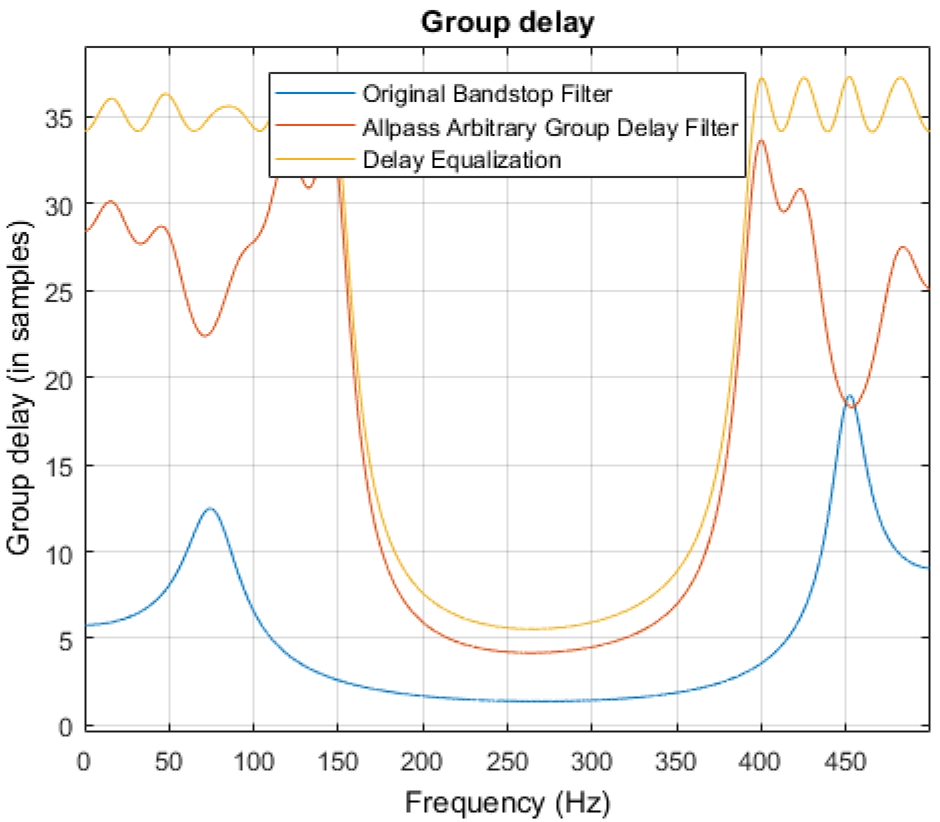


Multiband Delay Equalization

Perform multiband delay equalization outside the stopband.

```
Fs = 1e3;
Hcheby2 = design(fdesign.bandstop('N,Fst1,Fst2,Ast',10,150,400,60,Fs),'cheby2',...
    'SystemObject',true);
f1 = 0.0:0.5:150; % Hz
g1 = grpdelay(Hcheby2,f1,Fs).'/Fs; % seconds
f2 = 400:0.5:500; % Hz
g2 = grpdelay(Hcheby2,f2,Fs).'/Fs; % seconds
maxg = max([g1 g2]);
% Design an arbitrary group delay allpass filter to equalize the group
% delay of the bandstop filter. Use an order 18 multiband design and specify
```

```
% two bands.
hgd = fdesign.arbgrpdelay('N,B,F,Gd',18,2,f1,maxg-g1,f2,maxg-g2,Fs);
Hgd = design(hgd,'iirlpnorm','MaxPoleRadius',0.95,'SystemObject',true);
Hcascade = cascade(Hcheby2,Hgd);
hft = fvtool(Hcheby2,Hgd,Hcascade,'Analysis','grpdelay','Fs',Fs);
    legend(hft,'Original Bandstop Filter','Allpass Arbitrary Group Delay Filter',...
    'Delay Equalization', 'Location','North');
```



Definitions

Group Delay in Discrete-Time Filter Design

The frequency response of a rational discrete-time filter is:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})}$$

The argument of the frequency response as a function of the angle, ω, is referred to as the *phase response*.

The negative of the first derivative of the argument with respect to ω is the group delay.

$$\tau(\omega) = -\frac{d}{d\omega} Arg(H(e^{j\omega}))$$

Systems with nonlinear phase responses have nonconstant group delay, which causes dispersion of the frequency components of the signal. You may not want this phase distortion even if the magnitude distortion introduced by the filter produces the desired effect. See “Design an Arbitrary Group Delay Filter” on page 5-521 for an illustration of frequency dispersion resulting from nonconstant group delay.

In these cases, you can cascade the frequency-selective filter with an allpass filter that compensates for the group delay. This process is often referred to as *delay equalization*.

Allpass Systems

The general form of an allpass system function with a real-valued impulse response is:

$$H_{ap}(z) = \prod_{k=1}^{M} \frac{z^{-1} - d_k}{1 - d_k z^{-1}} \prod_{k=1}^{N} \frac{(z^{-1} - c_k)(z^{-1} - c_k^*)}{(1 - c_k z^{-1})(1 - c_k^* z^{-1})}$$

where the d_k denote the real-valued poles and the c_k denote the complex-valued poles, which occur in conjugate pairs.

The preceding equation demonstrates that allpass systems with real-valued impulse responses have *2N+M* zeros and poles. The poles and zeros occur in pairs with reciprocal magnitudes. The filter order is always the same for the numerator and denominator.

Because `fdesign.arbgrpdelay` uses robust second-order section (biquad) filter structures to implement the allpass arbitrary group delay filter, the filter order must be even.

Algorithms

`fdesign.arbgrpdelay` uses a least *p*-th norm iterative optimization described in [1].

Alternatives

`iirgrpdelay` — Returns an allpass arbitrary group delay filter. The `iirgrpdelay` function returns the numerator and denominator coefficients. This behavior differs from that of `fdesign.arbgrpdelay`, which returns the filter in second-order sections. `iirgrpdelay` accepts only normalized frequencies.

Topics

"Design a Filter in Fdesign — Process Overview"

Introduced in R2011b

fdesign.arbmag

Arbitrary response magnitude filter specification object

Syntax

```
D= fdesign.arbmag
D= fdesign.arbmag(SPEC)
D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)
D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)
D = fdesign.arbmag(...,Fs)
```

Description

`D= fdesign.arbmag` constructs an arbitrary magnitude filter specification object `D`.

`D= fdesign.arbmag(SPEC)` initializes the `Specification` property to `SPEC`. The input argument `SPEC` must be one of the entries shown in the following table. Specification entries are not case sensitive.

Note: Specification entries marked with an asterisk require the DSP System Toolbox software.

- `'N,F,A'` — Single band design (default)
- `'F,A,R'` — Single band minimum order design *
- `'N,B,F,A'` — Multiband design
- `'N,B,F,A,C'` — Constrained multiband design *
- `'B,F,A,R'` — Multiband minimum order design *
- `'Nb,Na,F,A'` — Single band design *
- `'Nb,Na,B,F,A'` — Multiband design *

The `SPEC` entries are defined as follows:

- A — Amplitude vector. Values in A define the filter amplitude at frequency points you specify in f, the frequency vector. If you use A, you must use F as well. Amplitude values must be real. For complex values designs, use fdesign.arbmagnphase.
- B — Number of bands in the multiband filter
- C — Constrained band flag. This enables you to constrain the passband ripple in your multiband design. You cannot constrain the passband ripple in all bands simultaneously.
- F — Frequency vector. Frequency values in specified in F indicate locations where you provide specific filter response amplitudes. When you provide F, you must also provide A.
- N — Filter order for FIR filters and the numerator and denominator orders for IIR filters.
- Nb — Numerator order for IIR filters
- Na — Denominator order for IIR filter designs
- R — Ripple

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

Specifying Frequency and Amplitude Vectors

F and A are the input arguments you use to define the filter response desired. Each frequency value you specify in F must have a corresponding response value in A. The following table shows how F and A are related.

Define the frequency vector F as [0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]

Define the response vector A as [1 1 0 0 0 0 0 1 1]

These specifications connect F and A as shown here:

F (Normalized Frequency)	A (Response Desired at F)
0	1
0.25	1
0.3	0
0.4	0
0.5	0

F (Normalized Frequency)	A (Response Desired at F)
0.6	0
0.7	0
0.75	1
1.0	1

Different specifications can have different design methods available. Use `designmethods` to get a list of design methods available for a given specification and filter specification object.

Use `designopts` to get a list of design options available for a filter specification object and a given design method. Enter `help(D,METHOD)` to get detailed help on the available design options for a given design method.

`D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)` initializes the specifications with `specvalue1`, `specvalue2`. Use `get(D,'Description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ... `specvalueN`.

`D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)` uses the default specification `'N,F,A'`, setting the filter order, filter frequency vector, and the amplitude vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`D = fdesign.arbmag(...,Fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `Fs`.

Examples

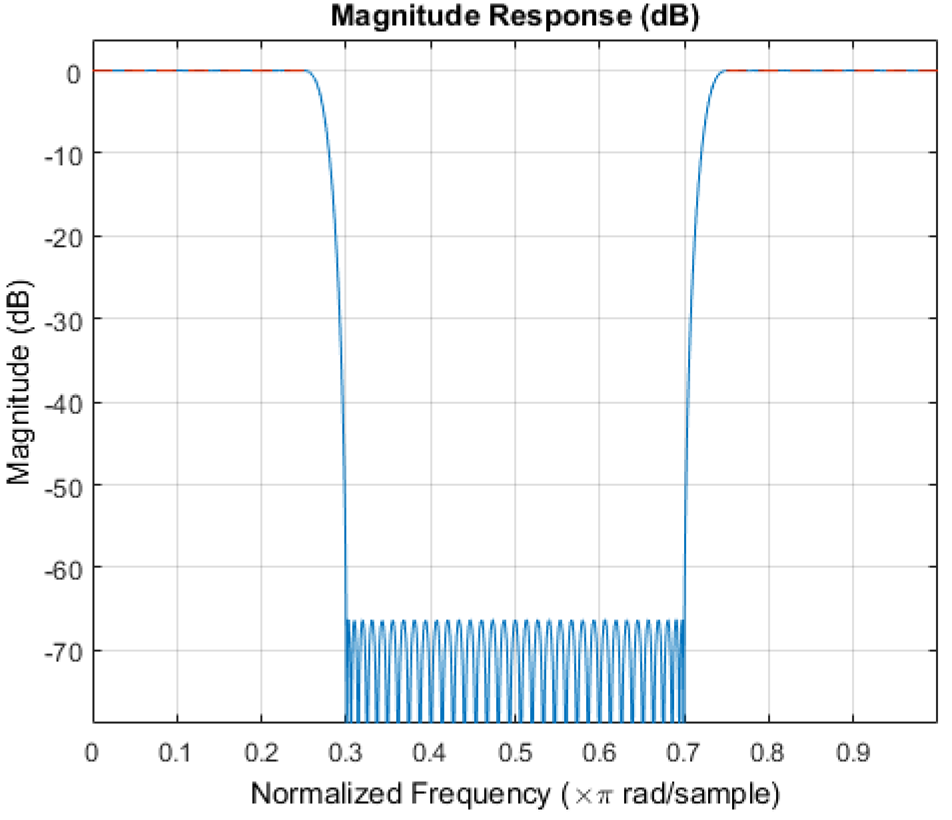
Design Multiband Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a three-band filter.

- Define the frequency vector `F` = [0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0].
- Define the response vector `A` = [1 1 0 0 0 0 0 1 1].

```
N = 150;
B = 3;
F = [0 .25 .3 .4 .5 .6 .7 .75 1];
A = [1 1 0 0 0 0 0 1 1];
A1 = A(1:2);
A2 = A(3:7);
```

```
A3 = A(8:end);
F1 = F(1:2);
F2 = F(3:7);
F3 = F(8:end);
d = fdesign.arbmag('N,B,F,A',N,B,F1,A1,F2,A2,F3,A3);
Hd = design(d);
fvtool(Hd)
```



A response with two passbands -- one roughly between 0 and 0.25 and the second between 0.75 and 1 -- results from the mapping between F and A.

Design Single-Band Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a single band equiripple filter.

Specify 100 frequency points.

```
n = 120;
f = linspace(0,1,100);

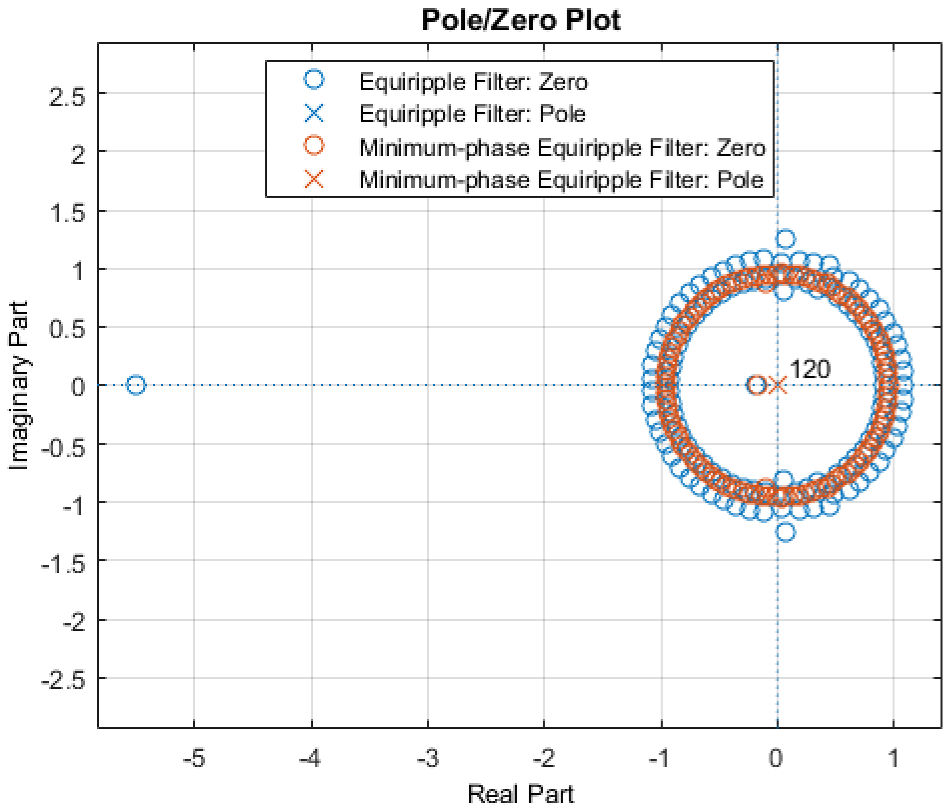
as = ones(1,100)-f*0.2;
absorb = [ones(1,30),1-0.6*bohmanwin(10)',ones(1,5), ...
    1-0.5*bohmanwin(8)',ones(1,47)];
a = as.*absorb;

d = fdesign.arbmag('N,F,A',n,f,a);
hd1 = design(d,'equiripple');
```

Design a minimum-phase equiripple filter. Visualize the poles and zeros of the two filters.

```
hd2 = design(d,'equiripple','MinPhase',true);

hfvt = fvtool(hd1,hd2,'Analysis','polezero');
legend(hfvt,'Equiripple Filter','Minimum-phase Equiripple Filter')
```



Design Multiband Minimum-Order Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a multiband minimum order filter.

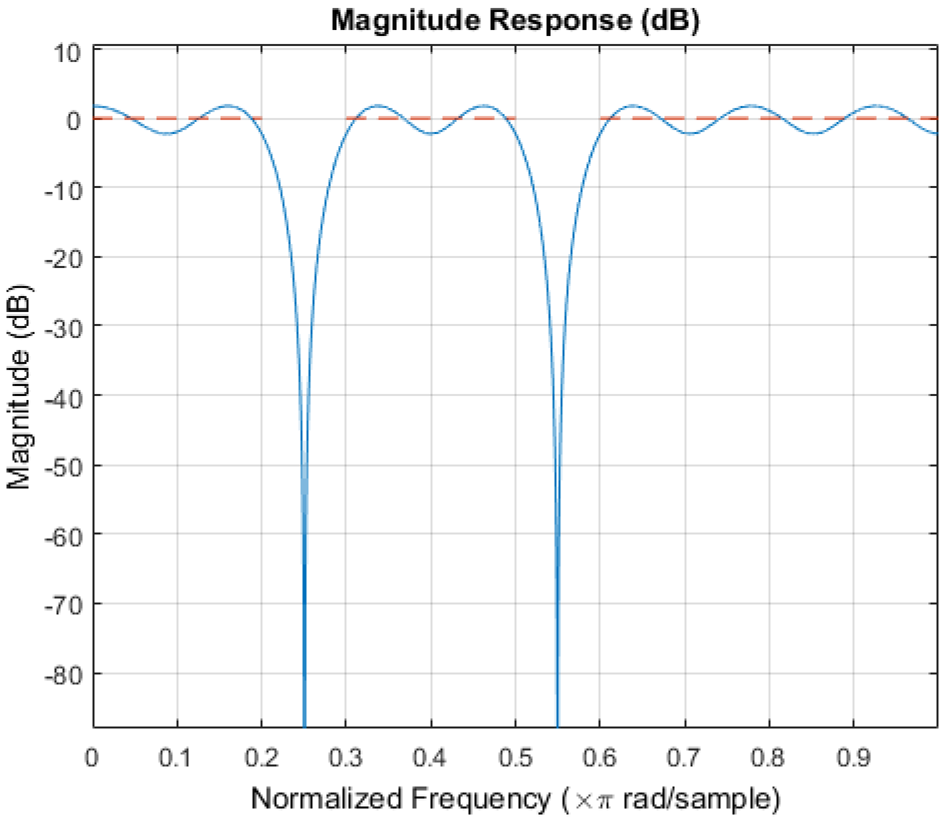
Place the notches at 0.25π and 0.55π rad/sample.

```
d = fdesign.arbmag('B,F,A,R');
d.NBands = 5;
d.B1Frequencies = [0 0.2];
d.B1Amplitudes = [1 1];
d.B1Ripple = 0.25;
d.B2Frequencies = 0.25;
d.B2Amplitudes = 0;
d.B3Frequencies = [0.3 0.5];
```

```
d.B3Amplitudes = [1 1];
d.B3Ripple = 0.25;
d.B4Frequencies = 0.55;
d.B4Amplitudes = 0;
d.B5Frequencies = [0.6 1];
d.B5Amplitudes = [1 1];
d.B5Ripple = 0.25;
Hd = design(d,'equiripple');
```

Visualize the frequency response of the resulting filter.

```
fvtool(Hd)
```



Design Multiband Constrained Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a multiband constrained FIR filter.

Force the frequency response at 0.15π rad/sample to 0 dB.

```
d = fdesign.arbmag('N,B,F,A,C',82,2);
d.B1Frequencies = [0 0.06 0.1];
d.B1Amplitudes = [0 0 0];
d.B2Frequencies = [0.15 1];
d.B2Amplitudes = [1 1];
```

Design a filter with no constraints.

```
Hd1 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
```

Add a constraint to the first band to increase attenuation.

```
d.B1Constrained = true;
d.B1Ripple = 0.001;
Hd2 = design(d,'equiripple','B2ForcedFrequencyPoints',0.15);
```

Visualize the frequency response.

```
hfvt = fvtool(Hd1,Hd2);
legend(hfvt,'Original Design','Design with Constrained Stopband Ripple')
```

Introduced in R2009a

fdesign.arbmagnphase

Arbitrary response magnitude and phase filter specification object

Syntax

```
d = fdesign.arbmagnphase
d = fdesign.arbmagnphase(specification)
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)
d = fdesign.arbmagnphase(...,fs)
```

Description

`d = fdesign.arbmagnphase` constructs an arbitrary magnitude filter specification object `d`.

`d = fdesign.arbmagnphase(specification)` initializes the `Specification` property for specifications object `d` to `specification`. The input argument `specification` must be one of the choices shown in the following table. Specification options are not case sensitive.

Specification	Description of Resulting Filter
`n,f,h`	Single band design (default). FIR and IIR (`n` is the order for both numerator and denominator).
`n,b,f,h`	FIR multiband design where `b` defines the number of bands.
`nb,na,f,h`	IIR single band design.

The following table describes the specification arguments.

Argument	Description
`b`	Number of bands in the multiband filter.
`f`	Frequency vector. Frequency values specified in `f` indicate locations where you provide specific filter response amplitudes. When you provide `f` you must also provide `h` which contains the response values.

Argument	Description
h	Complex frequency response values.
n	Filter order for FIR filters and the numerator and denominator orders for IIR filters (when not specified by nb and na).
nb	Numerator order for IIR filters.
na	Denominator order for IIR filter designs.

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

Specifying f and h

f and h are the input arguments you use to define the filter response desired. Each frequency value you specify in f must have a corresponding response value in h. This example creates a filter with two passbands (b = 4) and shows how f and h are related. This example is for illustration only. It is not an actual filter.

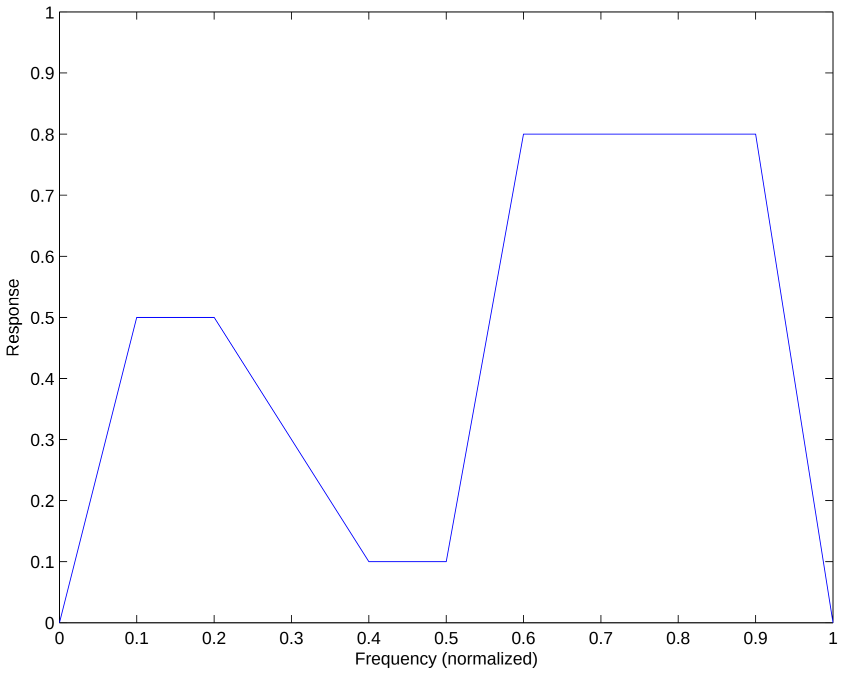
Define the frequency vector f as `[0 0.1 0.2 0.4 0.5 0.6 0.9 1.0]`

Define the response vector h as `[0 0.5 0.5 0.1 0.1 0.8 0.8 0]`

These specifications connectf and h as shown in the following table.

f (Normalized Frequency)	h (Response Desired at f)
0	0
0.1	0.5
0.2	0.5
0.4	0.1
0.5	0.1
0.6	0.8
0.9	0.8
1.0	0.0

A response with two passbands—one roughly between 0.1 and 0.2 and the second between 0.6 and 0.9—results from the mapping between f and h. Plotting f and h yields the following figure that resembles a filter with two passbands.



The second example in Examples shows this plot in more detail with a complex filter response for `h`. In the example, `h` uses complex values for the response.

Different specification types often have different design methods available. Use `designmethods(d)` to get a list of design methods available for a given specification option and specifications object.

`d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)` initializes the filter specification object with `specvalue1`, `specvalue2`, and so on. Use `get(d,'description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ...`spec`*n*.

`d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)` uses the default specification option `n,f,h`, setting the filter order, filter frequency vector, and the complex frequency response vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

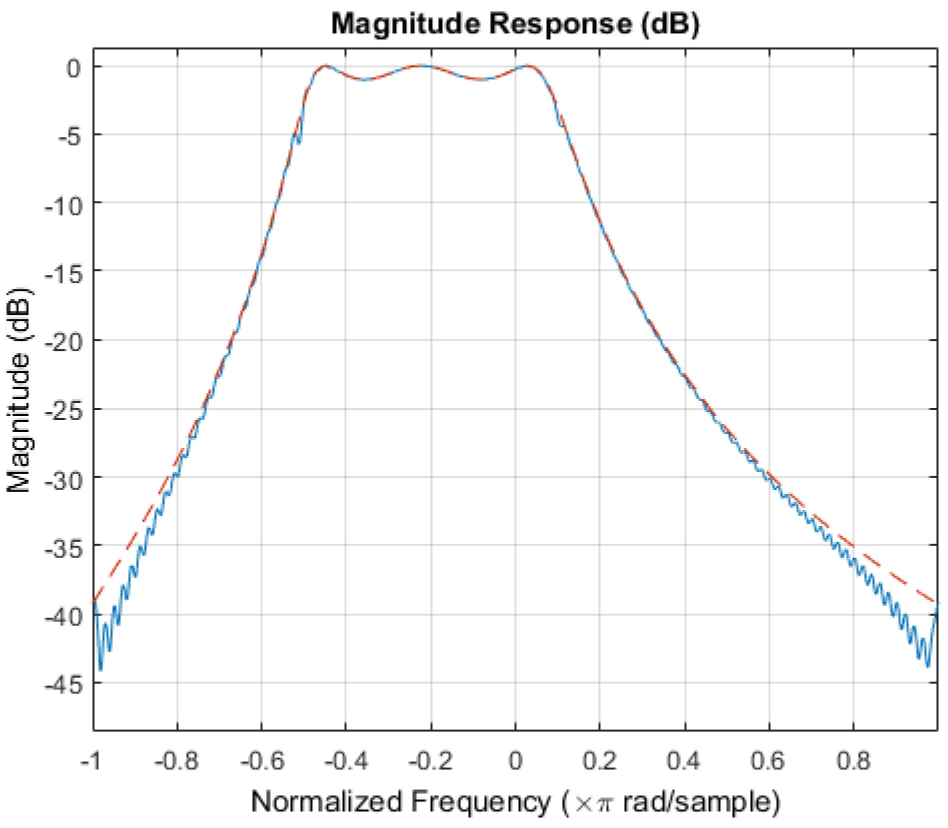
`d = fdesign.arbmagnphase(...,fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `fs`.

Examples

Construct a Complex Analog Filter

Use `fdesign.arbmagnphase` to model a complex analog filter.

```
d = fdesign.arbmagnphase('n,f,h',100); % N=100, f and h set to defaults.
design(d,'freqsamp','SystemObject',true);
```



For a more complex example, design a bandpass filter with low group delay by specifying the desired delay and using f and h to define the filter bands.

```
n = 50;     % Group delay of a linear phase filter would be 25.
gd = 12;    % Set the desired group delay for the filter.
f1=linspace(0,.25,30); % Define the first stopband frequencies.
f2=linspace(.3,.56,40);% Define the passband frequencies.
f3=linspace(.62,1,30); % Define the second stopband frequencies.
h1 = zeros(size(f1));  % Specify the filter response at the freqs in f1.
h2 = exp(-1j*pi*gd*f2); % Specify the filter response at the freqs in f2.
h3 = zeros(size(f3));  % Specify the response at the freqs in f3.
d=fdesign.arbmagnphase('n,b,f,h',50,3,f1,h1,f2,h2,f3,h3);
D = design(d,'equiripple','SystemObject',true);
fvtool(D,'Analysis','freq');
```

Introduced in R2011a

fdesign.audioweighting

Audio weighting filter specification object

Syntax

```
HAwf = fdesign.audioweighting
HAwf = fdesign.audioweighting(spec)
HAwf = fdesign.audioweighting(spec,specvalue1,specvalue2)
HAwf = fdesign.audioweighting(specvalue1,specvalue2)
HAwf = fdesign.audioweighting(...,Fs)
```

Description

Supported audio weighting filter types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting.

`HAwf = fdesign.audioweighting` constructs an audio weighting filter specification object *HAwf* with a weighting type of A and a filter class of 1. Use the `design` method and set the `'SystemObject'` flag to `true`, to instantiate a System object based on the specifications in *HAwf*. Use `designmethods` to find valid filter design methods. Because the standards for audio weighting filters are in Hz, normalized frequency specifications are not supported for `fdesign.audioweighting` objects. The default sampling frequency for A weighting, C weighting, C-message, and ITU-T 0.41 filters is 48 kHz. The default sampling frequency for the ITU-R 468–4 filter is 80 kHz. If you invoke the `normalizefreq` method, a warning is issued when you instantiate the System object and the default sampling frequencies in Hz are used.

`HAwf = fdesign.audioweighting(spec)` returns an audio weighting filter specification object using default values for the specification string in *spec*. The following are valid entries for *spec*. The entries are not case sensitive.

- `'WT,Class'` (default *spec*)

  The `'WT,Class'` specification is valid for A weighting and C weighting filters of class 1 or 2.

  The weighting type is specified by the string: `'A'` or `'C'`. The class is the scalar 1 or 2.

The default values for `'WT,Class'` are `'A',1`.

- `'WT'`

  The `'WT'` specification is valid for C-message (default), ITU-T 0.41, and ITU-R 468–4 weighting filters.

  The weighting type is specified by the string: `'Cmessage'`, `'ITUT041'`, or `'ITUR4684'`.

`HAwf = fdesign.audioweighting(spec,specvalue1,specvalue2)` constructs an audio weighting filter specification object `HAwf` and sets its specifications at construction time.

`HAwf = fdesign.audioweighting(specvalue1,specvalue2)` constructs an audio weighting filter specification object `HAwf` with the specification `'WT,Class'` using the values you provide. The valid weighting types are `'A'` or `'C'`.

`HAwf = fdesign.audioweighting(...,Fs)` specifies the sampling frequency in Hz. The sampling frequency is a scalar trailing all other input arguments.

Input Arguments

Parameter Name/Value Pairs

`'WT'`

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468–4 weighting. The weighting types are described in “Definitions” on page 5-550.

`'Class'`

Filter Class

Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards [1],

[2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.

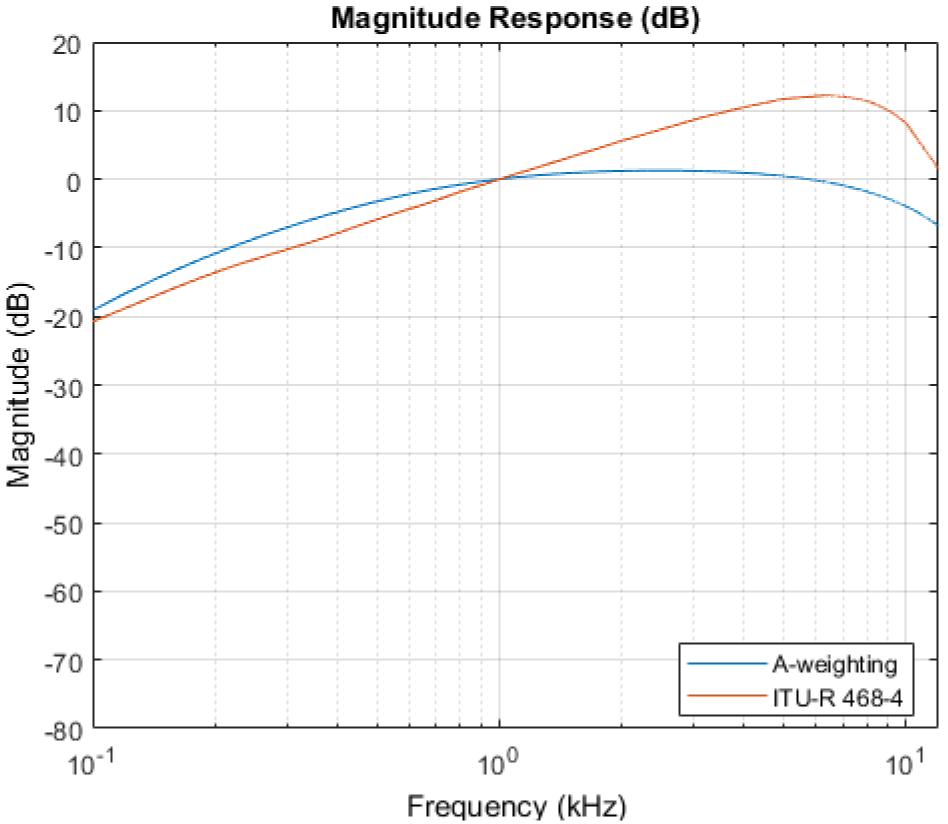
Default: 1

Examples

Compare Class 1 A and ITU-R 468-4 Weighting Filters

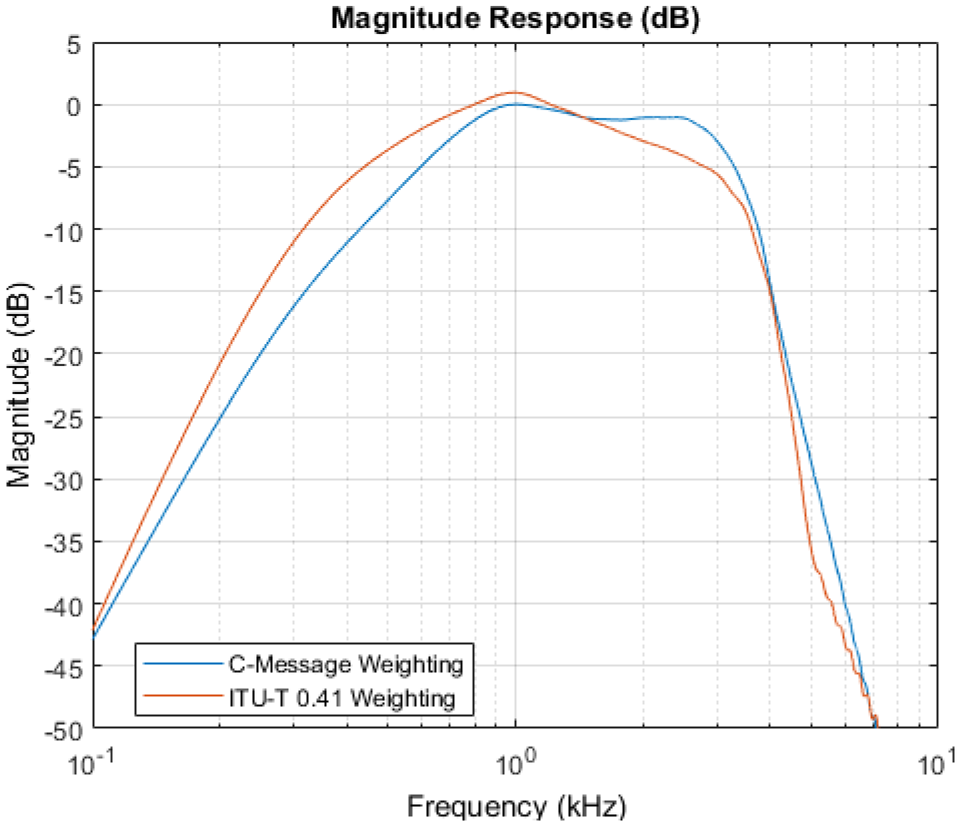
Compare class 1 A weighting and ITU-R 468-4 filters between 0.1 and 12 kHz. % Sampling frequency is 44.1 kHz

```
HawfA = fdesign.audioweighting('WT,Class','A',1,44.1e3);
HawfITUR = fdesign.audioweighting('WT','ITUR4684',44.1e3);
Afilter = design(HawfA,'SystemObject',true);
ITURfilter = design(HawfITUR,'SystemObject',true);
hfvt = fvtool(Afilter,ITURfilter);
axis([0.1 12 -80 20]);
legend(hfvt,'A-weighting','ITU-R 468-4');
```



Compare C-message and ITU-T 0.41 Weighting Filters

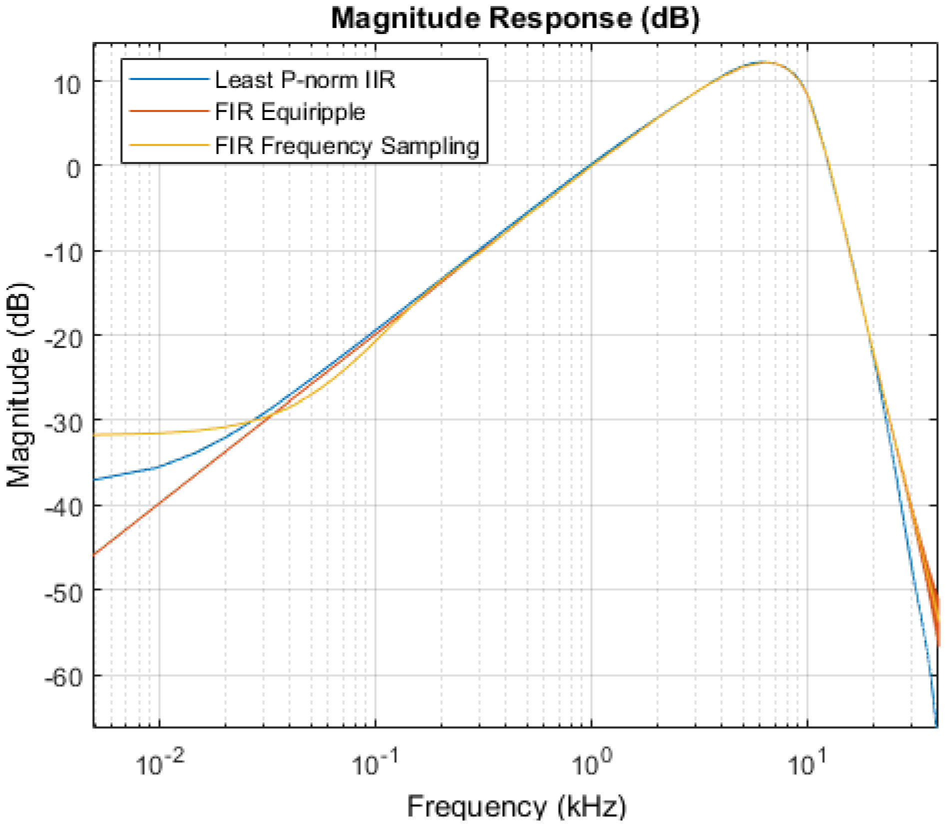
```
hCmessage = fdesign.audioweighting('WT','Cmessage',24e3);
hITUT = fdesign.audioweighting('WT','ITUT041',24e3);
dCmessage = design(hCmessage,'SystemObject',true);
dITUT = design(hITUT,'SystemObject',true);
hfvt = fvtool(dCmessage,dITUT);
legend(hfvt,'C-Message Weighting','ITU-T 0.41 Weighting');
axis([0.1 10 -50 5]);
```



Construct an ITU-R 468-4 Weighting Filter

Construct an ITU-R 468-4 filter using all available design methods.

```
HAwf = fdesign.audioweighting('WT','ITUR4684');
ValidDesigns = designmethods(HAwf);
% returns iirlpnorm,equiripple,freqsamp in cell array
D = design(HAwf,'all','SystemObject',true); % returns all designs
hfvt = fvtool(D{1},D{2},D{3});
legend(hfvt,'Least P-norm IIR','FIR Equiripple',...,
'FIR Frequency Sampling')
```



Definitions

A weighting

The specifications for the A weighting filter are found in ANSI standard S1.42-2001. The A weighting filter is based on the 40–phon Fletcher-Munson equal loudness contour [3]. One phon is equal to one dB sound pressure level (SPL) at one kHz. The Fletcher-Munson equal loudness contours are designed to account for frequency and level dependent differences in the perceived loudness of tonal stimuli. The 40–phon contour reflects the fact that the human auditory system is more sensitive to frequencies around 1–2 kHz than lower and higher frequencies. The filter roll off is more pronounced at lower frequencies and more modest at higher frequencies. While A weighting is based on the equal loudness contour for low-level (40–phon) tonal stimuli, it is commonly used in the United States for assessing potential health risks associated with noise exposure to narrowband and broadband stimuli at high levels.

C weighting

The specifications for the C weighting filter are found in ANSI standard S1.42-2001. The C weighting filter approximates the 100–phon Fletcher-Munson equal loudness contour for tonal stimuli. The C weighting magnitude response is essentially flat with 3–dB frequencies at 31.5 Hz and 8000 Hz. While C weighting is not as common as A weighting, sound level meters frequently have a C weighting filter option.

C-message

The specifications for the C–message weighting filter are found in Bell System Technical Reference, PUB 41009. C-message weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [6]. C-message weighting filters are commonly used in North America, while the ITU-T 0.41 filter is more commonly used outside of North America.

ITU-R 468–4

The specifications for the ITU-R 486–4 weighting filter are found in the International Telecommunication Union Recommendation ITU-R BS.468-4. ITU-R 486–4 is an equal loudness contour weighting filter. Unlike the A weighting filter, the ITU-R 468–4 filter describes subjective loudness judgements for broadband stimuli [4]. A common criticism of the A weighting filter is that it underestimates the loudness judgement of real-world stimuli particularly in the frequency band from about 1–9 kHz. A comparison of A weighting and ITU-R 468–4 weighting curves shows that the ITU-R 468–4 curve applies more gain between 1 and 10 kHz with a peak difference of approximately 12 dB around 6–7 kHz.

ITU-T 0.41

The specifications for the ITU-T 0.41 filter are found in the ITU-T Recommendation 0.41. ITU-T 0.41 weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [5]. ITU-T 0.41 weighting filters are commonly used outside of North America, while the C-message weighting filter is more common in North America.

Audio Weighting Filters Example
“Design a Filter in Fdesign — Process Overview”

Introduced in R2011a

fdesign.bandpass

Bandpass filter specification object

Syntax

```
D = fdesign.bandpass
D = fdesign.bandpass(SPEC)
D = fdesign.bandpass(spec,specvalue1,specvalue2,...)
D = fdesign.bandpass(specvalue1,specvalue2,specvalue3,
specvalue4,...specvalue4,specvalue5,specvalue6)
D = fdesign.bandpass(...,Fs)
D = fdesign.bandpass(...,MAGUNITS)
```

Description

`D = fdesign.bandpass` constructs a bandpass filter specification object `D`, applying default values for the properties `Fstop1`, `Fpass1`, `Fpass2`, `Fstop2`, `Astop1`, `Apass`, and `Astop2` — one possible set of values you use to specify a bandpass filter.

`D = fdesign.bandpass(SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below and used to define the bandpass filter. These entries are not case sensitive.

Note: Specifications marked with an asterisk require the DSP System Toolbox software.

- `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default `spec`)
- `'N,F3dB1,F3dB2'`
- `"N,F3dB1,F3dB2,Ap'` *
- `'N,F3dB1,F3dB2,Ast'` *
- `'N,F3dB1,F3dB2,Ast1,Ap,Ast2'` *
- `'N,F3dB1,F3dB2,BWp` *

- 'N,F3dB1,F3dB2,BWst' *
- 'N,Fc1,Fc2'
- 'N,Fc1,Fc2,Ast1,Ap,Ast2'
- 'N,Fp1,Fp2,Ap'
- 'N,Fp1,Fp2,Ast1,Ap,Ast2'
- 'N,Fst1,Fp1,Fp2,Fst2'
- 'N,Fst1,Fp1,Fp2,Fst2,C' *
- 'N,Fst1,Fp1,Fp2,Fst2,Ap' *
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fst1,Fp1,Fp2,Fst2' *

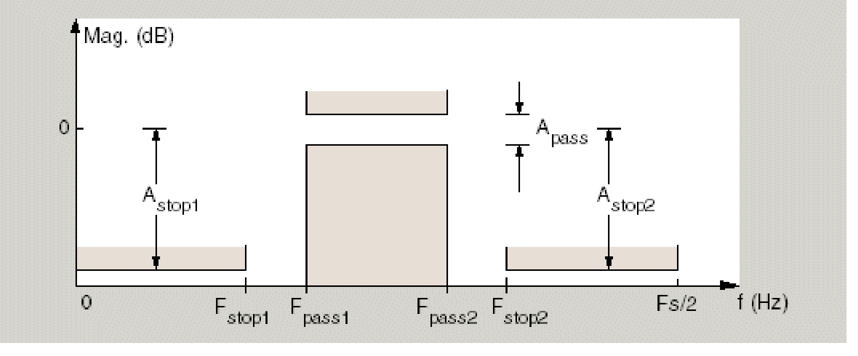
The filter specifications are defined as follows:

- Ap — amount of ripple allowed in the pass band. Also called Apass.
- Ast1 — attenuation in the first stop band in decibels (the default units). Also called Astop1.
- Ast2 — attenuation in the second stop band in decibels (the default units). Also called Astop2.
- BWp — bandwidth of the filter passband. Specified in normalized frequency units.
- BWst — bandwidth of the filter stopband. Specified in normalized frequency units.
- C — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

  In the specification 'N,Fst1,Fp1,Fp2,Fst2,C', you cannot specify constraints in both stopbands and the passband simultaneously. You can specify constraints in any one or two bands.
- F3dB1 — cutoff frequency for the point 3 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (IIR filters)
- F3dB2 — cutoff frequency for the point 3 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (IIR filters)
- Fc1 — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. Specified in normalized frequency units. (FIR filters)
- Fc2 — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. Specified in normalized frequency units. (FIR filters)

- `Fp1` — frequency at the edge of the start of the pass band. Specified in normalized frequency units. Also called Fpass1.
- `Fp2` — frequency at the edge of the end of the pass band. Specified in normalized frequency units. Also called Fpass2.
- `Fst1` — frequency at the edge of the start of the first stop band. Specified in normalized frequency units. Also called Fstop1.
- `Fst2` — frequency at the edge of the start of the second stop band. Specified in normalized frequency units. Also called Fstop2.
- `N` — filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when na and nb are not provided.
- `Na` — denominator order for IIR filters
- `Nb` — numerator order for IIR filters

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like `Fst1` and `Fp1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandpass filter specification object change depending on the `Specification`. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandpass(spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandpass(specvalue1,specvalue2,specvalue3, specvalue4,...specvalue4,specvalue5,specvalue6)` constructs `D`with the default `Specification` property, using the values you provide as input arguments for `specvalue1,specvalue2,specvalue3,specvalue4,specvalue4,specvalue5, specvalue6` and `specvalue7`.

`D = fdesign.bandpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Bandpass Filtering of Sinusoids

Filter a discrete-time signal with a bandpass filter. The signal is a sum of three discrete-time sinusoids, $\pi/8$, $\pi/2$, and 3π/4 rad/sample.

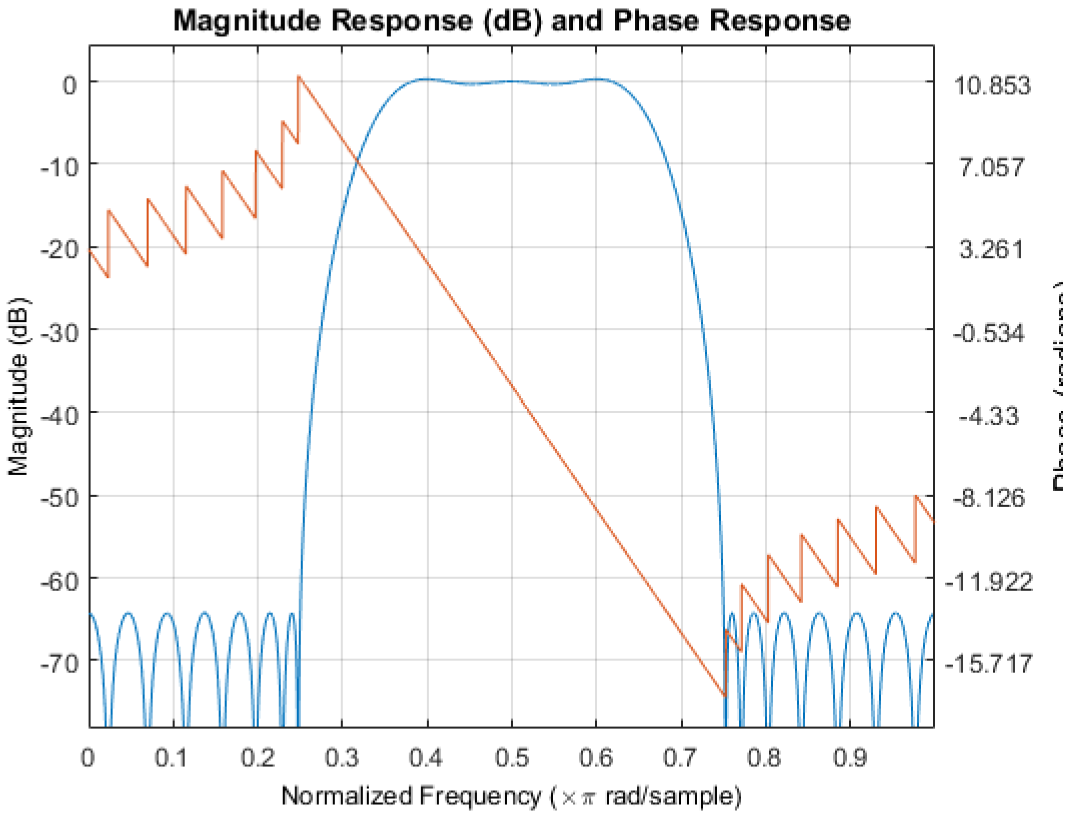
```
n = 0:159;
x = cos(pi/8*n)+cos(pi/2*n)+sin(3*pi/4*n);
```

Design an FIR equiripple bandpass filter to remove the lowest and highest discrete-time sinusoids. View the frequency response of the filter.

```
d = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2', ...
    1/4,3/8,5/8,6/8,60,1,60);
```

```
Hd = design(d,'equiripple');

freqz(Hd)
```

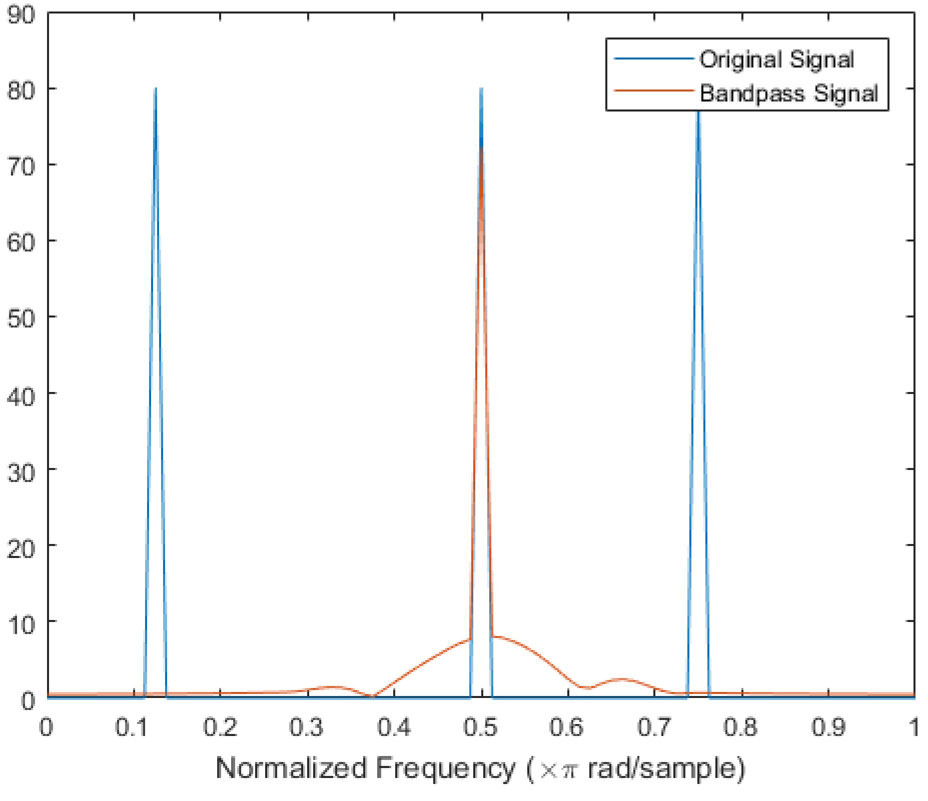


Apply the filter to the discrete-time signal. Plot the original and filtered signals in the frequency domain.

```
y = filter(Hd,x);
freq = 0:(2*pi)/length(x):pi;
xdft = fft(x);
ydft = fft(y);

plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
```

```
plot(freq/pi,abs(ydft(1:length(x)/2+1)))
hold off
xlabel('Normalized Frequency (\times\pi rad/sample)')
legend('Original Signal','Bandpass Signal')
```

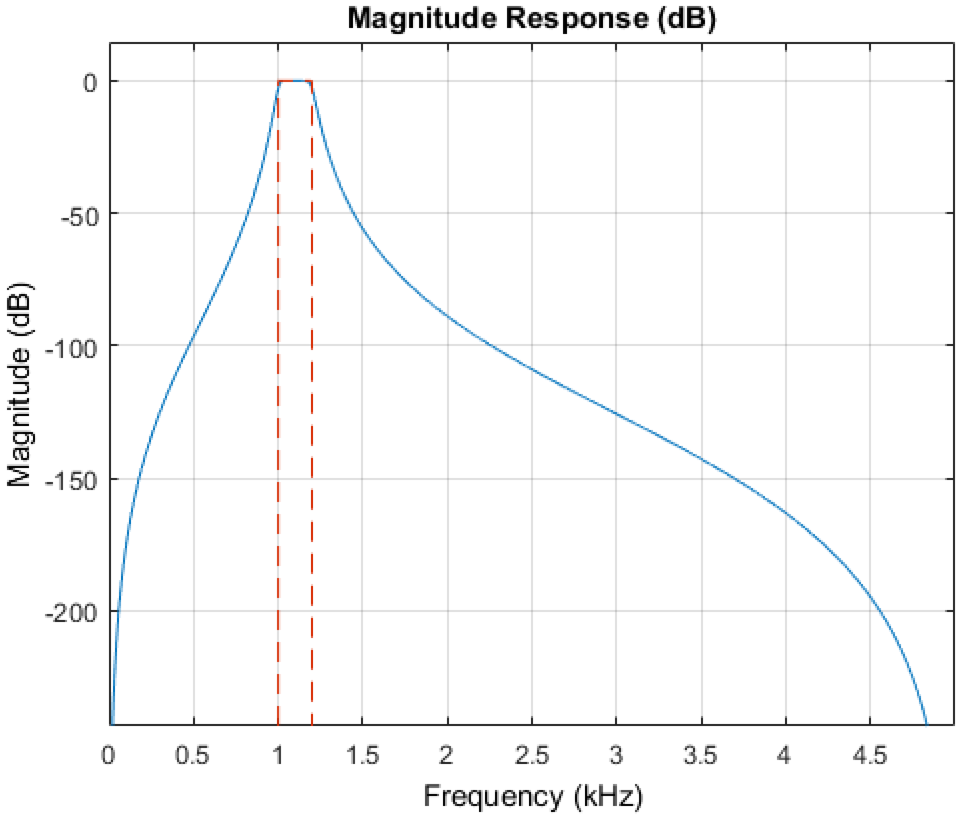


Butterworth Bandpass Filter

Design an IIR Butterworth filter of order 10 with 3-dB frequencies of 1 and 1.2 kHz. The sample rate is 10 kHz. Visualize the frequency response of the filter.

```
d = fdesign.bandpass('N,F3dB1,F3dB2',10,1e3,1.2e3,1e4);
Hd = design(d,'butter');
```

```
fvtool(Hd)
```



Equiripple FIR Passband Filter

Design a constrained-band FIR equiripple filter of order 100 with a passband of [1, 1.4] kHz. Both stopband attenuation values are constrained to 60 dB. The sample rate is 10 kHz.

```
d = fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4);
d.Stopband1Constrained = true;
d.Astop1 = 60;
d.Stopband2Constrained = true;
d.Astop2 = 60;
```

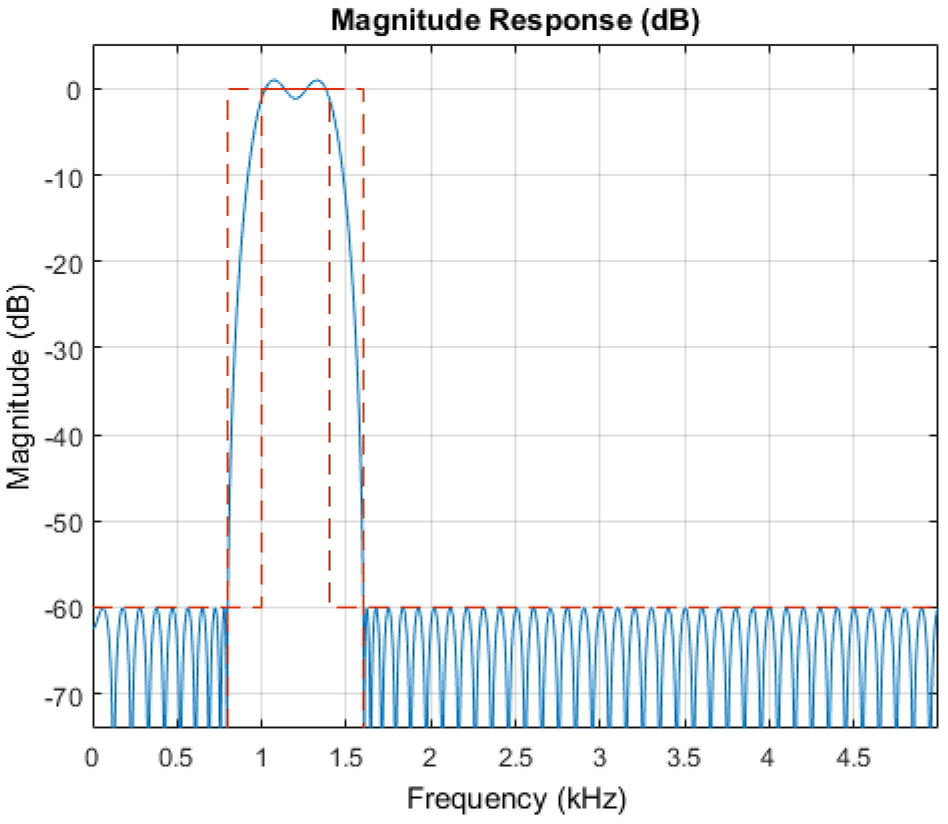
```
Hd = design(d,'equiripple');
```

Visualize and measure the magnitude response of the filter.

```
fvtool(Hd)
measure(Hd)

ans =

Sample Rate               : 10 kHz
First Stopband Edge       : 800 Hz
First 6-dB Point          : 946.7621 Hz
First 3-dB Point          : 975.1807 Hz
First Passband Edge       : 1 kHz
Second Passband Edge      : 1.4 kHz
Second 3-dB Point         : 1.4248 kHz
Second 6-dB Point         : 1.4533 kHz
Second Stopband Edge      : 1.6 kHz
First Stopband Atten.     : 60.0614 dB
Passband Ripple           : 2.1443 dB
Second Stopband Atten.    : 60.0399 dB
First Transition Width    : 200 Hz
Second Transition Width   : 200 Hz
```



The passband ripple is slightly over 2 dB. Because the design constrains both stopbands, you cannot constrain the passband ripple.

Introduced in R2009a

fdesign.bandstop

Bandstop filter specification object

Syntax

```
D = fdesign.bandstop
D = fdesign.bandstop(SPEC)
D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)
D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,...
specvalue5,specvalue6,specvalue7)
D = fdesign.bandstop(...,Fs)
D = fdesign.bandstop(...,MAGUNITS)
```

Description

`D = fdesign.bandstop` constructs a bandstop filter specification object `D`, applying default values for the properties `Fpass1`, `Fstop1`, `Fstop2`, `Fpass2`, `Apass1`, `Astop1` and `Apass2`.

`D = fdesign.bandstop(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. These entries are not case sensitive.

Note: Specification options marked with an asterisk require the DSP System Toolbox software.

- `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default spec)
- `'N,F3dB1,F3dB2'`
- `'N,F3dB1,F3dB2,Ap'` *
- `'N,F3dB1,F3dB2,Ap,Ast'` *
- `'N,F3dB1,F3dB2,Ast'` *

- 'N,F3dB1,F3dB2,BWp' *
- 'N,F3dB1,F3dB2,BWst' *
- 'N,Fc1,Fc2'
- 'N,Fc1,Fc2,Ap1,Ast,Ap2'
- 'N,Fp1,Fp2,Ap'
- 'N,Fp1,Fp2,Ap,Ast'
- 'N,Fp1,Fst1,Fst2,Fp2'
- 'N,Fp1,Fst1,Fst2,Fp2,C' *
- 'N,Fp1,Fst1,Fst2,Fp2,Ap' *
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fp1,Fst1,Fst2,Fp2' *

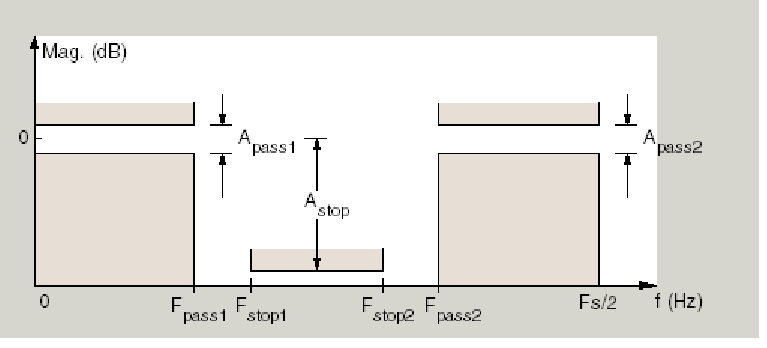
The filter specifications are defined as follows:

- Ap — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- Ap1 — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass1.
- Ap2 — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass2.
- Ast — attenuation in the first stopband in decibels (the default units). Also called Astop1.
- BWp — bandwidth of the filter passband. Specified in normalized frequency units.
- BWst — bandwidth of the filter stopband. Specified in normalized frequency units.
- C — Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

  In the specification 'N,Fp1,Fst1,Fst2,Fp2,C', you cannot specify constraints simultaneously in both passbands and the stopband. You can specify constraints in any one or two bands.
- F3dB1 — cutoff frequency for the point 3 dB point below the passband value for the first cutoff.
- F3dB2 — cutoff frequency for the point 3 dB point below the passband value for the second cutoff.

- `Fc1` — cutoff frequency for the point 6 dB point below the passband value for the first cutoff. (FIR filters)
- `Fc2` — cutoff frequency for the point 6 dB point below the passband value for the second cutoff. (FIR filters)
- `Fp1` — frequency at the start of the pass band. Also called Fpass1.
- `Fp2` — frequency at the end of the pass band. Also called Fpass2.
- `Fst1` — frequency at the end of the first stop band. Also called Fstop1.
- `Fst2` — frequency at the start of the second stop band. Also called Fstop2.
- `N` — filter order.
- `Na` — denominator order for IIR filters.
- `Nb` — numerator order for IIR filters.

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like `Fp1` and `Fst1` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a bandstop filter specification object change depending on the `Specification`. Use `designmethods` to determine which design methods apply to an object and the `Specification` property value.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.bandstop(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.bandstop(specvalue1,specvalue2,specvalue3,specvalue4,... specvalue5,specvalue6,specvalue7)` constructs an object `D` with the default `Specification` property, using the values you provide in `specvalue1,specvalue2,specvalue3,specvalue4,specvalue5, specvalue6` and `specvalue7`.

`D = fdesign.bandstop(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. If you specify the sampling frequency as a trailing scalar, all frequencies in the specifications are in Hz as well.

`D = fdesign.bandstop(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

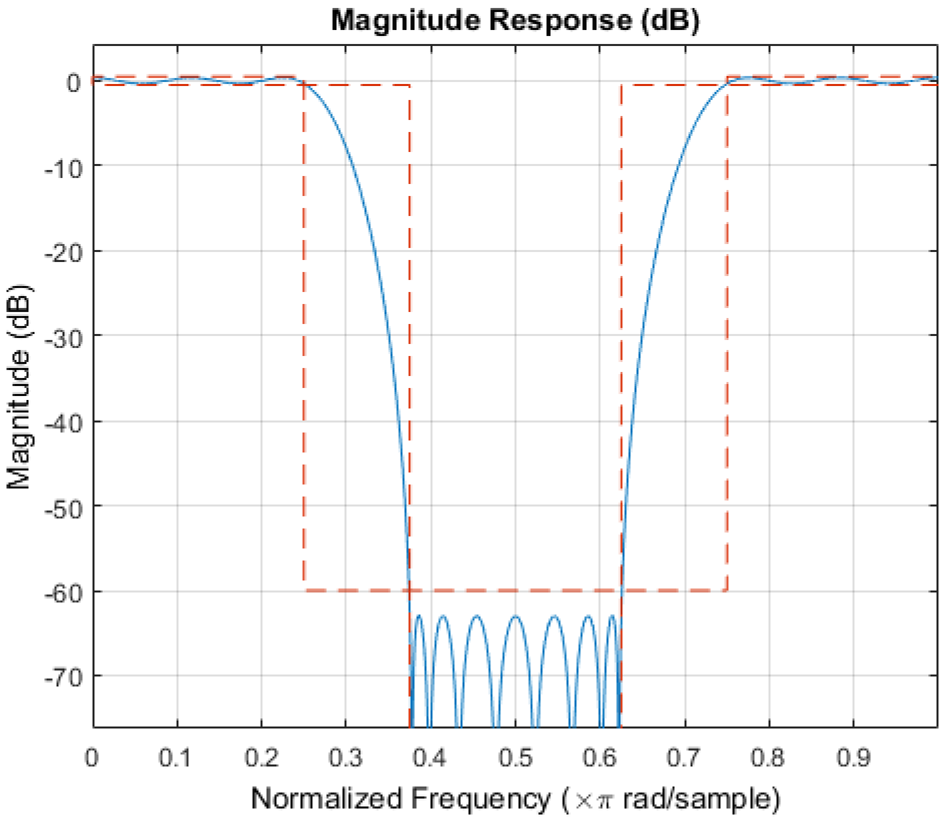
Bandstop Filtering of Sinusoids

Construct a bandstop filter to reject the discrete frequency band between 3π/8 and 5π/8 rad/sample. Apply the filter to a discrete-time signal consisting of the superposition of three discrete-time sinusoids.

Design an FIR equiripple filter and view its magnitude response.

```
d = fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2', ...
    2/8,3/8,5/8,6/8,1,60,1);
Hd = design(d,'equiripple');

fvtool(Hd)
```



Construct the discrete-time signal and filter it.

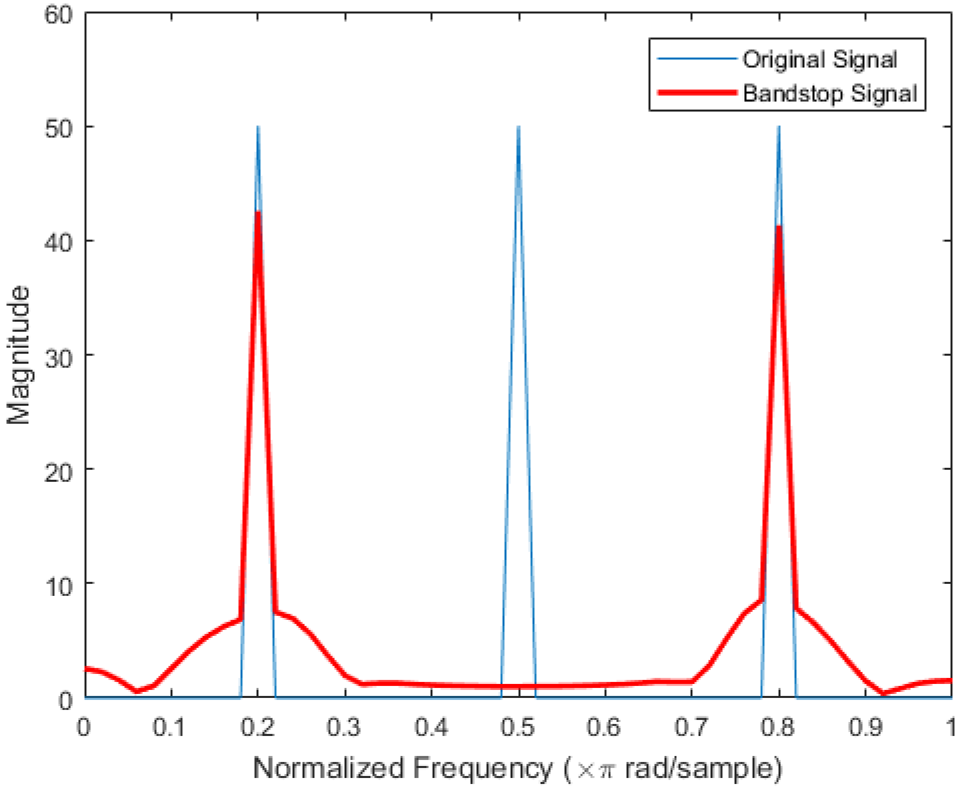
```
n = 0:99;
x = cos(pi/5*n)+sin(pi/2*n)+cos(4*pi/5*n);
y = filter(Hd,x);
```

Plot the original and filtered signals in the frequency domain.

```
xdft = fft(x);
ydft = fft(y);
freq = 0:(2*pi)/length(x):pi;

plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
```

```
plot(freq/pi,abs(ydft(1:length(y)/2+1)),'r','linewidth',2)
hold off
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude')
legend('Original Signal','Bandstop Signal')
```

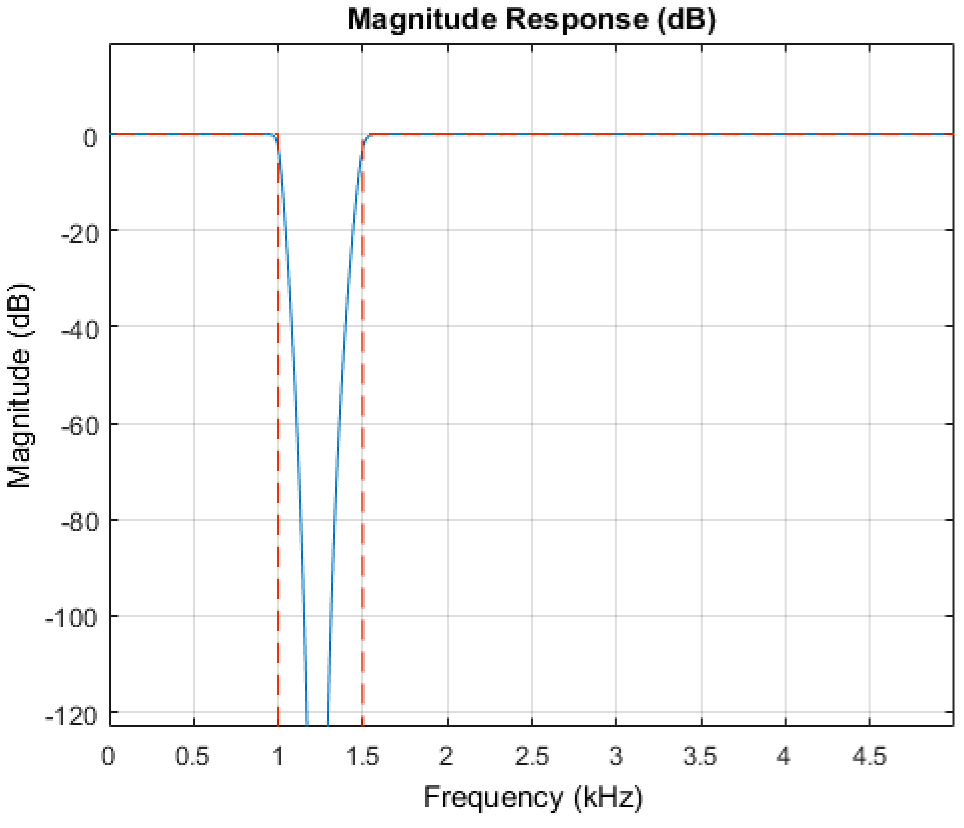


Butterworth Bandstop Filter

Create a Butterworth bandstop filter for data sampled at 10 kHz. The stopband is [1,1.5] kHz. The order of the filter is 20. Visualize the frequency response.

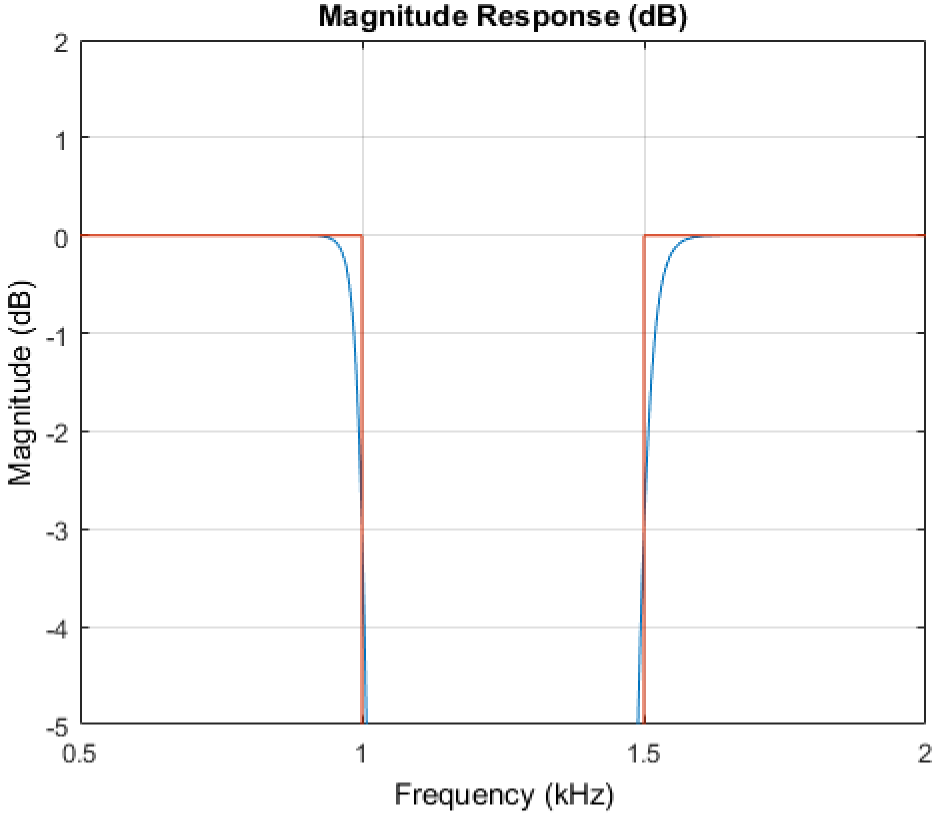
```
d = fdesign.bandstop('N,F3dB1,F3dB2',20,1e3,1.5e3,1e4);
Hd = design(d,'butter');
```

```
fvtool(Hd)
```



Zoom in on the magnitude response plot to verify that the 3-dB down points are located at 1 and 1.5 kHz.

```
axis([0.5 2 -5 2])
```



Equiripple FIR Bandstop Filter

Design a constrained-band FIR equiripple filter of order 100 for data sampled at 10 kHz. You can specify constraints on at most two of the three bands: two passbands and one stopband. In this example, constrain the passband ripple to be 0.5 dB in each passband.

```
d = fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',100,800,1e3,1.5e3,1.7e3,1e4);
d.Passband1Constrained = true; d.Apass1 = 0.5;
d.Passband2Constrained = true; d.Apass2 = 0.5;
Hd = design(d,'equiripple');
```

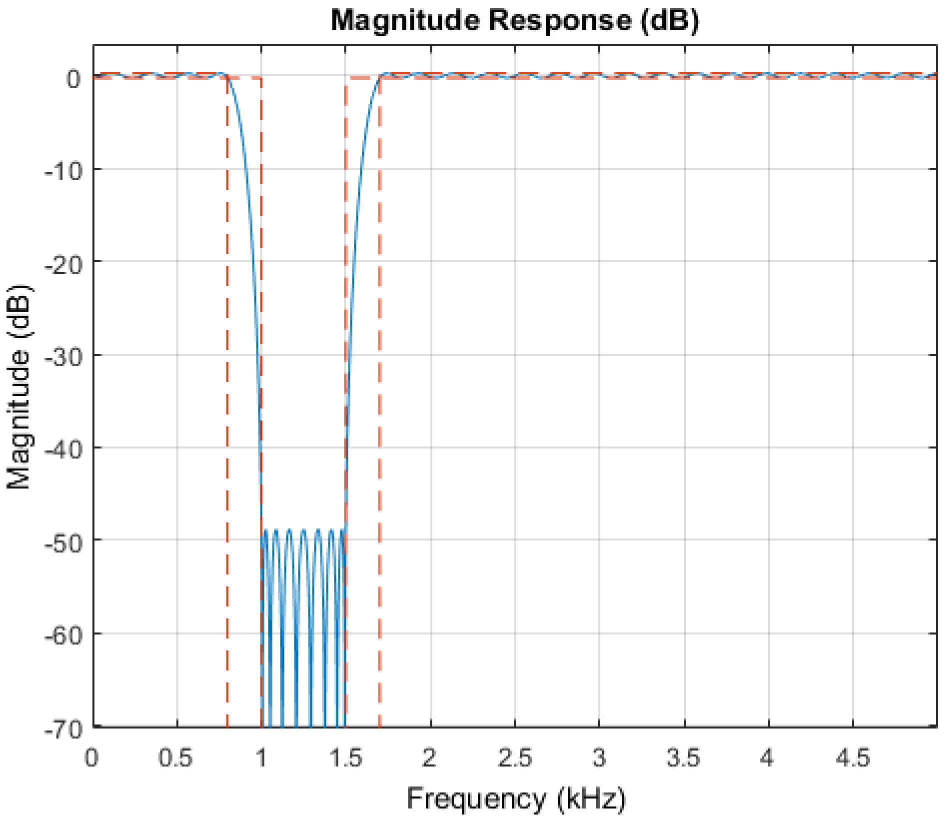
Visualize the magnitude response and measure the design.

```
fvtool(Hd)
```

```
measure(Hd)

ans =

Sample Rate             : 10 kHz
First Passband Edge     : 800 Hz
First 3-dB Point        : 852.4565 Hz
First 6-dB Point        : 881.7834 Hz
First Stopband Edge     : 1 kHz
Second Stopband Edge    : 1.5 kHz
Second 6-dB Point       : 1.6185 kHz
Second 3-dB Point       : 1.6478 kHz
Second Passband Edge    : 1.7 kHz
First Passband Ripple   : 0.49642 dB
Stopband Atten.         : 48.8466 dB
Second Passband Ripple  : 0.49634 dB
First Transition Width  : 200 Hz
Second Transition Width : 200 Hz
```



With this order filter and passband ripple constraints, you achieve approximately 50 dB of stopband attenuation.

`fdesign` | `fdesign.bandpass` | `fdesign.highpass` | `fdesign.lowpass`

Introduced in R2009a

fdesign.ciccomp

CIC compensator filter specification object

Syntax

```
d= fdesign.ciccomp
d= fdesign.ciccomp(d,nsections,rcic)
d= fdesign.ciccomp(...,spec)
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

Description

`d= fdesign.ciccomp` constructs a CIC compensator specifications object `d`, applying default values for the properties Fpass, Fstop, Apass, and Astop. In this syntax, the filter has two sections and the differential delay is 1.

Using `fdesign.ciccomp` with `design` method creates a System object, if the `'SystemObject'` flag is set to `true`.

`d= fdesign.ciccomp(d,nsections,rcic)` constructs a CIC compensator specifications object with the filter differential delay set to `d`, the number of sections in the filter set to `nsections`, and the CIC rate change factor set to `rcic`. The default values of these parameters are: the differential delay equal to 1, the number of sections equal to 2, and the CIC rate change factor equal to 1.

If the CIC rate change factor is equal to 1, the filter passband response is an inverse sinc that is an approximation to the true inverse passband response of the CIC filter.

If you specify a CIC rate change factor not equal to 1, the filter passband response is an inverse Dirichlet sinc that matches exactly the true inverse passband response of the CIC filter.

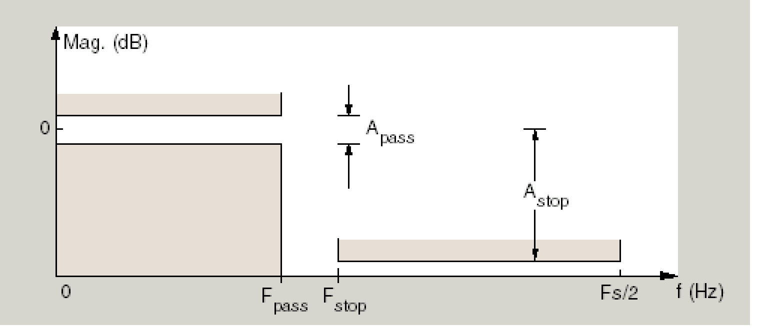
`d= fdesign.ciccomp(...,`*`spec`*`)` constructs a CIC Compensator specifications object and sets its `Specification` property to *`spec`*. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown in the list below. The entries are not case sensitive.

- `'fp,fst,ap,ast'` (default `spec`)
- `'n,fc,ap,ast'`
- `'n,fp,ap,ast'`
- `'n,fp,fst'`
- `'n,fst,ap,ast'`

The filter specifications are defined as follows:

- `ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- `ast` — attenuation in the stop band in decibels (the default units). Also called Astop.
- `fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- `fp` — frequency at the end of the pass band. Specified in normalized frequency units. Also called Fpass.
- `fst` — frequency at the start of the stop band. Specified in normalized frequency units. Also called Fstop.
- `n` — filter order.

In graphic form, the filter specifications look like this:



Regions between specification values like `fp` and `fst` are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a CIC compensator specifications object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...) constructs an object and sets the specifications in the order they are specified in the spec input when you construct the object.

Designing CIC Compensators

Typically, when they develop filters, designers want flat passbands and transition regions that are as narrow as possible. CIC filters present a (sinx/x) profile in the passband and relatively wide transitions.

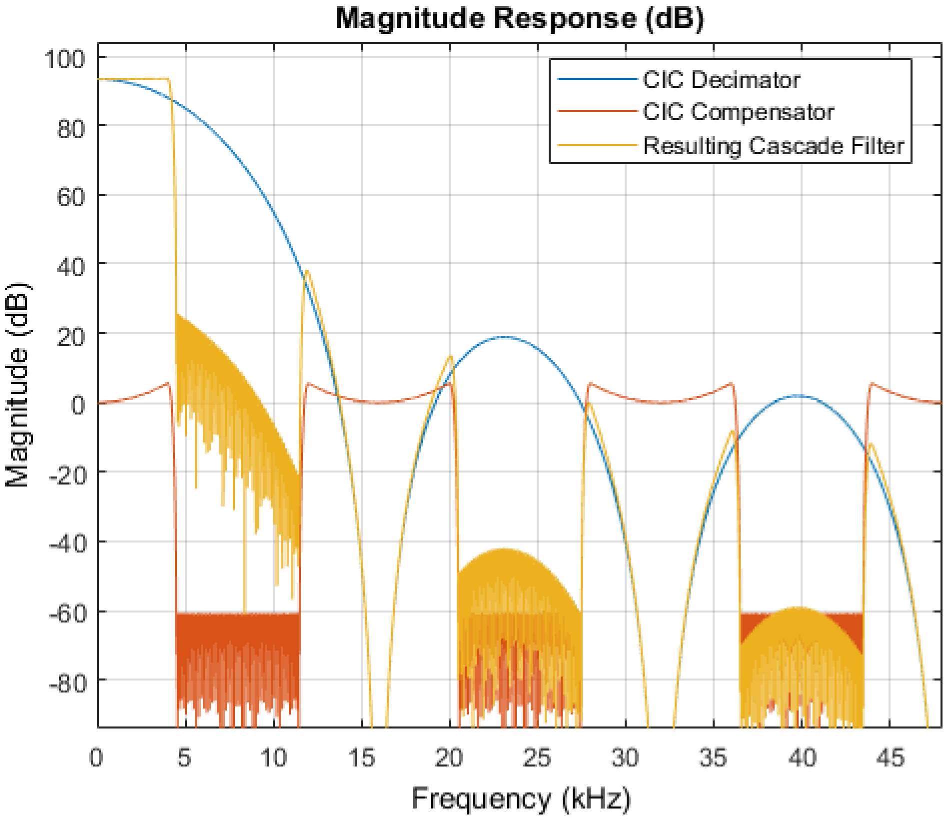
To compensate for this fall off in the passband, and to try to reduce the width of the transition region, you can use a CIC compensator filter that demonstrates an (x/sinx) profile in the passband. fdesign.ciccomp is specifically tailored to designing CIC compensators.

You can design a compensator for CIC filter using differential delay, d, number of sections, numberofsections, and the usable passband frequency, Fpass.

By taking the number of sections, passband, and differential delay from your CIC filter and using them in the definition of the CIC compensator, the resulting compensator filter effectively corrects for the passband droop of the CIC filter, and narrows the transition region.

As a demonstration of this concept, this example creates a CIC decimator and its compensator.

```
fs = 96e3;   % Input sampling frequency.
fpass = 4e3; % Frequency band of interest.
m = 6;  % Decimation factor.
hcic = design(fdesign.decimator(m,'cic',1,fpass,60,fs),'SystemObject',true);
hd = design(fdesign.ciccomp(hcic.DifferentialDelay, ...
            hcic.NumSections,fpass,4.5e3,.1,60,fs/m),'SystemObject',true);
fvtool(hcic,hd,...
cascade(hcic,hd),'ShowReference','off','Fs',[96e3 96e3/m 96e3])
legend('CIC Decimator','CIC Compensator','Resulting Cascade Filter');
```



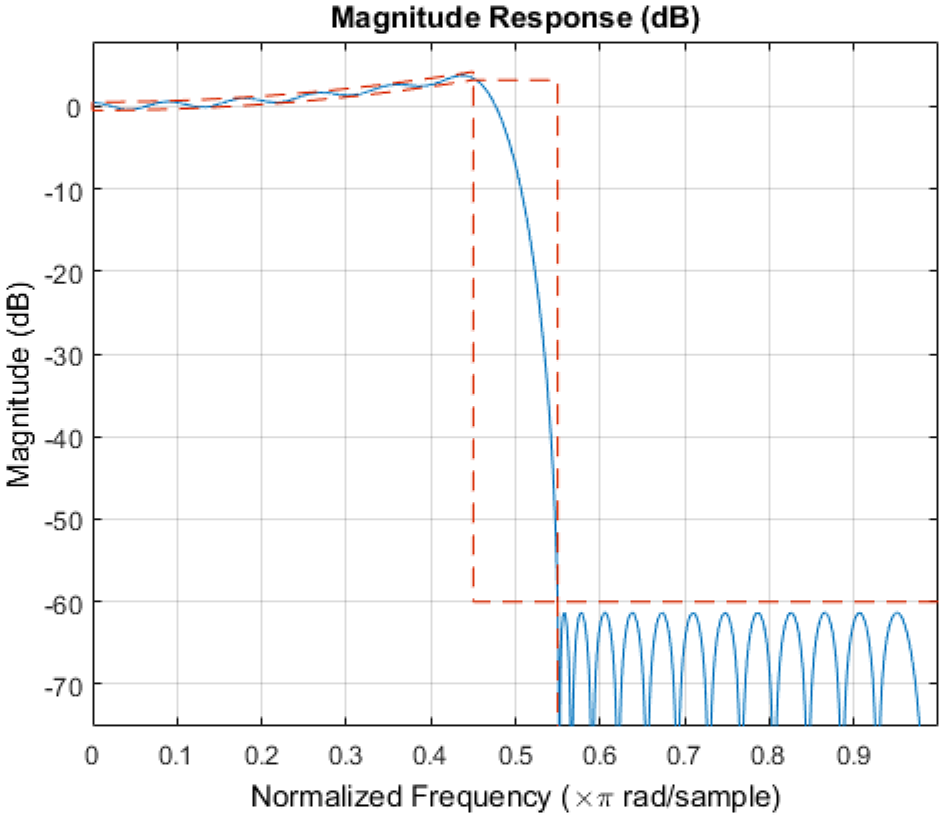
Here is a plot of a CIC filter and a compensator for that filter.

Examples

Design a CIC Compensator Using `fdesign` Object

Designed to compensate for the rolloff inherent in CIC filters, CIC compensators can improve the performance of your CIC design. This example designs a compensator d with five sections and a differential delay equal to one. The plot displayed after the code shows the increasing gain in the passband that is characteristic of CIC compensators, to overcome the droop in the CIC filter passband. Ideally, cascading the CIC compensator with the CIC filter results in a lowpass filter with flat passband response and narrow transition region.

```
h = fdesign.ciccomp;
set(h, 'NumberOfSections', 5, 'DifferentialDelay', 1);
cicComp = design(h,'equiripple','SystemObject',true);
fvtool(cicComp);
```



This compensator would work for a decimator or interpolator that had differential delay of 1 and 5 sections.

Introduced in R2011a

fdesign.comb

IIR comb filter specification object

Syntax

```
d=fdesign.comb
d=fdesign.comb(combtype)
d=fdesign(combtype,specstring)
d=fdesign(combtype,specstring,specvalue1,specvalue2,...)
d=fdesign.comb(...,Fs)
```

Description

`fdesign.comb` specifies a peaking or notching comb filter. Comb filters amplify or attenuate a set of harmonically related frequencies.

`d=fdesign.comb` creates a notching comb filter specification object and applies default values for the filter order (`N=10`) and quality factor (`Q=16`).

`d=fdesign.comb(combtype)` creates a comb filter specification object of the specified type and applies default values for the filter order and quality factor. The valid entries for `combtype` are shown in the following table. The entries are not case-sensitive.

Argument	Description
`notch`	creates a comb filter that attenuates a set of harmonically related frequencies.
`peak`	creates a comb filter that amplifies a set of harmonically related frequencies.

`d=fdesign(combtype,`*`specstring`*`)` creates a comb filter specification object of type `combtype` and sets its `Specification` property to *`specstring`* with default values. The entries in *`specstring`* determine the number of peaks or notches in the comb filter as well as their bandwidth and slope. Valid entries for *`specstring`* are shown below. The entries are not case-sensitive.

- `'N,Q'` (default)

- `''N,BW'`
- `'L,BW,GWB,Nsh'`

The following table describes the arguments in *`specstring`*.

Argument	Description
`BW`	Bandwidth of the notch or peak. By default the bandwidth is calculated at the point –3 dB down from the center frequency of the peak or notch. For example, setting `BW=0.01` specifies that the –3 dB point will be +/- 0.005 (in normalized frequency) from the center of the notch or peak.
`GWB`	Gain at which the bandwidth is measured. This allows the user to specify the bandwidth of the notch or peak at a gain different from the –3 dB default.
`L`	Upsampling factor for a shelving filter of order `Nsh`. `L` determines the number of peaks or notches, which are equally spaced over the normalized frequency interval [-1,1].
`N`	Filter order. Specifies a filter with `N+1` numerator and denominator coefficients. The filter will have `N` peaks or notches equally spaced over the interval [–1,1] .
`Nsh`	Shelving filter order. `Nsh` represents a positive integer that determines the sharpness of the peaks or notches. The greater the value of the shelving filter order, the steeper the slope of the peak or notch. This results in a filter of order `L*Nsh`.
`Q`	Peak or notch quality factor. `Q` represents the ratio of the lowest center frequency peak or notch (not including DC) to the bandwidth calculated at the –3 dB point.

`d=fdesign(combtype,`*`specstring`*`,specvalue1,specvalue2,...)` creates an IIR comb filter specification object of type `combtype` and sets its `Specification` property to the values in `specvalue1,specvalue2,...`

`d=fdesign.comb(...,Fs)` creates an IIR comb filter specification object using the sampling frequency, `Fs`, of the signal to be filtered. The function assumes that `Fs` is in Hertz and must be specified as a scalar trailing all other provided values.

Examples

Construct a Peaking and Notching Combing Filter

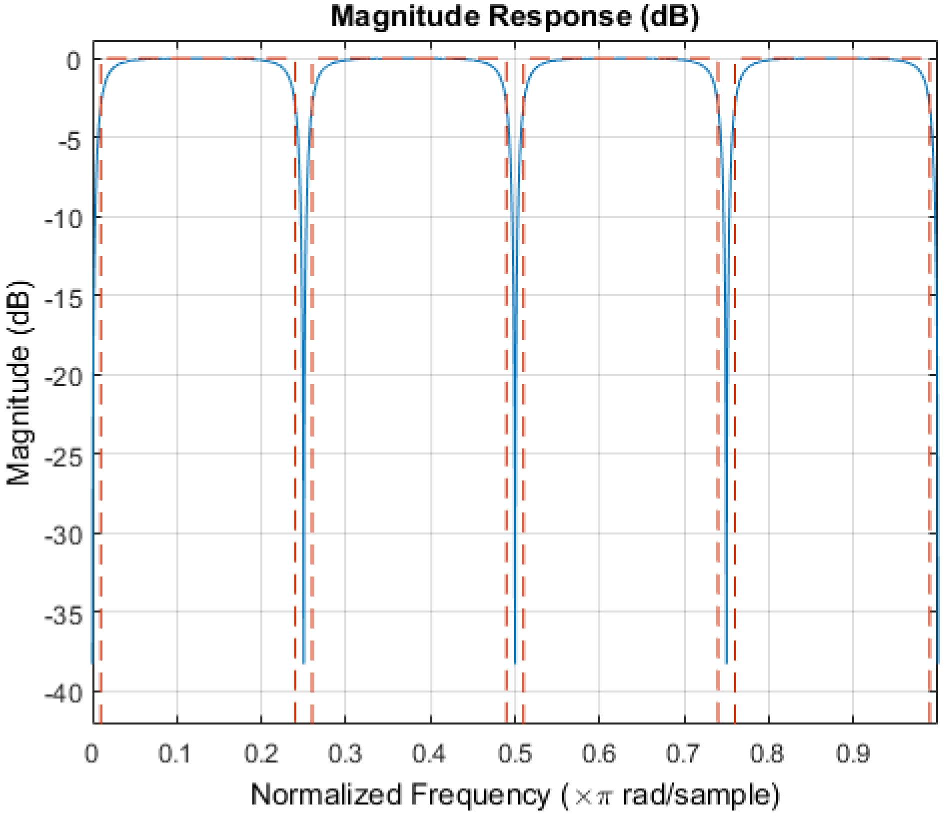
These examples demonstrate how to create IIR comb filter specification objects.

First, create a default specification object.

```
d = fdesign.comb;
```

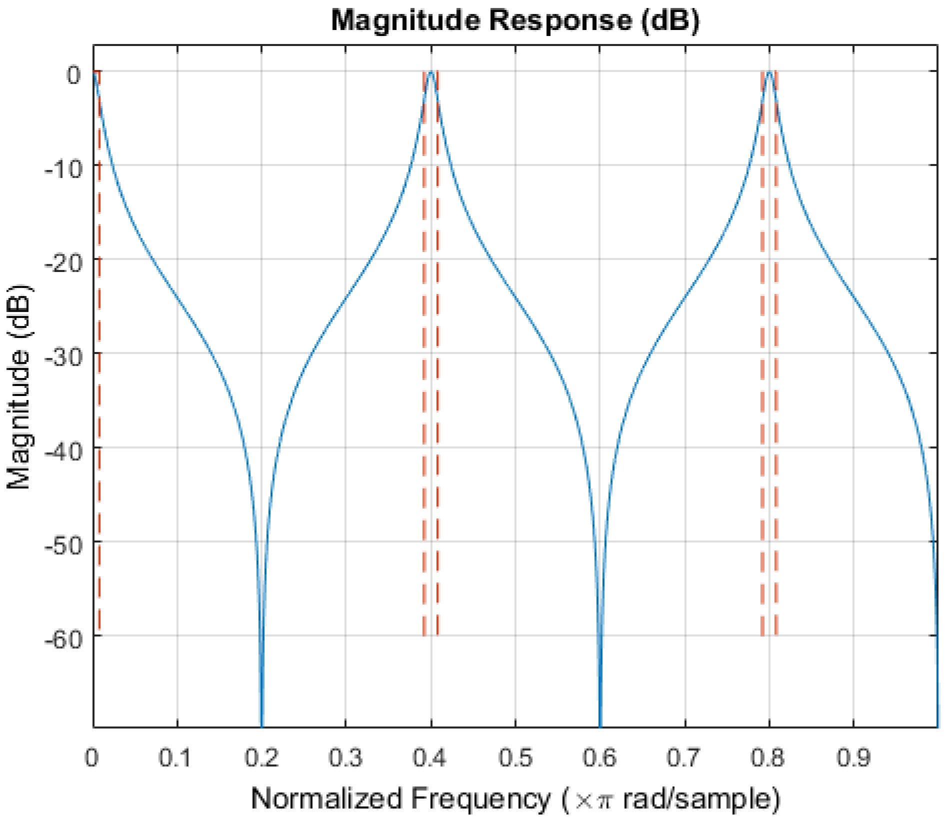
In the next example, create a notching filter of order 8 with a bandwidth of 0.02 (normalized frequency) referenced to the -3 dB point.

```
d  = fdesign.comb('notch','N,BW',8,0.02);
Hd = design(d,'SystemObject',true);
fvtool(Hd);
```



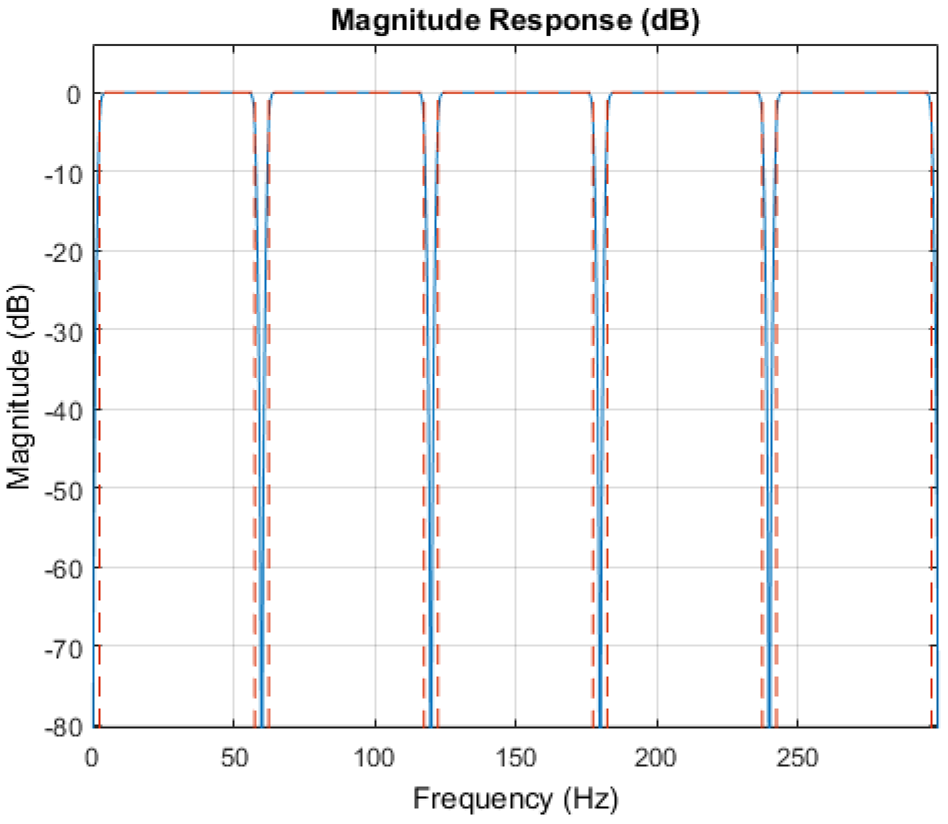
Next, create a peaking comb filter with 5 peaks and a quality factor of 25.

```
d = fdesign.comb('peak','N,Q',5,25);
Hd = design(d,'SystemObject',true);
fvtool(Hd);
```



In the next example, create a notching filter to remove interference at 60 Hz and its harmonics. The following code creates a filter with 10 notches and a notch bandwidth of 5 Hz referenced to the -4dB level. The filter has a shelving filter order of 4 and a sampling frequency of 600 Hz. Because the notches are equidistantly spaced in the interval [-300, 300] Hz, they occur at multiples of 60 Hz.

```
d = fdesign.comb('notch','L,BW,GBW,Nsh',10,5,-4,4,600);
Hd=design(d,'SystemObject',true);
fvtool(Hd);
```



Introduced in R2011a

fdesign.decimator

Decimator filter specification object

Syntax

```
D = fdesign.decimator(M)
D = fdesign.decimator(M, RESPONSE)
D = fdesign.decimator(M, CICRESPONSE, D)
D = fdesign.decimator(M, RESPONSE, SPEC)
D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)
D = fdesign.decimator(...,Fs)
D = fdesign.decimator(...,MAGUNITS)
```

Description

`D = fdesign.decimator(M)` constructs a decimator filter specification object `D` with the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.decimator(M, RESPONSE)` constructs a decimator specification object with the decimation factor `M` and the `'Response'` property.

`D = fdesign.decimator(M, CICRESPONSE, D)` constructs a CIC or CIC compensator decimator specification object with the decimation factor, `M`, `'Response'` property equal to `'CIC'` or `'CICCOMP'`, and `D` equal to the differential delay. The differential delay, `D`, must precede any specification option.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters. The decimation factor `M` is not included in the specification options. Different filter responses support different specifications. The following table lists the supported response types and specification options. The options are not case sensitive.

Design Method	Valid Specification Options
`'Arbitrary Magnitude'`	See `fdesign.arbmag` for a description of the specification entries. • `'N,F,A'` (default option) • `'N,B,F,A'`
`'Arbitrary Magnitude and Phase'`	See `fdesign.arbmagnphase` for a description of the specification entries. • `'N,F,H'` (default option) • `'N,B,F,H'`
`'Bandpass'`	See `fdesign.bandpass` for a description of the specification entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default option) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
`'Bandstop'`	See `fdesign.bandstop` for a description of the specification entries. • `'N,Fc1,Fc2'` • `'N,Fp1,Fst1,Fst2,Fp2'` • `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default option)

`'CIC'`	`'Fp,Ast'` — Only valid specification. `Fp` is the passband frequency and `Ast` is the stopband attenuation in decibels.
	To specify a CIC decimator, include the differential delay after `'CIC'` and before the filter specification option: `'Fp,Ast'`. For example:
	`d =`
	`fdesign.decimator(2,'cic',4,'Fp,Ast',0.4,40);`

Design Method	Valid Specification Options
'CIC Compensator'	See `fdesign.ciccomp` for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast' To specify a CIC compensator decimator, include the differential delay after 'CICCOMP' and before the filter specification. For example: `d = fdesign.decimator(2,'ciccomp',4);`
'Differentiator'	'N' — filter order
'Gaussian'	'Nsym,BT — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product. The specification must be preceded by an integer-valued SamplesPerSymbol.
'Halfband	See `fdesign.halfband` for a description of the specification entries. • 'TW,Ast' (default option) • 'N,TW' • ‘N’ • 'N,Ast' If you use the quasi-linear IIR design method, `iirlinphase`, with a halfband specification, the interpolation factor must be 2.

Design Method	Valid Specification Options
'Highpass'	See fdesign.highpass for a description of the specification entries. • 'Fst,Fp,Ast,Ap' (default option) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification entries. • 'N,TW' (default option) • 'TW,Ap'
'Inverse-sinc Lowpass'	See fdesign.isinclp for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,Fc,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast'
'Inverse-sinc Highpass'	See fdesign.isinchp for a description of the specification entries. • 'Fst,Fp,Ast,Ap' (default option) • 'N,Fc,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap'

Design Method	Valid Specification Options
'Lowpass'	See `fdesign.lowpass` for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,F3dB' • 'N,Fc' • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fp,Fst,Ap' • 'N,Fp,Fst,Ast' • 'N,Fst,Ap,Ast'
'Nyquist'	See `fdesign.nyquist` for a description of the specification entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the `DecimationFactor`. • 'TW,Ast' (default option) • 'N' • 'N,Ast' • 'N,Ast'

`D = fdesign.decimator(M, RESPONSE, SPEC)` constructs object `D` and sets the `Specification` property to `SPEC` for the response type, `RESPONSE`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` depend on the `RESPONSE` type.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters with such response types as `fdesign.lowpass`. The options are not case sensitive.

The decimation factor `M` is not in the specification options.

`D = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.decimator(...,Fs)` provides the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. `Fs` is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.decimator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units.
- `'dB'` — specify the magnitude in dB (decibels).
- `'squared'` — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Construct a Decimator Using `fdesign` Object

These examples show how to construct decimating filter specification objects.

First, create a default specifications object without using input arguments except for the decimation factor m.

```
d = fdesign.decimator(2,'Nyquist',2,0.1,80) % Set tw=0.1, and ast=80.
```

```
d = 

  decimator with properties:

          MultirateType: 'Decimator'
               Response: 'Nyquist'
       DecimationFactor: 2
          Specification: 'TW,Ast'
            Description: {2×1 cell}
                   Band: 2
    NormalizedFrequency: 1
        TransitionWidth: 0.1000
                  Astop: 80
```

Now create an object by passing a specification type option 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design - the resulting object uses default values for the filter specifications. You must provide the design input argument, bandpass in this example, when you include a specification.

```
d = fdesign.decimator(8,'bandpass',...
'fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another decimating filter specification object, passing the specification values to the object rather than accepting the default values for fp,fst,ap,ast.

```
d = fdesign.decimator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications - n,fc,ap,ast.

```
d = fdesign.decimator(3,'ciccomp',1,2,'n,fc,ap,ast',...
20,0.45,.05,50);
```

Now design a decimator using the equiripple design method.

```
equiDecimator = design(d,'equiripple','SystemObject',true);
```

Pass a new specification type for the filter, specifying the filter order. Note that the inputs must include the differential delay dd with the CIC input argument to design a CIC specification object.

```
m = 5;
dd = 2;
d = fdesign.decimator(m,'cic',dd,'fp,ast',0.55,55);
```

In this example, you specify a sampling frequency as the last input argument. Here is it 1000 Hz. Design an equiripple filter and plot the magnitude response:

```
d = fdesign.decimator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...
100,150,250,300,50,.05,50,1000);
fvtool(design(d,'equiripple','SystemObject',true))
```

`fdesign` | `fdesign.arbmag` | `fdesign.arbmagnphase` | `fdesign.interpolator` | `fdesign.rsrc`

Introduced in R2011a

fdesign.differentiator

Differentiator filter specification object

Syntax

```
D = fdesign.differentiator
D = fdesign.differentiator(SPEC)
D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)
D = fdesign.differentiator(specvalue1)
D = fdesign.differentiator(...,Fs)
D = fdesign.differentiator(...,MAGUNITS)
```

Description

`D = fdesign.differentiator` constructs a default differentiator filter designer `D` with the filter order set to 31.

`D = fdesign.differentiator(SPEC)` initializes the filter designer `Specification` property to `SPEC`. You provide one of the following filter entries as input to replace `SPEC`. These entries are not case sensitive.

Note: Specifications marked with an asterisk require the DSP System Toolbox software.

- `'N'` — Full band differentiator (default)
- `'N,Fp,Fst'` — Partial band differentiator
- `'N,Fp,Fst,Ap'` — Partial band differentiator *
- `'N,Fp,Fst,Ast'` — Partial band differentiator *
- `'Ap'` — Minimum order full band differentiator *
- `'Fp,Fst,Ap,Ast'` — Minimum order partial band differentiator *

The filter specifications are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- `Ast` — attenuation in the stop band in decibels (the default units). Also called Astop.
- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- `N` — filter order.

By default, `fdesign.differentiator` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)` initializes the filter designer specifications in `SPEC` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1`, `specvalue2`, and more, enter

```
get(d,'description')
```

at the Command prompt.

`D = fdesign.differentiator(specvalue1)` assumes the default specification `N`, setting the filter order to the value you provide.

`D = fdesign.differentiator(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.differentiator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

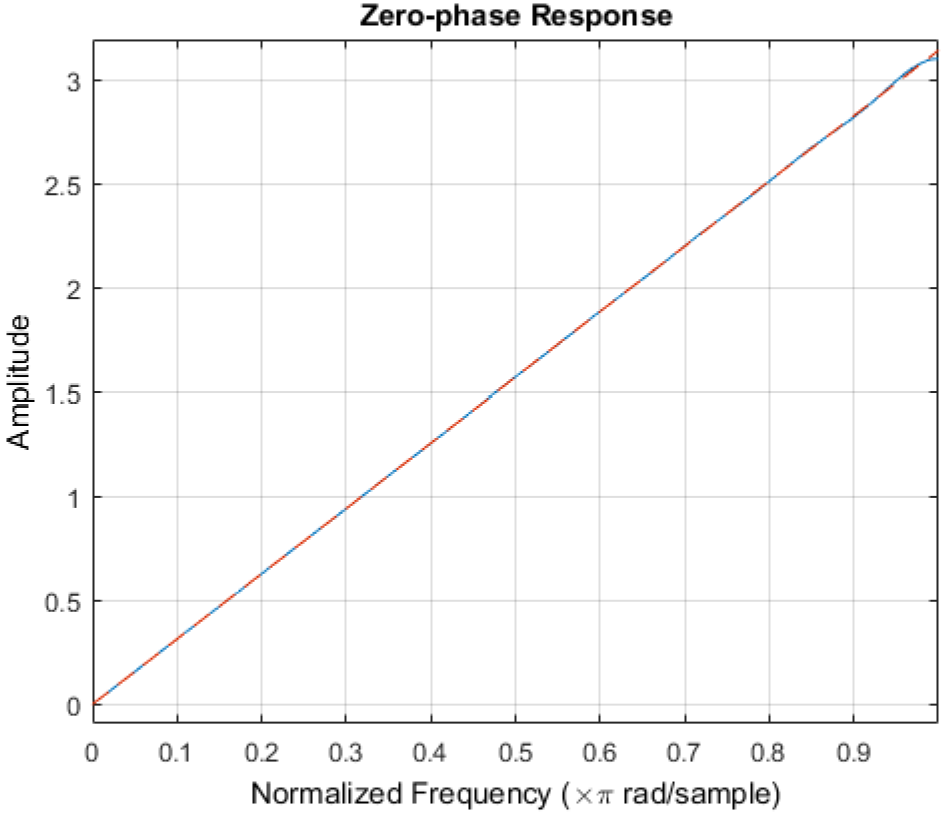
Examples

FIR Differentiator Filters

Design a 33rd-order FIR differentiator using least squares. Plot the zero-phase response of the filter.

```
d = fdesign.differentiator(33);
hd = design(d,'firls','SystemObject',true);

zerophase(hd)
```



Design a 54th-order narrowband equiripple differentiator. Differentiate the lowest 25% of the frequencies in the Nyquist range and filter the higher frequencies. Specify a sample rate of 20 kHz, a passband frequency of 2.5 kHz, and a stopband frequency of 3 kHz.

```
Fs = 20000;

d = fdesign.differentiator('N,Fp,Fst',54,2500,3000,Fs);
Hd = design(d,'equiripple','SystemObject',true);
```

Redesign the filter, but this time weight the stopband to increase the attenuation.

```
Hd1 = design(d,'equiripple','Wstop',4,'SystemObject',true);

hfvt = fvtool(Hd,Hd1,'MagnitudeDisplay','zero-phase', ...
    'FrequencyRange','[0, Fs/2)');
legend(hfvt,'No stopband weighting','Stopband weighting');
```

`design` | `fdesign`

Introduced in R2009a

fdesign.fracdelay

Fractional delay filter specification object

Syntax

```
d = fdesign.fracdelay(delta)
d = fdesign.fracdelay(delta,'N')
d = fdesign.fracdelay(delta,'N',n)
d = fdesign.fracdelay(delta,n)
d = fdesign.fracdelay(...,fs)
```

Description

`d = fdesign.fracdelay(delta)` constructs a default fractional delay filter designer `d` with the filter order set to 3 and the delay value set to `delta`. The fractional delay `delta` must be between 0 and 1 samples.

`d = fdesign.fracdelay(`*`delta,`*`'N')` initializes the filter designer specification to `N`, where `N` specifies the fractional delay filter order and defaults to filter order of 3.

Use `designmethods(d)` to get a list of the design methods available for a specification.

`d = fdesign.fracdelay(delta,'N',n)` initializes the filter designer to `N` and sets the filter order to `n`.

`d = fdesign.fracdelay(delta,n)` assumes the default specification `N`, filter order, and sets the filter order to the value you provide in input `n`.

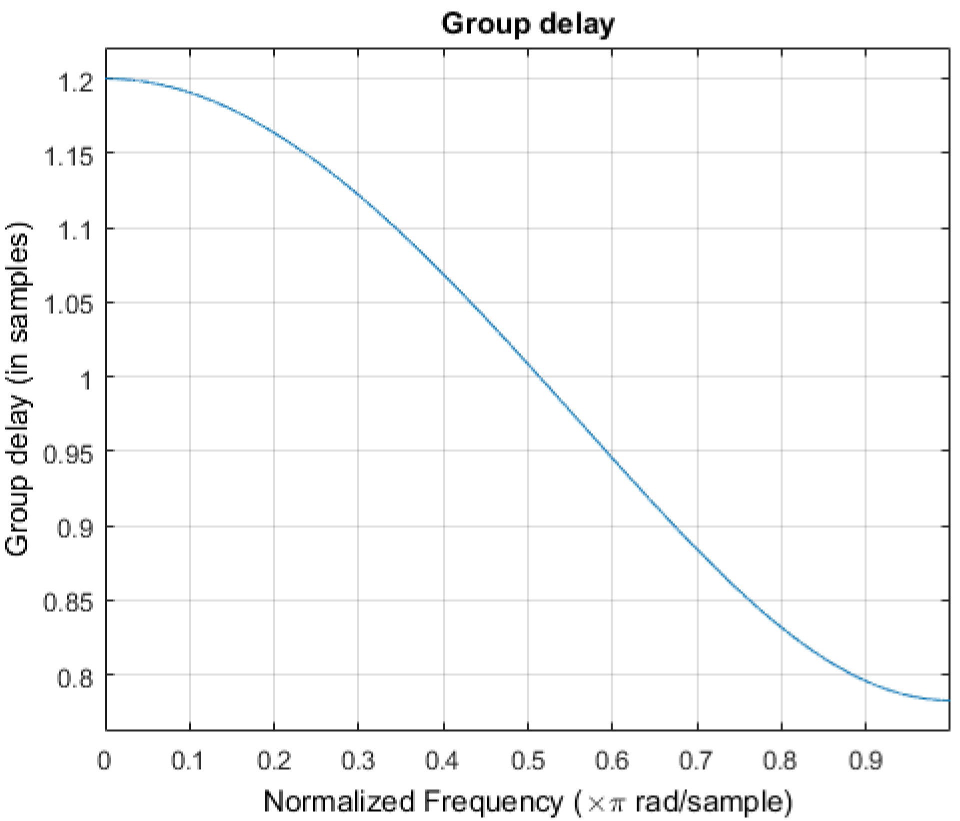
`d = fdesign.fracdelay(...,fs)` adds the argument `fs`, specified in units of Hertz (Hz) to define the sampling frequency. In this case, specify the fractional delay `delta` to be between 0 and 1/`fs`.

Examples

Create a Fractional Delay Filter Using `fdesign` Object

Design a second-order fractional delay filter of 0.2 samples using the Lagrange method. Implement the filter using a Farrow fractional delay (fd) structure.

```
d = fdesign.fracdelay(0.2,'N',2);
secondOrderFrac = design(d,'lagrange','filterstructure','farrowfd');
fvtool(secondOrderFrac,'analysis','grpdelay')
```



Design a cubic fractional delay filter with a sampling frequency of 8 kHz and fractional delay of 50 microseconds using the Lagrange method.

```
d = fdesign.fracdelay(50e-6,'N',3,8000);
cubicFrac = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
```

design | designopts | fdesign | setspecs

Introduced in R2011a

fdesign.halfband

Halfband filter specification object

Syntax

```
d = fdesign.halfband
d = fdesign.halfband('type',type)
d = fdesign.halfband(spec)
d = fdesign.halfband(spec,specvalue1,specvalue2,...)
d = fdesign.halfband(specvalue1,specvalue2)
d = fdesign.halfband(...,fs)
d = fdesign.halfband(...,magunits)
```

Description

`d = fdesign.halfband` constructs a halfband filter specification object `d`, applying default values for the properties `tw` and `ast`.

Using `fdesign.halfband` along with `design` method generates a System object, if the `'SystemObject'` flag in the `design` method is set to `true`.

`d = fdesign.halfband('type',type)` initializes the filter designer 'Type' property with `type`. '`type`' must be either `lowpass` or `highpass` and is not case sensitive.

`d = fdesign.halfband(`*`spec`*`)` constructs object `d` and sets its '`Specification`' to *`spec`*. Entries in `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown below. These options are not case sensitive.

- `tw,ast` (default `spec`)
- `n,tw`
- `n`
- `n,ast`

where,

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

By default, all frequency specifications are assumed to be in normalized frequency units. Moreover, all magnitude specifications are assumed to be in dB. Different specification types may have different design methods available.

The filter design methods that apply to a halfband filter specification object change depending on the `Specification` choice. Use `designmethods` to determine which design method applies to an object and its specification choice. Different filter design methods also have options that you can specify. Use `designopts` with the design method to see the available options. For example:

```
f=fdesign.halfband('N,TW');
designmethods(f)
```

`d = fdesign.halfband(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.halfband(specvalue1,specvalue2)` constructs an object `d` assuming the default `Specification` property `tw,ast`, using the values you provide for the input arguments `specvalue1` and `specvalue2` for `tw` and `ast`.

`d = fdesign.halfband(...,fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.halfband(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Create Halfband Filters Using `fdesign` Object

Create a default halfband filter specifications object.

```
d=fdesign.halfband;
```

Create another halfband filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d2 = fdesign.halfband('n,ast', 42, 80);
```

For another example, pass the filter values that correspond to the default Specification - n,ast.

```
d3 = fdesign.halfband(.01, 80);
```

This example designs an equiripple FIR filter, starting by passing a new specification type and specification values to fdesign.halfband.

```
hs = fdesign.halfband('n,ast',80,70);
hd =design(hs,'equiripple','SystemObject',true);
```

In this example, pass the specifications for the filter, and then design a least-squares FIR filter from the object, using firls as the design method.

```
hs = fdesign.halfband('n,tw', 42, .04);
hd2 = design(hs,'firls','SystemObject',true);
```

Create two equiripple halfband filters with and without a nonnegative zero phase response:

```
f=fdesign.halfband('N,TW',12,0.2);
```

Equiripple halfband filter with nonnegative zero phase response

```
Hd1 = design(f,'equiripple','ZeroPhase',true,'SystemObject',true);
```

Equiripple halfband filter with zero phase false 'zerophase',false is the default

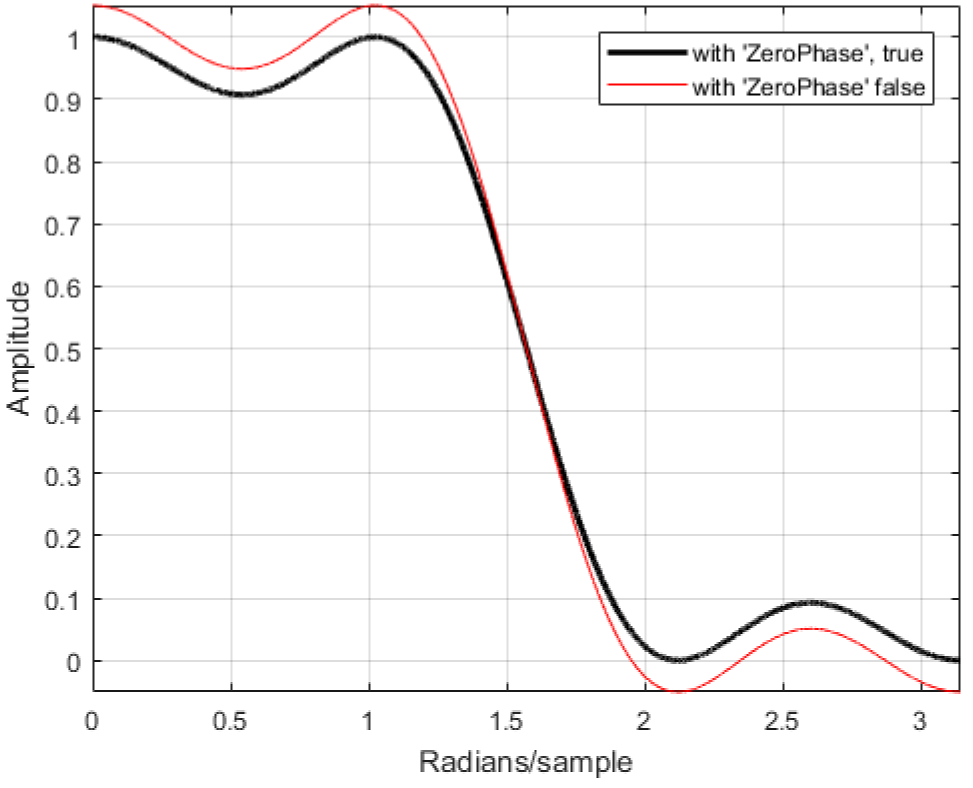
```
Hd2=design(f,'equiripple','ZeroPhase',false,'SystemObject',true);
```

Obtain real-valued amplitudes (not magnitudes)

```
[Hr_zerophase,W]=zerophase(Hd1);
[Hr,W]=zerophase(Hd2);
```

Plot and compare response

```
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```



Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies. The 'ZeroPhase' option is valid only for equiripple halfband designs with the

'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

Introduced in R2011a

fdesign.highpass

Highpass filter specification object

Syntax

```
D = fdesign.highpass
D = fdesign.highpass(SPEC)
D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.highpass(specvalue1,specvalue2,specvalue3,
specvalue4)
D = fdesign.highpass(...,Fs)
D = fdesign.highpass(...,MAGUNITS)
```

Description

`D = fdesign.highpass` constructs a highpass filter specification object `D`, applying default values for the specification, `'Fst,Fp,Ast,Ap'`.

`D = fdesign.highpass(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. These entries are not case sensitive.

Note: Specification entries marked with an asterisk require the DSP System Toolbox software.

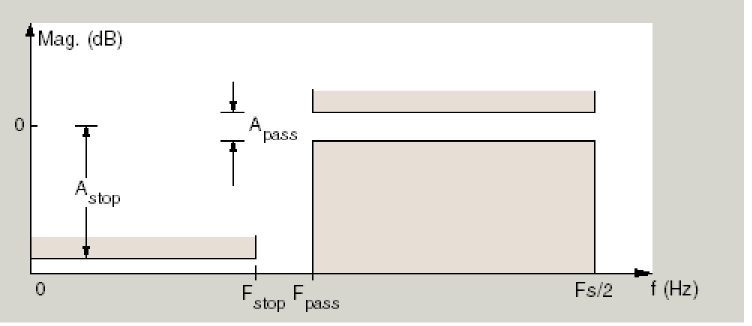
- `'Fst,Fp,Ast,Ap'` (default `spec`)
- `'N,F3db'`
- `'N,F3db,Ap'` *
- `'N,F3db,Ast'` *
- `'N,F3db,Ast,Ap'` *
- `'N,F3db,Fp` *

- 'N,Fc'
- 'N,Fc,Ast,Ap'
- 'N,Fp,Ap'
- 'N,Fp,Ast,Ap'
- 'N,Fst,Ast'
- 'N,Fst,Ast,Ap'
- 'N,Fst,F3db' *
- 'N,Fst,Fp'
- 'N,Fst,Fp,Ap' *
- 'N,Fst,Fp,Ast' *
- 'Nb,Na,Fst,Fp' *

The filter specifications are defined as follows:

- Ap — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- Ast — attenuation in the stop band in decibels (the default units). Also called Astop.
- F3db — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- Fc — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- Fp — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- Fst — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- N — filter order.
- Na and Nb are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like Fst and Fp are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a highpass filter specification object change depending on the Specification. Use designmethods to determine which design method applies to an object and its specification.

Use designopts to determine which design options are valid for a given design method. For detailed information on design options for a given design method, METHOD, enter help(D,METHOD) at the MATLAB command line.

D = fdesign.highpass(SPEC,specvalue1,specvalue2,...) constructs an object d and sets its specification values at construction time.

D = fdesign.highpass(specvalue1,specvalue2,specvalue3, specvalue4) constructs an object D with the default Specification property and the values you enter for specvalue1,specvalue2,....

D = fdesign.highpass(...,Fs) provides the sampling frequency for the filter specification object. Fs is in Hz and must be specified as a scalar trailing the other numerical values provided. If you specify a sampling frequency, all other frequency specifications are in Hz.

D = fdesign.highpass(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the MAGUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Highpass Filtering of Sinusoids

Highpass filter a discrete-time signal consisting of two sine waves.

Create a highpass filter specification object. Specify the passband frequency to be 0.25π rad/sample and the stopband frequency to be 0.15π rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.highpass('Fst,Fp,Ast,Ap',0.15,0.25,60,1);
```

Query the valid design methods for your filter specification object.

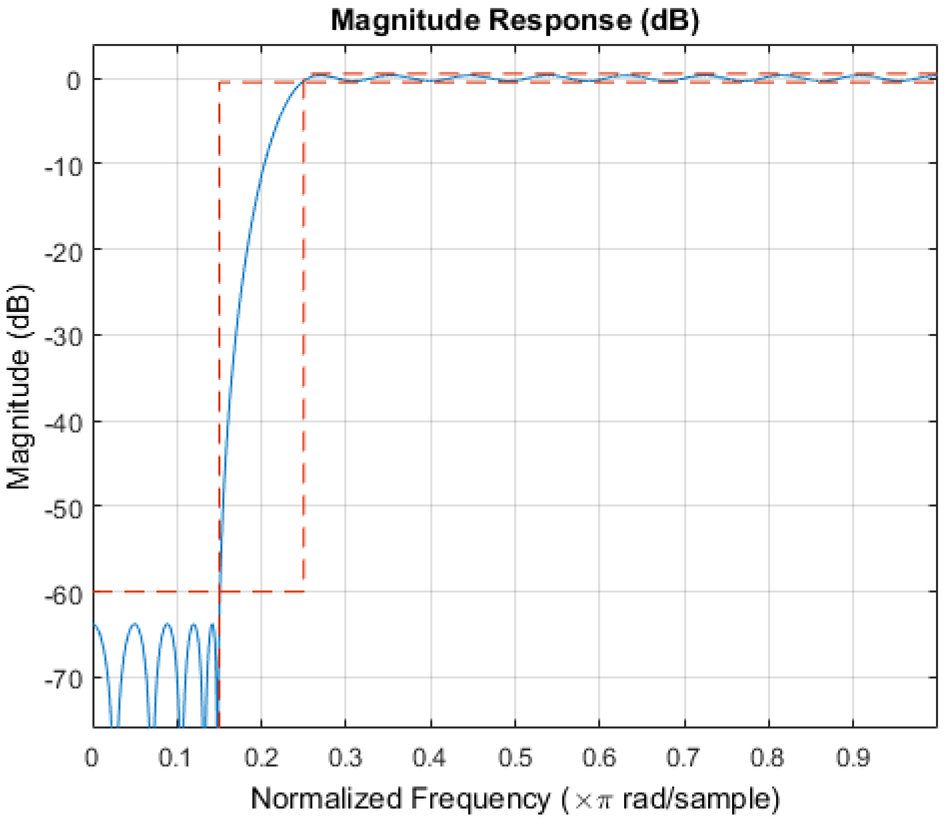
```
designmethods(d)
```

```
Design Methods for class fdesign.highpass (Fst,Fp,Ast,Ap):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
```

Create an FIR equiripple filter and view the filter magnitude response with FVTool.

```
Hd = design(d,'equiripple');
fvtool(Hd)
```



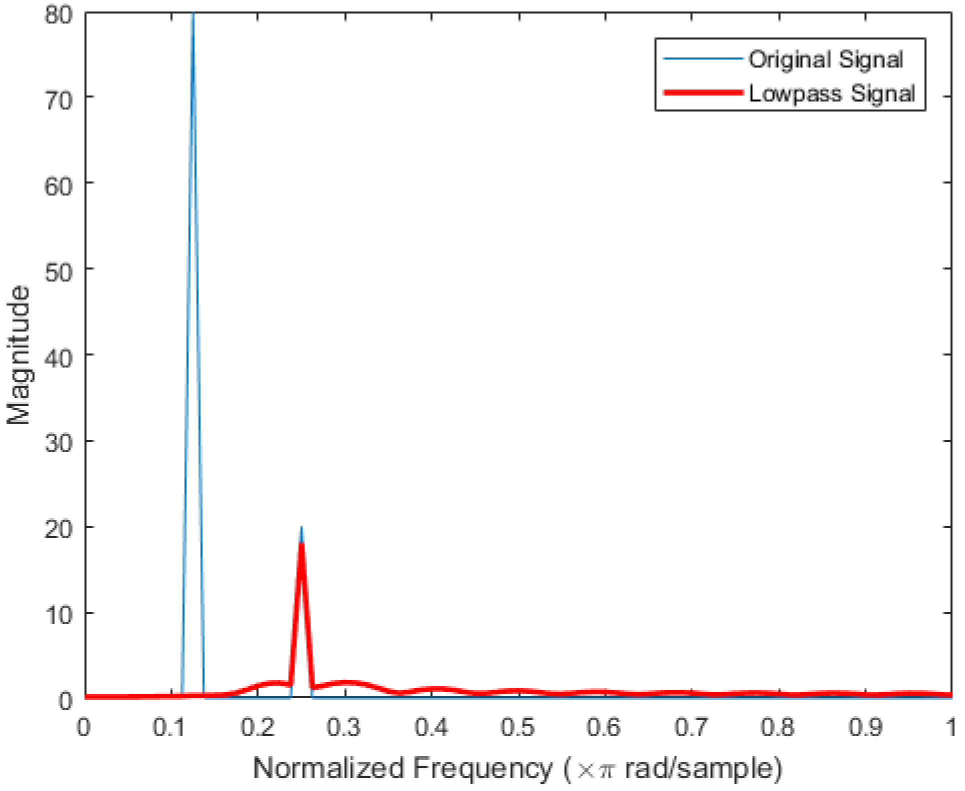
Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of π/8 and π/4 rad/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object.

```
n = 0:159;
x = cos(pi/8*n)+0.25*sin(pi/4*n);
y = filter(Hd,x);
```

Plot the original and filtered signals in the frequency domain.

```
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);
```

```
plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
plot(freq/pi,abs(ydft(1:length(y)/2+1)),'r','linewidth',2)
hold off
legend('Original Signal','Lowpass Signal','Location','NorthEast')
ylabel('Magnitude')
xlabel('Normalized Frequency (\times\pi rad/sample)')
```



Window Method Highpass Design

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sample rate of 48 kHz. Look at the available design methods.

```
d=fdesign.highpass('N,Fc',10,9600,48000);
```

```
designmethods(d)
```

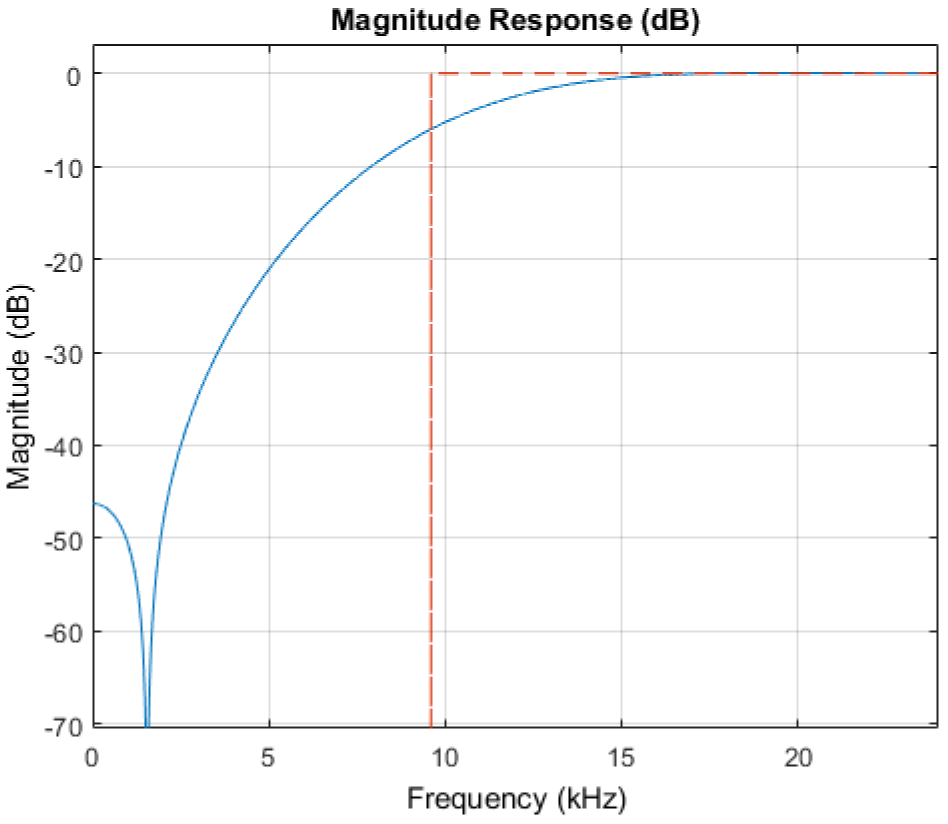
```
Design Methods for class fdesign.highpass (N,Fc):

window
```

The only available method is the FIR window method. Design the filter and display its magnitude response.

```
Hd = design(d);

fvtool(Hd)
```



Stopband Constraints

You can specify the shape of the stopband and the rate at which the stopband decays.

Create two FIR equiripple filters with different linear stopband slopes. Specify the passband frequency to be 0.3π rad/sample and the stopband frequency to be 0.35π rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB. Design one filter with a 20 dB/(rad/sample) stopband slope and another filter with a slope of 40 dB/(rad/sample).

```
D = fdesign.highpass('Fst,Fp,Ast,Ap',0.3,0.35,60,1);
Hd1 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);
Hd2 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',40);
```

Visualize the magnitude responses of the filters.

```
hfvt = fvtool([Hd1 Hd2]);
legend(hfvt,'20 dB/rad/sample','40 dB/rad/sample')
```

`design` | `designmethods` | `fdesign`

Introduced in R2009a

fdesign.hilbert

Hilbert filter specification object

Syntax

```
d = fdesign.hilbert
d = fdesign.hilbert(specvalue1,specvalue2)
d = fdesign.hilbert(spec)
d = fdesign.hilbert(spec,specvalue1,specvalue2)
d = fdesign.hilbert(...,Fs)
d = fdesign.hilbert(...,MAGUNITS)
```

Description

`d = fdesign.hilbert` constructs a default Hilbert filter designer `d` with `N`, the filter order, set to 30 and `TW`, the transition width set to 0.1π radians/sample.

`d = fdesign.hilbert(specvalue1,specvalue2)` constructs a Hilbert filter designer `d` assuming the default specification `'N,TW'`. You input `specvalue1` and `specvalue2` for `N` and `TW`.

`d = fdesign.hilbert(`*`spec`*`)` initializes the filter designer `Specification` property to `spec`. You provide one of the following as input to replace `spec`. The specification options are not case sensitive.

Note: Specifications marked with an asterisk require the DSP System Toolbox software.

- `'N,TW'` default specification option.
- `'TW,Ap'` *

The filter specifications are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.

- `N` — filter order.
- `TW` — width of the transition region between the passband and the stopband.

By default, `fdesign.hilbert` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Different specifications may have different design methods available. Use `designmethods(d)` to get a list of the design methods available for a given specification.

`d = fdesign.hilbert(`*`spec`*`,specvalue1,specvalue2)` initializes the filter designer specifications in `spec` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1` and `specvalue2`, enter

```
get(d,'description')
```

at the Command prompt.

`d = fdesign.hilbert(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.hilbert(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

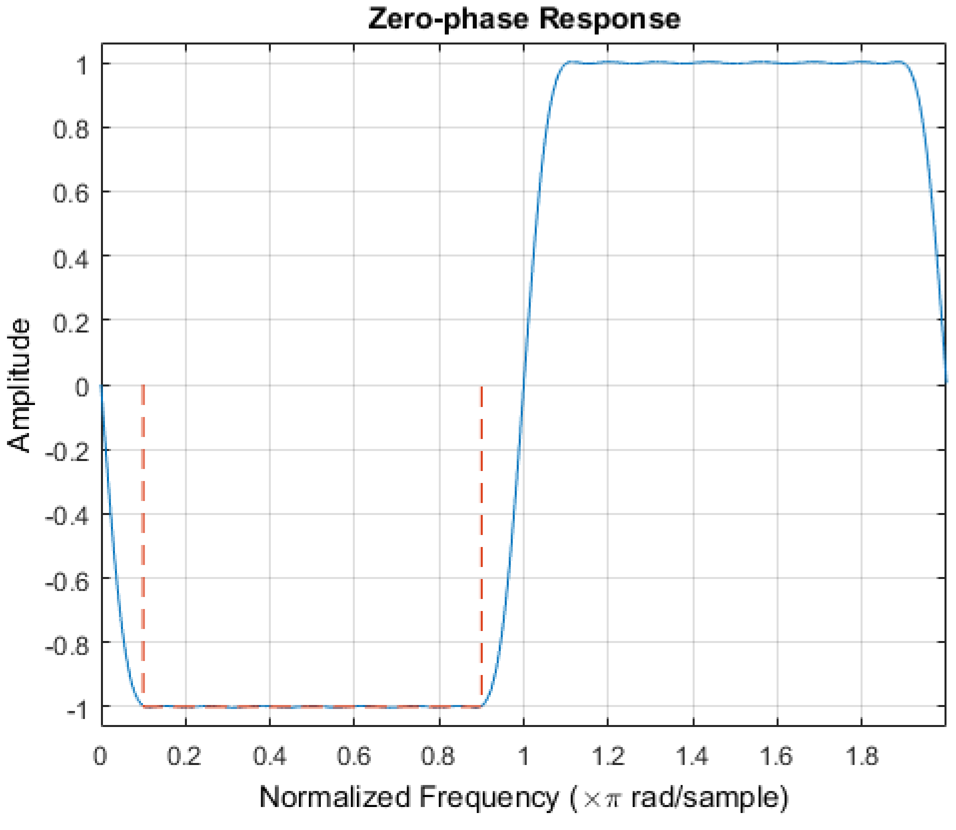
When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Hilbert Transformers

Design a Hilbert transformer of order 30 with a transition width of 0.2π rad/sample. Use least-squares minimization to obtain an equiripple linear-phase FIR filter. Plot the zero-phase response in the interval [–π,π).

```
d = fdesign.hilbert('N,TW',30,0.2);
Hd = design(d,'equiripple','SystemObject',true);
zerophase(Hd,'whole')
```

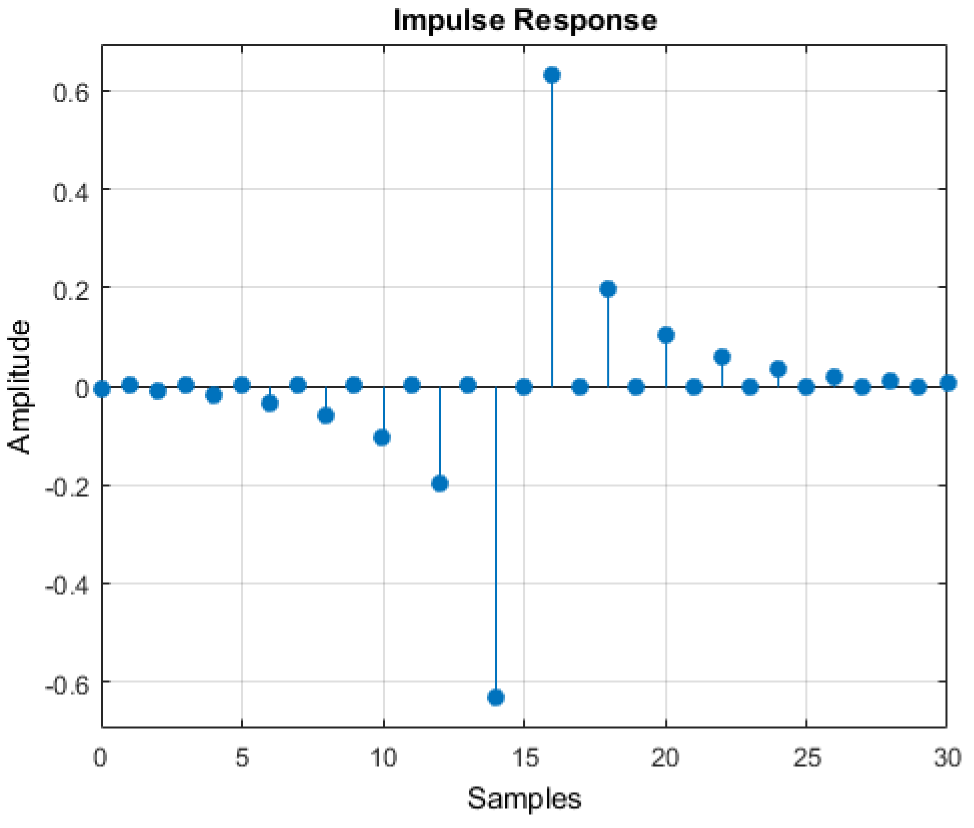


The impulse response of this even-order type-3 filter is antisymmetric.

```
impz(Hd)
ftype = firtype(Hd)
```

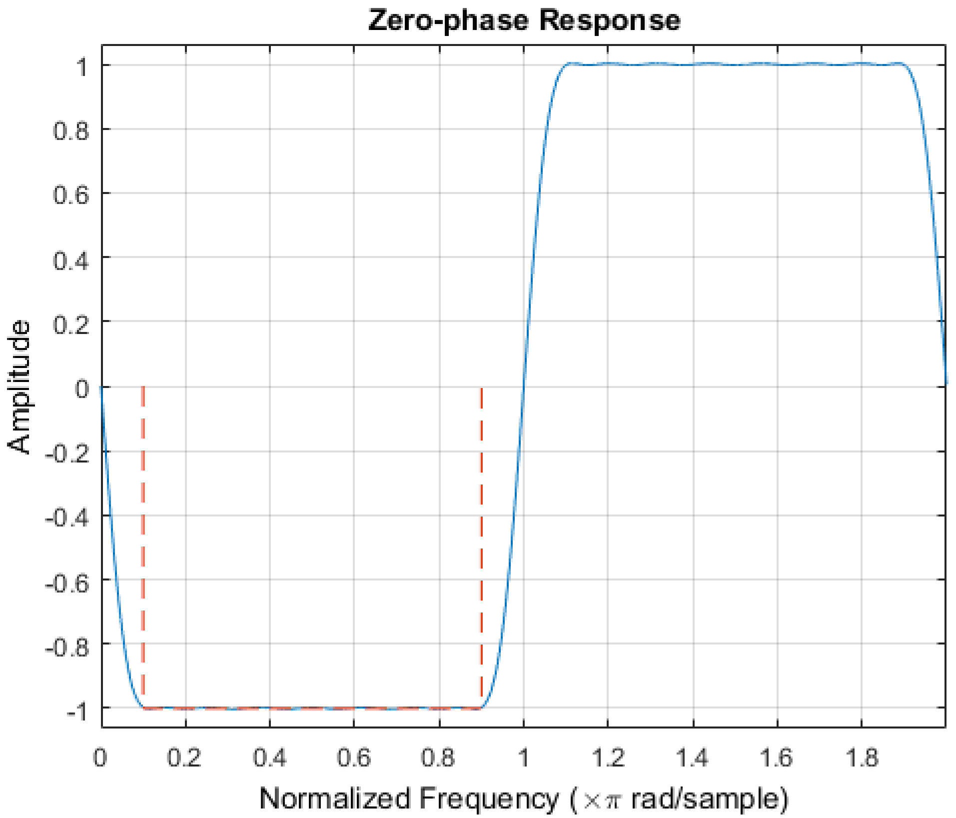
```
ftype =

     3
```



Design a minimum-order Hilbert transformer that has a sample rate of 1 kHz. Specify the passband ripple to be 1 dB. Display the zero-phase response of the filter.

```
d = fdesign.hilbert('TW,Ap',1,0.1,1e3);
hd = design(d,'equiripple','SystemObject',true);
zerophase(Hd,'whole')
```



See Also

See Also

`design` | `fdesign` | `setspecs`

Introduced in R2009a

fdesign.interpolator

Interpolator filter specification

Syntax

```
D = fdesign.interpolator(L)
D = fdesign.interpolator(L,RESPONSE)
D = fdesign.interpolator(L,CICRESPONSE,D)
D = fdesign.interpolator(L,RESPONSE,spec)
D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)
D = fdesign.interpolator(...,Fs)
d = fdesign.interpolator(...,MAGUNITS)
```

Description

`D = fdesign.interpolator(L)` constructs an interpolator filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 2.

`D = fdesign.interpolator(L,RESPONSE)` constructs a interpolator specification object with the interpolation factor `L` and the `'Response'` property set to one of the supported types.

`D = fdesign.interpolator(L,CICRESPONSE,D)` constructs a CIC or CIC compensator interpolator specification object with the interpolation factor, `L`, and `'Response'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede any specification option.

`D = fdesign.interpolator(L,RESPONSE,spec)` constructs object `D` and sets its `Specification` property to `spec`. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` depend on the design type of the specifications object.

When you add the `spec` input argument, you must also add the `RESPONSE` input argument.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters with design methods such as `fdesign.lowpass`. The options are not case sensitive.

The interpolation factor `L` is not in the specification options. The different filter responses support different specifications. The following table lists the supported response types and specification options.

Design Method	Valid Specification Options
`'Arbitrary Magnitude'`	See `fdesign.arbmag` for a description of the specification entries. • `'N,F,A'` (default option) • `'N,B,F,A'`
`'Arbitrary Magnitude and Phase'`	See `fdesign.arbmagnphase` for a description of the specification entries. • `'N,F,H'` (default option) • `'N,B,F,H'`
`'Bandpass'`	See `fdesign.bandpass` for a description of the specification entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default option) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
`'Bandstop'`	See `fdesign.bandstop` for a description of the specification entries. • `'N,Fc1,Fc2'` • `'N,Fp1,Fst1,Fst2,Fp2'` • `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default option)
`'CIC'`	`'Fp,Ast'` — Only valid specification. `Fp` is the passband frequency and `Ast` is the stopband attenuation in decibels. To specify a CIC interpolator, include the differential delay after `'CIC'` and before the filter specification: `'Fp,Ast'`. For example:

Design Method	Valid Specification Options
	d = fdesign.interpolator(2,'cic',4,'Fp,Ast',0.4,40);
'CIC Compensator'	See fdesign.ciccomp for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast' To specify a CIC compensator interpolator, include the differential delay after 'CICCOMP' and before the filter specification. For example: d = fdesign.interpolator(2,'ciccomp',4);
'Differentiator'	'N' — filter order
'Gaussian'	'Nsym,BT — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product. The specification must be preceded by an integer-valued SamplesPerSymbol.
'Halfband	See fdesign.halfband for a description of the specification entries. • 'TW,Ast' (default option) • 'N,TW' • ‘N’ • 'N,Ast' If you use the quasi-linear IIR design method, iirlinphase, with a halfband specification, the interpolation factor must be 2.

Design Method	Valid Specification Options
'Highpass'	See fdesign.highpass for a description of the specification entries. • 'Fst,Fp,Ast,Ap' (default option) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification entries. • 'N,TW' (default option) • 'TW,Ap'
'Inverse-sinc Lowpass'	See fdesign.isinclp for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,Fc,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast'
'Inverse-sinc Highpass'	See fdesign.isinchp for a description of the specification entries. • 'Fst,Fp,Ast,Ap' (default option) • 'N,Fc,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap'

Design Method	Valid Specification Options
'Lowpass'	See `fdesign.lowpass` for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,F3dB' • 'N,Fc' • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fp,Fst,Ap' • 'N,Fp,Fst,Ast' • 'N,Fst,Ap,Ast'
'Nyquist'	See `fdesign.nyquist` for a description of the specification entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. • 'TW,Ast' (default option) • 'N' • 'N,Ast' • 'N,Ast'

`D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.interpolator(...,Fs)` adds the argument `Fs`, specified in Hz, to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.interpolator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units.
- `'dB'` — specify the magnitude in dB (decibels).

- `'squared'` — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Create an Interpolator Using `fdesign` Object

These examples show how to construct interpolating filter specification objects.

First, create a default specifications object without using input arguments except for the interpolation factor l.

```
l = 2;
d = fdesign.interpolator(2);
```

Now create an object by passing a specification option 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design - the resulting object uses default values for all of the filter specifications. You must provide the design input argument when you include a specification.

```
d = fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2');
```

Create another interpolating filter object, passing the specification values to the object rather than accepting the default values for, in this case, fp,fst,ap,ast.

```
d = fdesign.interpolator(3,'lowpass',.45,0.55,.1,60);
```

Now pass the filter specifications that correspond to the specifications - n,fc,ap,ast.

```
d = fdesign.interpolator(3,'ciccomp',1,2,'n,fc,ap,ast',...
20,0.45,.05,50);
```

With the specifications object in your workspace, design an interpolator using the equiripple design method.

```
hm = design(d,'equiripple','SystemObject',true);
```

Pass a new specification type for the filter, specifying the filter order.

```
d = fdesign.interpolator(5,'CIC',1,'fp,ast',0.05,55);
```

With the specifications object in your workspace, design an interpolator using the multisection design method.

```
hm = design(d,'multisection','SystemObject',true);
```

In this example, you specify a sampling frequency as the right most input argument. Here, it is set to 1000 Hz.

```
d = fdesign.interpolator(8,'bandpass','fst1,fp1,fp2,fst2,ast1,ap,ast2',...
    0.25,0.35,.55,.65,50,.05,1e3);
```

In this, the last example, use the linear option for the filter specification object and specify the stopband ripple attenuation in linear form.

```
d = fdesign.interpolator(4,'lowpass','n,fst,ap,ast',15,0.55,.05,0.001,...
    'linear');
```

Now design a CIC interpolator for a signal sampled at 19200 Hz. Specify the differential delay of 2 and set the attenuation of information beyond 50 Hz to be at least 80 dB.

```
% The filter object sampling frequency is (l x fs) where fs is the sampling frequency o

dd  = 2;     % Differential delay.
fp  = 50;    % Passband of interest.
ast = 80;    % Minimum attenuation of alias components in passband.
fs  = 600;   % Sampling frequency for input signal.
l   = 32;    % Interpolation factor.
d   = fdesign.interpolator(l,'cic',dd,'fp,ast',fp,ast,l*fs);
hm = design(d,'SystemObject',true);  %Use the default design method.
```

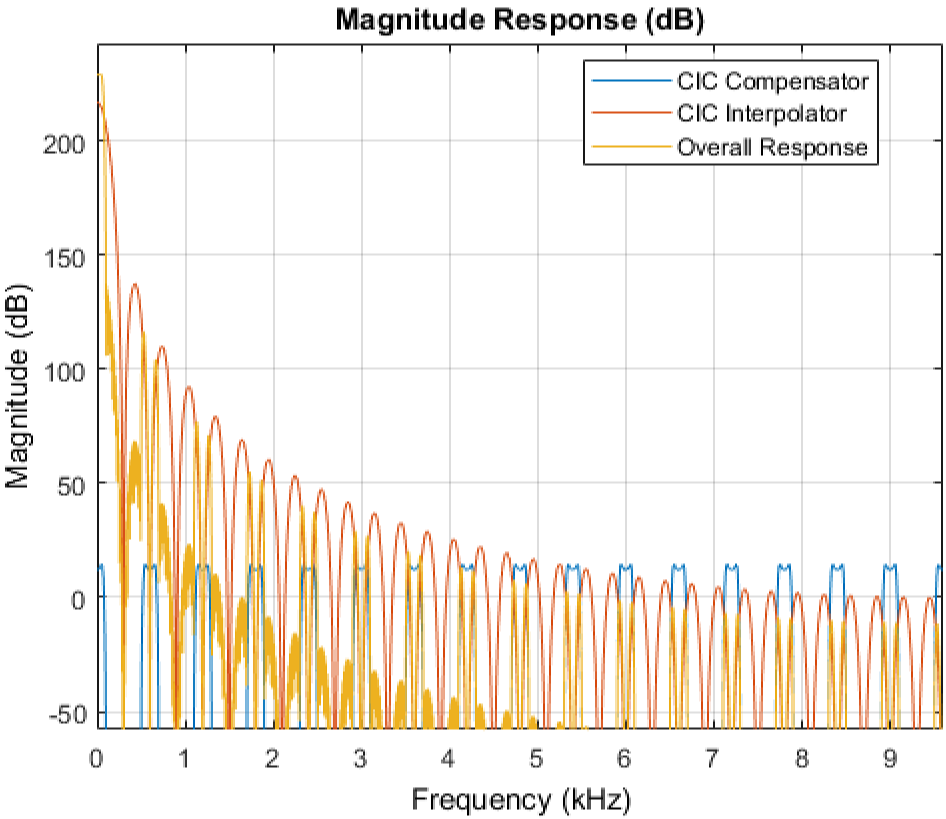
This next example results in a minimum-order CIC compensator that interpolates by 4 and compensates for the droop in the passband for the CIC filter hm from the previous example.

```
nsecs = hm.NumSections;
d = fdesign.interpolator(4,'ciccomp',dd,nsecs,...
50,100,0.1,80,fs);
hmc = design(d,'equiripple','SystemObject',true);
```

hmc is designed to compensate for hm. To see the effect of the compensating CIC filter, use `fvtool` to analyze both filters individually and include the compound filter response by cascading hm and hmc.

```
hfvt = fvtool(hmc,hm,cascade(hmc,hm),'fs',[fs,l*fs,l*fs],'ShowReference','off');
```

```
legend(hfvt,'CIC Compensator','CIC Interpolator',...
'Overall Response');
```

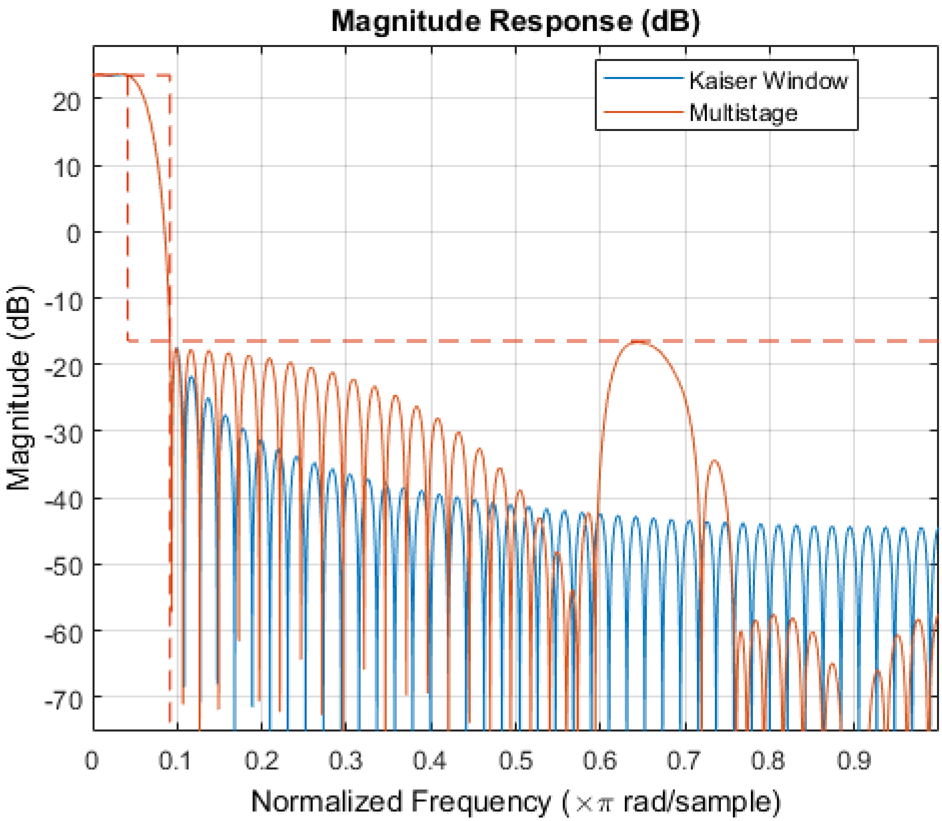


`fvtool` returns with this plot.

For the third example, use fdesign.interpolator to design a minimum-order Nyquist interpolator that uses a Kaiser window. For comparison, design a multistage interpolator as well and compare the responses.

```
l   = 15;   % Set the interpolation factor and the Nyquist band.
tw  = 0.05; % Specify the normalized transition width.
ast = 40;   % Set the minimum stopband attenuation in dB.
d   = fdesign.interpolator(l,'nyquist',l,tw,ast);
hm = design(d,'kaiserwin','SystemObject',true);
```

```
hm2 = design(d,'multistage','SystemObject',true); % Design the multistage interpolator
hfvt = fvtool(hm,hm2);
legend(hfvt,'Kaiser Window','Multistage')
```



`fvtool` shows both responses.

Design a lowpass interpolator for an interpolation factor of 8. Compare the single-stage equiripple design to a multistage design with the same interpolation factor.

```
l = 8; % Interpolation factor.
d = fdesign.interpolator(l,'lowpass');
hm1 = design(d,'equiripple','SystemObject',true);
% Use halfband filters whenever possible.
hm2 = design(d,'multistage','usehalfbands',true,'SystemObject',true);
```

```
hfvt = fvtool(hm1,hm2);
legend(hfvt,'Single-Stage Equiripple','Multistage')
```

Introduced in R2011a

fdesign.isinchp

Inverse sinc highpass filter specification

Syntax

```
D = fdesign.isinchp
D = fdesign.isinchp(SPEC)
D = fdesign.isinchp(SPEC,specvalue1,specvalue2,...)
D = fdesign.isinchp(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.isinchp(...,Fs)
D = fdesign.isinchp(...,MAGUNITS)
```

Description

`D = fdesign.isinchp` constructs an inverse sinc highpass filter specification object `D`, applying default values for the default specification `'Fst,Fp,Ast,Ap'`.

`D = fdesign.isinchp(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The entries are not case sensitive.

- `'Fst,Fp,Ast,Ap'` (default `spec`)
- `'N,Fc,Ast,Ap'`
- `'N,Fst,Fp'`
- `'N,Fp,Ast,Ap'`
- `'N,Fst,Ast,Ap'`

The filter specifications are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called Astop.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called Fpass.

- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called Fstop.
- `N` — filter order.

The filter design methods that apply to an inverse sinc highpass filter specification object change depending on the value of the `Specification` property. Use `designmethods` to determine which design method applies to a specific `Specification`.

Use `designopts` to see the available design options for a specific design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed information on the design options for a given design method, `METHOD`.

`D = fdesign.isinchp(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specifications at construction time.

`D = fdesign.isinchp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` assuming the default `Specification` property `'Fst,Fp,Ast,Ap'`, using the values you provide in `specvalue1,specvalue2, specvalue3, and specvalue4`.

`D = fdesign.isinchp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.isinchp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinchp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = sinc(C(1-\omega))^{-P}$$

You can control the values of the sinc frequency factor, C, and the sinc power, P, using the 'SincFrequencyFactor' and 'SincPower' options in the design method. 'SincFrequencyFactor' and 'SincPower' default to 0.5 and 1 respectively.

Examples

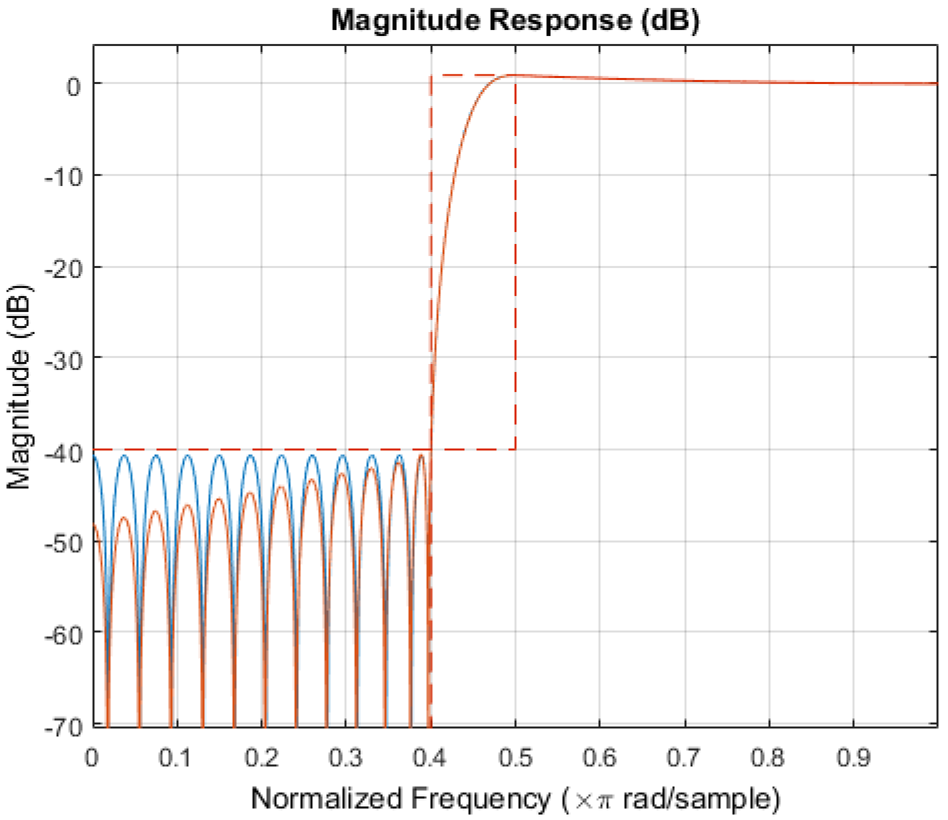
Construct an Inverse Sinc Highpass Filter Using fdesign Object

Design a minimum order inverse sinc highpass filter and shape the stopband to have a slope of 20 dB/radian/sample.

```
d = fdesign.isinchp('Fst,Fp,Ast,Ap',.4,.5,40,0.01);
Hd = design(d,'SystemObject',true);
```

Shape the stopband to have a linear slope of 20 dB/rad/sample

```
Hd1 = design(d,'StopbandShape','linear','StopbandDecay',20,'SystemObject',...
    true);
fvtool(Hd,Hd1);
```



Design a 50th order inverse sinc highpass filter. Set the sinc frequency factor to 0.25, and the sinc power to 16 to achieve a magnitude response in the passband of the form H(?) = sinc(0.25*(1-?))^(-16) .

```
d = fdesign.isinchp('N,Fst,Fp',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16,...
    'SystemObject',true);
fvtool(Hd);
```

Introduced in R2011b

fdesign.isinclp

Inverse sinc lowpass filter specification

Syntax

```
d = fdesign.isinclp
d = fdesign.isinclp(spec)
d = fdesign.isinclp(spec,specvalue1,specvalue2,...)
d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)
d = fdesign.isinclp(...,Fs)
d = fdesign.isinclp(...,MAGUNITS)
```

Description

`d = fdesign.isinclp` constructs an inverse sinc lowpass filter specification object `d`, applying default values for the default specification, `'Fp,Fst,Ap,Ast'`.

`d = fdesign.isinclp(`*`spec`*`)` constructs object `d` and sets its '`Specification`' to *`spec`*. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown below. The options are not case sensitive.

- `'Fp,Fst,Ap,Ast'` (default option)
- `'N,Fc,Ap,Ast'`
- `'N,Fp,Ap,Ast'`
- `'N,Fp,Fst'`
- `'N,Fst,Ap,Ast'`

The filter specifications are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called Astop.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called Apass.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called Fpass.

- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called Fstop.
- `N` — filter order.

The filter design methods that apply to an inverse sinc lowpass filter specification object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

`d = fdesign.isinclp(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `d` assuming the default `Specification` property `'Fp,Fst,Ap,Ast'`, using the values you provide in `specvalue1,specvalue2, specvalue3, and specvalue4`.

`d = fdesign.isinclp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.isinclp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinclp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = sinc(C\omega)^{-P}$$

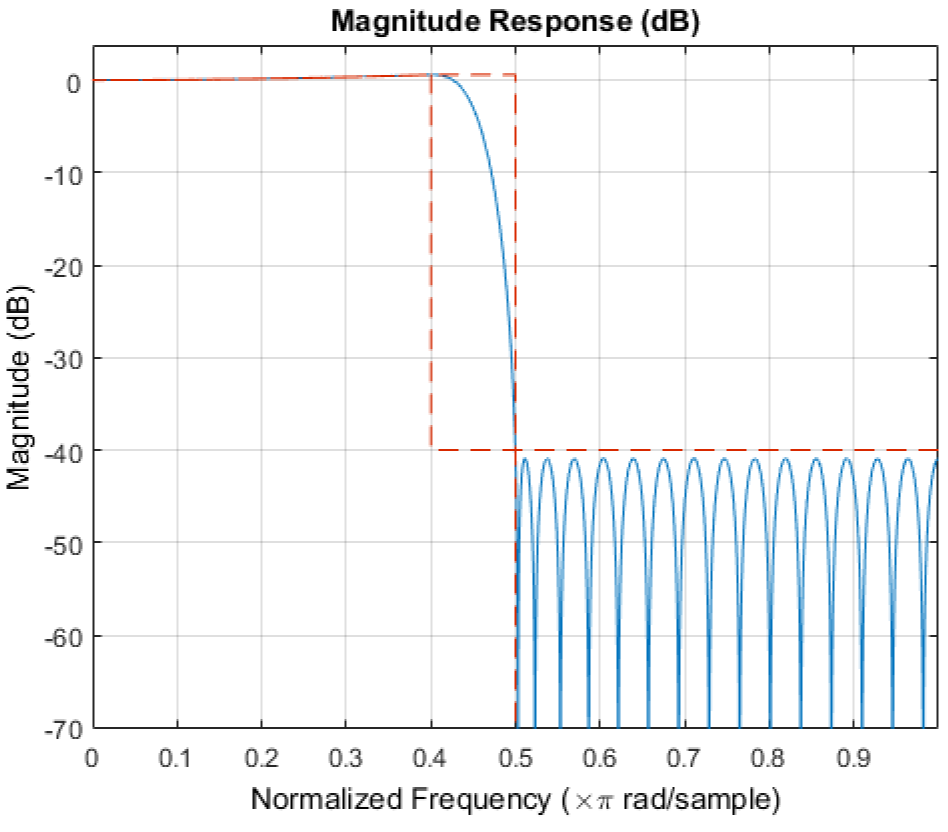
You can control the values of the sinc frequency factor, C, and the sinc power, P, using the `'SincFrequencyFactor'` and `'SincPower'` options in the `design` method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

Examples

Construct an Inverse Sinc Lowpass Filter Using `fdesign` Object

Pass the specifications for the default specification - 'Fp,Fst,Ap,Ast', as input arguments to the specifications object.

```
d = fdesign.isinclp(.4,.5,.01,40);
hd = design(d,'equiripple','SystemObject',true);
fvtool(hd);
```



Design a 50th order inverse sinc lowpass filter. Set the sinc frequency factor to 0.25 and the sinc power to 16 to achieve a magnitude response in the passband of the form H(w) = sinc(0.25*w)^(-16) .

```
d = fdesign.isinclp('N,Fp,Fst',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16,'SystemObject',...
    true);
fvtool(Hd, 'MagnitudeDisplay', 'Magnitude');
```

Introduced in R2011a

fdesign.lowpass

Lowpass filter specification

Syntax

```
D = fdesign.lowpass
D = fdesign.lowpass(SPEC)
D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.lowpass(...,Fs)
D = fdesign.lowpass(...,MAGUNITS)
```

Description

`D = fdesign.lowpass` constructs a lowpass filter specification object `D`, applying default values for the default specification option `'Fp,Fst,Ap,Ast'`.

`D = fdesign.lowpass(SPEC)` constructs object `D` and sets the `Specification` property to the entry in `SPEC`. Entries in `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The options are not case sensitive.

Note: Specifications options marked with an asterisk require the DSP System Toolbox software.

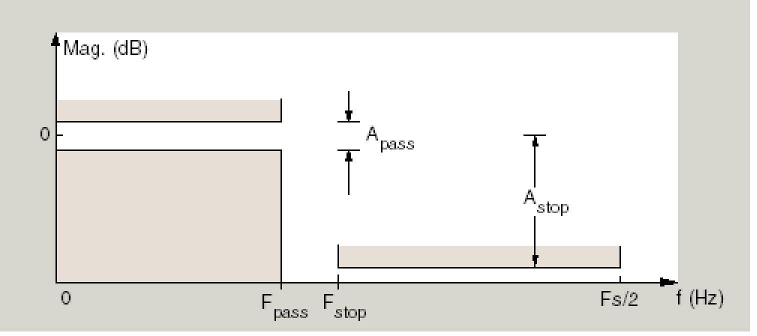
- `'Fp,Fst,Ap,Ast'` (default option)
- `'N,F3db'`
- `'N,F3db,Ap'` *
- `'N,F3db,Ap,Ast'` *
- `'N,F3db,Ast'` *
- `'N,F3db,Fst'` *
- `'N,Fc'`

- `'N,Fc,Ap,Ast'`
- `'N,Fp,Ap'`
- `'N,Fp,Ap,Ast'`
- `'N,Fp,Fst,Ap'` *
- `'N,Fp,F3db'` *
- `'N,Fp,Fst'`
- `'N,Fp,Fst,Ast'` *
- `'N,Fst,Ap,Ast'` *
- `'N,Fst,Ast'`
- `'Nb,Na,Fp,Fst'` *

The filter specifications are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called Apass.
- `Ast` — attenuation in the stop band in decibels (the default units). Also called Astop.
- `F3db` — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- `Fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called Fpass.
- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called Fstop.
- `N` — filter order.
- `Na` and `Nb` are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values like Fp and Fst are transition regions where the filter response is not explicitly defined.

D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...) constructs an object D and sets the specification values at construction time using specvalue1, specvalue2, and so on for all of the specification variables in SPEC.

D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4) constructs an object D with values for the default Specification property 'Fp,Fst,Ap,Ast' using the specifications you provide as input arguments specvalue1,specvalue2,specvalue3,specvalue4.

D = fdesign.lowpass(...,Fs) adds the argument Fs, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

D = fdesign.lowpass(...,MAGUNITS) specifies the units for any magnitude specification you provide in the input arguments. MAGUNITS can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the MAGNUNITS argument, fdesign assumes that all magnitudes are in decibels. Note that fdesign stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Lowpass Filtering of Sinusoids

Lowpass filter a discrete-time signal consisting of two sine waves.

Create a lowpass filter specification object. Specify the passband frequency to be 0.15π rad/sample and the stopband frequency to be 0.25π rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
```

Query the valid design methods for your filter specification object, `d`.

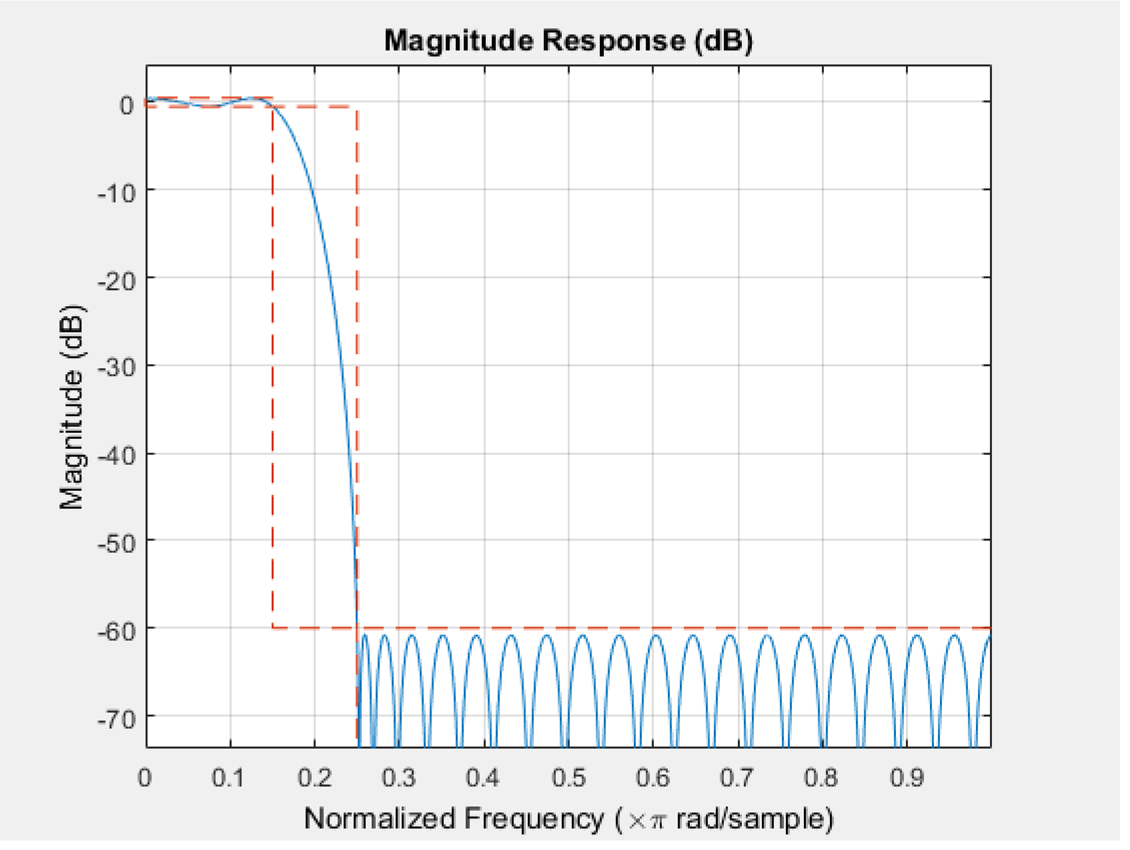
```
designmethods(d)
```

```
Design Methods for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Create an FIR equiripple filter and view the filter magnitude response with `fvtool`.

```
Hd = design(d,'equiripple');
fvtool(Hd)
```



Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of $\pi/8$ and $\pi/4$ rad/sample and amplitudes of 1 and 0.25, respectively. Filter the discrete-time signal with the FIR equiripple filter object, Hd.

```
n = 0:159;
x = (0.25*cos((pi/8)*n)+sin((pi/4)*n));
y = filter(Hd,x);
```

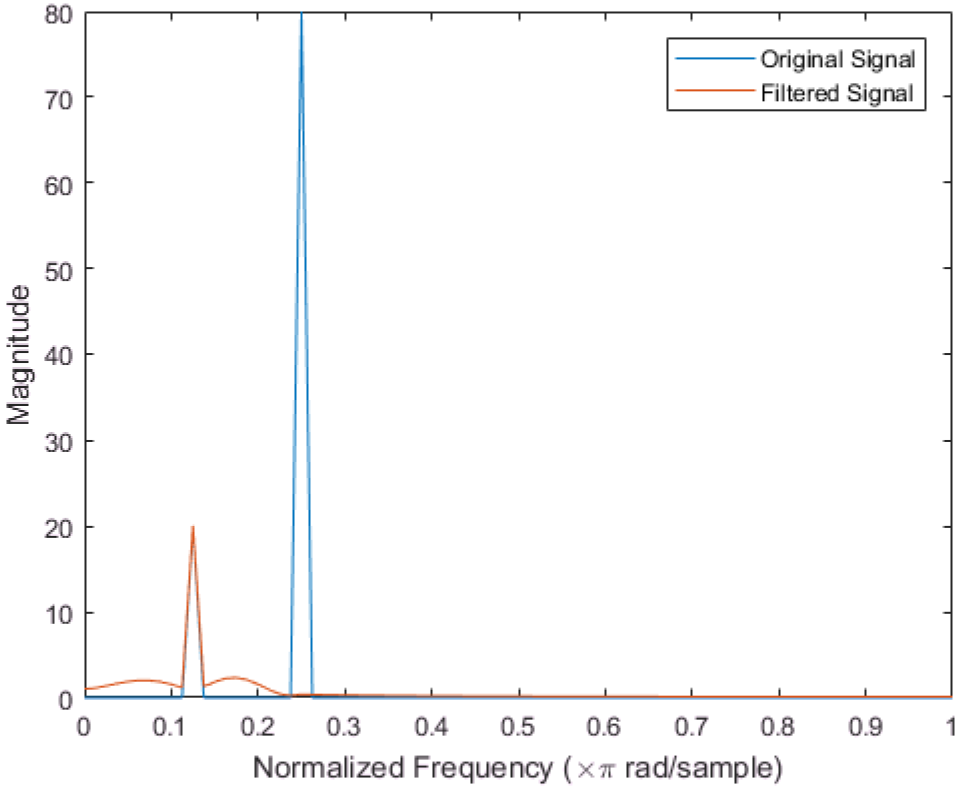
Compute the Fourier transform of the original signal and the filtered signal. Verify that the high-frequency component has been filtered out.

```
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
```

```
ydft = fft(y);

figure
plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
plot(freq/pi,abs(ydft(1:length(y)/2+1)))
hold off

legend('Original Signal','Filtered Signal')
ylabel('Magnitude')
xlabel('Normalized Frequency (\times\pi rad/sample)')
```



Window Method Lowpass Design

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz. Look at the available design methods.

```
d = fdesign.lowpass('N,Fc',10,9600,48000);
designmethods(d)
```

```
Design Methods for class fdesign.lowpass (N,Fc):

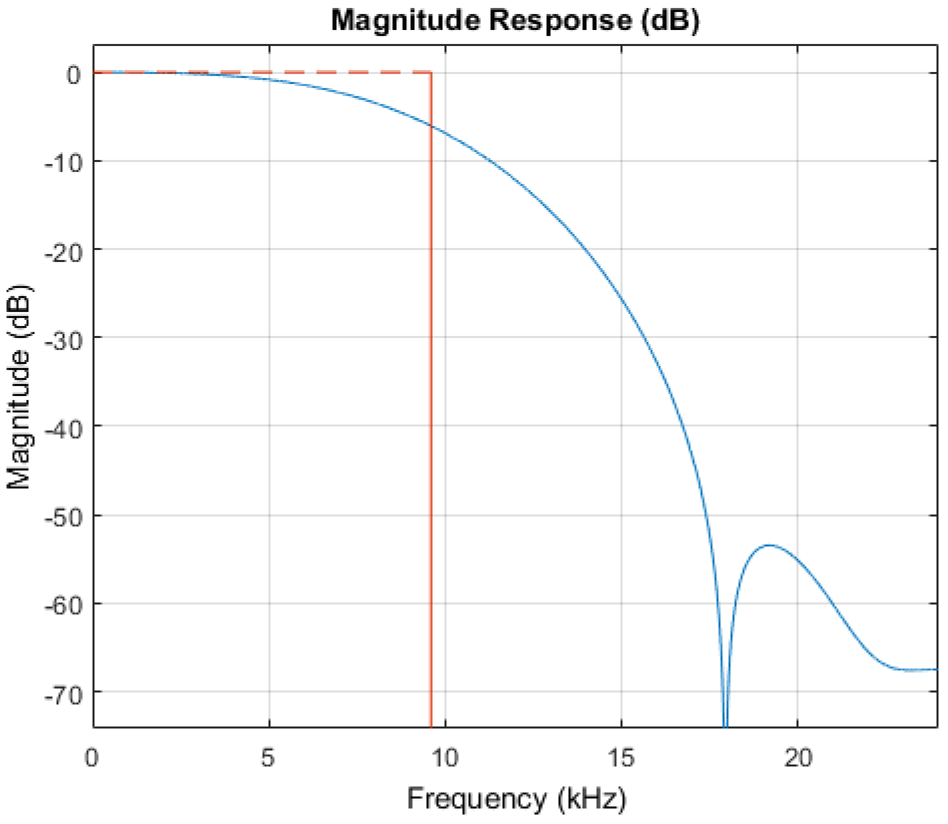
window
```

The only valid design method is the FIR window method. Design the filter.

```
Hd = design(d);
```

Display the filter magnitude response. The -6 dB point is at 9.6 kHz, as expected.

```
fvtool(Hd)
```



Stopband Shape and Decay

Create an FIR equiripple filter with a passband frequency of 0.2π rad/sample, a stopband frequency of 0.25π rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 60 dB. Design the filter with a 20 dB/rad/sample linear stopband.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,1,60);
Hd = design(D,'equiripple','StopbandShape','linear','StopbandDecay',20);
```

Visualize the frequency response of the filter.

```
fvtool(Hd)
```

design | designmethods | fdesign

Introduced in R2009a

fdesign.notch

Notch filter specification

Syntax

```
d = fdesign.notch(specstring, value1, value2, ...)
d = fdesign.notch(n,f0,q)
d = fdesign.notch(...,Fs)
d = fdesign.notch(...,MAGUNITS)
```

Description

`d = fdesign.notch(specstring, value1, value2, ...)` constructs a notch filter specification object `d`, with the specification set to `specstring` and values provided for all members of the `specstring`. The possible specification entries, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth

- Ap - Passband Ripple (decibels)
- Ast - Stopband Attenuation (decibels)

Different specification entries, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
d  = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
designmethods(d);
```

`d = fdesign.notch(n,f0,q)` constructs a notch filter specification object using the default `specstring ('N,F0,Q')` and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.notch(...,Fs)` constructs a notch filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as are all the other frequency values provided.

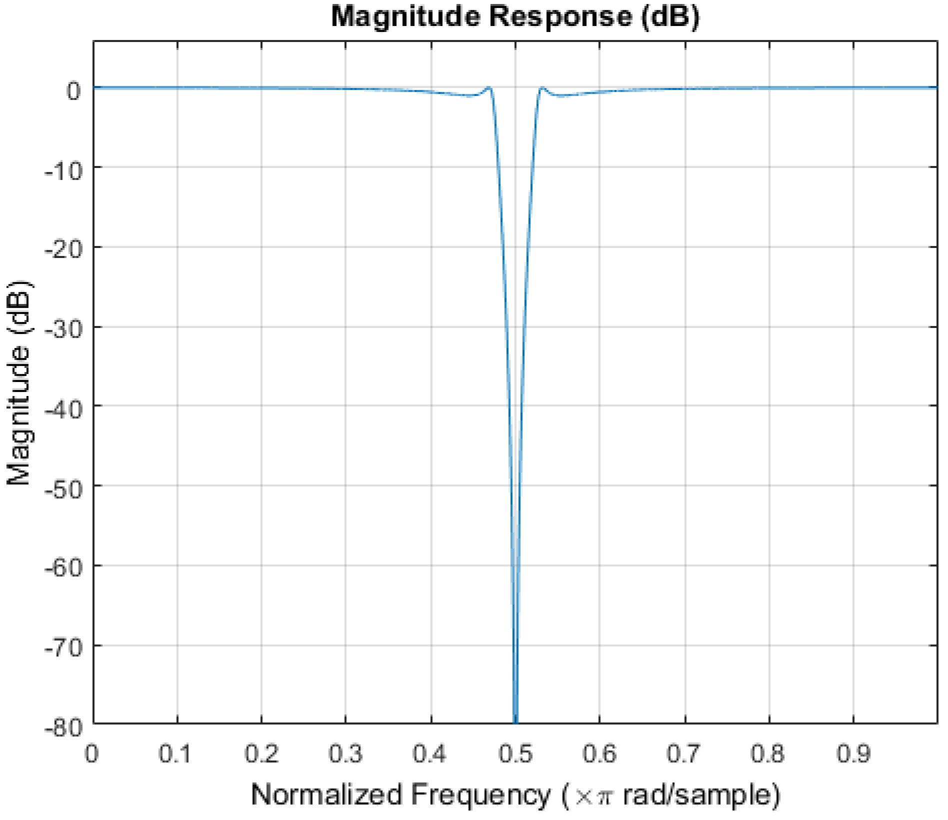
`d = fdesign.notch(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

Examples

Design a Notch Filter

Design a notching filter with a passband ripple of 1 dB.

```
d  = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
Hd = design(d,'SystemObject',true);
fvtool(Hd)
```



See Also

`fdesign` | `fdesign.peak`

Introduced in R2011a

fdesign.nyquist

Nyquist filter specification

Syntax

```
d = fdesign.nyquist
d = fdesign.nyquist(l, spec)
d = fdesign.nyquist(l,spec,specvalue1,specvalue2,...)
d = fdesign.nyquist(l,specvalue1,specvalue2)
d = fdesign.nyquist(...,fs)
d = fdesign.nyquist(...,magunits)
```

Description

`d = fdesign.nyquist` constructs a Nyquist or L-band filter specification object `d`, applying default values for the properties `tw` and `ast`. By default, the filter object designs a minimum-order half-band (L=2) Nyquist filter.

Using `fdesign.nyquist` along with `design` method generates a System object, if the `'SystemObject'` flag in the `design` method is set to `true`.

`d = fdesign.nyquist(l, spec)` constructs object `d` and sets its `Specification` property to *`spec`*. Use `l` to specify the desired value for L. L = 2 designs a half-band FIR filter, L = 3 a third-band FIR filter, and so on. When you use a Nyquist filter as an interpolator, l or L is the interpolation factor. The first input argument must be l when you are not using the default syntax `d = fdesign.nyquist`.

Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for *`spec`* are shown below. The entries are not case sensitive.

- `tw`,`ast` (default option)
- `n`,`tw`
- `n`
- `n`,`ast`

where,

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

The filter design methods that apply to a Nyquist filter specification object change depending on the `Specification` option. Use `designmethods` to determine which design method applies to an object and its specification option. Different filter design methods also have options that you can specify. Use `designopts` with the design method to see the available options. For example:

```
f=fdesign.nyquist(4,'N,TW');
designmethods(f)
```

`d = fdesign.nyquist(l,spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specification to *`spec`*, and the specification values to `specvalue1`, `specvalue2`, and so on at construction time.

`d = fdesign.nyquist(l,specvalue1,specvalue2)` constructs an object `d` with the values you provide in `l`, `specvalue1,specvalue2` as the values for `l`, `tw` and `ast`.

`d = fdesign.nyquist(...,fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.nyquist(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Limitations of the Nyquist fdesign Object

Using Nyquist filter specification objects with the `equiripple` design method imposes a few limitations on the resulting filter, caused by the `equiripple` design algorithm.

- When you request a minimum-order design from `equiripple` with your Nyquist object, the design algorithm might not converge and can fail with a filter convergence error.
- When you specify the order of your desired filter, and use the `equiripple` design method, the design might not converge.
- Generally, the following specifications, alone or in combination with one another, can cause filter convergence problems with Nyquist objects and the `equiripple` design method.
  - very high order
  - small transition width
  - very large stopband attenuation

Note that halfband filters (filters where band = 2) do not exhibit convergence problems.

When convergence issues arise, either in the cases mentioned or in others, you might be able to design your filter with the `kaiserwin` method.

In addition, if you use Nyquist objects to design decimators or interpolators (where the interpolation or decimation factor is not a prime number), using multistage filter designs might be your best approach.

Examples

Construct a Nyquist Filter Using `fdesign` Object

These examples show how to construct a Nyquist filter specification object.

First, create a default specifications object without using input arguments.

```
d = fdesign.nyquist;
```

Now create an object by passing a specification type 'n,ast' - the resulting object uses default values for n and ast.

```
d = fdesign.nyquist(2,'n,ast');
```

Create another Nyquist filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d = fdesign.nyquist(3,'n,ast',42,80)
```

```
d =

  nyquist with properties:

               Response: 'Nyquist'
          Specification: 'N,Ast'
            Description: {2×1 cell}
    NormalizedFrequency: 1
            FilterOrder: 42
                  Astop: 80
                   Band: 3
```

Finally, pass the filter specifications that correspond to the default Specification - tw,ast. When you pass only the values, fdesign.nyquist assumes the default Specification option.

```
d = fdesign.nyquist(4,.01,80)
```

```
d =

  nyquist with properties:

               Response: 'Nyquist'
          Specification: 'TW,Ast'
            Description: {2×1 cell}
    NormalizedFrequency: 1
        TransitionWidth: 0.0100
                  Astop: 80
                   Band: 4
```

Now design a Nyquist filter using the kaiserwin design method.

```
hd = design(d,'kaiserwin','SystemObject',true);
```

Create two equiripple Nyquist 4th-band filters with and without a nonnegative zero phase response:

```
f = fdesign.nyquist(4,'N,TW',12,0.2);
```

Equiripple Nyquist 4th-band filter with nonnegative zero phase response

```
Hd1 = design(f,'equiripple','zerophase',true,'SystemObject',true);
```

Equiripple Nyquist 4th-band filter with 'ZeroPhase' set to false 'zerophase',false is the default

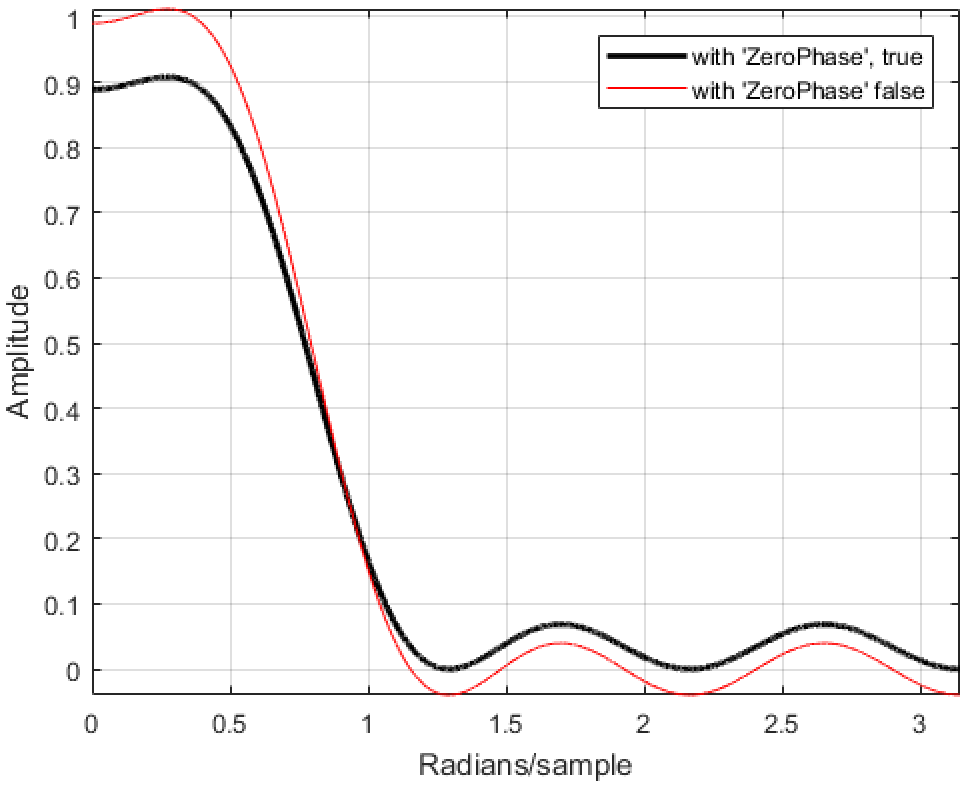
```
Hd2 = design(f,'equiripple','zerophase',false,'SystemObject',true);
```

Obtain real-valued amplitudes (not magnitudes)

```
[Hr_zerophase,W] = zerophase(Hd1);
[Hr,W] = zerophase(Hd2);
```

Plot and compare response

```
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```



Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.

The 'ZeroPhase' option is valid only for equiripple Nyquist designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

Introduced in R2011a

fdesign.octave

Octave filter specification

Syntax

```
d = fdesign.octave(l)
d = fdesign.octave(l, MASK)
d = fdesign.octave(l, MASK, spec)
d = fdesign.octave(..., Fs)
```

Description

`d = fdesign.octave(l)` constructs an octave filter specification object `d`, with `l` bands per octave. The default value for `l` is one.

Note: The filters created by `fdesign.octave` comply with the ANSI® S1.11-2004 and IEC 61260:1995 standards.

`d = fdesign.octave(l, MASK)` constructs an octave filter specification object `d` with `l` bands per octave and `MASK` specification for the FVTool. The available values for mask are:

- `'class 0'`
- `'class 1'`
- `'class 2'`

`d = fdesign.octave(l, MASK, spec)` constructs an octave filter specification object `d` with `l` bands per octave, `MASK` specification for the FVTool, and the `spec` specification string. The specification strings available are:

- `'N, F0'`

(not case sensitive), where:

- N is the filter order
- F0 is the center frequency. The center frequency is specified in normalized frequency units assuming a sampling frequency of 48 kHz, unless a sampling frequency in Hz is included in the specification: `d = fdesign.octave(..., Fs)`. If you specify an invalid center frequency, a warning is issued and the center frequency is rounded to the nearest valid value. You can determine the valid center frequencies for your design by using `validfrequencies` with your octave filter specification object. For example:

```
d = fdesign.octave(1,'Class 1','N,F0',6,1000,44.1e3);
validcenterfreq = validfrequencies(d);
```

Valid center frequencies:

- Must be greater than 20 Hz and less than 20 kHz if you specify a sampling frequency. The range 20 Hz to 20 kHz is the standard range of human hearing.
- Are calculated according to the following algorithm if the number of bands per octave, L, is even:

```
G = 10^(3/10);
x = -1000:1350;
validcenterfreq = 1000*(G.^((2*x-59)/(2*L)));
validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
```

- Are calculated according to the following algorithm if the number of bands per octave, L, is odd:

```
G = 10^(3/10);
x = -1000:1350;
validcenterfreq = 1000*(G.^((x-30)/L));
validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
```

Only center frequencies greater than 20 and less than 20,000 are retained. The center frequencies and the corresponding upper band frequencies must be less than the Nyquist frequency, which is half the sampling rate (`samplingfreq`). The vector of upper band frequencies (`upperbandfreq`) corresponding to the center frequencies (`validcenterfreq`) is computed using the following algorithm:

```
upperbandfreq = validcenterfreq.*(G^(1/(2*L)));
```

The algorithm removes the center frequencies whose corresponding upper band frequencies do not obey the Nyquist rule.

```
validcenterfreq = validcenterfreq(upperbandfreq < samplingfreq/2);
```

If you do not specify a sampling frequency, `fdesign.octave` assumes a `samplingfreq` of 48 kHz. To obtain valid normalized center frequencies, the remaining center frequencies are divided by 24,000.

```
validcenterfreq = validcenterfreq/24000;
```

Examples

Design an Octave Band Filter

Design a sixth order, octave-band class 0 filter with a center frequency of 1000 Hz and, a sampling frequency of 44.1 kHz.

```
d = fdesign.octave(1,'Class 0','N,F0',6,1000,44100)
Hd = design(d,'SystemObject',true)
fvtool(Hd)
```

```
d =

  octave with properties:

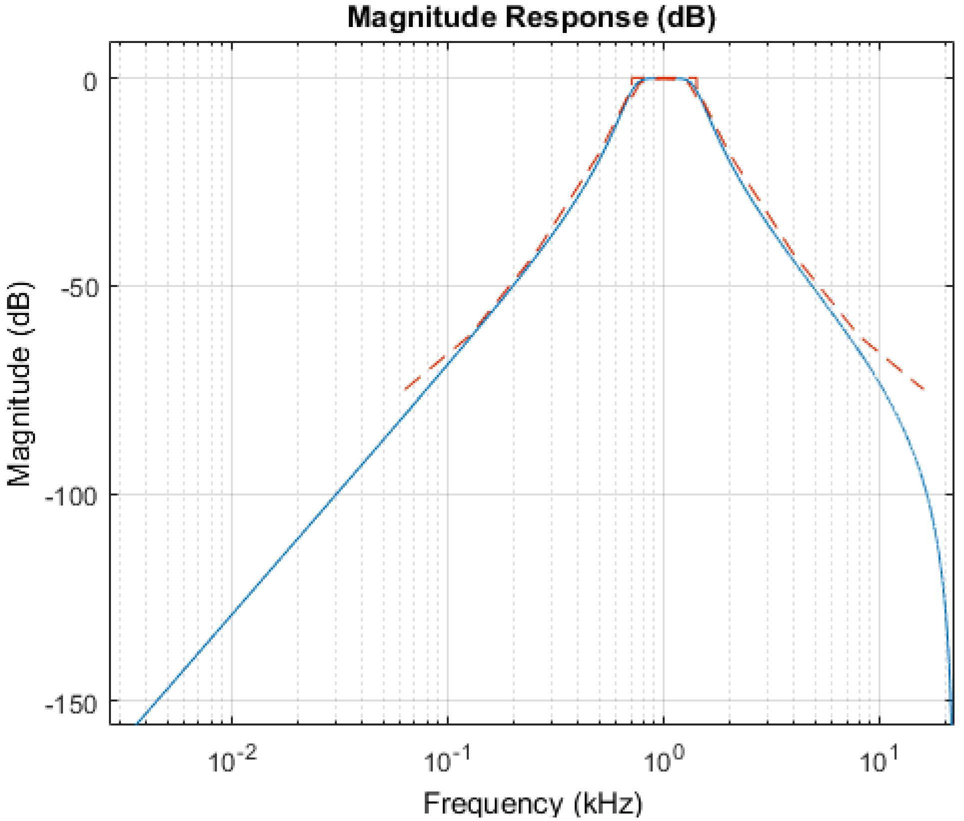
               Response: 'Octave and Fractional Octave'
         BandsPerOctave: 1
                   Mask: 'Class 0'
          Specification: 'N,F0'
            Description: {2×1 cell}
    NormalizedFrequency: 0
                     Fs: 44100
            FilterOrder: 6
                     F0: 1000

Hd =

  dsp.BiquadFilter with properties:

                  Structure: 'Direct form II'
            SOSMatrixSource: 'Property'
                  SOSMatrix: [3×6 double]
                ScaleValues: [4×1 double]
          InitialConditions: 0
    OptimizeUnityScaleValues: true
```

```
Use get to show all properties
```



The figure shows the magnitude response plot of the filter. The logarithmic scale for frequency is automatically set by FVTool for the octave filters.

`fdesign`

Introduced in R2011a

fdesign.parameq

Parametric equalizer filter specification

Note: The `fdesign.parameq` function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the `fdesign.parameq` function from Audio System Toolbox instead.

Syntax

```
d = fdesign.parameq(spec, specvalue1, specvalue2, ...)
d = fdesign.parameq(... fs)
```

Description

`d = fdesign.parameq(spec, specvalue1, specvalue2, ...)` constructs a parametric equalizer filter design object, where `spec` is a non-case sensitive specification string. The choices for `spec` are as follows:

- `'F0, BW, BWp, Gref, G0, GBW, Gp'` (minimum order default)
- `'F0, BW, BWst, Gref, G0, GBW, Gst'`
- `'F0, BW, BWp, Gref, G0, GBW, Gp, Gst'`
- `'N, F0, BW, Gref, G0, GBW'`
- `'N, F0, BW, Gref, G0, GBW, Gp'`
- `'N, F0, Fc, Qa, G0'`
- `'N, F0, Fc, S, G0'`
- `'N, F0 ,BW, Gref, G0, GBW, Gst'`
- `'N, F0, BW, Gref, G0, GBW, Gp, Gst'`
- `'N, Flow, Fhigh, Gref, G0, GBW'`
- `'N, Flow, Fhigh, Gref, G0, GBW, Gp'`
- `'N, Flow, Fhigh, Gref, G0, GBW, Gst'`

- `'N, Flow, Fhigh, Gref, G0, GBW, Gp, Gst'`

where the parameters are defined as follows:

- BW — Bandwidth
- BWp — Passband Bandwidth
- BWst — Stopband Bandwidth
- Gref — Reference Gain (decibels)
- G0 — Center Frequency Gain (decibels)
- GBW — Gain at which Bandwidth (BW) is measured (decibels)
- Gp — Passband Gain (decibels)
- Gst — Stopband Gain (decibels)
- N — Filter Order
- F0 — Center Frequency
- Fc— Cutoff frequency
- Fhigh - Higher Frequency at Gain GBW
- Flow - Lower Frequency at Gain GBW
- Qa-Quality Factor
- S-Slope Parameter for Shelving Filters

Regardless of the specification string chosen, there are some conditions that apply to the specification parameters. These are as follows:

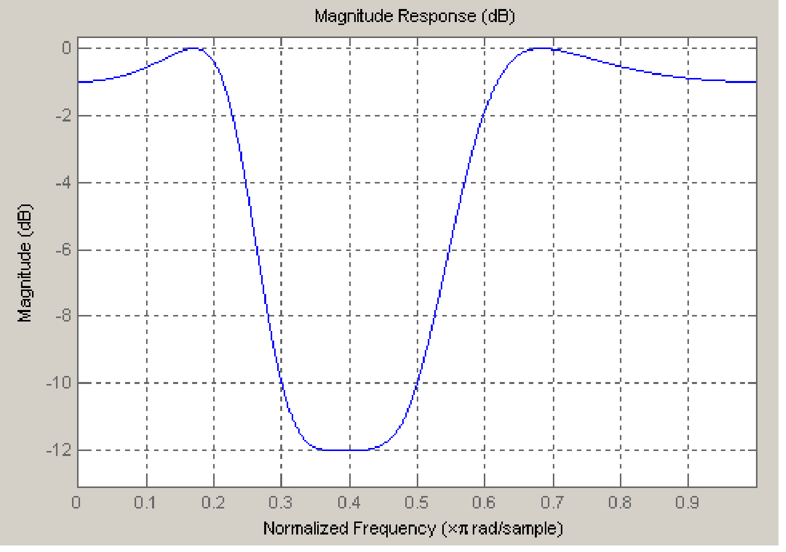
- Specifications for parametric equalizers must be given in decibels
- To boost the input signal, set `G0 > Gref`; to cut, set `Gref > G0`
- For boost: `G0 > Gp > GBW > Gst > Gref`; For cut: `G0 < Gp < GBW < Gst < Gref`
- Bandwidth must satisfy: `BWst > BW > BWp`

`d = fdesign.parameq(... fs)` adds the input sampling frequency. Fs must be specified as a scalar trailing the other numerical values provided, and is assumed to be in Hz.

Examples

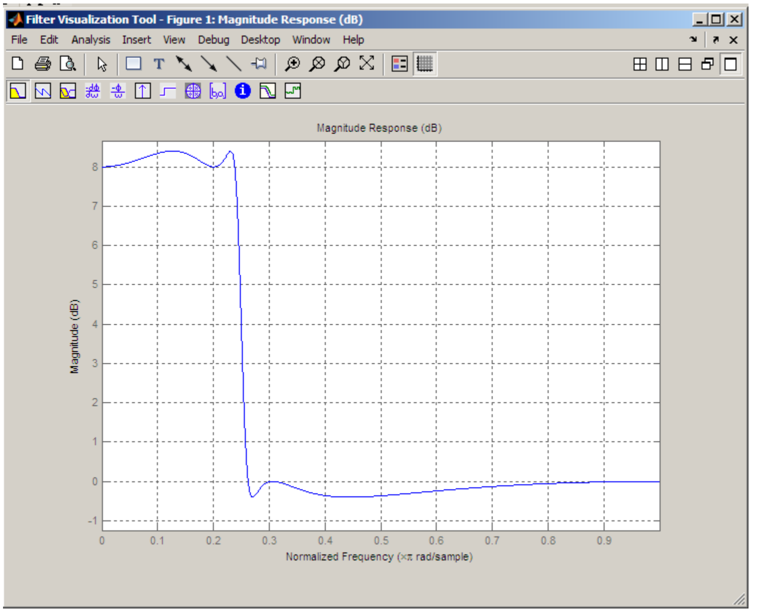
Design a Chebyshev Type II parametric equalizer filter that cuts by 12 dB:

```
d = fdesign.parameq('N,Flow,Fhigh,Gref,G0,GBW,Gst',...
      4,.3,.5,0,-12,-10,-1);
Hd = design(d,'cheby2');
fvtool(Hd)
```



Design a 4th order audio lowpass (F0 = 0) shelving filter with cutoff frequency of Fc = 0.25, quality factor Qa =10, and boost gain of G0 = 8 dB:

```
d = fdesign.parameq('N,F0,Fc,Qa,G0',4,0,0.25,10,8);
Hd = design(d);
fvtool(Hd)
```



Design 4th-order highpass shelving filters with S=1.5 and S=3:

```
N=4;
F0 = 1;
Fc = .4; % Cutoff Frequency
G0 = 10;
S = 1.5;
S2=3;
f = fdesign.parameq('N,F0,Fc,S,G0',N,F0,Fc,S,G0);
h1 = design(f);
f.S=3;
h2=design(f);
hfvt=fvtool([h1 h2]);
set(hfvt,'Filters',[h1 h2]);
legend(hfvt,'S=1.5','S=3');
```

`fdesign`

Introduced in R2011a

fdesign.peak

Peak filter specification

Syntax

```
d = fdesign.peak(specstring, value1, value2, ...)
d = fdesign.peak(n,f0,q)
d = fdesign.peak(...,Fs)
d = fdesign.peak(...,MAGUNITS)
```

Description

`d = fdesign.peak(specstring, value1, value2, ...)` constructs a peaking filter specification object `d`, with specification set to `specstring` and values provided for all members of the `specstring`. The possible specification options, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth
- Ap - Passband Ripple (decibels)

- Ast - Stopband Attenuation (decibels)

Different specification options, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
>> d  = fdesign.peak('N,F0,Q,Ap',6,0.5,10,1);
>> designmethods(d)

Design Methods for class fdesign.peak (N,F0,Q,Ap):

cheby1
```

`d = fdesign.peak(n,f0,q)` constructs a peaking filter specification object using the default `specstring ('N,F0,Q')` and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.peak(...,Fs)` constructs a peak filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as all the other frequency values provided.

`d = fdesign.peak(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

Examples

Design a Chebyshev Type II Peaking Filter

Design a Chebyshev Type II peaking filter with a stopband attenuation of 80 dB.

```
d = fdesign.peak('N,F0,BW,Ast',8,.65,.02,80);
Hd = design(d,'cheby2','SystemObject',true);
```

```
fvtool(Hd)
```

fdesign.polysrc

Construct polynomial sample-rate converter (POLYSRC) filter designer

Syntax

```
d = fdesign.polysrc(l,m)
d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)
d = fdesign.polysrc(...,Fs)
```

Description

`d = fdesign.polysrc(l,m)` constructs a polynomial sample-rate converter filter designer D with an interpolation factor L and a decimation factor M. L defaults to 3. M defaults to 2. L and M can be arbitrary positive numbers.

`d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)` initializes the filter designer specification with Np and sets the polynomial order to the value Np. If omitted Np defaults to 3.

`d = fdesign.polysrc(...,Fs)` specifies the sampling frequency (in Hz).

Examples

Design a Sample-Rate Converter

This example shows how to design sample-rate converter that uses a 3rd order Lagrange interpolation filter to convert from 44.1kHz to 48kHz.

```
[L,M] = rat(48/44.1);
f = fdesign.polysrc(L,M,'Fractional Delay','Np',3);
Hm = design(f,'lagrange');
```

Original sampling frequency

```
Fs = 44.1e3;
```

9408 samples, 0.213 seconds long

```
n = 0:9407;
```

Original signal, sinusoid at 1kHz

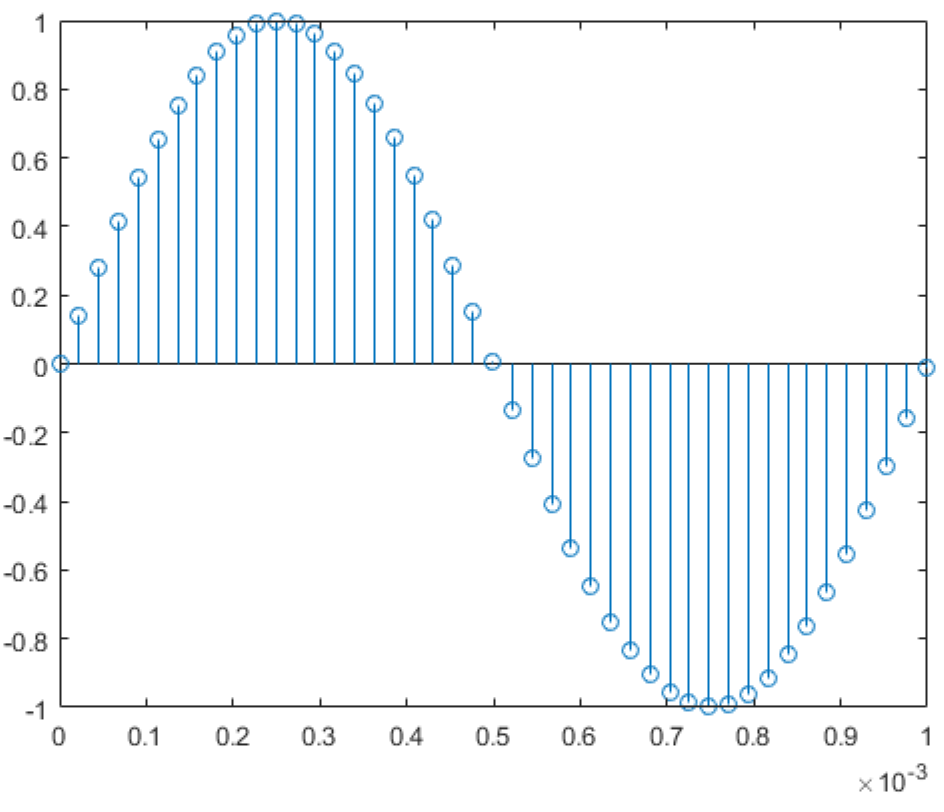
```
x  = sin(2*pi*1e3/Fs*n);
```

10241 samples, still 0.213 seconds

```
y = filter(Hm,x);
```

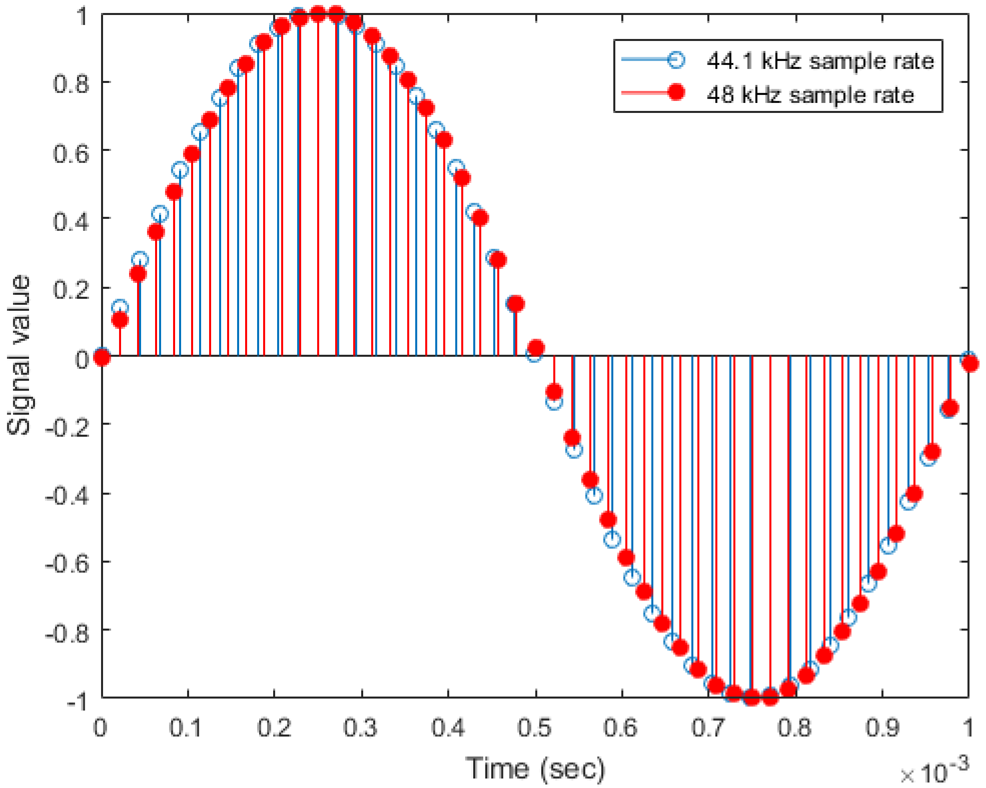
Plot original sampled at 44.1kHz

```
stem(n(1:45)/Fs,x(1:45))
hold on
```



Plot fractionally interpolated signal (48kHz) in red

```
stem((n(3:51)-2)/(Fs*L/M),y(3:51),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48 kHz sample rate')
```



For more information about Farrow SRCs, see the "Efficient Sample Rate Conversion between Arbitrary Factors" example, `efficientsrcdemo`.

See Also

`fdesign`

Introduced in R2011a

fdesign.pulseshaping

Pulse-shaping filter specification object

Syntax

```
D = fdesign.pulseshaping
D = fdesign.pulseshaping(sps)
D = fdesign.pulseshaping(sps,shape)
d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)
d = fdesign.pulseshaping(...,fs)
d = fdesign.pulseshaping(...,magunits)
```

Description

Note: The use of `fdesign.pulseshaping` is not recommended. Use `rcosdesign` or `gaussdesign` instead.

`D = fdesign.pulseshaping` constructs a specification object `D`, which can be used to design a minimum-order raised cosine filter object with a default stop band attenuation of 60dB and a rolloff factor of 0.25.

`D = fdesign.pulseshaping(sps)` constructs a minimum-order raised cosine filter specification object `d` with a positive integer-valued oversampling factor, `SamplesPerSymbol` .

`D = fdesign.pulseshaping(sps,shape)` constructs `d` where `shape` specifies the `PulseShape` property. Valid entries for `shape` are:

- `'Raised Cosine'`
- `'Square Root Raised Cosine'`
- `'Gaussian'`

`d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)` constructs `d` where `spec` defines the `Specification` properties. The entries for `spec` specify various properties of the filter, including the order and frequency response. Valid entries for `spec` depend upon the `shape` property. For `'Raised Cosine'` and `'Square Root Raised Cosine'` filters, the valid entries for `spec` are:

- `'Ast,Beta'` (minimum order; default)
- `'Nsym,Beta'`
- `'N,Beta'`

The filter specifications are defined as follows:

- `Ast` —stopband attenuation (in dB). The default stopband attenuation for a raised cosine filter is 60 dB. The default stopband attenuation for a square root raised cosine filter is 30 dB. If `Ast` is specified, the minimum-order filter is returned.
- `Beta` —rolloff factor expressed as a real-valued scalar ranging from 0 to 1. Smaller rolloff factors result in steeper transitions between the passband and stopband of the filter.
- `Nsym` —filter order in symbols. The length of the impulse response is given by `Nsym*SamplesPerSymbol+1`. The product `Nsym*SamplesPerSymbol` must be even.
- `N` —filter order (must be even). The length of the impulse response is `N+1`.

If the `shape` property is specified as `'Gaussian'`, the valid entries for `spec` are:

- `'Nsym,BT'` (default)

The filter specifications are defined as follows:

- `Nsym`—filter order in symbols. `Nsym` defaults to 6. The length of the filter impulse response is `Nsym*SamplesPerSymbol+1`. The product `Nsym*SamplesPerSymbol` must be even.
- `BT` —the 3–dB bandwidth-symbol time product. `BT` is a positive real-valued scalar, which defaults to 0.3. Larger values of `BT` produce a narrower pulse width in time with poorer concentration of energy in the frequency domain.

`d = fdesign.pulseshaping(...,fs)` specifies the sampling frequency of the signal to be filtered. `fs` must be specified as a scalar trailing the other numerical values provided. For this case, `fs` is assumed to be in Hz and is used for analysis and visualization.

`d = fdesign.pulseshaping(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. Valid entries for `magunits` are:

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

After creating the specification object `d`, you can use the `design` function to create a filter object such as `h` in the following example:

```
d = fdesign.pulseshaping(8,'Raised Cosine','Nsym,Beta',6,0.25);
h = design(d);
```

Normally, the `Specification` property of the specification object also determines which design methods you can use when you create the filter object. Currently, regardless of the `Specification` property, the `design` function uses the `window` design method with all `fdesign.pulseshaping` specification objects. The `window` method creates an FIR filter with a windowed impulse response.

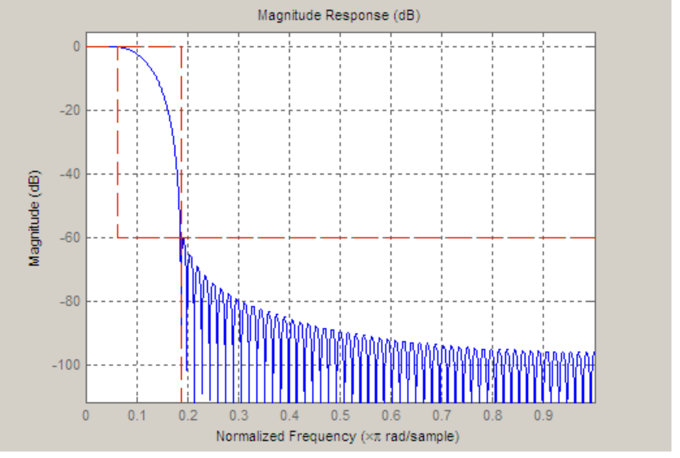
Examples

Pulse-shaping can be used to change the waveform of transmitted pulses so the signal bandwidth matches that of the communication channel. This helps to reduce distortion and intersymbol interference (ISI).

This example shows how to design a minimum-order raised cosine filter that provides a stop band attenuation of 60 dB, rolloff factor of 0.50, and 8 samples per symbol.

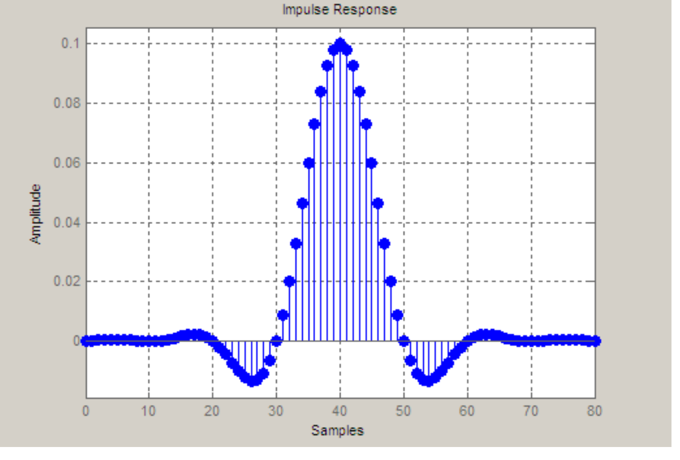
```
h  = fdesign.pulseshaping(8,'Raised Cosine','Ast,Beta',60,0.50);
    Hd = design(h);
    fvtool(Hd)
```

This code generates the following figure.



This example shows how to design a raised cosine filter that spans 8 symbol durations (i.e., of order 8 symbols), has a rolloff factor of 0.50, and oversampling factor of 10.

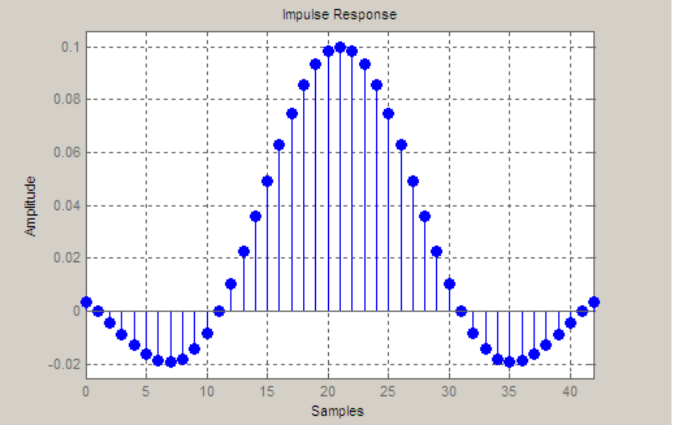
```
h  = fdesign.pulseshaping(10,'Raised Cosine','Nsym,Beta',8,0.50);
    Hd = design(h);
    fvtool(Hd, 'impulse')
```



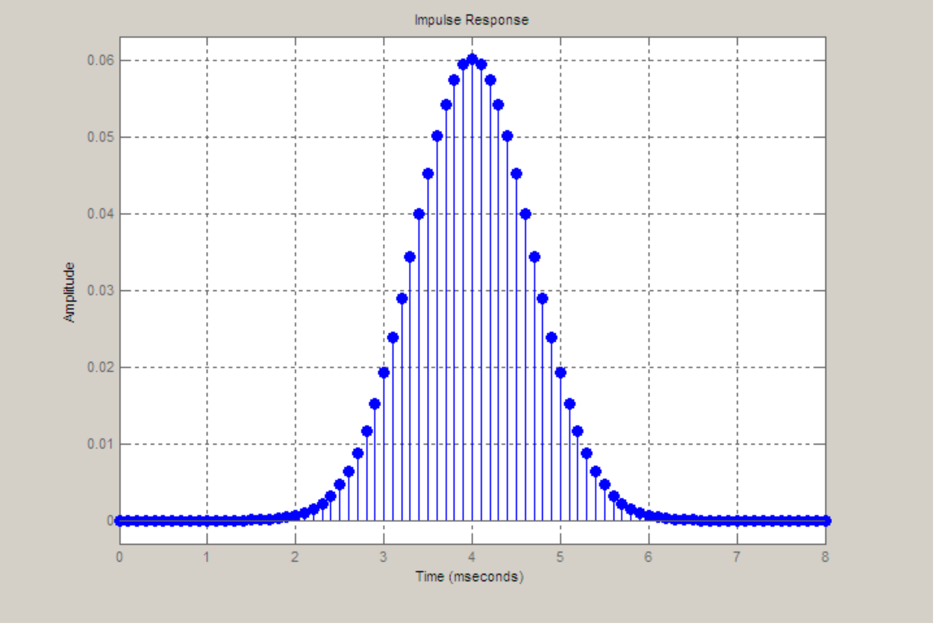
This example shows how to design a square root raised cosine filter of order 42, rolloff factor of 0.25, and 10 samples per symbol.

```
h  = fdesign.pulseshaping(10,'Square Root Raised Cosine','N,Beta',42);
```

```
Hd = design(h);
fvtool(Hd, 'impulse')
```



The following example demonstrates how to create a Gaussian pulse-shaping filter with an oversampling factor (sps) of 10, a bandwidth-time symbol product of 0.2, and 8 symbol periods. The sampling frequency is specified as 10 kHz.



Introduced in R2011a

fdesign.rsrc

Rational-factor sample-rate converter specification

Syntax

```
D = fdesign.rsrc(L,M)
D = fdesign.rsrc(L,M,RESPONSE)
D = fdesign.rsrc(L,M,CICRESPONSE,D)
D = fdesign.rsrc(L,M,RESPONSE,SPEC)
D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)
D = fdesign.rsrc(...,Fs)
D = fdesign.rsrc(...,MAGUNITS)
```

Description

`D = fdesign.rsrc(L,M)` constructs a rational-factor sample-rate filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L`, the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are 0.1π radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 3. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.rsrc(L,M,RESPONSE)` constructs an rational-factor sample-rate converter with the interpolation factor `L`, decimation factor `M`, and the response you specify in `RESPONSE`.

`D = fdesign.rsrc(L,M,CICRESPONSE,D)` constructs a CIC or CIC compensator rational-factor sample-rate convertor filter specification object with the `'RESPONSE'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede the filter specification.

Because you are designing multirate filters, the specification options available are not the same as the specification options for designing single-rate filters. The interpolation and decimation factors are not included in the specification. Different filter responses support different specifications. The following table lists the supported response types and specification options. These options are not case sensitive.

Design Method	Valid Specification Options
`'Arbitrary Magnitude'`	See `fdesign.arbmag` for a description of the specification entries. • `'N,F,A'` (default option) • `'N,B,F,A'`
`'Arbitrary Magnitude and Phase'`	See `fdesign.arbmagnphase` for a description of the specification entries. • `'N,F,H'` (default option) • `'N,B,F,H'`
`'Bandpass'`	See `fdesign.bandpass` for a description of the specification entries. • `'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'` (default option) • `'N,Fc1,Fc2'` • `'N,Fst1,Fp1,Fp2,Fst2'`
`'Bandstop'`	See `fdesign.bandstop` for a description of the specification entries. • `'N,Fc1,Fc2'` • `'N,Fp1,Fst1,Fst2,Fp2'` • `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'` (default option)
`'CIC'`	`'Fp,Fst,Ap,Ast'` — Only valid specification. `Fp` is the passband frequency, `Fst` is the stopband frequency, `Ap` is the passband ripple, and `Ast` is the stopband attenuation in decibels. To specify a CIC rational-factor sample-rate convertor, include the differential delay after `'CIC'` and before the filter specification: `'Fp,Ast'`. For example: `d = fdesign.rsrc(2,2,'cic',4);`

<table>
<tr><th>Design Method</th><th>Valid Specification Options</th></tr>
<tr><td><code>'CIC Compensator'</code></td><td>See <code>fdesign.ciccomp</code> for a description of the specification entries.

• <code>'Fp,Fst,Ap,Ast'</code> (default option)
• <code>'N,Fc,Ap,Ast'</code>
• <code>'N,Fp,Ap,Ast'</code>
• <code>'N,Fp,Fst'</code>
• <code>'N,Fst,Ap,Ast'</code>

To specify a CIC compensator rational-factor sample-rate convertor, include the differential delay after <code>'CICCOMP'</code> and before the filter specification. For example:
<code>d = fdesign.rsrc(2,2,'ciccomp',4);</code></td></tr>
<tr><td><code>'Differentiator'</code></td><td><code>'N'</code> — filter order</td></tr>
<tr><td><code>'Gaussian'</code></td><td><code>'Nsym,BT</code> — <code>Nsym</code> is the filter order in symbols and <code>BT</code> is the bandwidth-symbol time product.

The filter specification must be preceded by an integer-valued <code>SamplesPerSymbol</code>.</td></tr>
<tr><td><code>'Halfband</code></td><td>See <code>fdesign.halfband</code> for a description of the specification entries.

• <code>'TW,Ast'</code> (default option)
• <code>'N,TW'</code>
• <code>‘N’</code>
• <code>'N,Ast'</code>

If you use the quasi-linear IIR design method, <code>iirlinphase</code>, with a halfband specification, the interpolation factor must be 2.</td></tr>
</table>

Design Method	Valid Specification Options
'Highpass'	See fdesign.highpass for a description of the specification entries. • 'Fst,Fp,Ast,Ap' (default option) • 'N,F3db' • 'N,Fc' • 'N,Fc,Ast,Ap' • 'N,Fp,Ast,Ap' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap' • 'N,Fst,Fp,Ast'
'Hilbert'	See fdesign.hilbert for a description of the specification entries. • 'N,TW' (default option) • 'TW,Ap'
'Inverse-sinc Lowpass'	See fdesign.isinclp for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,Fc,Ap,Ast' • 'N,Fp,Fst' • 'N,Fst,Ap,Ast'
'Inverse-sinc Highpass'	See fdesign.isinchp for a description of the specification entries. • 'Fst,Fp,Ast,Ap' (default option) • 'N,Fc,Ast,Ap' • 'N,Fst,Fp' • 'N,Fst,Ast,Ap'

Design Method	Valid Specification Options
'Lowpass'	See fdesign.lowpass for a description of the specification entries. • 'Fp,Fst,Ap,Ast' (default option) • 'N,F3dB' • 'N,Fc' • 'N,Fc,Ap,Ast' • 'N,Fp,Ap,Ast' • 'N,Fp,Fst' • 'N,Fp,Fst,Ap' • 'N,Fp,Fst,Ast' • 'N,Fst,Ap,Ast'
'Nyquist'	See fdesign.nyquist for a description of the specification entries. For all Nyquist specifications, you must specify the *L*th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. • 'TW,Ast' (default option) • 'N' • 'N,Ast' • 'N,Ast'

D = fdesign.rsrc(L,M,RESPONSE,SPEC) constructs object D and sets its Specification property to SPEC. Entries in the SPEC represent various filter response features, such as the filter order, that govern the filter design. Valid entries for SPEC depend on the design type of the specifications object.

When you add the SPEC input argument, you must also add the RESPONSE input argument.

D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...) constructs an object D and sets its specifications at construction time.

`D = fdesign.rsrc(...,Fs)` provides the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. `Fs` is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.rsrc(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units.
- `'dB'` — specify the magnitude in dB (decibels).
- `'squared'` — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

Examples

Construct a Sample-Rate Converter Using `fdesign` Object

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use the default Nyquist design with a transition width of 0.05? radians/sample and stopband attenuation of 40 dB. The Lth band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,.05,40);
hm = design(d,'kaiserwin','SystemObject',true); %design with Kaiser window
```

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use a Nyquist design with the filter specification set to 'N,TW'. Set the order equal to 12 and the transition width to 0.1? radians/sample. The Lth band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,'N,TW',12,0.1);
```

Design a rational-factor sample-rate converter. Assume the data are sampled at 10 kHz. Set the rational sample-rate change to 3/2. Use a Nyquist design with the filter specification set to 'N,TW'. Set the order equal to 12 and the transition width to 100 Hz. The Lth band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(3,2,'nyquist',3,'N,TW',12,100,1e4);
```

```
hd = design(d,'equiripple','SystemObject',true);
```

Introduced in R2011a

fftcoeffs

Frequency-domain coefficients

Syntax

```
c = fftcoeffs(hd)
```

Description

`c = fftcoeffs(hd)` return the frequency-domain coefficients used when filtering with the `dfilt.fftfir` object. c contains the coefficients

Examples

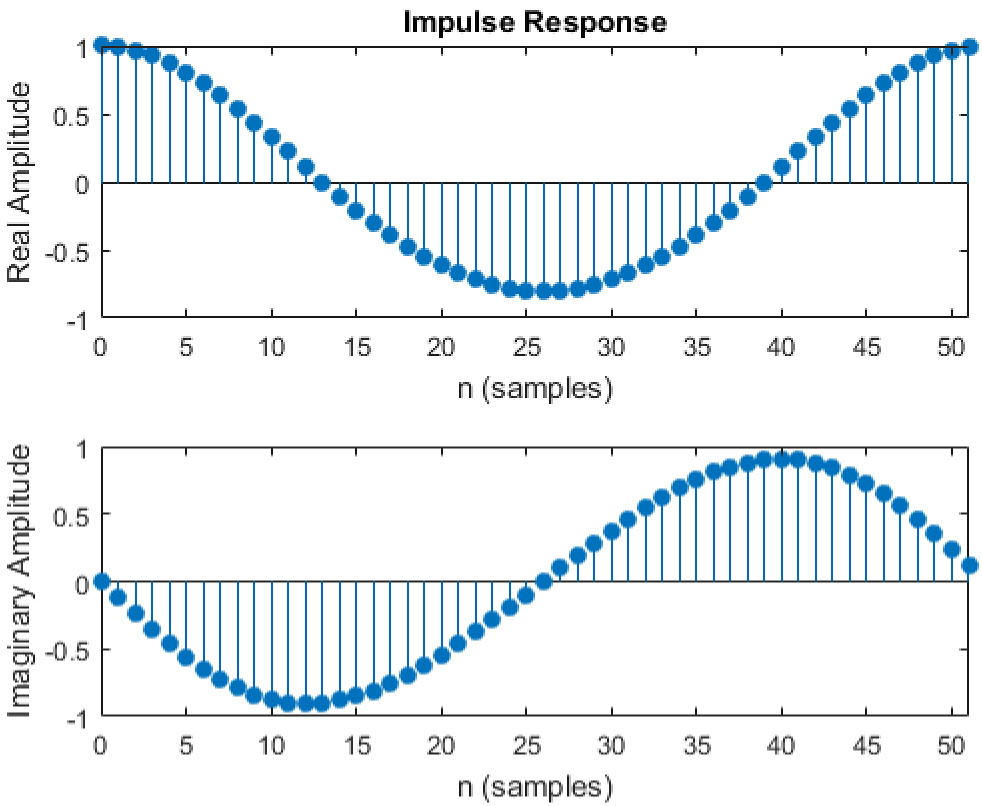
Frequency Domain Coefficients of FIR Filter

This example demonstrates returning the FFT coefficients from the discrete-time filter hd.

```
b = [0.05 0.9 0.05];
len = 50;
hd = dfilt.fftfir(b,len);
c=fftcoeffs(hd);
```

Plot the impulse response of the coefficients.

```
impz(c);
```



Introduced in R2011a

filter

Filter data with filter object

Syntax

Fixed-Point Filter Syntaxes

```
y = filter(hd,x)
y = filter(hd,x,dim)
```

Description

Fixed-Point Filter Syntaxes

`y = filter(hd,x)` filters a vector of real or complex input data `x` through a fixed-point filter `hd`, producing filtered output data `y`. The vectors `x` and `y` have the same length. filter stores the final conditions for the filter in the `States` property of `hd` — `hd.states`.

When you set the property `PersistentMemory` to `false` (the default setting), the initial conditions for the filter are set to zero before filtering starts. To use nonzero initial conditions for `hd`, set `PersistentMemory` to `true`. Then set `hd.states` to a vector of `nstates(hd)` elements, one element for each state to set. If you specify a scalar for `hd.states`, `filter` expands the scalar to a vector of the proper length for the states. All elements of the expanded vector have the value of the scalar.

If `x` is a matrix, `y = filter(hd,x)` filters along each column of `x` to produce a matrix `y` of independent channels. If `x` is a multidimensional array, `y = filter(hd,x)` filters `x` along the first nonsingleton dimension of `x`.

To use nonzero initial conditions when you are filtering a matrix `x`, set the filter states to a matrix of initial condition values. Set the initial conditions by setting the `States` property for the filter (`hd.states`) to a matrix of `nstates(hd)` rows and `size(x,2)` columns.

`y = filter(hd,x,dim)` applies the filter `hd` to the input data located along the specific dimension of `x` specified by `dim`.

When you are filtering multichannel data, `dim` lets you specify which dimension of the input matrix to filter along — whether a row represents a channel or a column represents a channel. When you provide the `dim` input argument, the filter operates along the dimension specified by `dim`. When your input data `x` is a vector or matrix and `dim` is 1, each column of `x` is treated as a one input channel. When `dim` is 2, the filter treats each row of the input `x` as a channel.

To filter multichannel data in a loop environment, you must use the `dim` input argument to set the proper processing dimension.

You specify the initial conditions for each channel individually, when needed, by setting `hm.states` to a matrix of `nstates(hd)` rows (one row containing the states for one channel of input data) and `size(x,2)` columns (one column containing the filter states for each channel).

Examples

Filter a Signal Using the `filter` function

Filter a signal using a filter with various initial conditions (IC) or no initial conditions.

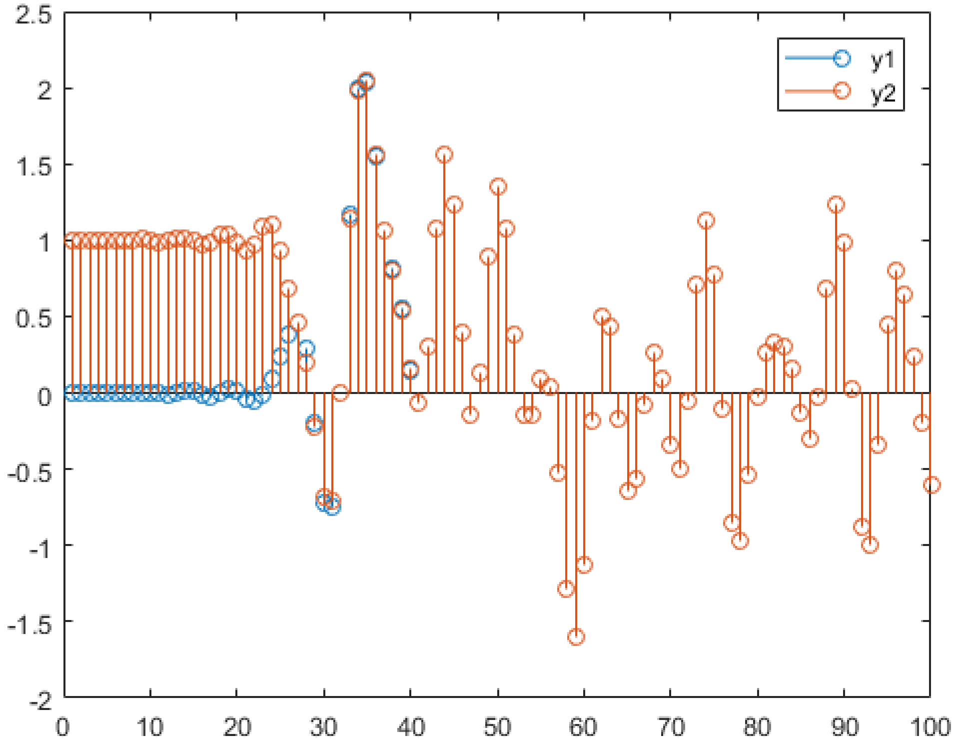
```
x = randn(100,1);    % Original signal.
b = fir1(50,.4);     % 50th-order linear-phase FIR filter.
hd = dfilt.dffir(b);    % Direct-form FIR implementation.
```

Do not set specific initial conditions.

```
y1 = filter(hd,x);   % 'PersistentMemory'='false'(default).
zf = hd.states;      % Final conditions.
```

Now use nonzero initial conditions by setting ICs after before you filter.

```
hd.persistentmemory = true;
hd.states = 1;       % Uses scalar expansion.
y2 = filter(hd,x);
stem([y1 y2])        % Different sequences at beginning.
legend('y1','y2');
```



Looking at the stem plot shows that the sequences are different at the beginning of the filter process.

Here is one way to use filter with streaming data.

```
reset(hd);            % Clear filter history.
y3 = filter(hd,x);    % Filter entire signal in one block.
```

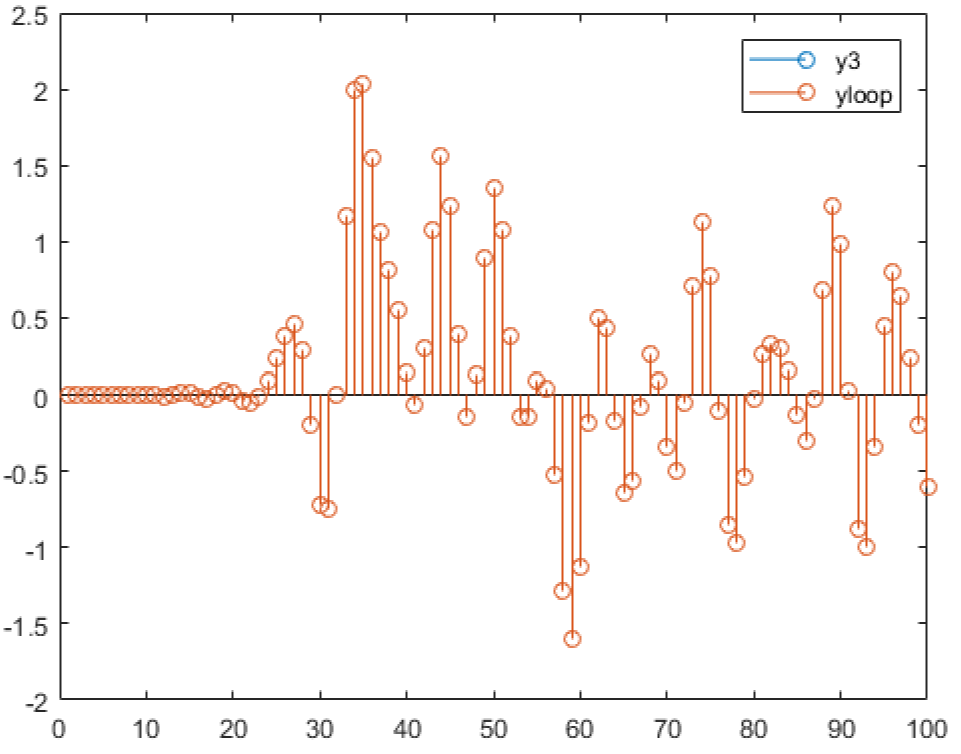
As an experiment, repeat the process, filtering the data as sections, rather than in streaming form.

```
reset(hd);               % Clear filter history.
yloop = zeros(20,5);     % Preallocate output array.
xblock = reshape(x,[20 5]);
```

```
for i=1:5
   yloop(:,i) = filter(hd,xblock(:,i));
end
```

Use a stem plot to see the comparison between streaming and block-by-block filtering.

```
stem([y3 yloop(:)]);
legend('y3','yloop')
```



Filtering the signal section-by-section is equivalent to filtering the entire signal at once.

Algorithms

Quantized Filters

The `filter` command implements fixed- or floating-point arithmetic on the quantized filter structure you specify.

The algorithm applied by `filter` when you use a discrete-time filter object on an input signal depends on the response you chose for the filter, such as lowpass or Nyquist or bandstop. To learn more about each filter algorithm, refer to the literature reference provided on the appropriate discrete-time filter reference page.

Note `dfilt/filter` does not normalize the filter coefficients automatically. Function `filter` supplied by MATLAB does normalize the coefficients.

Adaptive Filters

The algorithm used by `filter` when you apply an adaptive filter object to a signal depends on the algorithm you chose for your adaptive filter. To learn more about each adaptive filter algorithm, refer to the literature reference provided on the appropriate adaptive filter object reference page.

Introduced in R2011a

filterBuilder

Interactive filter design

Syntax

```
filterBuilder(h)
filterBuilder('response')
```

Description

`filterBuilder` starts a interactive tool for building filters. It relies on the `fdesign` object-object oriented filter design paradigm, and is intended to reduce development time during the filter design process. `filterBuilder` uses a specification-centered approach to find the best algorithm for the desired response.

Note: You must have the Signal Processing Toolbox installed to use `fdesign` and `filterBuilder`. Some of the features described below may be unavailable if your installation does not additionally include the DSP System Toolbox. You can verify the presence of both toolboxes by typing `ver` at the command prompt.

For more information on how to use `filterBuilder`, see “Filter Builder Design Process”.

To use `filterBuilder`, enter `filterBuilder` at the MATLAB command line using one of three approaches:

- Simply enter `filterBuilder`. MATLAB opens a dialog for you to select a filter response type. After you select a filter response type, `filterBuilder` launches the appropriate filter design dialog box.
- Enter `filterBuilder(h)`, where h is an existing filter object. For example, if `h` is a bandpass filter, `filterBuilder(h)` opens the bandpass filter design dialog box. The `h` object must have been created using `filterBuilder` or using `fdesign`.

Note: You must have the DSP System Toolbox software to create and import filter System objects.

- Enter `filterBuilder('`*`response`*`')` to replace *`response`* with a response method from the following table. MATLAB opens a filter design dialog that corresponds to the specified response.

Note: You must have the DSP System Toolbox software to implement a number of the filter designs listed in the following table. If you only have the Signal Processing Toolbox software, you can design a limited set of the following filter-response types.

Response Method	Description of Resulting Filter Design	Filter Object
arbgrpdelay	Arbitrary group delay filter design	`fdesign.arbgrpdelay`
arbmag	Arbitrary magnitude filter design	`fdesign.arbmag`
arbmagnphase	Arbitrary response filter (magnitude and phase)	`fdesign.arbmagnphase`
audioweighting	Audio weighting filter	`fdesign.audioweighting`
bandpass or `bp`	Bandpass filter	`fdesign.bandpass`
bandstop or `bs`	Bandstop filter	`fdesign.bandstop`

cic	CIC filter	`fdesign.decimator(M,'cic',...)`
		or
		`fdesign.interpolator(L,'cic',...`
		See `fdesign.decimator`
		and
		`fdesign.interpolator`

ciccomp	CIC compensator	`fdesign.ciccomp`
comb	Comb filter	`fdesign.comb`
diff	Differentiator filter	`fdesign.differentiator`
fracdelay	Fractional delay filter	`fdesign.fracdelay`

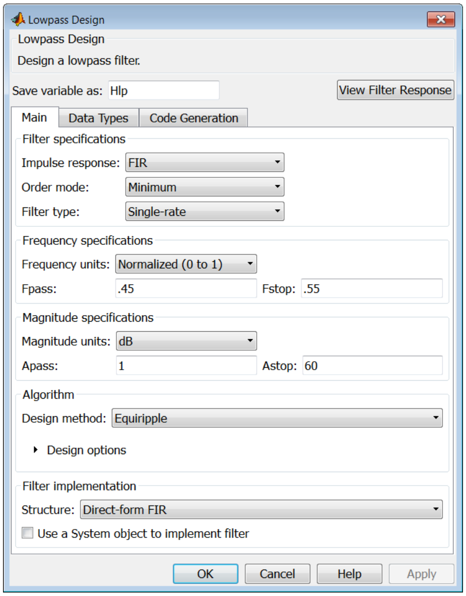
Response Method	Description of Resulting Filter Design	Filter Object
halfband or `hb`	Halfband filter	`fdesign.halfband`
highpass or `hp`	Highpass filter	`fdesign.highpass`
hilb	Hilbert filter	`fdesign.hilbert`
isinc, isinclp, or isinchp	Inverse sinc lowpass or highpass filter	`fdesign.isinclp` and `fdesign.isinchp`
lowpass or `lp`	Lowpass filter (default)	`fdesign.lowpass`
notch	Notch filter	`fdesign.notch`
nyquist	Nyquist filter	`fdesign.nyquist`
octave	Octave filter	`fdesign.octave`
parameq	Parametric equalizer filter	`fdesign.parameq`
peak	Peak filter	`fdesign.peak`

Note: Because they do not change the filter structure, the magnitude specifications and design method are tunable when using `filterBuilder`.

Filter Builder Design Panes

Main Design Pane

The main pane of Filter Builder varies depending on the filter response type, but the basic structure is the same. The following figure shows the basic layout of the dialog box.



As you choose the response for the filter, the available options and design parameters displayed in the dialog box change. This display allows you to focus only on parameters that make sense in the context of your filter design.

Every filter design dialog box includes the options displayed at the top of the dialog box, shown in the following figure.

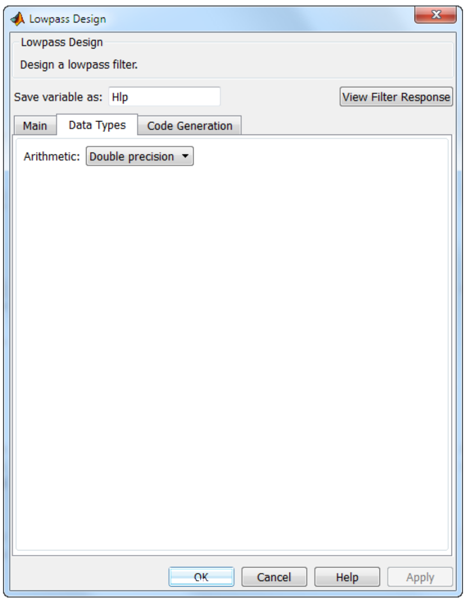
- **Save variable as** — When you click **Apply** to apply your changes or **OK** to close this dialog box, `filterBuilder` saves the current filter to your MATLAB workspace as a filter object with the name you enter.
- **View Filter Response** — Displays the magnitude response for the current filter specifications and design method by opening the Filter Visualization Tool (`fvtool`).

Note: The `filterBuilder` dialog box includes an **Apply** option. Each time you click **Apply**, `filterBuilder` writes the modified filter to your MATLAB workspace. This modified filter has the variable name you assign in **Save variable as**. To apply changes without overwriting the variable in you workspace, change the variable name in **Save variable as** before you click **Apply**.

There are three tabs in the Filter Builder dialog box, containing three panes: **Main**, **Data Types**, and **Code Generation**. The first pane changes according to the filter being designed. The last two panes are the same for all filters. These panes are discussed in the following sections.

Data Types Pane

The second tab in the Filter Builder dialog box is shown in the following figure.

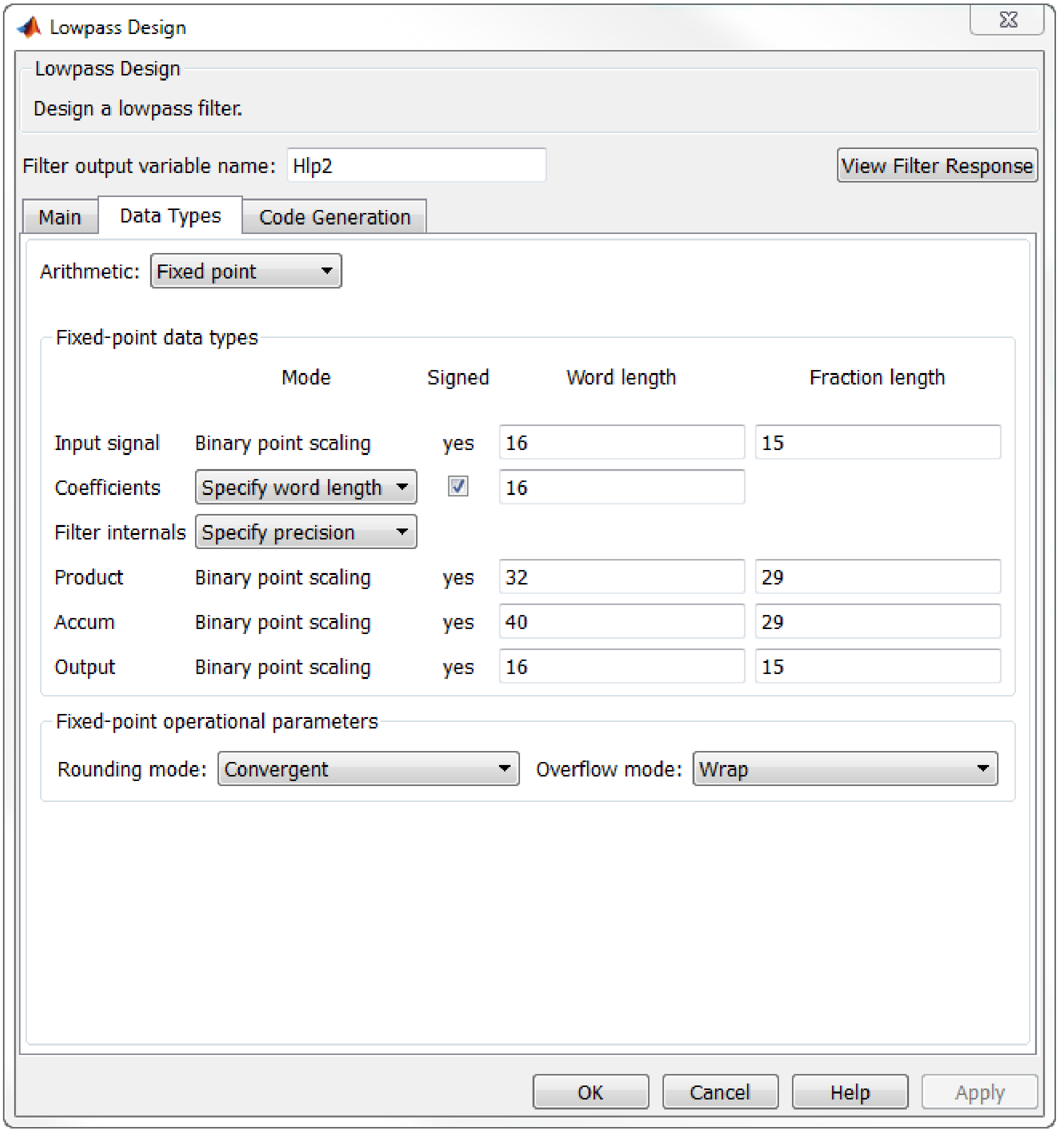


The **Arithmetic** drop down box allows the choice of `Double precision`, `Single precision`, or `Fixed point`. Some of these options may be unavailable depending on the filter parameters. The following table describes these options.

Arithmetic List Entry	Effect on the Filter
`Double precision`	All filtering operations and coefficients use double-precision, floating-point representations and math. When you use

Arithmetic List Entry	Effect on the Filter
	`filterBuilder` to create a filter, `double precision` is the default value for the Arithmetic property.
`Single precision`	All filtering operations and coefficients use single-precision floating-point representations and math.
`Fixed point`	This entry applies selected default values, typically used on many digital processors, for the properties in the fixed-point filter. These properties include coefficient word lengths, fraction lengths, and various operating modes. This setting allows signed fixed data types only. Fixed-point filter design with `filterBuilder` is available only when you install Fixed-Point Designer software along with DSP System Toolbox software.

The following figure shows the **Data Types** pane after you select `Fixed point` for **Arithmetic** and set **Filter internals** to `Specify precision`. This figure shows the **Data Types** pane for the case where the **Use a System object to implement filter** check box is not selected in the **Main** pane.



When you select **Use a System object to implement filter** check box in the **Main** pane, the **Data Types** pane appears as below:

Not all parameters described in the following section apply to all filters. For example, FIR filters do not have the **Section input** and **Section output** parameters.

Input signal

Specify the format the filter applies to data to be filtered. For all cases, `filterBuilder` implements filters that use binary point scaling and signed input. You set the word length and fraction length as needed.

Coefficients

Choose how you specify the word length and the fraction length of the filter numerator and denominator coefficients:

- `Specify word length` enables you to enter the word length of the coefficients in bits. In this mode, `filterBuilder` automatically sets the fraction length of the coefficients to the binary-point only scaling that provides the best possible precision for the value and word length of the coefficients.
- `Binary point scaling` enables you to enter the word length and the fraction length of the coefficients in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.
- The filter coefficients do not obey the **Rounding mode** and **Overflow mode** parameters that are available when you select `Specify precision` from the Filter internals list. Coefficients are always saturated and rounded to `Nearest`.

Section Input

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section input in bits.
- `Specify word length` enables you to enter the word lengths in bits.

Section Output

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- `Binary point scaling` enables you to enter the word and fraction lengths of the section output in bits.
- `Specify word length` enables you to enter the output word lengths in bits.

State

Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Use this parameter to specify how to designate the state word and fraction lengths. This parameter is not visible for direct form and direct form I filter structures because `filterBuilder` deduces the state directly from the input format. States always use signed representation:

- `Binary point scaling` enables you to enter the word length and the fraction length of the accumulator in bits.
- `Specify precision` enables you to enter the word length and fraction length in bits (if available).

Product

Determines how the filter handles the output of product operations. Choose from the following options:

- `Full precision` — Maintain full precision in the result.
- `Keep LSB` — Keep the least significant bit in the result when you need to shorten the data words.
- `Specify Precision` — Enables you to set the precision (the fraction length) used by the output from the multiplies.

Filter internals

Specify how the fixed-point filter performs arithmetic operations within the filter. The affected filter portions are filter products, sums, states, and output. Select one of these options:

- `Full precision` — Specifies that the filter maintains full precision in all calculations for products, output, and in the accumulator.
- `Specify precision` — Set the word and fraction lengths applied to the results of product operations, the filter output, and the accumulator. Selecting this option enables the word and fraction length controls.

Signed

Selecting this option directs the filter to use signed representations for the filter coefficients.

Word length

Sets the word length for the associated filter parameter in bits.

Fraction length

Sets the fraction length for the associate filter parameter in bits.

Accum

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

Determines how the accumulator outputs stored values. Choose from the following options:

- `Full precision` — Maintain full precision in the accumulator.
- `Keep MSB` — Keep the most significant bit in the accumulator.
- `Keep LSB` — Keep the least significant bit in the accumulator when you need to shorten the data words.
- `Specify Precision` — Enables you to set the precision (the fraction length) used by the accumulator.

Output

Sets the mode the filter uses to scale the output data after filtering. You have the following choices:

- `Avoid Overflow` — Set the output data fraction length to avoid causing the data to overflow. `Avoid overflow` is considered the conservative setting because it is independent of the input data values and range.
- `Best Precision` — Set the output data fraction length to maximize the precision in the output data.
- `Specify Precision` — Set the fraction length used by the filtered data.

Fixed-point operational parameters

Parameters in this group control how the filter rounds fixed-point values and how it treats values that overflow.

Rounding mode

Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).

- `ceil` — Round toward positive infinity.
- `convergent` — Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.

- `zero/fix` — Round toward zero.
- `floor` — Round toward negative infinity.
- `nearest` — Round toward nearest. Ties round toward positive infinity.
- `round` — Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

Overflow mode

Sets the mode the filter uses to respond to overflow conditions in fixed-point arithmetic. Choose from the following options:

- `Saturate` — Limit the output to the largest positive or negative representable value.
- `Wrap` — Set overflowing values to the nearest representable value using modular arithmetic.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

Cast before sum

Specifies whether to cast numeric data to the appropriate accumulator format before performing sum operations. Selecting **Cast before sum** ensures that the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

If you clear **Cast before sum**, the filter prevents the addends from being cast to the sum format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use. The input format referenced by **Cast before sum** depends on the filter structure you are using.

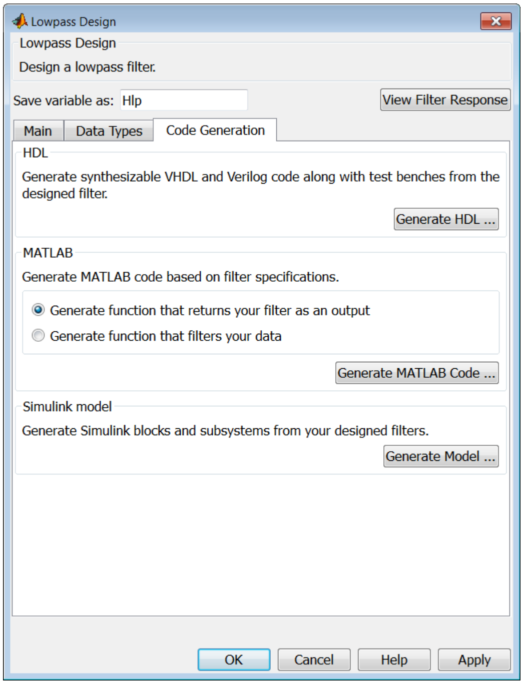
The effect of clearing or selecting **Cast before sum** is as follows:

- Cleared — Configures filter summation operations to retain the addends in the format carried from the previous operation.

- Selected — Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually, selecting **Cast before sum** generates results from the summation that more closely match those found from digital signal processors.

Code Generation Pane

The code generation pane contains options for various implementations of the completed filter design. Depending on your installation, you can generate MATLAB, VHDL, and Verilog code from the designed filter. You can also choose to create or update a Simulink model from the designed filter. The following section explains these options.



HDL

For more information on this option, see “Opening the Filter Design HDL Coder GUI from the Filter Builder” (Filter Design HDL Coder).

MATLAB

Generate MATLAB code based on filter specifications

- **Generate function that returns your filter as an output**

  Selecting this option generates a function that designs a filter object using `fdesign`.

- **Generate function that filters your data**

  Selecting this option generates a function that takes data as input, and outputs data filtered with the designed filter. The data type of the filter output is set according to the data type settings in the **Data Types** pane.

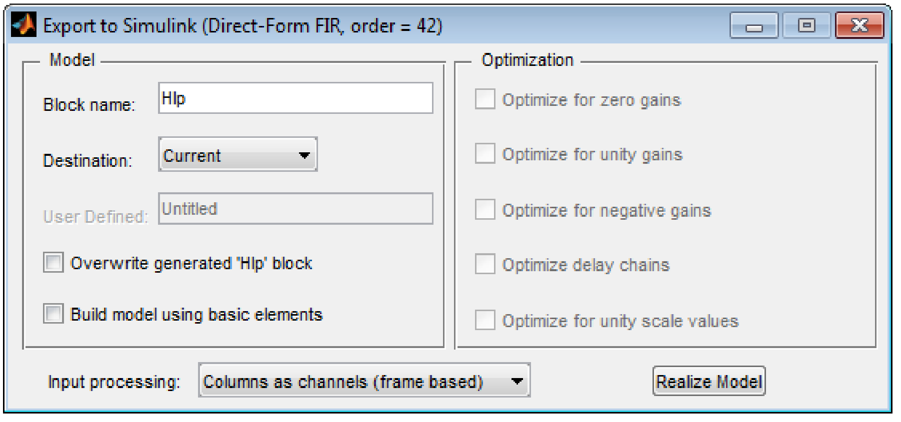
Clicking on the **Generate MATLAB code** button, brings up a Save File dialog. Specify the file name and location, and save. The filter is now contained in an editable file.

Simulink Model

Generate Simulink blocks and subsystems from your designed filters

When you click **Generate Model**, the filter builder generates Simulink blocks and subsystems from your designed filters.

Clicking on the **Generate Model** button opens the Export to Simulink dialog box.



- **Block Name** — The name for the new subsystem block, set to **Filter** by default.
- **Destination** — `Current` saves the generated model to the current Simulink model. `New` creates a new model to contain the generated block. `User Defined` creates a new model or subsystem at the location specified in `User Defined`.

- **Overwrite generated 'Filter' block** — Overwrites an existing block with the name specified in **Block Name**. Clear this check box to create a new block with the same name.
- **Build model using basic elements** — Builds the model using only basic blocks.
- **Optimize for zero gains** — Removes all zero-gain blocks from the model.
- **Optimize for unity gains** — Replaces all unity gains with direct connections.
- **Optimize for negative gains** — Removes all negative unity gain blocks, and changes sign at the nearest summation block.
- **Optimize delay chains** — Replaces delay chains made up of *n* unit delays with a single delay by *n*.
- **Optimize for unity scale values** — Removes all scale value multiplications by 1 from the filter structure.
- **Input processing** — Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

  - `Columns as channels (frame based)` — The block treats each column of the input as a separate channel.
  - `Elements as channels (sample based)` — The block treats each element of the input as a separate channel.

  For more information about sample-based and frame-based processing, see "Sample- and Frame-Based Concepts".
- **Realize Model** — Builds the model with the set parameters.

When the **Use a System object to implement filter** check box is selected in the **Main** pane, the **Generate Model** button in the **Simulink model** panel is disabled under the following conditions:

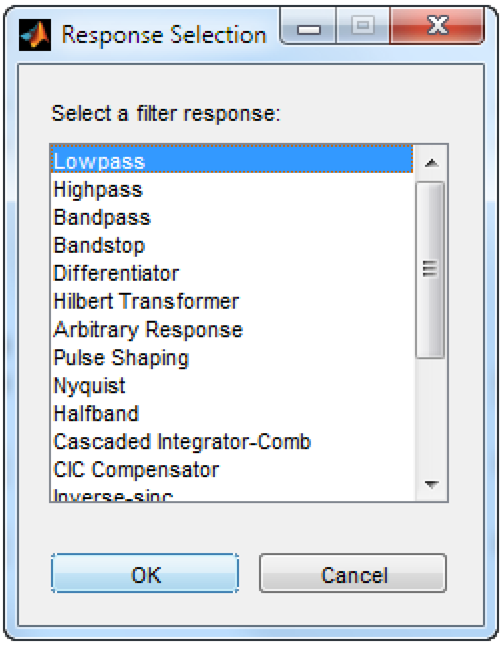
- Select **Filter response** as `Comb` and **Arithmetic** on the **Data Types** pane as `Fixed point`.
- Select **Filter response** as `Arbitrary Response`, **Impulse response** as `IIR`, set **Specify response as** to either `Magnitudes and phases` or `Frequency response`, and **Arithmetic** on the **Data Types** pane as `Fixed point`.

These settings design a `dsp.IIRFilter` System object with fixed point arithmetic. Generating a Simulink model for fixed point `dsp.IIRFilter` object is not supported.

Filter Responses

Select your filter response from the `filterBuilder` **Response Selection** main menu.

If you have the DSP System Toolbox software, the following **Response Selection** menu appears.



Select your desired filter response from the menu and design your filter.

The following sections describe the options available for each response type.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

This dialog only applies if you have the DSP System Toolbox software. Select either `FIR` or `IIR` from the drop down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. Arbitrary group delay designs are only available if **Impulse response** is `IIR`. Without the DSP System Toolbox, the only available arbitrary response filter design is FIR.

Order mode

This dialog only applies if you have the DSP System Toolbox software. Choose `Minimum` or `Specify`. Choosing `Specify` enables the **Order** dialog.

Order

This dialog only applies when **Order mode** is `Specify`. For an FIR design, specify the filter order. For an IIR design, you can specify an equal order for the numerator and denominator, or you can specify different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box. Because the Signal Processing Toolbox only supports FIR arbitrary-magnitude filters, you do not have the option to specify a denominator order.

Denominator order

Select the check box and enter the denominator order. This option is enabled only if `IIR` is selected for **Impulse response**.

Filter type

This dialog only applies if you have the DSP System Toolbox software and is only available for FIR filters. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2 for `Decimator` and 3 for `Sample-rate converter`.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Response Specification

Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

Specify response as:

Specify the response as `Amplitudes`, `Magnitudes and phase`, `Frequency response`, or `Group delay`. `Amplitudes` is the only option if you do not have the DSP System Toolbox software. `Group delay` is only available for IIR designs.

Frequency units

Specify frequency units as either `Normalized`, `Hz`, `kHz`, `MHz`, or `GHz`.

Input Fs

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down box. This option is enabled when **Frequency units** is set to an option in hertz.

Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down box. Two or three columns are presented for input. The first column is always Frequencies. The other columns are either Amplitudes, Magnitudes, Phases, or Frequency Response. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if you select `Amplitudes` in the **Specify response as** drop-down box.

- **Frequencies**, **Magnitudes**, and **Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is `Magnitudes and phases`.
- **Frequencies** and **Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is `Frequency response`.

Algorithm

The options for each design are specific for each design method. In the arbitrary response design, the available options also depend on the **Response specifications**. This section does not present all of the available options for all designs and design methods.

Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

Design Options

- **Window** — Valid when the **Design method** is `Frequency Sampling`. Replace the square brackets with the name of a `window` function or function handle. For example, `'hamming'` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{‘kaiser’,3.5}` or `{@chebwin,60}`.
- **Density factor** — Valid when the **Design method** is `equiripple`. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

  Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

  The default changes to 20 for an IIR arbitrary group delay design.
- **Phase constraint** — Valid when the **Design method** is `equiripple`, you have the DSP System Toolbox installed, and **Specify response as** is set to `Amplitudes`. Choose one of `Linear`, `Minimum`, or `Maximum`.
- **Weights** — Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes

to **B1 Weights**, **B2 Weights** to designate the separate bands. Use **Bi Weights** to specify weights for the i-th band. The **Bi Weights** design option is only available when you specify the i-th band as an unconstrained.

- **Bi forced frequency point** — This option is only available in a multi-band constrained equiripple design when **Specify response as** is `Amplitudes`. **Bi forced frequency point** is the frequency point in the i-th band at which the response is forced to be zero. The index **i** corresponds to the frequency bands in **Band properties**. For example, if you specify two bands in **Band properties**, you have **B1 forced frequency point** and **B2 forced frequency point**.
- **Norm** — Valid only for IIR arbitrary group delay designs. **Norm** is the norm used in the optimization. The default value is 128, which essentially equals the L-infinity norm. The norm must be even.
- **Max pole radius** — Valid only for IIR arbitrary group delay designs. Constrains the maximum pole radius. The default is 0.999999. Reducing the **Max pole radius** can produce a transfer function more resistant to quantization.
- **Init norm** — Valid only for IIR arbitrary group delay designs. The initial norm used in the optimization. The default initial norm is 2.
- **Init numerator** — Specifies an initial estimate of the filter numerator coefficients.
- **Init denominator** — Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems. In allpass filters, you only have to specify either the denominator or numerator coefficients. If you specify the denominator coefficients, you can obtain the numerator coefficients.

Filter implementation

Structure

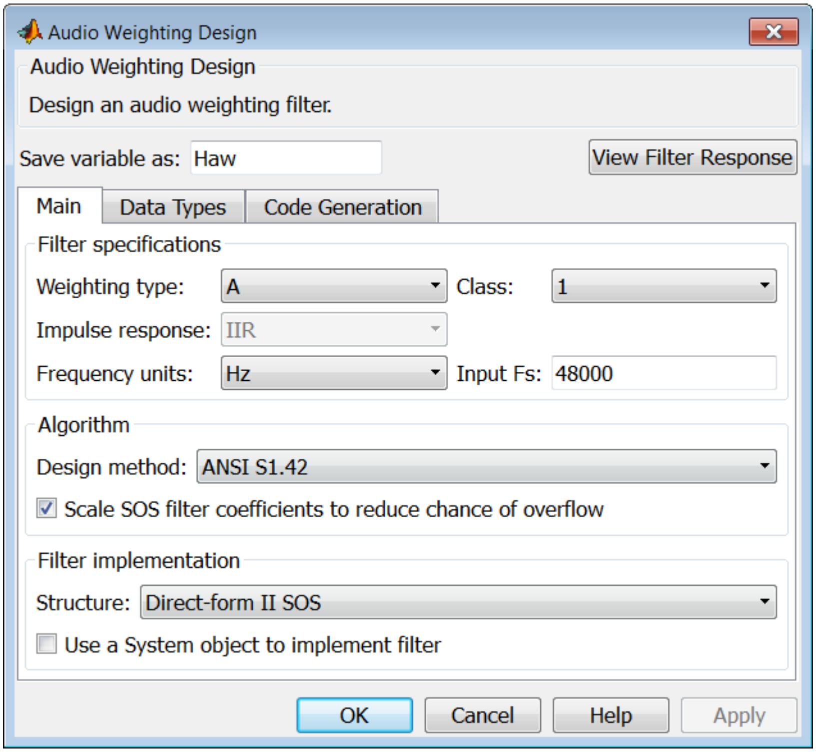
Select the structure for the filter. The available filter structures depend on the parameters you select for your filter.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Audio Weighting Filter Design — Main Pane



Filter specifications

- **Weighting type** — The weighting type defines the frequency response of the filter. The valid weighting types are: A, C , C-message, ITU-T 0.41, and ITU-R 468–4 weighting. See `fdesign.audioweighting` for definitions of the weighting types.
- **Class** — Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in `fvtool` for the analysis of the filter design.

- **Impulse response** — Impulse response type as one of `IIR` or `FIR`. For A, C , C-message, and ITU-R 468–4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.
- **Frequency units** — Choose `Hz`, `kHz`, `MHz`, or `GHz`. Normalized frequency designs are not supported for audio weighting filters.
- **Input Fs** — The sampling frequency in **Frequency units**. For example, if **Frequency units** is set to `kHz`, setting **Input Fs** to 40 is equivalent to a 40 kHz sampling frequency.

Algorithm

- **Design method** — Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is `ANSI S1.42`. This is an IIR design method that follows ANSI standard S1.42–2001. For a C message filter, the only valid design method is `Bell 41009`, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468–4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is `IIR least p-norm`. If you choose an FIR design, the design method choices are: `Equiripple` or `Frequency Sampling`. For an ITU-T 0.41 weighting filter, the available FIR design methods are `Equiripple` or `Frequency Sampling`
- **Scale SOS filter coefficients to reduce chance of overflow** — Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter implementation

- **Structure** — For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

  For FIR designs, you can choose direct form, direct-form transposed, direct-form symmetric, direct-form asymmetric structures, or an overlap and add structure.
- **Use a System object to implement filter** — Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down box. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type — This dialog only applies if you have the DSP System Toolbox software.

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

Order

Enter the filter order. This option is enabled only if you select `Specify` for **Order mode**.

Decimation Factor

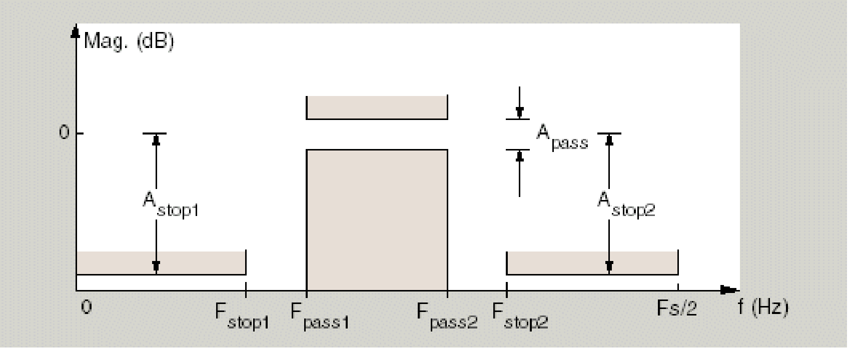
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, regions between specification values such as Fstop1 and Fpass1 represent transition regions where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
- `3dB points` — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3-dB point is the frequency for the point 3 dB below the passband value.
- `3dB points and passband width` — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the passband. (IIR filters)

- `3dB points and stopband widths` — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the stopband. (IIR filters)
- `6dB points` — Define the filter response by specifying the locations of the 6-dB points. The 6-dB point is the frequency for the point 6 dB below the passband value. (FIR filters)

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in hertz, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fstop1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fpass1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fpass2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify as `Unconstrained` or `Constrained bands`. You must have the DSP System Toolbox software to select `Constrained bands`. Selecting `Constrained bands` enables dialogs for both stopbands and the passband: **Astop1**, **Astop2**, and **Apass**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to `Constrained bands` enables the **Wstop** and **Wpass** options under **Design options**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in dB (decibels). This is the default setting.
- `Squared` — Specify the magnitude in squared units.

Astop1

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Valid when the **Design method** is `equiripple` and you have the DSP System Toolbox installed. Choose one of `Linear`, `Minimum`, or `Maximum`.

Minimum order

This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Wstop1

Weight for the first stopband.

Wpass

Passband weight.

Wstop2

Weight for the second stopband.

Max pole radius

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

Init norm

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

Init numerator

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

Init denominator

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

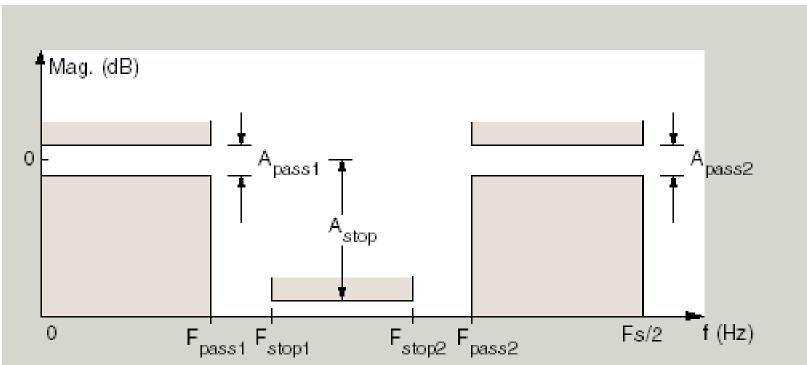
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
- `3dB points` — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3 dB point is the frequency for the point 3 dB point below the passband value.

- `3dB points and passband width` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband (IIR filters).
- `3dB points and stopband widths` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband (IIR filters).
- `6dB points` — Define the filter response by specifying the locations of the 6-dB points (FIR filters). The 6-dB point is the frequency for the point 6 dB point below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

When you design an interpolator, Fs represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is `interpolator`.

Fpass1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

Fstop1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fpass2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

Specify as `Unconstrained` or `Constrained bands`. You must have the DSP System Toolbox software to select `Constrained bands`. Selecting `Constrained bands` enables dialogs for both passbands and the stopband: **Apass1**, **Apass2**, and **Astop**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to `Constrained bands` enables the **Wstop** and **Wpass** options under **Design options**.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

Apass2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Valid when the **Design method** is `equiripple` and you have the DSP System Toolbox installed. Choose one of `Linear`, `Minimum`, or `Maximum`.

Minimum order

This option only applies when you have the DSP System Toolbox software and **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Wpass1

Weight for the first passband.

Wstop

Stopband weight.

Wpass2

Weight for the second passband.

Match exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` .

Max pole radius

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

Init norm

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

Init numerator

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

Init denominator

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

Filter implementation

Structure

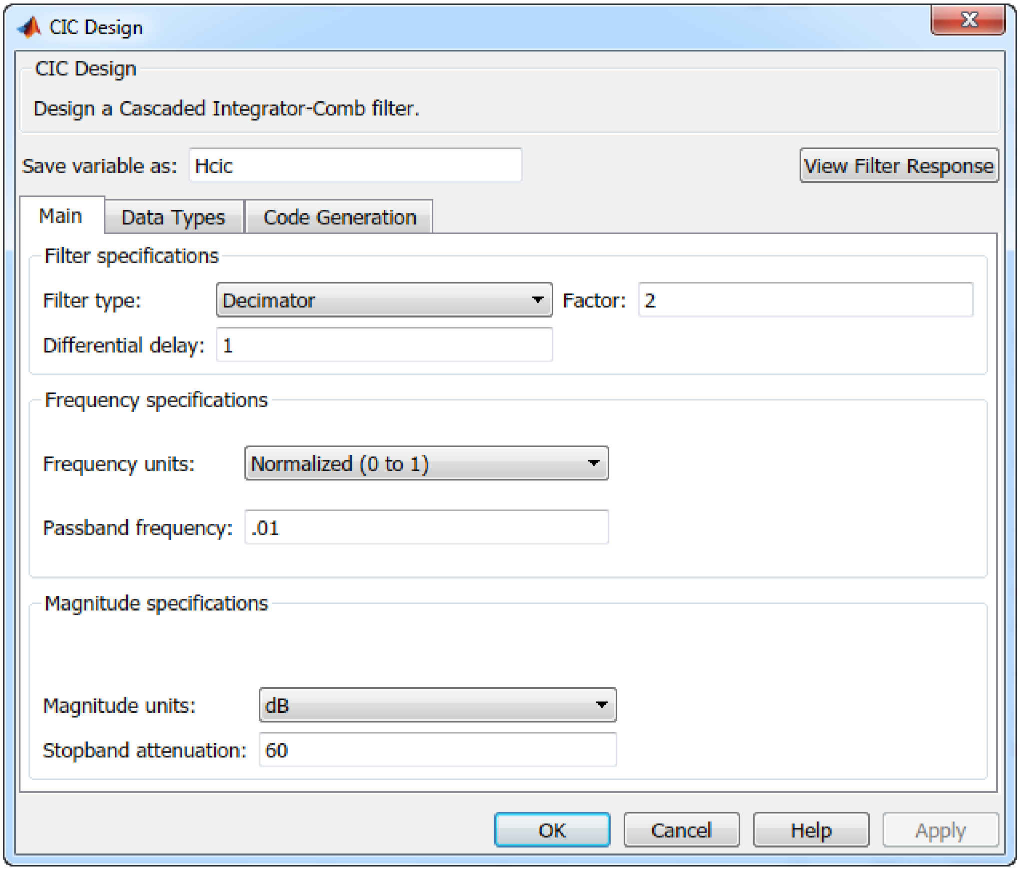
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

CIC Filter Design — Main Pane



Filter specifications

Parameters in this group enable you to specify your CIC filter format, such as the filter type and the differential delay.

Filter type

Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output Fs** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

Differential Delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

Frequency specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the filter order mode and the filter type.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

Differential Delay

Specify the differential delay of your target CIC filter. The default value is `1`. Most CIC filters use 1 or 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve.

Frequency specifications

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Output Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.

- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Note: Generally, **Minimum order** designs are not available for IIR filters.

Match exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterBuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

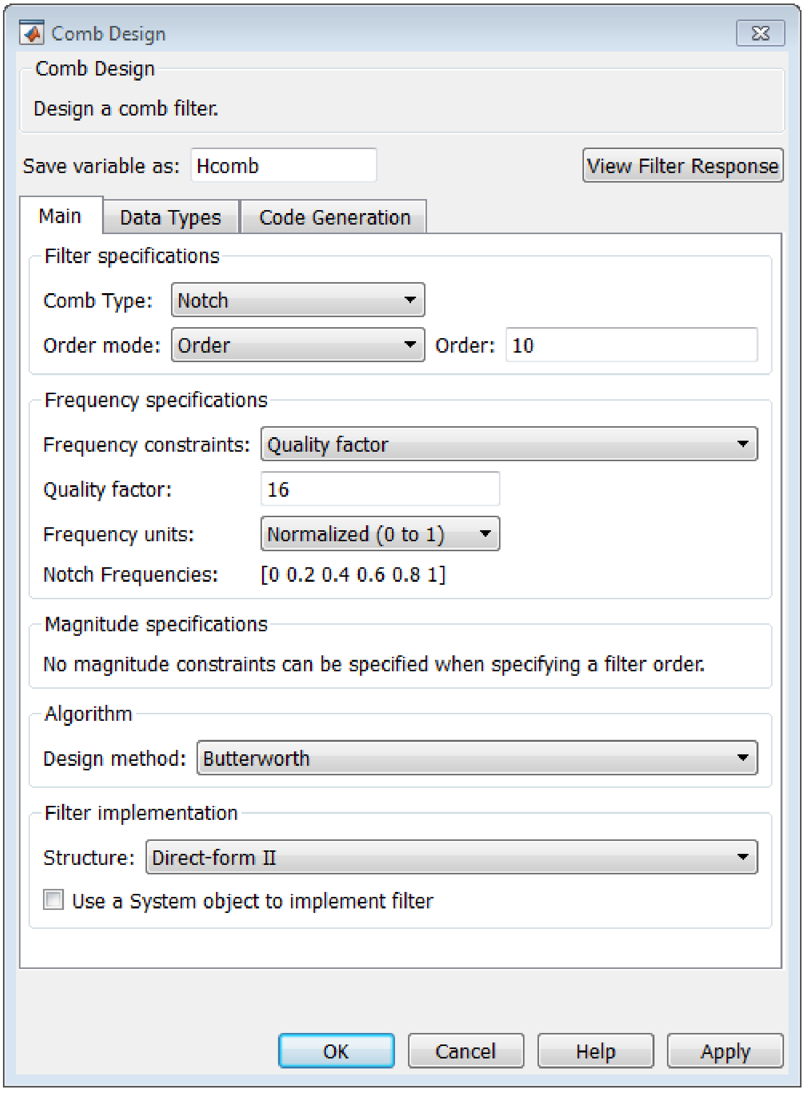
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Comb Filter Design —Main Pane



Filter specifications

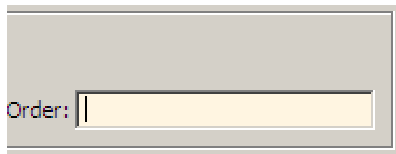
Parameters in this group enable you to specify the type of comb filter and the number of peaks or notches.

Comb Type

Select `Notch` or `Peak` from the drop-down list. `Notch` creates a comb filter that attenuates a set of harmonically related frequencies. `Peak` creates a comb filter that amplifies a set of harmonically related frequencies.

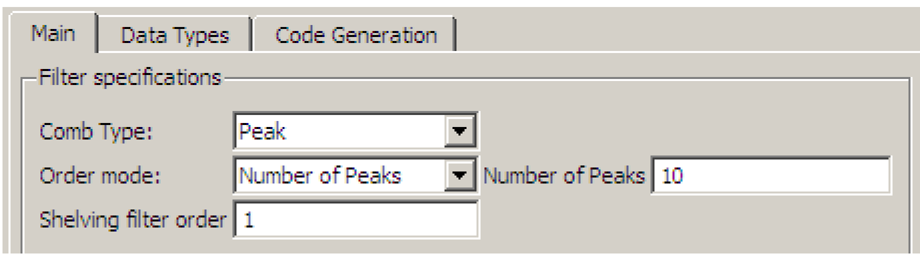
Order mode

Select `Order` or `Number of Peaks/Notches` from the drop-down menu.



Select `Order` to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of 2/`Order` in normalized frequency units.

Select `Number of Peaks` or `Number of Notches` to specify the number of peaks or notches and the `Shelving filter order`



.

Shelving filter order

The `Shelving filter order` is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

Frequency specifications

Parameters in this group enable you to specify the frequency constraints and frequency units.

Frequency specifications

Select `Quality factor` or `Bandwidth`.

`Quality factor` is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the –3 dB point.

`Bandwidth` specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the –3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input Fs** dialog box.

Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Bandwidth gain — Specify the gain at which the bandwidth is measured. The default is –3 dB.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

Filter implementation

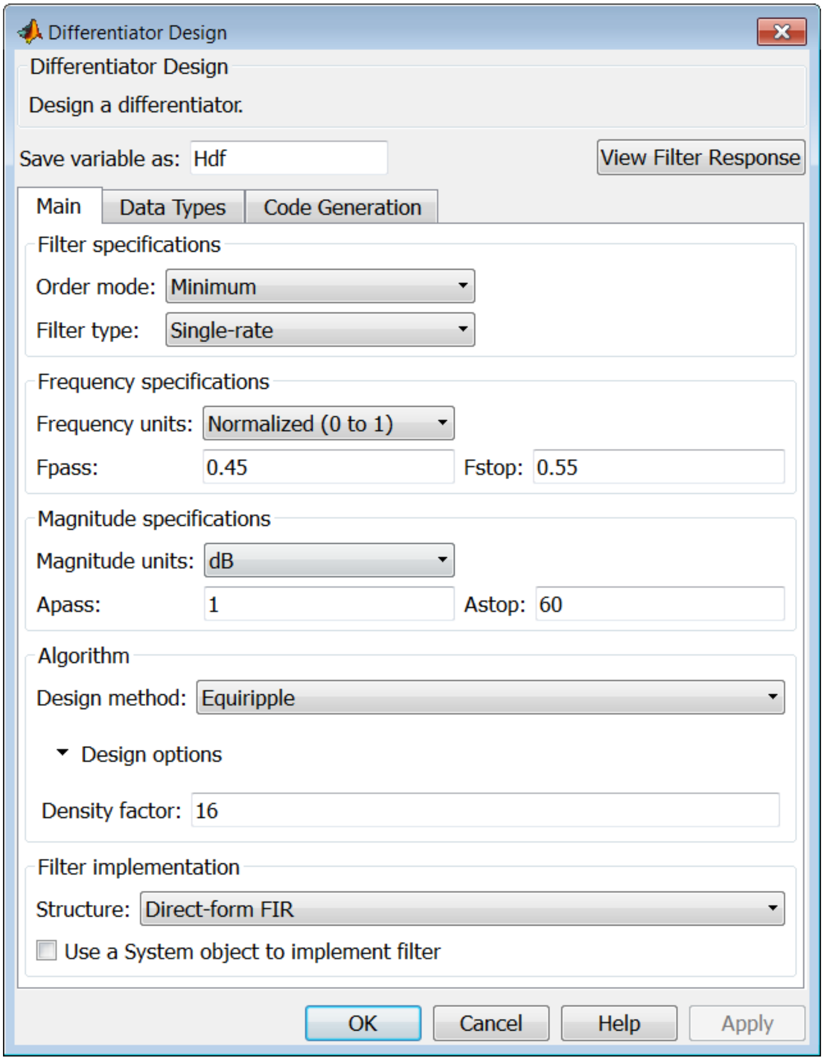
Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use a System object to implement filter

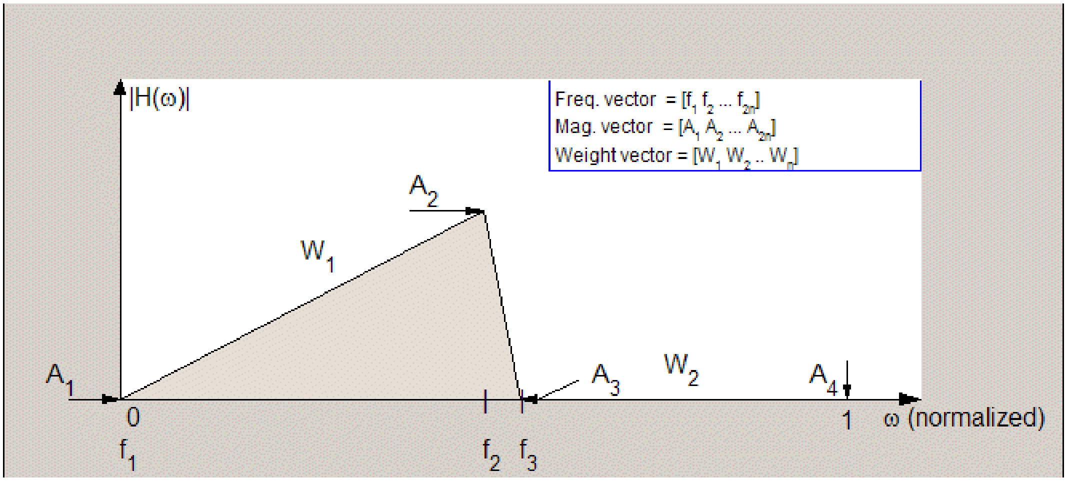
Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

Differentiator Filter Design — Main Pane



Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, regions between specification values such as **Fpass** (f_1) and **Fstop** (f_3) represent transition regions where the filter response is not explicitly defined.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve.

Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are `Unconstrained` and `Passband edge and stopband edge`.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0—1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude constraints

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. If the value of **Frequency constraints** is `Unconstrained`, **Magnitude constraints** must be `Unconstrained`. If the value of **Frequency constraints** is `Passband edge and stopband edge`, **Magnitude constraints** can be `Unconstrained`, `Passband ripple`, or `Stopband attenuation`.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Wstop

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to `Passband edge and stopband edge` and the **Design method** is `Equiripple`.

Filter implementation

Structure

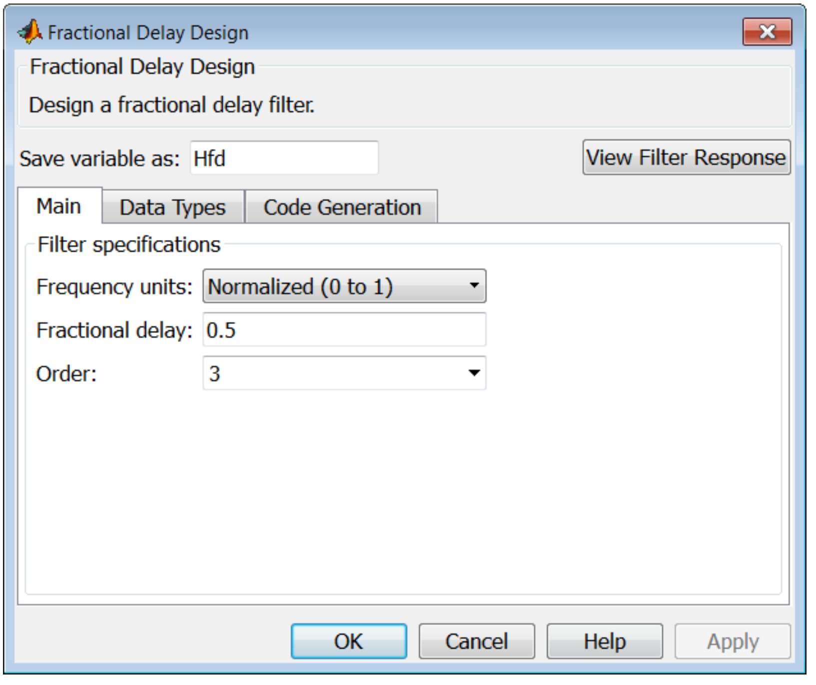
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Fractional Delay Design — Main Pane



Frequency specifications

Parameters in this group enable you to specify your filter format, such as the fractional delay and the filter order.

Order

If you choose `Specify` for **Order mode**, enter your filter order in this field, or select the order from the drop-down list.`filterBuilder` designs a filter with the order you specify.

Fractional delay

Specify a value between 0 and 1 samples for the filter fractional delay. The default value is `0.5` samples.

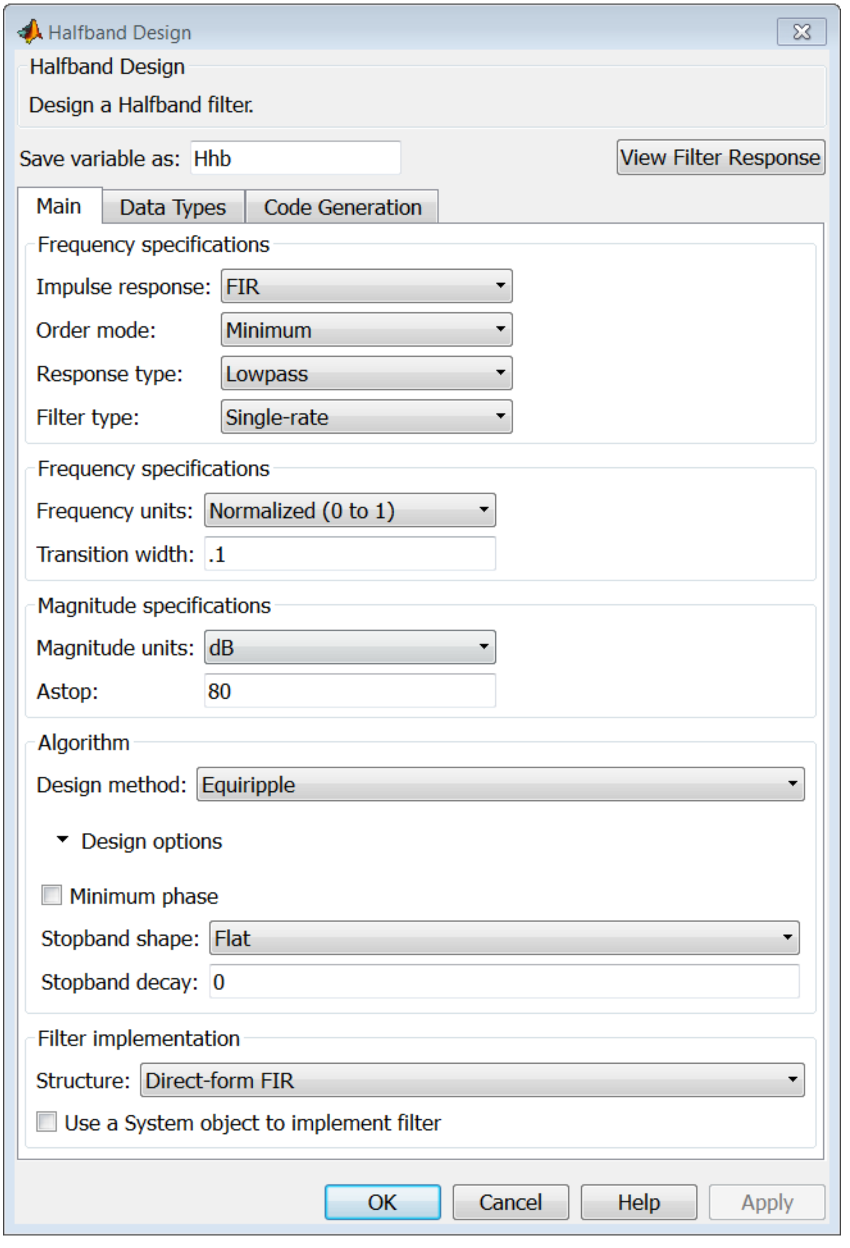
Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Halfband Filter Design — Main Pane



Filter specifications

Parameters in this group enable you to specify your filter type and order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, or `Interpolator`. By default, `filterBuilder` specifies single-rate filters.

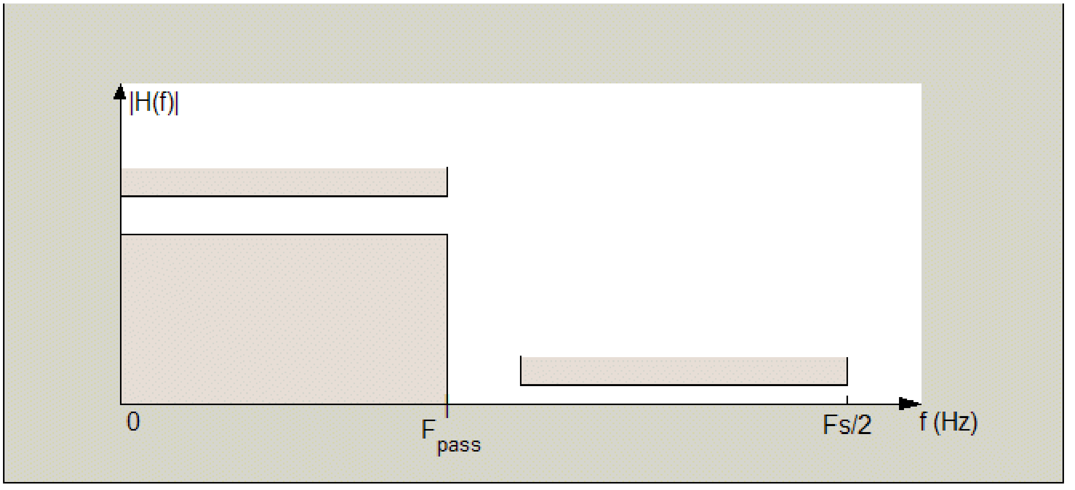
When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that decimates or interpolates your input by a factor of two.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.



In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are `Equiripple` and `Kaiser window`. For IIR halfband filters, the available design options are `Butterworth`, `Elliptic`, and `IIR quasi-linear phase`.

Design Options

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterBuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to either `Interpolator` or `Decimator`. The filter builder always implements the filter as a System object.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option so you can enter the filter order.

If your **Impulse response** is `IIR`, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

This option is only available if you have the DSP System Toolbox software. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a highpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

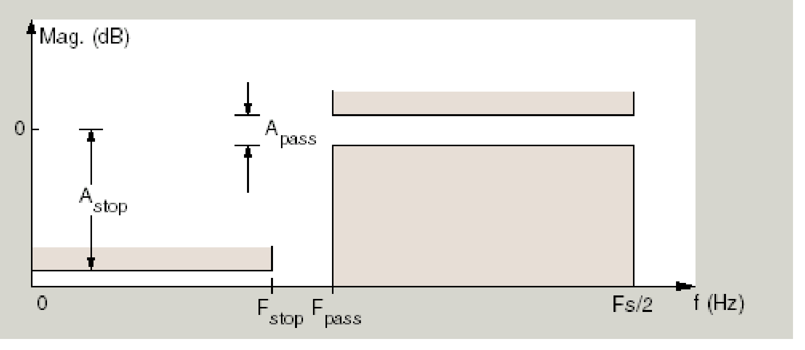
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, the region between specification values Fstop and Fpass represents the transition region where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Stopband edge and passband edge` — Define the filter by specifying the frequencies for the edges for the stopband and passband.
- `Passband edge` — Define the filter by specifying the frequency for the edge of the passband.
- `Stopband edge` — Define the filter by specifying the frequency for the edges of the stopband.
- `Stopband edge and 3dB point` — Define the filter by specifying the stopband edge frequency and the 3-dB down point (IIR designs).
- `3dB point and passband edge` — Define the filter by specifying the 3-dB down point and passband edge frequency (IIR designs).

- `3dB point` — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- `6dB point` — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

Minimum order — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterBuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Wpass

Passband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Wstop

Stopband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Filter implementation

Structure

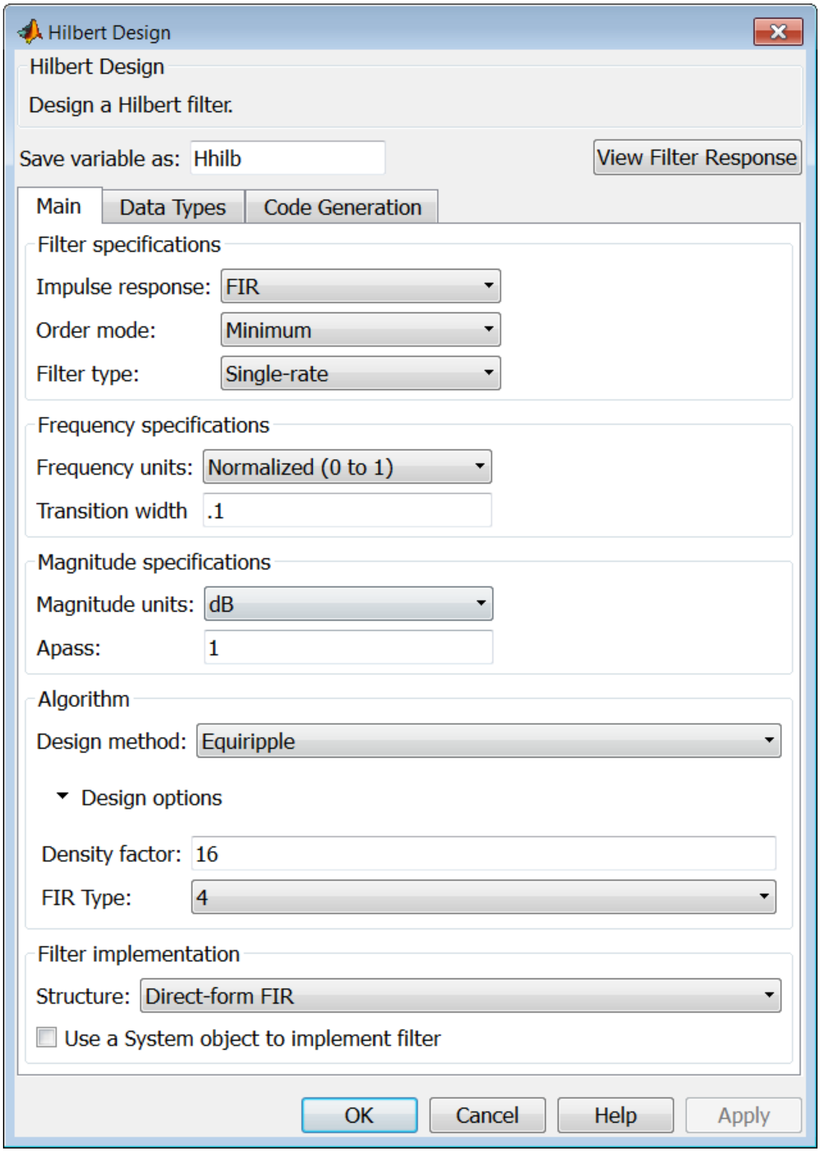
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Hilbert Filter Design — Main Pane



Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

This option is only available if you have the DSP System Toolbox software. Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

This option is only available if you have the DSP System Toolbox software. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

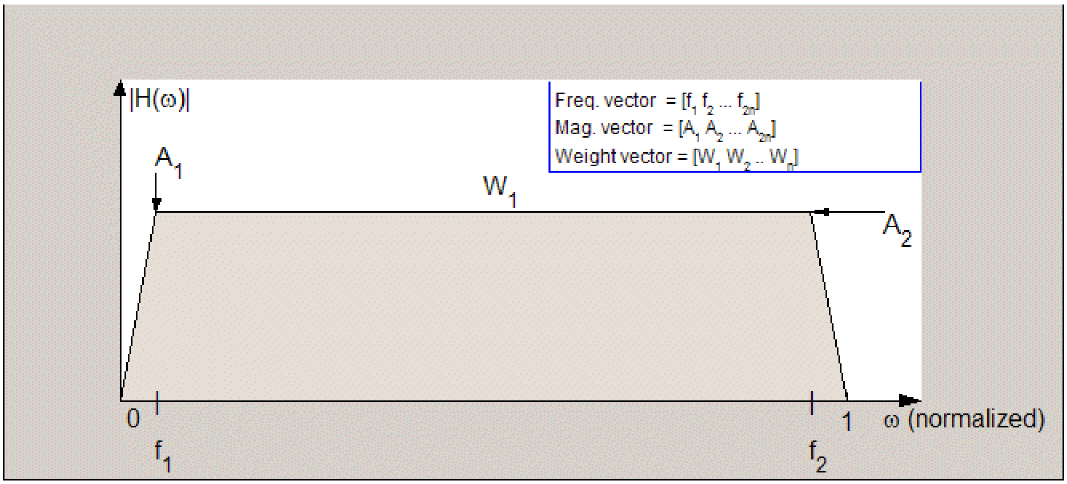
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, the regions between 0 and f_1 and between f_2 and 1 represent the transition regions where the filter response is explicitly defined by the transition width.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is

available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

FIR Type

This option is only available in a minimum-order design. Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select `3` or `4` from the drop-down list.

Filter implementation

Structure

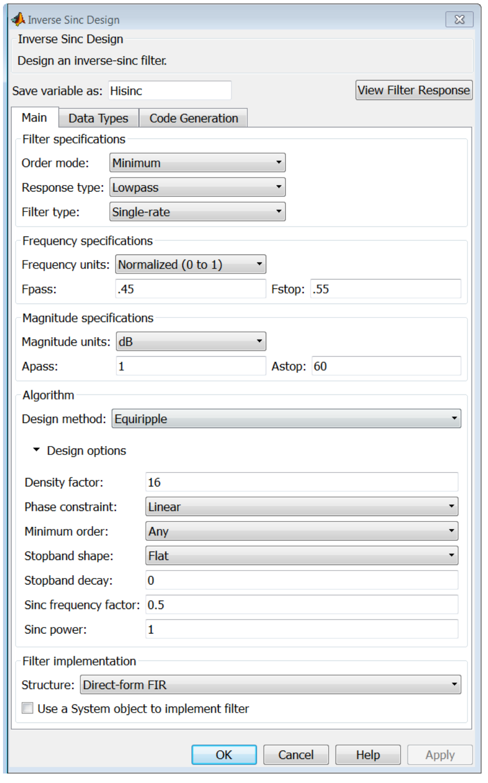
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Inverse Sinc Filter Design — Main Pane



Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Response type

Select `Lowpass` or `Highpass` to design an inverse sinc lowpass or highpass filter.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

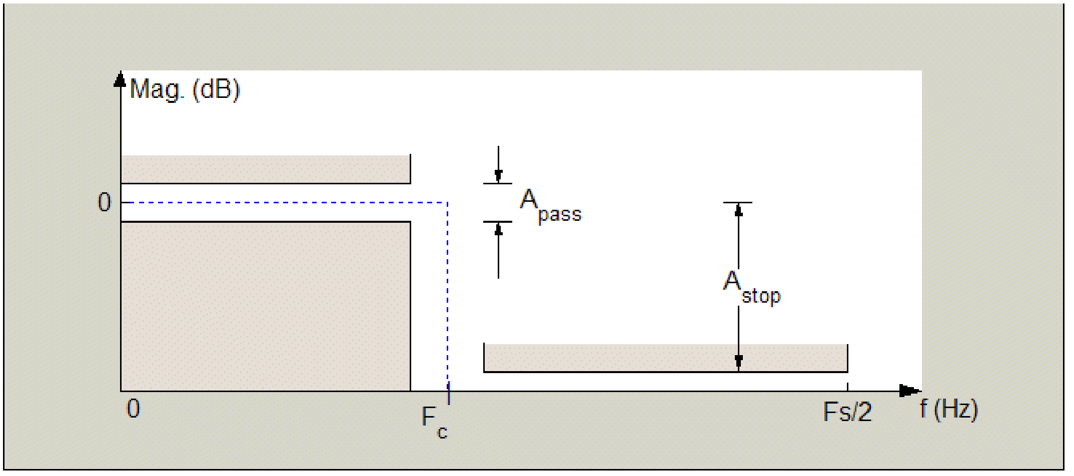
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



Regions between specification values such as Fpass and Fstop represent transition regions where the filter response is not explicitly defined.

Frequency constraints

This option is only available when you specify the filter order. The following options are available:

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- `Passband edge` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edge` — Define the filter by specifying frequencies for the edges of the stopbands.
- `6dB point` — The 6-dB point is the frequency for the point 6 dB point below the passband value.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

Available options are `Linear`, `Minimum`, and `Maximum`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent *n* in the relation $(1/f)^n$ to define the stopband decay. `filterBuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Sinc frequency factor

A frequency dilation factor. The sinc frequency factor, C , parameterizes the passband magnitude response for a lowpass design through $H(\omega) = \text{sinc}(C\omega)$^$(-P)$ and for a highpass design through $H(\omega) = \text{sinc}(C(1-\omega))$^$(-P)$.

Sinc power

Negative power of passband magnitude response. The sinc power, P, parameterizes the passband magnitude response for a lowpass design through $H(\omega) = \text{sinc}(C\omega)$^$(-P)$ and for a highpass design through $H(\omega) = \text{sinc}(C(1-\omega))$^$(-P)$.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

If your **Impulse response** is `IIR`, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

Filter type

This option is only available if you have the DSP System Toolbox. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

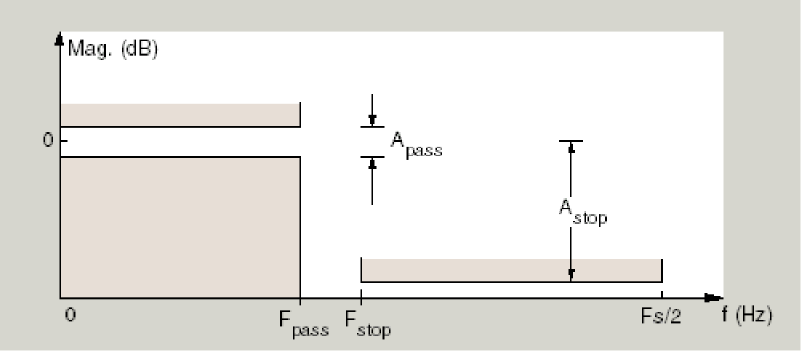
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.



In the figure, regions between specification values such as F_{pass} and F_{stop} represent transition regions where the filter response is not explicitly defined.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edge` — Define the filter by specifying the frequencies for the edge of the stopband and passband.
- `Passband edge` — Define the filter by specifying the frequency for the edge of the passband.
- `Stopband edge` — Define the filter by specifying the frequency for the edges of the stopband.

- `Passband edge and 3dB point` — Define the filter by specifying the passband edge frequency and the 3-dB down point (IIR designs).
- `3dB point and stopband edge` — Define the filter by specifying the 3-dB down point and stopband edge frequency (IIR designs).
- `3dB point` — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- `6dB point` — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Fpass

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Fstop

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.

- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Apass

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is `equiripple`. Select one of `Linear`, `Minimum`, or `Maximum`.

Minimum order — This option only applies when you have the DSP System Toolbox software and the **Order mode** is `Minimum`.

Select `Any` (default), `Even`, or `Odd`. Selecting `Even` or `Odd` forces the minimum-order design to be an even or odd order.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select `Passband` or `Stopband`.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.

- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterBuilder` applies the $(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Wpass

Passband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Wstop

Stopband weight. This option only applies when **Impulse response** is `FIR` and **Order mode** is `Specify`.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

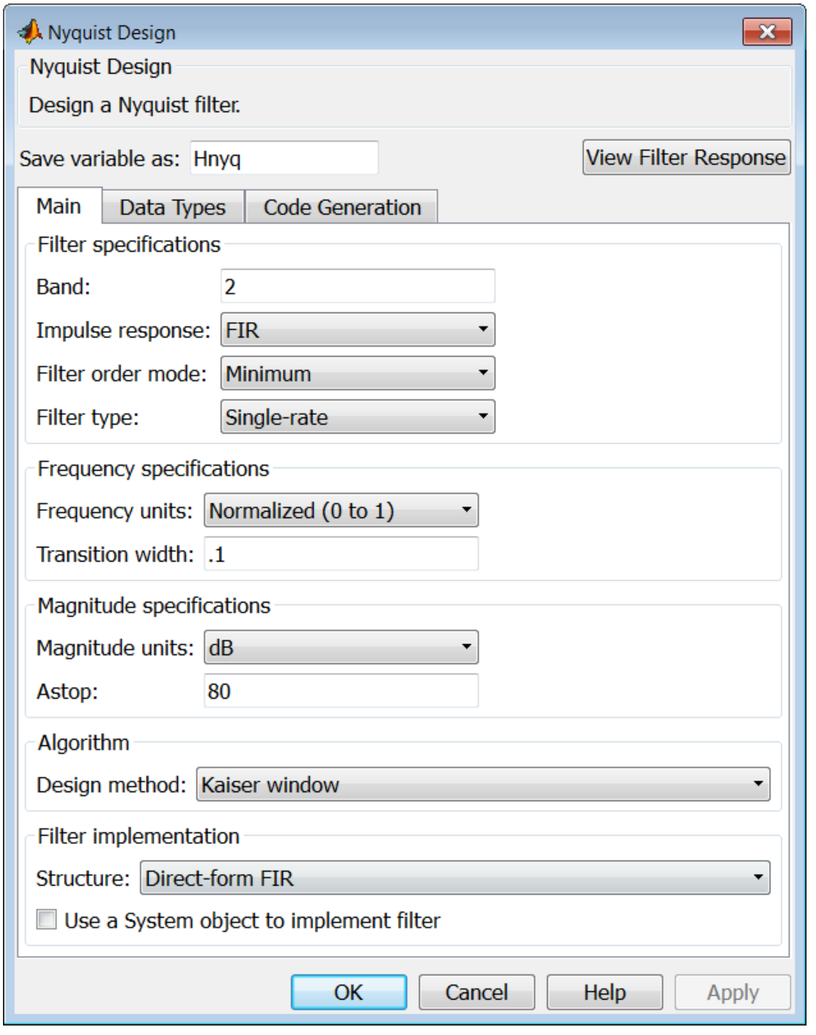
This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Notch

See “Peak/Notch Filter Design — Main Pane” on page 5-793.

Nyquist Filter Design — Main Pane



Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, bw, is calculated using the value for Band:

bw = Fs/(2 × Band).

Impulse response

Select `FIR` or `IIR` from the drop-down list, where `FIR` is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

Note: The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

Decimation Factor

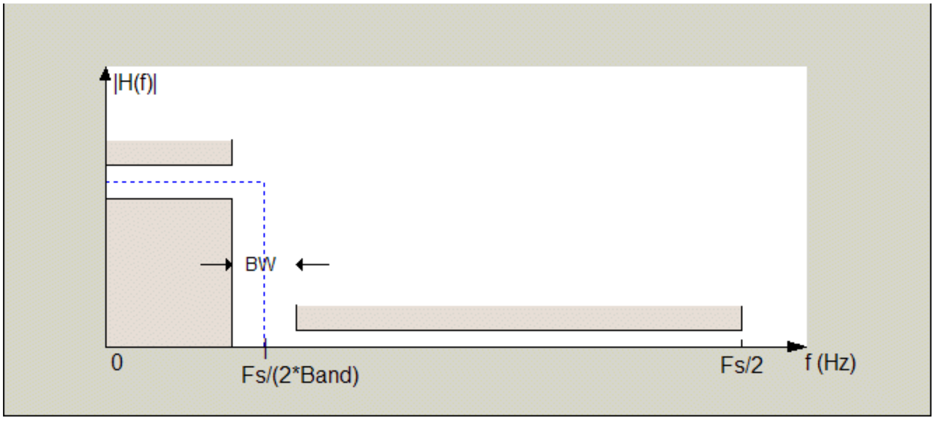
Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default factor value is 2.

Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default factor value is 2.

Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.



In the figure, BW is the width of the transition region and **Band** determines the location of the center of the region.

Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- `Passband and stopband edges` — Define the filter by specifying the frequencies for the edges for the stopbands and passbands.
- `Passband edges` — Define the filter by specifying frequencies for the edges of the passband.
- `Stopband edges` — Define the filter by specifying frequencies for the edges of the stopbands.
- `3 dB points` — Define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point 3 dB point below the passband value.

- `3 dB points and passband width` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- `3 dB points and stopband widths` — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.

Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `kHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input Fs** parameter.

Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

Transition width

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default)
- `Squared` — Specify the magnitude in squared units.

Astop

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

Minimum order

When you select this parameter, the design method determines and designs the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

Note: Generally, **Minimum order** designs are not available for IIR filters.

Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or `both` from the drop-down list.

Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- `Flat` — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- `Linear` — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- `1/f` — Specifies that the stopband attenuation changes exponentially as the frequency increases, where `f` is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to `Flat`, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to `Linear`, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to `1/f`, enter a value for the exponent n in the relation $(1/f)^n$ to define the stopband decay. `filterBuilder` applies the

$(1/f)^n$ relation to the stopband to result in an exponentially decreasing stopband attenuation.

Filter implementation

Structure

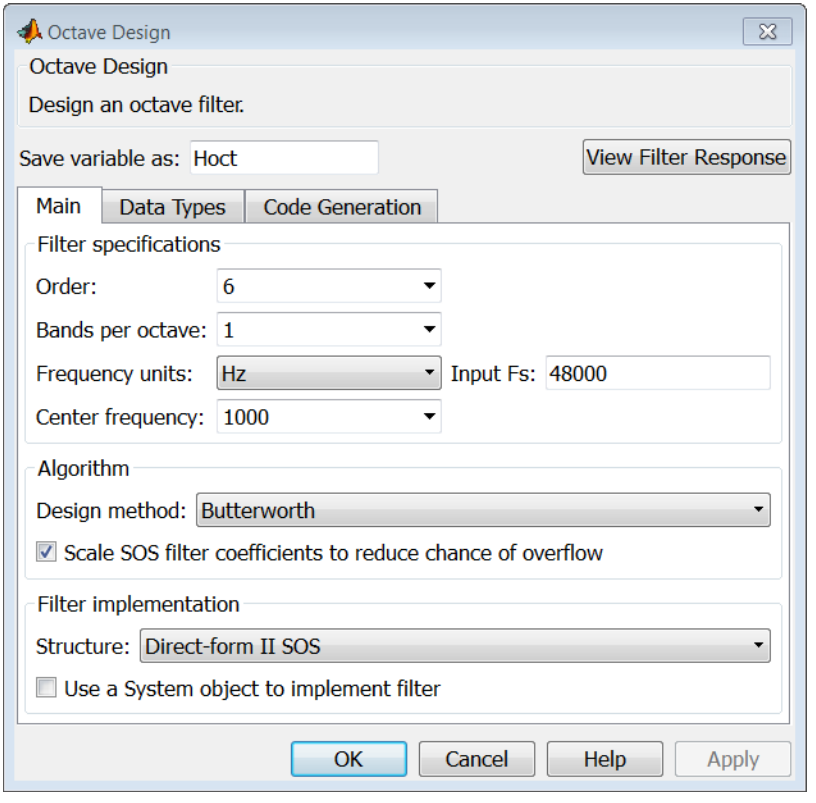
For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Octave Filter Design — Main Pane



Filter specifications

Order

Specify filter order. Possible values are: `4, 6, 8, 10`.

Bands per octave

Specify the number of bands per octave. Possible values are: `1, 3, 6, 12, 24`.

Frequency units

Specify frequency units as `Hz` or `kHz`.

Input Fs

Specify the input sampling frequency in the frequency units specified previously.

Center Frequency

Select from the drop-down list of available center frequency values.

Algorithm

Design Method

Butterworth is the design method used for this type of filter.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter implementation

Structure

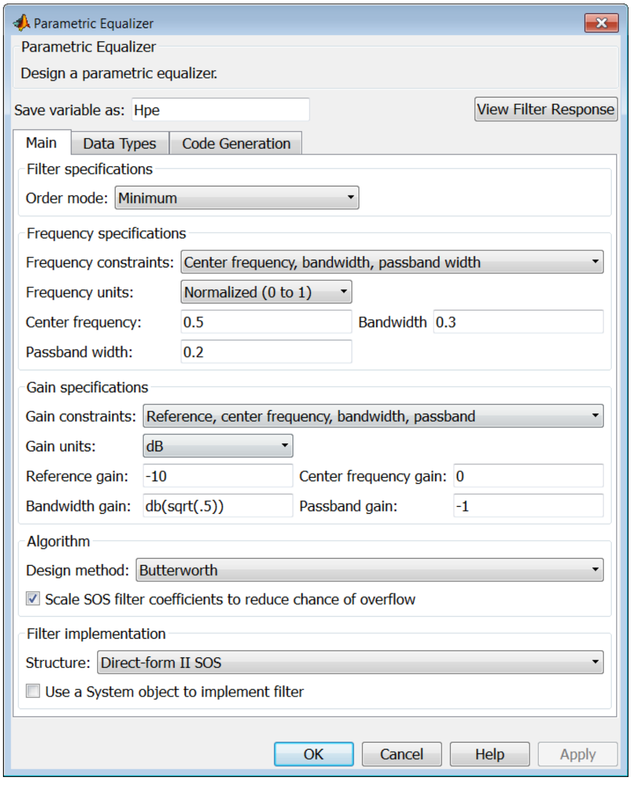
Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

Parametric Equalizer Filter Design — Main Pane



Filter specifications

Order mode

Select `Minimum` to design a minimum order filter that meets the design specifications, or `Specify` to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a `Minimum` order filter, the available frequency constraints are:

- `Center frequency, bandwidth, passband width`
- `Center frequency, bandwidth, stopband width`

If you select `Specify`, the available frequency constraints are:

- `Center frequency, bandwidth`
- `Center frequency, quality factor`
- `Shelf type, cutoff frequency, quality factor`
- `Shelf type, cutoff frequency, shelf slope parameter`
- `Low frequency, high frequency`

Order

This parameter is enabled only if the **Order mode** is set to `Specify`. Enter the filter order in this text box.

Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- `Center frequency, bandwidth, passband width` (available for minimum order only)
- `Center frequency, bandwidth, stopband width` (available for minimum order only)
- `Center frequency, bandwidth` (available for a specified order only)
- `Center frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, quality factor` (available for a specified order only)
- `Shelf type, cutoff frequency, shelf slope parameter` (available for a specified order only)
- `Low frequency, high frequency` (available for a specified order only)

Frequency units

Select the frequency units from the available drop down list (`Normalized, Hz, kHz, MHz, GHz`). If `Normalized` is selected, then the **Input Fs** box is disabled for input.

Input Fs

Enter the input sampling frequency. This input box is disabled for input if `Normalized` is selected in the **Frequency units** input box.

Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to `db(sqrt(.5))`, or –3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: `Center frequency, bandwidth, passband width`, `Center frequency, bandwidth, stopband width`, or `Center frequency, bandwidth`.

Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, passband width`.

Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is `Center frequency, bandwidth, stopband width`.

Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is `Low frequency, high frequency`. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

Gain specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- `Reference, center frequency, bandwidth, passband`
- `Reference, center frequency, bandwidth, stopband`
- `Reference, center frequency, bandwidth, passband, stopband`
- `Reference, center frequency, bandwidth`

Gain units

Specify the gain units either `dB` or `squared`. These units are used for all gain specifications in the dialog box.

Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a `bandwidth` parameter, or is `Low frequency, high frequency`.

Center frequency gain

Specify the center frequency in **Gain units**

Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are `Center frequency, bandwidth, stopband width`.

Boost/cut gain

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the `Shelf type` parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

Algorithm

Design method

Select the design method from the drop-down list. Different IIR design methods are available depending on the filter constraints you specify.

Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

Filter implementation

Structure

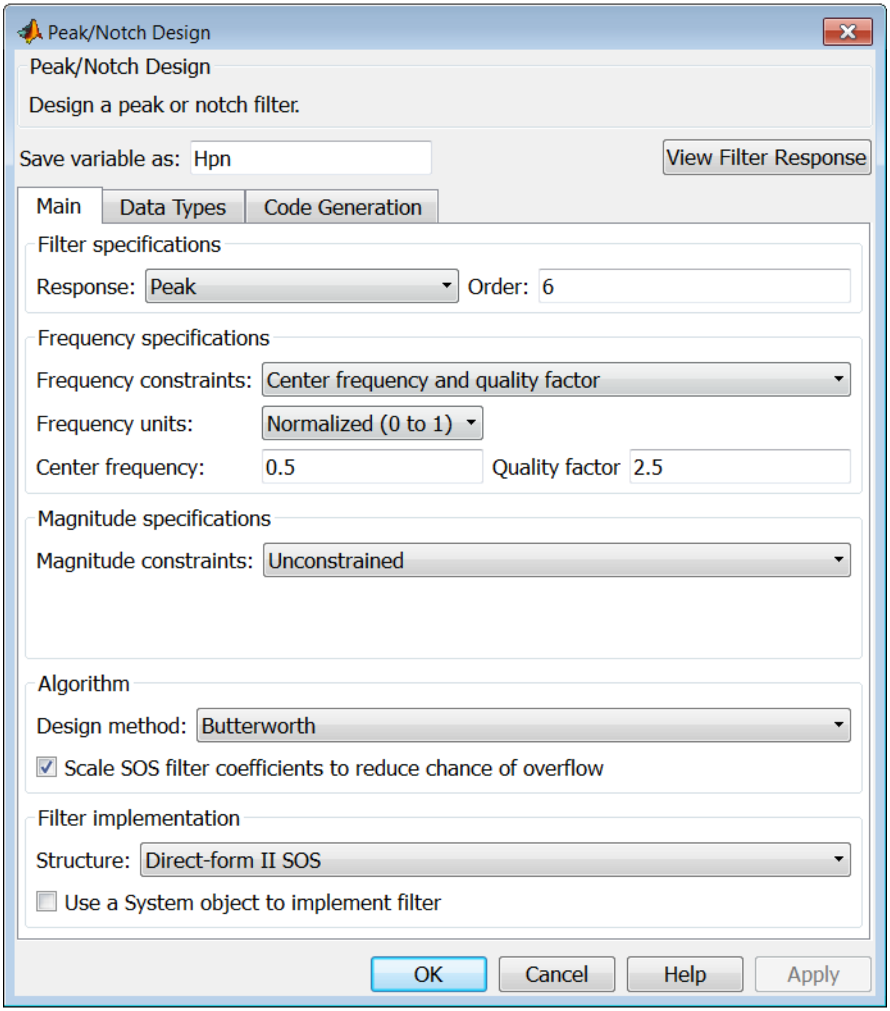
Select filter structure. The possible choices are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

Peak/Notch Filter Design — Main Pane



Filter specifications

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

Response

Select `Peak` or `Notch` from the drop-down box.

Order

Enter the filter order. The order must be even.

Frequency specifications

This group of parameters allows you to specify frequency constraints and units.

Frequency Constraints

Select the frequency constraints for filter specification. There are two choices as follows:

- `Center frequency and quality factor`
- `Center frequency and bandwidth`

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1), Hz, kHz, MHz, GHz`.

Input Fs

This input box is enabled if **Frequency units** other than `Normalized (0 to 1)` are specified. Enter the input sampling frequency.

Center frequency

Enter the center frequency in the units you specified in **Frequency units**.

Quality Factor

This input box is enabled only when `Center frequency and quality factor` is chosen for the **Frequency Constraints**. Enter the quality factor.

Bandwidth

This input box is enabled only when `Center frequency and bandwidth` is chosen for the **Frequency Constraints**. Enter the bandwidth.

Magnitude specifications

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- `Unconstrained`
- `Passband ripple`
- `Stopband attenuation`
- `Passband ripple and stopband attenuation`

Magnitude units

Select the magnitude units: either `dB` or `squared`.

Apass

This input box is enabled if the magnitude constraints selected are `Passband ripple` or `Passband ripple and stopband attenuation`. Enter the passband ripple.

Astop

This input box is enabled if the magnitude constraints selected are `Stopband attenuation` or `Passband ripple and stopband attenuation`. Enter the stopband attenuation.

Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

Filter implementation

Structure

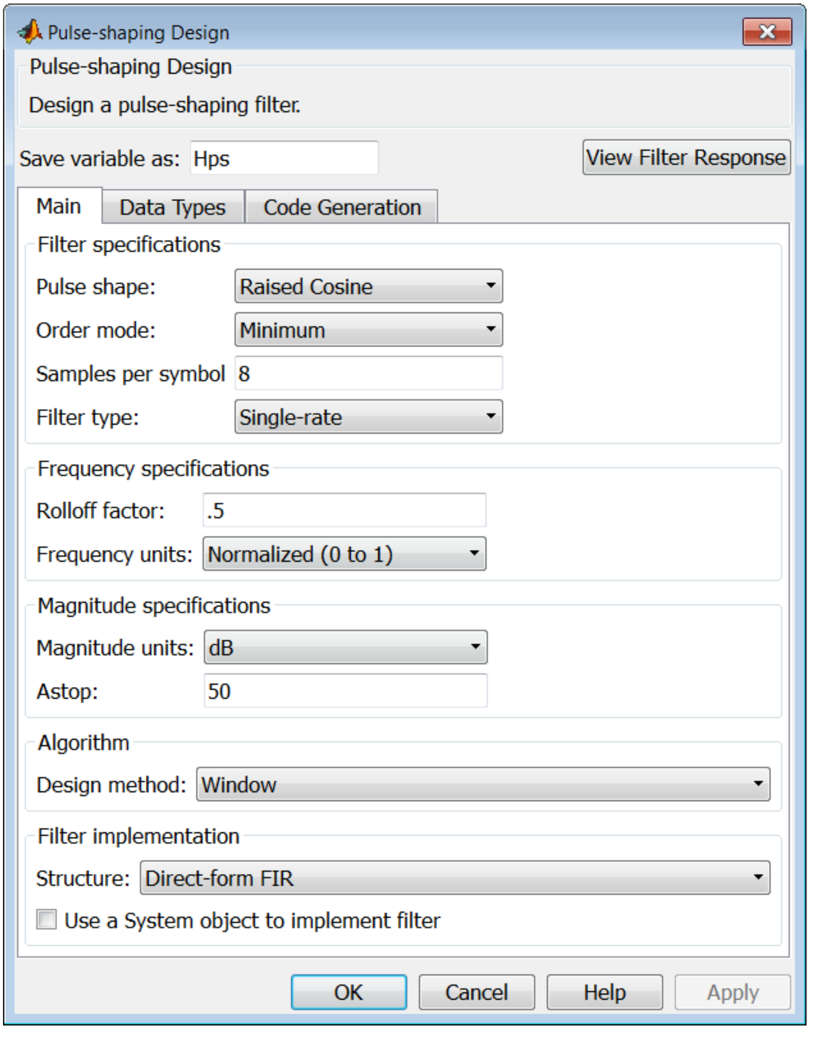
Lists all available filter structures for the filter specifications and design method you select. The typical options are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

Pulse-shaping Filter Design —Main Pane



Filter specifications

Parameters in this group enable you to specify the shape and length of the filter.

Pulse shape

Select the shape of the impulse response from the following options:

- `Raised Cosine`
- `Square Root Raised Cosine`
- `Gaussian`

Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- `Minimum`— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- `Specify order`—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be `Order+1` .
- `Specify symbols`—This option enables the user to specify the length of the impulse response in an alternative manner. If `Specify symbols` is chosen, the **Order** input box changes to the **Number of symbols** input box.

Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be **Number of symbols*Samples per symbol**+1. The product **Number of symbols*Samples per symbol** must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product **Number of symbols*Samples per symbol** must be an even number. The filter length will be **Number of symbols*Samples per symbol**+1.

Filter Type

This option is only available if you have the DSP System Toolbox software. Choose `Single rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. If you select `Decimator` or `Interpolator`, the decimation and interpolation factors default to the value of the **Samples per symbol**. If you select `Sample-rate converter`, the interpolation factor defaults to **Samples per symbol** and the decimation factor defaults to 3.

Frequency specifications

Parameters in this group enable you to specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1)`, `Hz`, `kHz`, `MHz`, `GHz`

For a Gaussian pulse shape, the available frequency specifications are:

Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: `Normalized (0 to 1)`, `Hz`, `kHz`, `MHz`, `GHz`

Magnitude specifications

If the **Order mode** is specified as `Minimum`, the **Magnitude units** may be selected from:

- `dB`— Specify the magnitude in decibels (default).
- `Linear`— Specify the magnitude in linear units.

Algorithm

The only **Design method** available for FIR pulse-shaping filters is the `Window` method.

Filter implementation

Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

Introduced in R2009a

filtstates.cic

Store CIC filter states

Description

`filtstates.cic` objects hold the states information for CIC filters. Once you create a CIC filter, the states for the filter are stored in `filtstates.cic` objects, and you can access them and change them as you would any property of the filter. This arrangement parallels that of the `filtstates` object that IIR direct-form I filters use (refer to `filtstates` for more information).

Each `States` property in the CIC filter comprises two properties — `Numerator` and `Comb` — that hold `filtstates.cic` objects. Within the `filtstates.cic` objects are the numerator-related and comb-related filter states. The states are column vectors, where each column represents the states for one section of the filter. For example, a CIC filter with four decimator sections and four interpolator sections has `filtstates.cic` objects that contain four columns of states each.

Examples

Integrator and Comb States of a CIC Filter

Construct an object with integrator and comb states as vectors of zeros.

```
h = filtstates.cic(zeros(4,1),zeros(4,1));
```

h has zero states now. You can use int to see the states as 32-bit integers.

```
intStates = int(h.Integrator)
combStates = int(h.Comb)
```

```
intStates =

  4×1 int32 column vector

   0
   0
```

```
   0
   0

combStates =

  4×1 int32 column vector

   0
   0
   0
   0
```

Introduced in R2011a

fircband

Constrained-band equiripple FIR filter

Syntax

```
b = fircband(n,f,a,w,c)
b = fircband(n,f,a,s)
b = fircband(...,'1')
b = fircband(...,'minphase')
b = fircband(..., 'check')
b = fircband(...,{lgrid})
[b,err] = fircband(...)
[b,err,res] = fircband(...)
```

Description

`fircband` is a minimax filter design algorithm that you use to design the following types of real FIR filters:

- Types 1-4 linear phase
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd), extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

`b = fircband(n,f,a,w,c)` designs filters having constrained error magnitudes (ripples). `c` is a cell array of character vectors of the same length as `w`. The entries of `c` must be either `'c'` to indicate that the corresponding element in `w` is a constraint (the ripple for that band cannot exceed that value) or `'w'` indicating that the corresponding entry in `w` is a weight. There must be at least one unconstrained band — `c` must contain at least one **`w`** entry. For instance, the example 'Design a Constrained Lowpass Filter' uses a weight of one in the passband, and constrains the stopband ripple not to exceed 0.2 (about 14 dB).

A hint about using constrained values: if your constrained filter does not touch the constraints, increase the error weighting you apply to the unconstrained bands.

Notice that, when you work with constrained stopbands, you enter the stopband constraint according to the standard conversion formula for power — the resulting filter attenuation or constraint equals 20*log(*constraint*) where *constraint* is the value you enter in the function. For example, to set 20 dB of attenuation, use a value for the constraint equal to 0.1. This applies to constrained stopbands only.

`b = fircband(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of character vectors and must be the same length as `f` and `a`. Entries of `s` must be one of:

- `'n'` — normal frequency point.
- `'s'` — single-point band. The frequency band is given by a single point. You must specify the corresponding gain at this frequency point in `a`.
- `'f'` — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- `'i'` — indeterminate frequency point. Use this argument when bands abut one another (no transition region).

`b = fircband(...,'1')` designs a type 1 filter (even-order symmetric). You could also specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), or type 4 (odd-order antisymmetric) filters. Note there are restrictions on `a` at `f` = 0 or `f` = 1 for types 2, 3, and 4.

`b = fircband(...,'minphase')` designs a minimum-phase FIR filter. There is also `'maxphase'`.

`b = fircband(..., 'check')` produces a warning when there are potential transition-region anomalies in the filter response.

`b = fircband(...,{lgrid})`, where {`lgrid`} is a scalar cell array containing an integer, controls the density of the frequency grid.

`[b,err] = fircband(...)` returns the unweighted approximation error magnitudes. `err` has one element for each independent approximation error.

`[b,err,res] = fircband(...)` returns a structure `res` of optional results computed by `fircband`, and contains the following fields:

Structure Field	Contents
`res.fgrid`	Vector containing the frequency grid used in the filter design optimization
`res.des`	Desired response on `fgrid`
`res.wt`	Weights on `fgrid`
`res.h`	Actual frequency response on the frequency grid
`res.error`	Error at each point (desired response - actual response) on the frequency grid
`res.iextr`	Vector of indices into `fgrid` of external frequencies
`res.fextr`	Vector of extremely frequencies
`res.order`	Filter order
`res.edgecheck`	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK , 0 = probable transition-region anomaly , -1 = edge not checked. Computed when you specify the `'check'` input option in the function syntax.
`res.iterations`	Number of Remez iterations for the optimization
`res.evals`	Number of function evaluations for the optimization

Examples

Design a Constrained Lowpass Filter

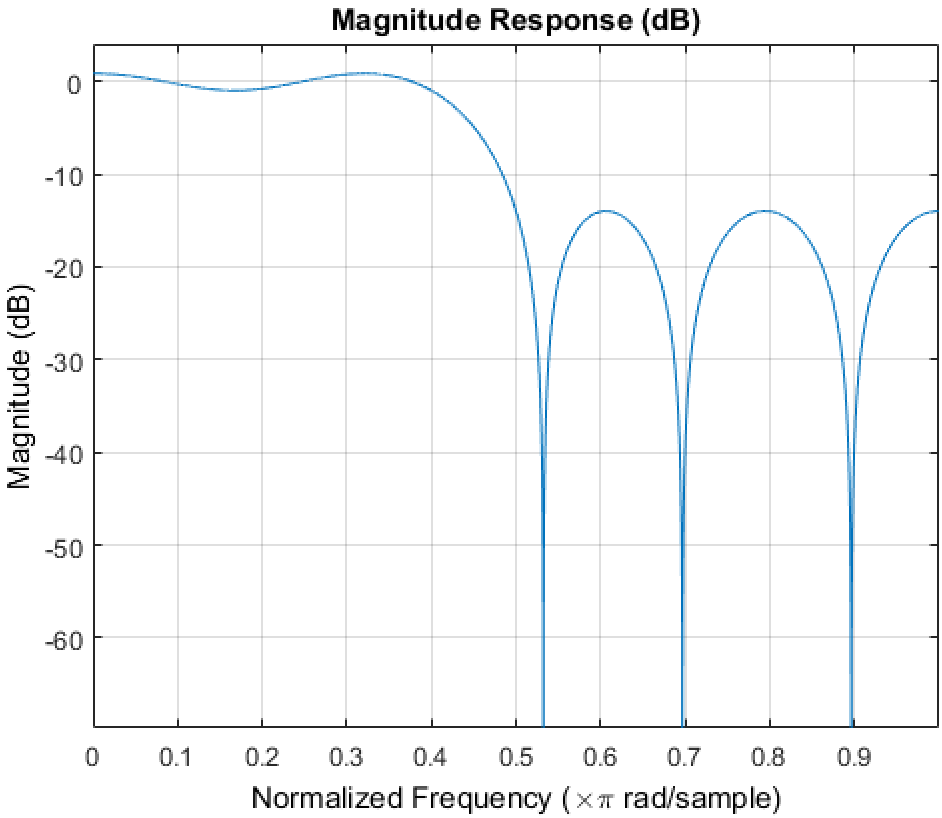
Design a 12th-order lowpass filter with a constraint on the filter response.

```
b = fircband(12,[0 0.4 0.5 1], [1 1 0 0], ...
```

```
[1 0.2], {'w' 'c'});
```

Using fvtool to display the result b shows you the response of the filter you designed.

```
fvtool(b)
```



Design two filters of different order with the stopband constrained to 60 dB. Use excess order (80) in the second filter to improve the passband ripple.

```
b1 = fircband(60,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
b2 = fircband(80,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
hfvt = fvtool(b1,1,b2,1);
```

```
legend(hfvt,'Filter Order 60','Filter Order 80');
```

Introduced in R2011a

fireqint

Equiripple FIR interpolators

Syntax

```
b = fireqint(n,l,alpha)
b = fireqint(n,l,alpha,w)
b = fireqint('minorder',l,alpha,r)
b = fireqint({'minorder',initord},l,alpha,r)
```

Description

`b = fireqint(n,l,alpha)` designs an FIR equiripple filter useful for interpolating input signals. `n` is the filter order and it must be an integer. `l`, also an integer, is the interpolation factor. `alpha` is the bandlimitedness factor, identical to the same feature in `intfilt`.

`alpha` is inversely proportional to the transition bandwidth of the filter. It also affects the bandwidth of the don't-care regions in the stopband. Specifying `alpha` allows you to control how much of the Nyquist interval your input signal occupies. This can be beneficial for signals to be interpolated because it allows you to increase the transition bandwidth without affecting the interpolation, resulting in better stopband attenuation for a given `l`. If you set `alpha` to 1, `fireqint` assumes that your signal occupies the entire Nyquist interval. Setting `alpha` to a value less than one allows for don't-care regions in the stopband. For example, if your input occupies half the Nyquist interval, you could set `alpha` to 0.5.

The signal to be interpolated is assumed to have zero (or negligible) power in the frequency band between (`alpha*π`) and π. `alpha` must therefore be a positive scalar between 0 and 1. `fireqint` treat such bands as don't-care regions for assessing filter design.

`b = fireqint(n,l,alpha,w)` allows you to specify a vector of weights in `w`. The number of weights required in `w` is given by 1 + `floor`(l/2). The weights in `w` are applied to the passband ripple and stopband attenuations. Using weights (values between 0 and 1) enables you to specify different attenuations in different parts of the stopband, as well as providing the ability to adjust the compromise between passband ripple and stopband attenuation.

`b = fireqint('minorder',l,alpha,r)` allows you to design a minimum-order filter that meets the design specifications. `r` is a vector of maximum deviations or ripples from the ideal filter magnitude response. When you use the input argument **`minorder`**, you must provide the vector `r`. The number of elements required in `r` is given by 1 + `floor`(`l`/2).

`b = fireqint({'minorder',initord},l,alpha,r)` adds the argument `initord` so you can provide an initial estimate of the filter order. Any positive integer is valid here. Again, you must provide `r`, the vector of maximum deviations or ripples, from the ideal filter magnitude response.

Examples

Design an FIR Equiripple Filter

Design a minimum order interpolation filter with `l` set to 6, and `alpha` set to 0.8. A vector of ripples must be supplied with the input argument `minorder`.

```
b = fireqint('minorder',6,.8,[0.01 .1 .05 .02]);
```

Create a polyphase interpolation filter.

```
hm = dsp.FIRInterpolator(6,'Numerator',b)
```

```
hm = 

  dsp.FIRInterpolator with properties:

        NumeratorSource: 'Property'
              Numerator: [1×70 double]
    InterpolationFactor: 6

  Use get to show all properties
```

Here is the zerophase response of the interpolator.

```
zerophase(hm);
```

Introduced in R2011a

firceqrip

Constrained equiripple FIR filter

Syntax

```
B = firceqrip(n,Fo,DEV)
B = firceqrip(...,'slope',r)
B = firceqrip(...,'passedge')
B = firceqrip(...,'stopedge')
B = firceqrip(...,'high')
B = firceqrip(...,'min')
B = firceqrip(...,'invsinc',C)
B = firceqrip(...,'invdiric',C)
```

Description

`B = firceqrip(n,Fo,DEV)` designs an order `n` filter (filter length equal `n` + 1) lowpass FIR filter with linear phase.

`firceqrip` produces the same equiripple lowpass filters that `firpm` produces using the Parks-McClellan algorithm. The difference is how you specify the filter characteristics for the function.

The input argument `Fo` specifies the frequency at the upper edge of the passband in normalized frequency (0<`Fo`<1). The two-element vector `dev` specifies the peak or maximum error allowed in the passband and stopbands. Enter `[d1 d2]` for `dev` where `d1` sets the passband error and `d2` sets the stopband error.

`B = firceqrip(...,'slope',r)` uses the input keyword '`slope`' and input argument `r` to design a filter with a nonequiripple stopband. `r` is specified as a positive constant and determines the slope of the stopband attenuation in dB/normalized frequency. Greater values of `r` result in increased stopband attenuation in dB/normalized frequency.

`B = firceqrip(...,'passedge')` designs a filter where `Fo` specifies the frequency at which the passband starts to rolloff.

`B = firceqrip(...,'stopedge')` designs a filter where `Fo` specifies the frequency at which the stopband begins.

`B = firceqrip(...,'high')` designs a high pass FIR filter instead of a lowpass filter.

`B = firceqrip(...,'min')` designs a minimum-phase filter.

`B = firceqrip(...,'invsinc',C)` designs a lowpass filter whose magnitude response has the shape of an inverse sinc function. This may be used to compensate for sinc-like responses in the frequency domain such as the effect of the zero-order hold in a D/A converter. The amount of compensation in the passband is controlled by `C`, which is specified as a scalar or two-element vector. The elements of `C` are specified as follows:

- If `C` is supplied as a real-valued scalar or the first element of a two-element vector, `firceqrip` constructs a filter with a magnitude response of 1/sinc(`C*`**`pi`**`*F`) where `F` is the normalized frequency.
- If `C` is supplied as a two-element vector, the inverse-sinc shaped magnitude response is raised to the positive power `C(2)`. If we set `P=C(2)`, `firceqrip` constructs a filter with a magnitude response 1/sinc(`C*`**`pi`**`*F`)^{P}.

If this FIR filter is used with a cascaded integrator-comb (CIC) filter, setting `C(2)` equal to the number of stages compensates for the multiplicative effect of the successive sinc-like responses of the CIC filters.

Note: Since the value of the inverse sinc function becomes unbounded at `C=1/F`, the value of `C` should be greater the reciprocal of the passband edge frequency. This can be expressed as `Fo<1/C`. For users familiar with CIC decimators, `C` is equal to 1/2 the product of the differential delay and decimation factor.

`B = firceqrip(...,'invdiric',C)` designs a lowpass filter with a passband that has the shape of an inverse Dirichlet sinc function. The frequency response of the inverse Dirichlet sinc function is given by

$$\{rC(\frac{\sin(f/2r)}{\sin(Cf/2)}\}^{p}$$

where C, r, and p are scalars. The input `C` can be a scalar or vector containing 2 or 3 elements. If `C` is a scalar, `p` and `r` equal 1. If `C` is a two-element vector, the first element is `C` and the second element is `p`, `[C p]`. If `C` is a three-element vector, the third element is `r`, `[C p r]`.

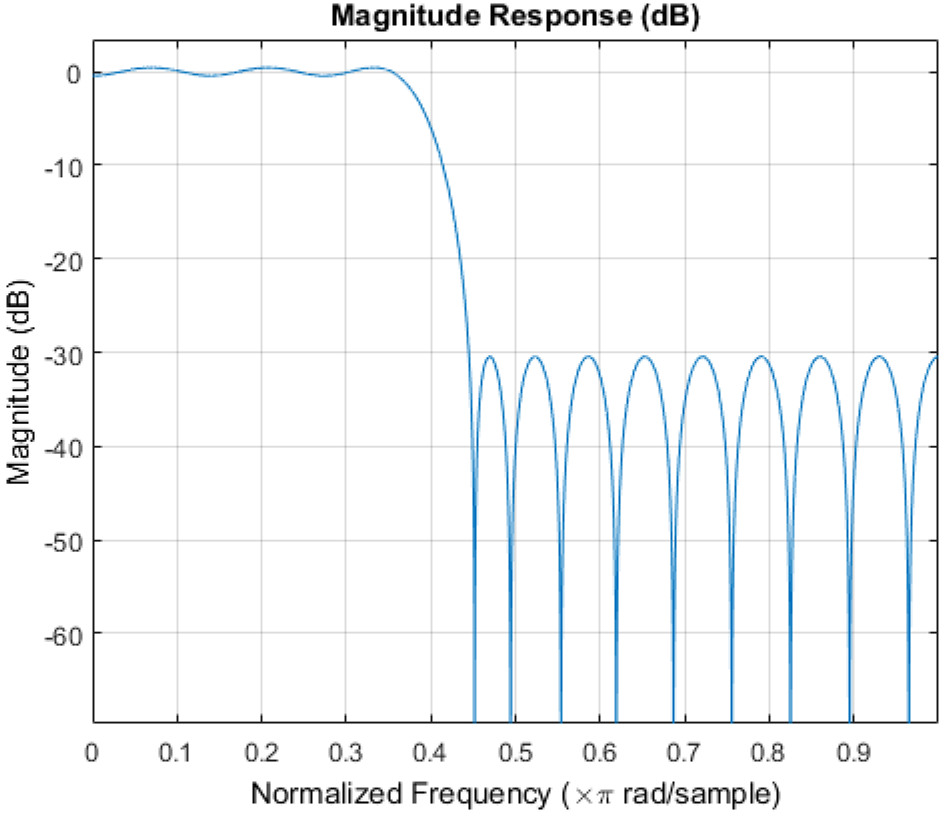
Examples

To introduce a few of the variations on FIR filters that you design with `firceqrip`, these five examples cover both the default syntax `b = firceqrip(n,wo,del)` and some of the optional input arguments. For each example, the input arguments `n`, `wo`, and `del` remain the same.

Filter design using `firceqrip`

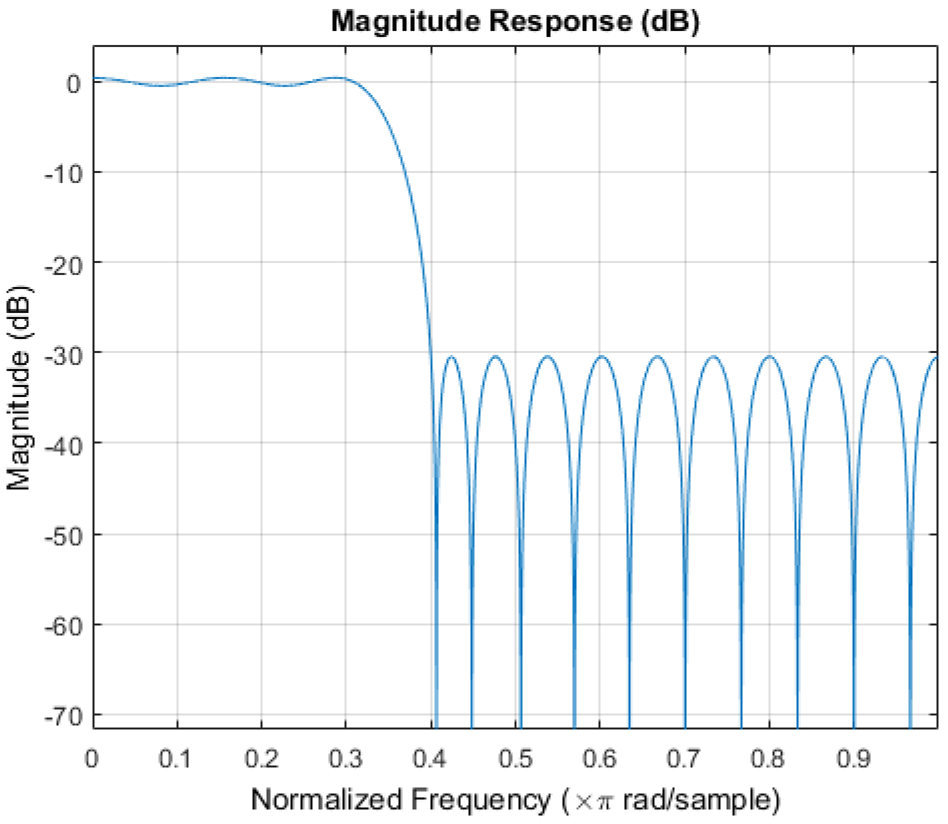
Design a 30th order FIR filter using `firceqrip`.

```
b = firceqrip(30,0.4,[0.05 0.03]); fvtool(b)
```



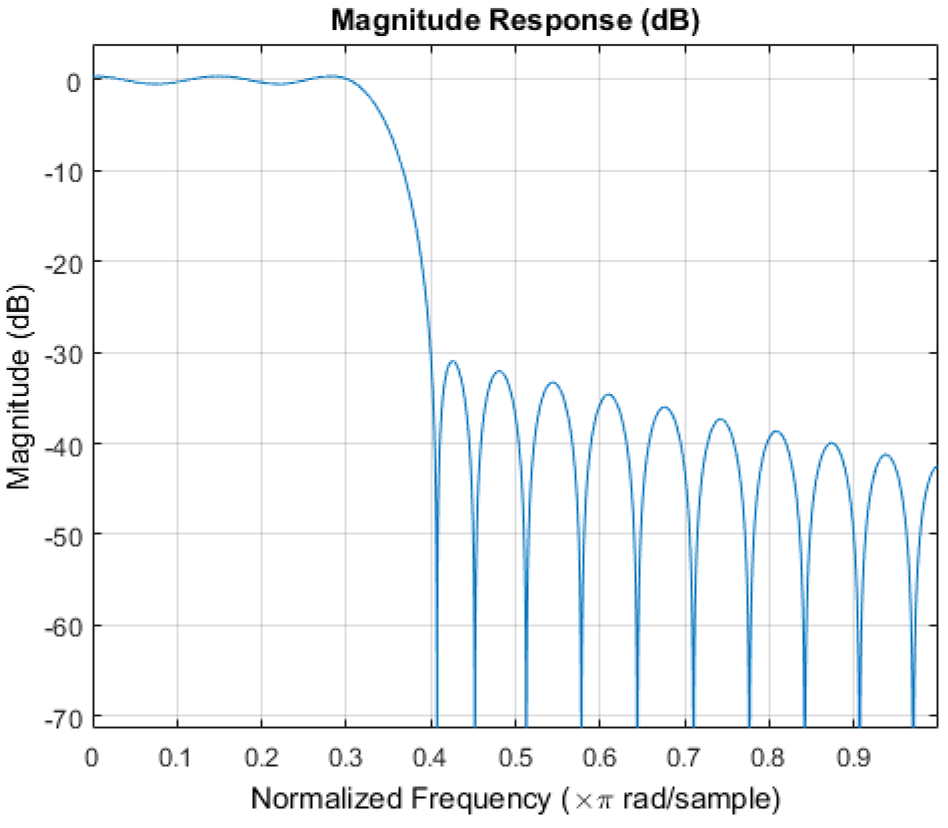
Design a 30th order FIR filter with the `stopedge` keyword to define the response at the edge of the filter stopband.

```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge'); fvtool(b)
```



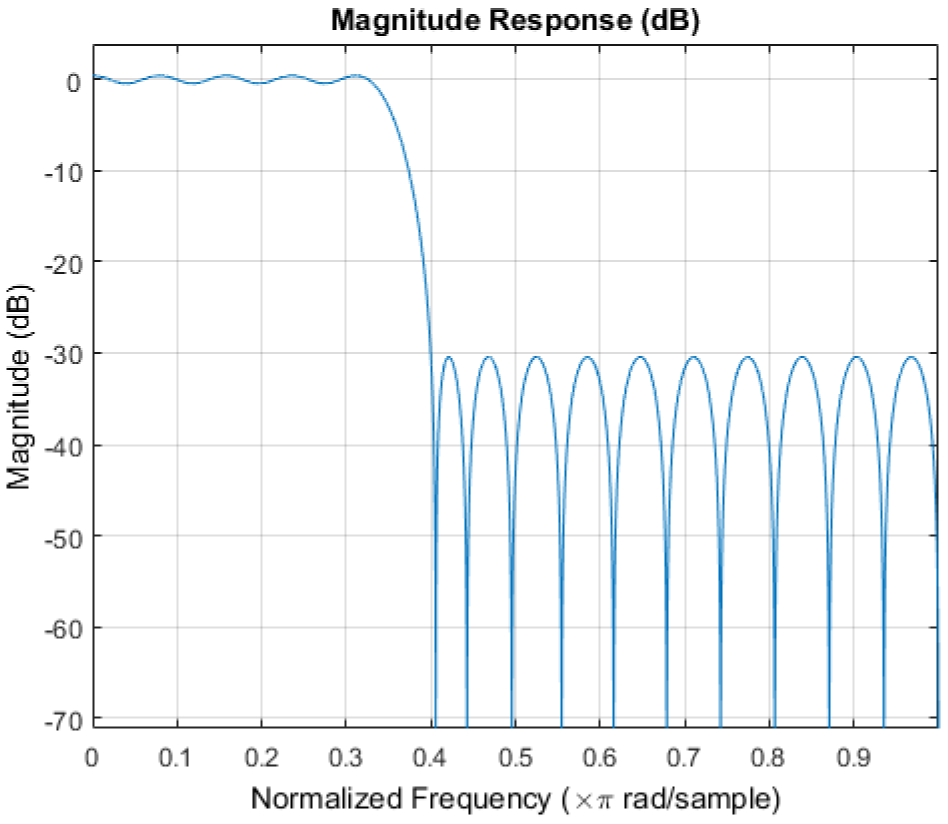
Design a 30th order FIR filter with the `slope` keyword and r = 20.

```
b = firceqrip(30,0.4,[0.05 0.03],'slope',20,'stopedge'); fvtool(b)
```



Design a 30th order FIR filter defining the stopband and specifying that the resulting filter is minimum phase with the `min` keyword.

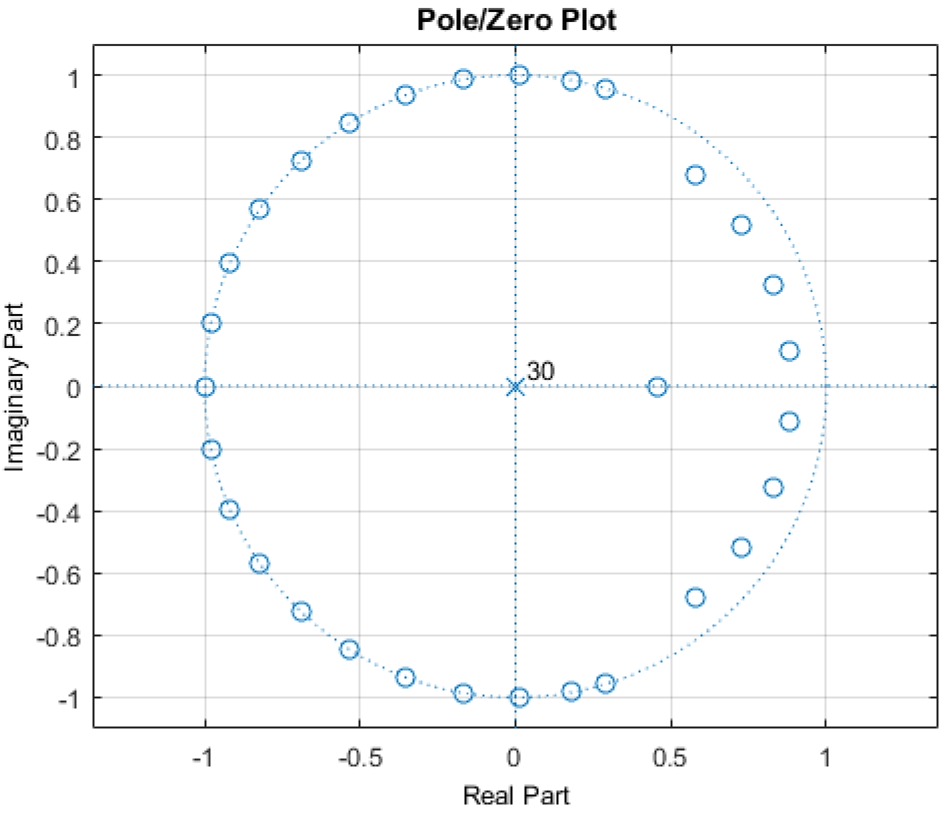
```
b = firceqrip(30,0.4,[0.05 0.03],'stopedge','min'); fvtool(b)
```



Comparing this filter to the filter in Figure 1. The cutoff frequency `wo = 0.4` now applies to the edge of the stopband rather than the point at which the frequency response magnitude is 0.5.

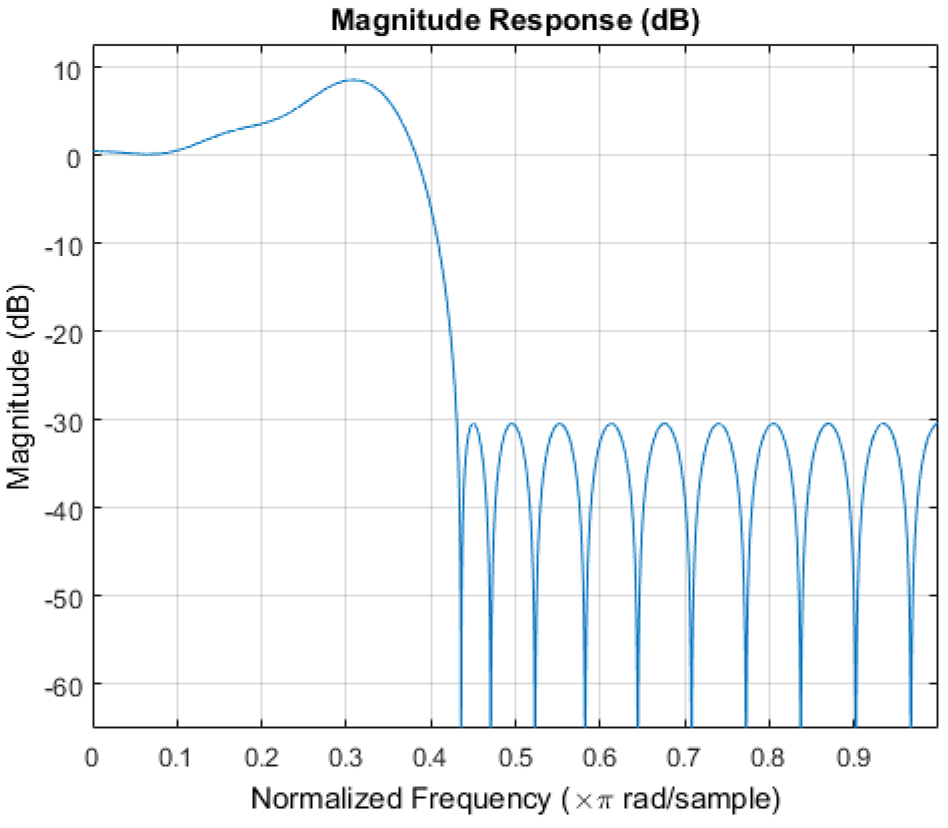
Viewing the zero-pole plot shown here reveals this is a minimum phase FIR filter - the zeros lie on or inside the unit circle, z = 1

```
fvtool(b,'polezero')
```



Design a 30th order FIR filter with the `invsinc` keyword to shape the filter passband with an inverse sinc function.

```
b = firceqrip(30,0.4,[0.05 0.03],'invsinc',[2 1.5]); fvtool(b)
```



The inverse sinc function being applied is defined as 1/sinc(2*w)^1.5.

Inverse-Dirichlet-Sinc-Shaped Passband

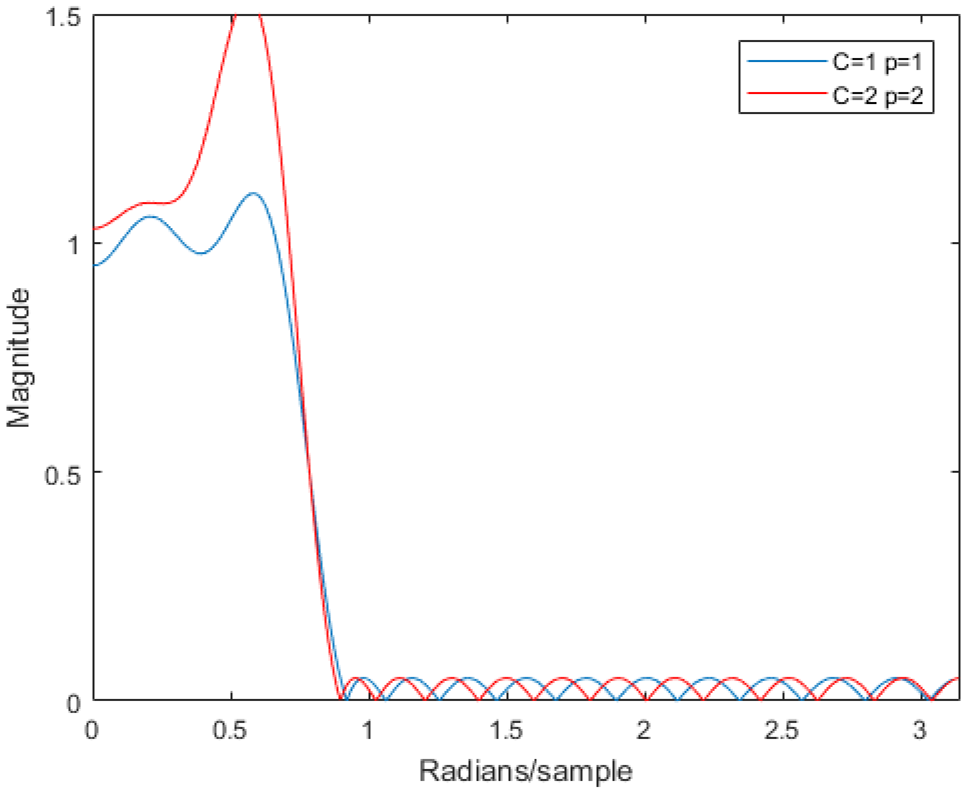
Design two order 30 constrained equiripple FIR filters with inverse-Dirichlet-sinc-shaped passbands. The cutoff frequency in both designs is pi/4 radians/sample. Set `C=1` in one design `C=2` in the second design. The maximum passband and stopband ripple is 0.05. Set `p=1` in one design and `p=2` in the second design.

Design the filters.

```
b1 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[1 1]);
b2 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[2 2]);
```

Obtain the filter frequency responses using `freqz`. Plot the magnitude responses.

```
[h1,~] = freqz(b1,1);
[h2,w] = freqz(b2,1);
plot(w,abs(h1)); hold on;
plot(w,abs(h2),'r');
axis([0 pi 0 1.5]);
xlabel('Radians/sample');
ylabel('Magnitude');
legend('C=1 p=1','C=2 p=2');
```



Inspect the stopband ripple in the design with `C=1` and `p=1`. The constrained design sets the maximum ripple to be 0.05. Zoom in on the stopband from the cutoff frequency of pi/4 radians/sample to 3pi/4 radians/sample.

```
figure;
plot(w,abs(h1));
set(gca,'xlim',[pi/4 3*pi/4]);
grid on;
```

fircls

FIR Constrained Least Squares filter

Syntax

```
clsFilter = design(d,'fircls','SystemObject',true)
clsFilter =
design(d,'fircls','FilterStructure',value,'SystemObject',true)
clsFilter =
design(d,'fircls','PassbandOffset',value,'SystemObject',true)
clsFilter = design(d,'fircls','zerophase',value,'SystemObject',true)
```

Description

`clsFilter = design(d,'fircls','SystemObject',true)` designs a FIR Constrained Least Squares (CLS) filter, `clsFilter`, from a filter specifications object, `d`.

`clsFilter = design(d,'fircls','FilterStructure',value,'SystemObject',true)` where `value` is one of the following filter structures:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)
- `'dffirt'`, a discrete-time, direct-form FIR transposed filter
- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter

`clsFilter = design(d,'fircls','PassbandOffset',value,'SystemObject',true)` where `value` sets the passband band gain in dB. The `PassbandOffset` and `Ap` values affect the upper and lower approximation bound in the passband as follows:

- Lower bound = (`PassbandOffset`-Ap/2)
- Upper bound = (`PassbandOffset`+A/2)

For bandstop filters, the `PassbandOffset` is a vector of length two that specifies the first and second passband gains. The `PassbandOffset` value defaults to 0 for lowpass, highpass and bandpass filters. The `PassbandOffset` value defaults to [0 0] for bandstop filters.

`clsFilter = design(d,'fircls','zerophase',value,'SystemObject',true)` where `value` is either `'true'` ('1') or `'false'` ('0') . If `zerophase` is true, the lower approximation bound in the stopband is forced to zero (i.e., the filter has a zero phase response). Zerophase is false (0) by default.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'fircls')
```

For complete help about using `fircls`, refer to the command line help system. For example, to get specific information about using `fircls` with `d`, the specification object, enter the following at the MATLAB prompt.

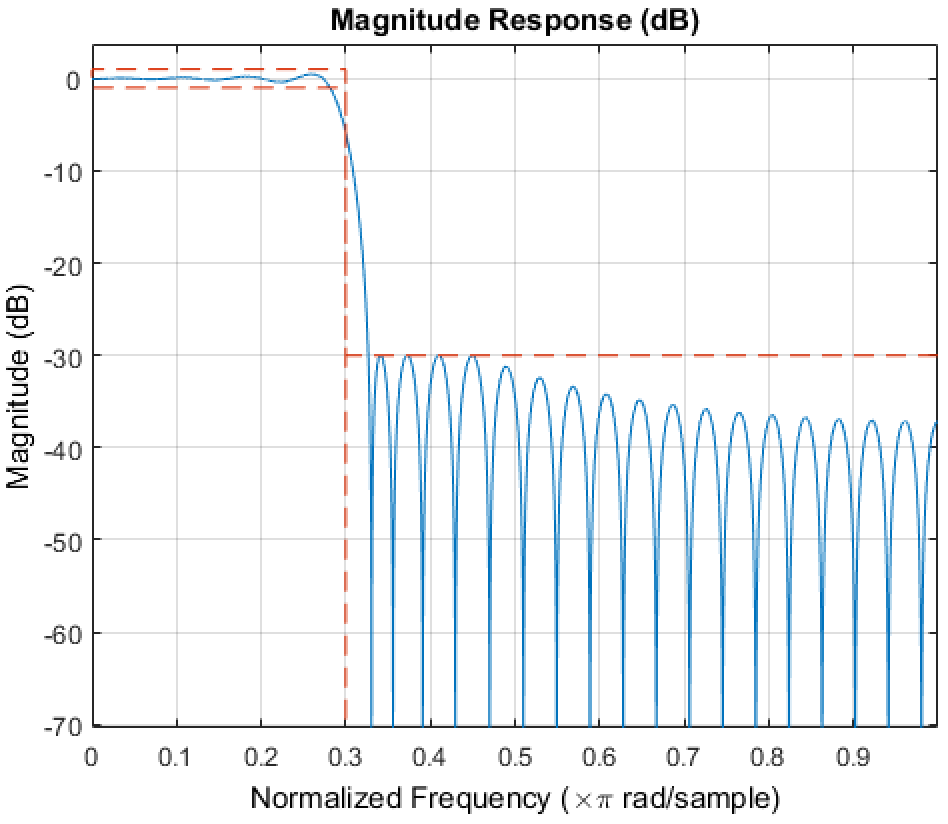
```
help(d,'fircls')
```

Examples

Create an FIR Constrained Least Squares (CLS) Filter

The following example designs a constrained least-squares FIR lowpass filter.

```
h  = fdesign.lowpass('n,fc,ap,ast', 50, 0.3, 2, 30);
firLPFilter = design(h, 'fircls','SystemObject',true);
fvtool(firLPFilter)
```



The following example constructs a constrained least-squares FIR bandpass filter.

```
d = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2',...
30,0.4,0.6,60,1,60);
firBPFilter = design(d,'fircls','SystemObject',true);
fvtool(firBPFilter)
```

firgr

Parks-McClellan FIR filter

Syntax

```
b = firgr(n,f,a,w)
b = firgr(n,f,a,'hilbert')
b = firgr(m,f,a,r),
b = firgr({m,ni},f,a,r)
b = firgr(n,f,a,w,e)
b = firgr(n,f,a,s)
b = firgr(n,f,a,s,w,e)
b = firgr(...,'1')
b = firgr(...,'minphase')
b = firgr(..., 'check')
b = firgr(...,{lgrid}),
[b,err] = firgr(...)
[b,err,res] = firgr(...)
b = firgr(n,f,fresp,w)
b = firgr(n,f,{fresp,p1,p2,...},w)
b = firgr(n,f,a,w)
```

Description

`firgr` is a minimax filter design algorithm you use to design the following types of real FIR filters:

- Types 1-4 linear phase:
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase

- Minimum order (even or odd)
- Extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

`b = firgr(n,f,a,w)` returns a length `n+1` linear phase FIR filter which has the best approximation to the desired frequency response described by `f` and `a` in the minimax sense. `w` is a vector of weights, one per band. When you omit `w`, all bands are weighted equally. For more information on the input arguments, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(n,f,a,'hilbert')` and `b = firgr(n,f,a,'differentiator')` design FIR Hilbert transformers and differentiators. For more information on designing these filters, refer to `firpm` in *Signal Processing Toolbox User's Guide*.

`b = firgr(m,f,a,r)`, where `m` is one of '`minorder`', '`mineven`' or '`minodd`', designs filters repeatedly until the minimum order filter, as specified in `m`, that meets the specifications is found. `r` is a vector containing the peak ripple per frequency band. You must specify `r`. When you specify '`mineven`' or '`minodd`', the minimum even or odd order filter is found.

`b = firgr({m,ni},f,a,r)` where `m` is one of '`minorder`', '`mineven`' or '`minodd`', uses `ni` as the initial estimate of the filter order. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

`b = firgr(n,f,a,w,e)` specifies independent approximation errors for different bands. Use this syntax to design extra ripple or maximal ripple filters. These filters have interesting properties such as having the minimum transition width. `e` is a cell array of character vectors specifying the approximation errors to use. Its length must equal the number of bands. Entries of `e` must be in the form '`e#`' where `#` indicates which approximation error to use for the corresponding band. For example, when `e = {'e1','e2','e1'}`, the first and third bands use the same approximation error `'e1'` and the second band uses a different one `'e2'`. Note that when all bands use the same approximation error, such as `{'e1','e1','e1',...}`, it is equivalent to omitting `e`, as in `b = firgr(n,f,a,w)`.

`b = firgr(n,f,a,s)` is used to design filters with special properties at certain frequency points. `s` is a cell array of character vectors and must be the same length as `f` and `a`. Entries of `s` must be one of:

- `'n'` — normal frequency point.
- `'s'` — single-point band. The frequency "band" is given by a single point. The corresponding gain at this frequency point must be specified in `a`.
- `'f'` — forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- `'i'` — indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

For example, the following command designs a bandstop filter with zero-valued single-point stop bands (notches) at 0.25 and 0.55.

```
b = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],...
[1 1 0 1 1 0 1 1],{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'})
```

`b = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...{'n' 'i' 'f' 'n' 'n' 'n'})` designs a highpass filter with the gain at 0.06 forced to be zero. The band edge at 0.055 is indeterminate since the first two bands actually touch. The other band edges are normal.

`b = firgr(n,f,a,s,w,e)` specifies weights and independent approximation errors for filters with special properties. The weights and properties are included in vectors `w` and `e`. Sometimes, you may need to use independent approximation errors to get designs with forced values to converge. For example,

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

`b = firgr(...,'1')` designs a type 1 filter (even-order symmetric). You can specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), and type 4 (odd-order antisymmetric) filters as well. Note that restrictions apply to `a` at f = 0 or f = 1 for FIR filter types 2, 3, and 4.

`b = firgr(...,'minphase')` designs a minimum-phase FIR filter. You can use the argument `'maxphase'` to design a maximum phase FIR filter.

`b = firgr(..., 'check')` returns a warning when there are potential transition-region anomalies.

`b = firgr(...,{lgrid})`, where `{lgrid}` is a scalar cell array. The value of the scalar controls the density of the frequency grid by setting the number of samples used along the frequency axis.

`[b,err] = firgr(...)` returns the unweighted approximation error magnitudes. `err` contains one element for each independent approximation error returned by the function.

`[b,err,res] = firgr(...)` returns the structure `res` comprising optional results computed by `firgr`. `res` contains the following fields.

Structure Field	Contents
`res.fgrid`	Vector containing the frequency grid used in the filter design optimization
`res.des`	Desired response on `fgrid`
`res.wt`	Weights on `fgrid`
`res.h`	Actual frequency response on the frequency grid
`res.error`	Error at each point (desired response - actual response) on the frequency grid
`res.iextr`	Vector of indices into `fgrid` of external frequencies
`res.fextr`	Vector of external frequencies
`res.order`	Filter order
`res.edgecheck`	Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the `'check'` input option in the function syntax.
`res.iterations`	Number of `s` iterations for the optimization
`res.evals`	Number of function evaluations for the optimization

`firgr` is also a "function function," allowing you to write a function that defines the desired frequency response.

`b = firgr(n,f,fresp,w)` returns a length N + 1 FIR filter which has the best approximation to the desired frequency response as returned by the user-defined function `fresp`. Use the following `firgr` syntax to call `fresp`:

```
[dh,dw] = fresp(n,f,gf,w)
```

where:

- `fresp` identifies the function that you use to define your desired filter frequency response.
- `n` is the filter order.
- `f` is the vector of frequency band edges which must appear monotonically between 0 and 1, where 1 is one-half of the sampling frequency. The frequency bands span `f(k)` to `f(k+1)` for `k` odd. The intervals `f(k+1)` to `f(k+2)` for `k` odd are “transition bands” or “don't care” regions during optimization.
- `gf` is a vector of grid points that have been chosen over each specified frequency band by `firgr`, and determines the frequencies at which `firgr` evaluates the response function.
- `w` is a vector of real, positive weights, one per band, for use during optimization. `w` is optional in the call to `firgr`. If you do not specify `w`, it is set to unity weighting before being passed to `fresp`.
- `dh` and `dw` are the desired frequency response and optimization weight vectors, evaluated at each frequency in grid `gf`.

`firgr` includes a predefined frequency response function named `'firpmfrf2'`. You can write your own based on the simpler `'firpmfrf'`. See the help for `private/firpmfrf` for more information.

`b = firgr(n,f,{`*`fresp`*`,p1,p2,...},w)` specifies optional arguments `p1`, `p2`,..., `pn` to be passed to the response function `fresp`.

`b = firgr(n,f,a,w)` is a synonym for `b = firgr(n,f,{'firpmfrf2',a},w)`, where `a` is a vector containing your specified response amplitudes at each band edge in `f`. By default, `firgr` designs symmetric (even) FIR filters. `'firpmfrf2'` is the predefined frequency response function. If you do not specify your own frequency response function (the `fresp` variable), `firgr` uses `'firpmfrf2'`.

`b = firgr(...,'h')` and `b = firgr(...,'d')` design antisymmetric (odd) filters. When you omit the `'h'` or `'d'` arguments from the `firgr` command syntax, each frequency response function `fresp` can tell `firgr` to design either an even or odd filter. Use the command syntax `sym = `*`fresp`*`('defaults',{n,f,[],w,p1,p2,...})`.

`firgr` expects `fresp` to return `sym = 'even'` or `sym = 'odd'`. If `fresp` does not support this call, `firgr` assumes even symmetry.

For more information about the input arguments to `firgr`, refer to `firpm`.

Examples

Design a Filter Using firgr

Design an FIR filter with two single-band notches at 0.25 and 0.55.

```
b1 = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],[1 1 0 1 1 0 1 1],...
{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'});
```

Design a highpass filter whose gain at 0.06 is forced to be zero. The gain at 0.055 is indeterminate since it should abut the band.

```
b2 = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'});
```

Design a second highpass filter with forced values and independent approximation errors.

```
b3 = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1], ...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

Use the filter visualization tool to view the results of the filters.

```
fvtool(b1,1,b2,1,b3,1)
legend('Filter b1','Filter b2','Filter b3');
```

firhalfband

Halfband FIR filter design

Syntax

```
b = firhalfband(n,fp)
b = firhalfband(n,win)
b = firhalfband(n,dev,'dev')
b = firhalfband('minorder',fp,dev)
b = firhalfband('minorder',fp,dev,'kaiser')
b = firhalfband(...,'high')
b = firhalfband(...,'minphase')
```

Description

`b = firhalfband(n,fp)` designs a lowpass halfband FIR filter of order `n` with an equiripple characteristic. `n` must be an even integer. `fp` determines the passband edge frequency, and it must satisfy 0 < `fp` < 1/2, where 1/2 corresponds to *π/2* rad/sample.

`b = firhalfband(n,win)` designs a lowpass Nth-order filter using the truncated, windowed-impulse response method instead of the equiripple method. `win` is an `n +1` length vector. The ideal impulse response is truncated to length `n + 1`, and then multiplied point-by-point with the window specified in `win`.

`b = firhalfband(n,dev,'dev')` designs an Nth-order lowpass halfband filter with an equiripple characteristic. Input argument `dev` sets the value for the maximum passband and stopband ripple allowed.

`b = firhalfband('minorder',fp,dev)` designs a lowpass minimum-order filter, with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the equiripple method.

`b = firhalfband('minorder',fp,dev,'kaiser')` designs a lowpass minimum-order filter, with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the Kaiser window method.

`b = firhalfband(...,'high')` returns a highpass halfband FIR filter.

`b = firhalfband(...,'minphase')` designs a minimum-phase FIR filter such that the filter is a spectral factor of a halfband filter (recall that `h = conv(b,fliplr(b))` is a halfband filter). This can be useful for designing perfect reconstruction, two-channel FIR filter banks. The **minphase** option for `firhalfband` is not available for the window-based halfband filter designs — `b = firhalfband(n,win)` and `b = firhalfband('minorder',fp,dev,'kaiser')`.

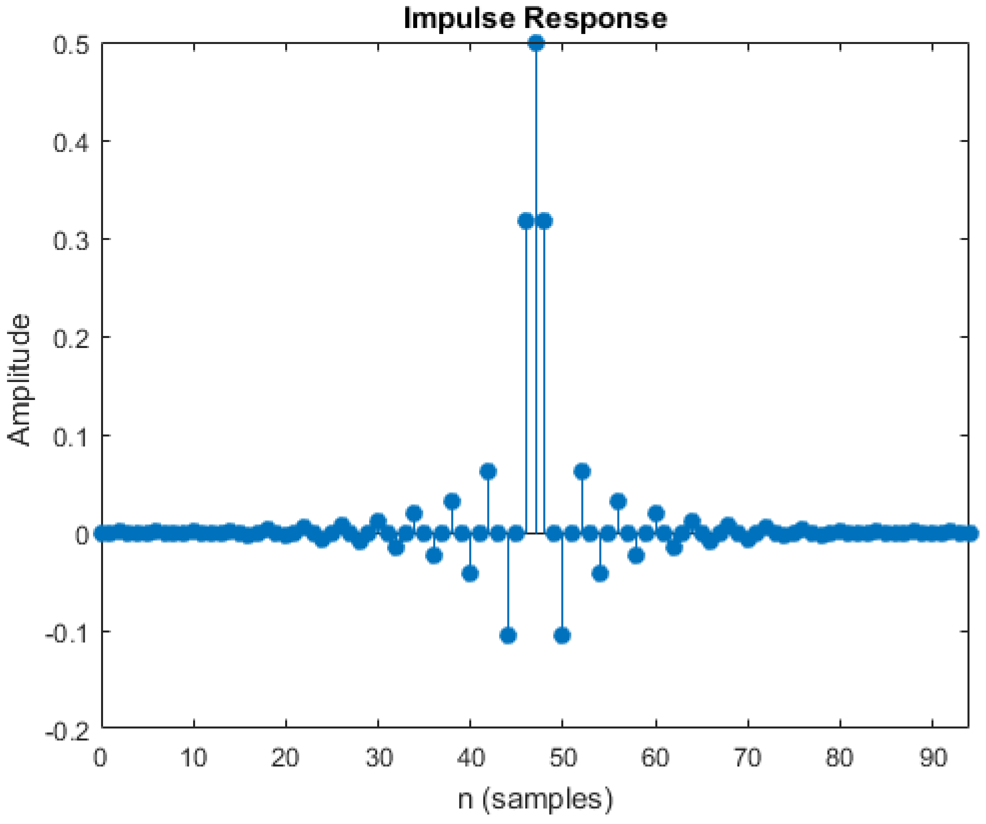
In the minimum phase cases, the filter order must be odd.

Examples

Design a Halfband Filter using halfband

This example designs a minimum order halfband filter with a specified maximum ripple.

```
b = firhalfband('minorder',.45,0.0001);
impz(b)
```



You can see that the impulse response is zero for every alternate sample.

Functions

`fir1` | `firgr` | `firls` | `firnyquist` | `firpm`

Introduced in R2011a

firlp2lp

Convert FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth

Syntax

```
g = firlp2lp(b)
```

Description

`g = firlp2lp(b)` transforms the Type I lowpass FIR filter `b` with zero-phase response Hr(w) to a Type I lowpass FIR filter `g` with zero-phase response [1 - Hr(π-w)].

When `b` is a narrowband filter, `g` will be a wideband filter and vice versa. The passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

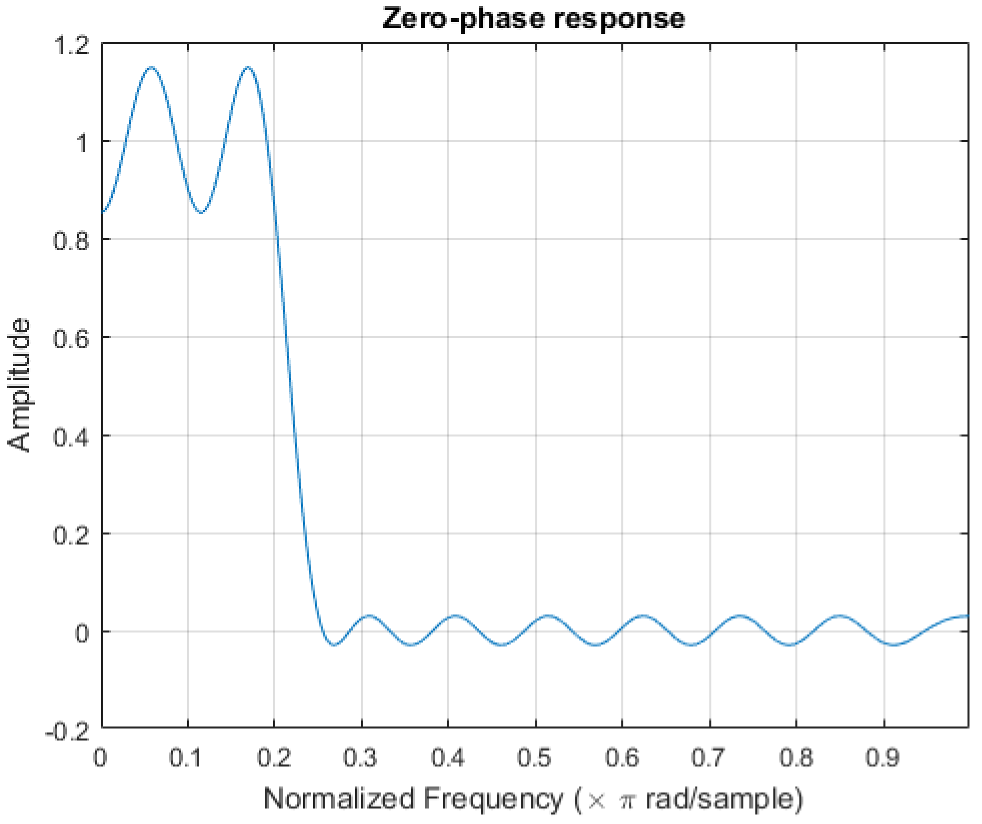
Examples

Convert Narrowband Lowpass Filter to Wideband Lowpass Filter

Create a narrowband lowpass filter to use as prototype. Display its zero-phase response.

```
b = firgr(36,[0 0.2 0.25 1],[1 1 0 0],[1 5]);
```

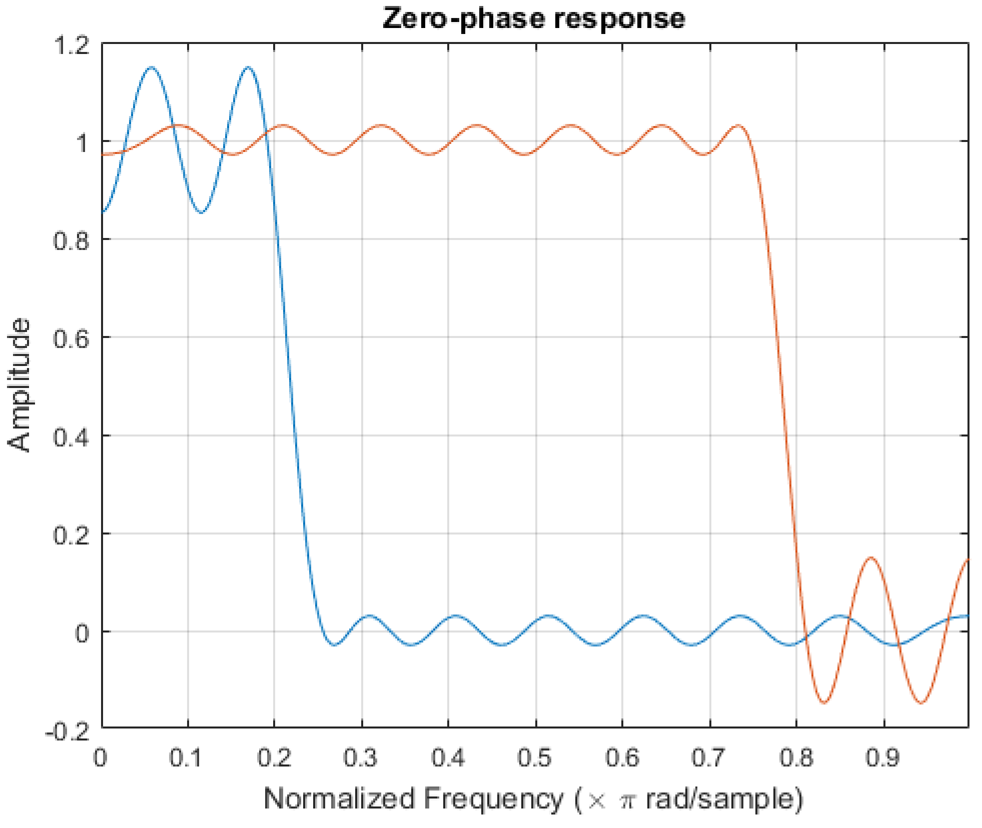
```
zerophase(b)
```



Convert the prototype filter to a wideband lowpass filter. Add to the plot the zero-phase response of the new filter.

```
h = firlp2lp(b);

hold on
zerophase(h)
```



Convert the previous filter back to a narrowband lowpass filter. Add to the plot the zero-phase response of the new filter.

```
g = firlp2lp(h);

[gr,w] = zerophase(g);
plot(w/pi,gr,'--')
hold off
```

`firlp2hp` | `zerophase`

Introduced in R2011a

firlp2hp

Convert FIR lowpass filter to Type I FIR highpass filter

Syntax

```
g = firlp2hp(b)
g = firlp2hp(b,'narrow')
g = firlp2hp(b,'wide')
```

Description

`g = firlp2hp(b)` transforms the lowpass FIR filter `b` into a Type I highpass FIR filter `g` with zero-phase response Hr(π-w). Filter `b` can be any FIR filter, including a nonlinear-phase filter.

The passband and stopband ripples of `g` will be equal to the passband and stopband ripples of `b`.

`g = firlp2hp(b,'narrow')` transforms the lowpass FIR filter `b` into a Type I narrow band highpass FIR filter `g` with zero-phase response Hr(π-w). `b` can be any FIR filter, including a nonlinear-phase filter.

`g = firlp2hp(b,'wide')` transforms the Type I lowpass FIR filter `b` with zero-phase response Hr(w) into a Type I wide band highpass FIR filter `g` with zero-phase response 1 - Hr(w). Note the restriction that b must be a Type I linear-phase filter.

For this case, the passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

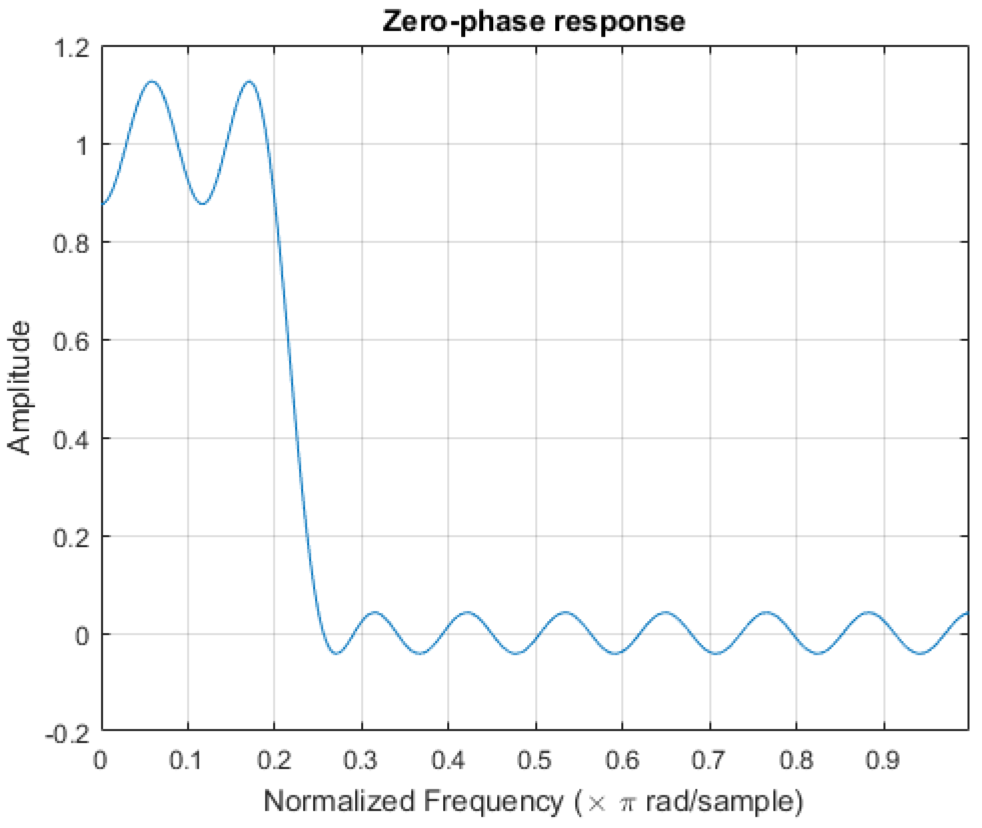
Examples

Convert Narrowband Lowpass Filter to Highpass Filter

Create a narrowband lowpass filter to use as prototype. Display its zero-phase response.

```
b = firgr(36,[0 0.2 0.25 1],[1 1 0 0],[1 3]);

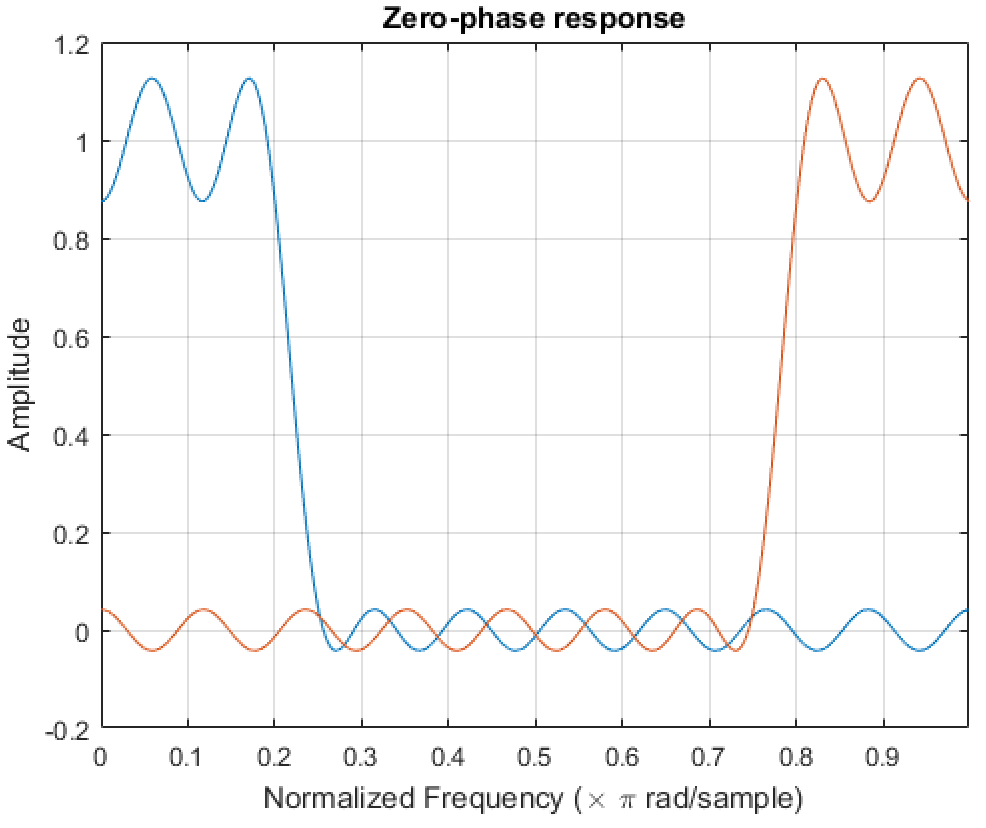
zerophase(b)
```



Convert the prototype filter to a narrowband highpass filter. Add to the plot the zero-phase response of the new filter.

```
h = firlp2hp(b);

hold on
zerophase(h)
```



Convert the prototype filter to a wideband highpass filter. Add to the plot the zero-phase response of the new filter.

```
g = firlp2hp(b,'wide');

zerophase(g)
hold off
```

`firlp2lp` | `zerophase`

Introduced in R2011a

firlpnorm

Least P-norm optimal FIR filter

Syntax

```
b = firlpnorm(n,f,edges,a)
b = firlpnorm(n,f,edges,a,w)
b = firlpnorm(n,f,edges,a,w,p)
b = firlpnorm(n,f,edges,a,w,p,dens)
b = firlpnorm(n,f,edges,a,w,p,dens,initnum)
b = firlpnorm(...,'minphase')
[b,err] = firlpnorm(...)
```

Description

`b = firlpnorm(n,f,edges,a)` returns a filter of numerator order `n` which represents the best approximation to the frequency response described by `f` and `a` in the least-Pth norm sense. P is set to 128 by default, which essentially equivalent to the infinity norm. Vector `edges` specifies the band-edge frequencies for multiband designs. `firlpnorm` uses an unconstrained quasi-Newton algorithm to design the specified filter.

`f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This lets you specify filters with any gain contour within each band. However, the frequencies in `edges` must also be in vector `f`. Always use `freqz` to check the resulting filter.

Note `firlpnorm` uses a nonlinear optimization routine that may not converge in some filter design cases. Furthermore the algorithm is not well-suited for certain large-order (order > 100) filter designs.

`b = firlpnorm(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `firlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. For example,

```
b = firlpnorm(20,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband, and with emphasis placed on minimizing the error in the stopband.

`b = firlpnorm(n,f,edges,a,w,p)` where `p` is a two-element vector [`pmin pmax`] lets you specify the minimum and maximum values of `p` used in the least-pth algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even numbers. The design algorithm starts optimizing the filter with `pmin` and moves toward an optimal filter in the `pmax` sense. When `p` is set to '**`inspect`**', `firlpnorm` does not optimize the resulting filter. You might use this feature to inspect the initial zero placement.

`b = firlpnorm(n,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is [`dens*(n+1)`]. The default is 20. You can specify `dens` as a single-element cell array. The grid is equally spaced.

`b = firlpnorm(n,f,edges,a,w,p,dens,initnum)` lets you determine the initial estimate of the filter numerator coefficients in vector `initnum`. This can prove helpful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum`.

`b = firlpnorm(...,'minphase')` where '`minphase`' is the last argument in the argument list generates a minimum-phase FIR filter. By default, `firlpnorm` design mixed-phase filters. Specifying input option '`minphase`' causes `firlpnorm` to use a different optimization method to design the minimum-phase filter. As a result of the different optimization used, the minimum-phase filter can yield slightly different results.

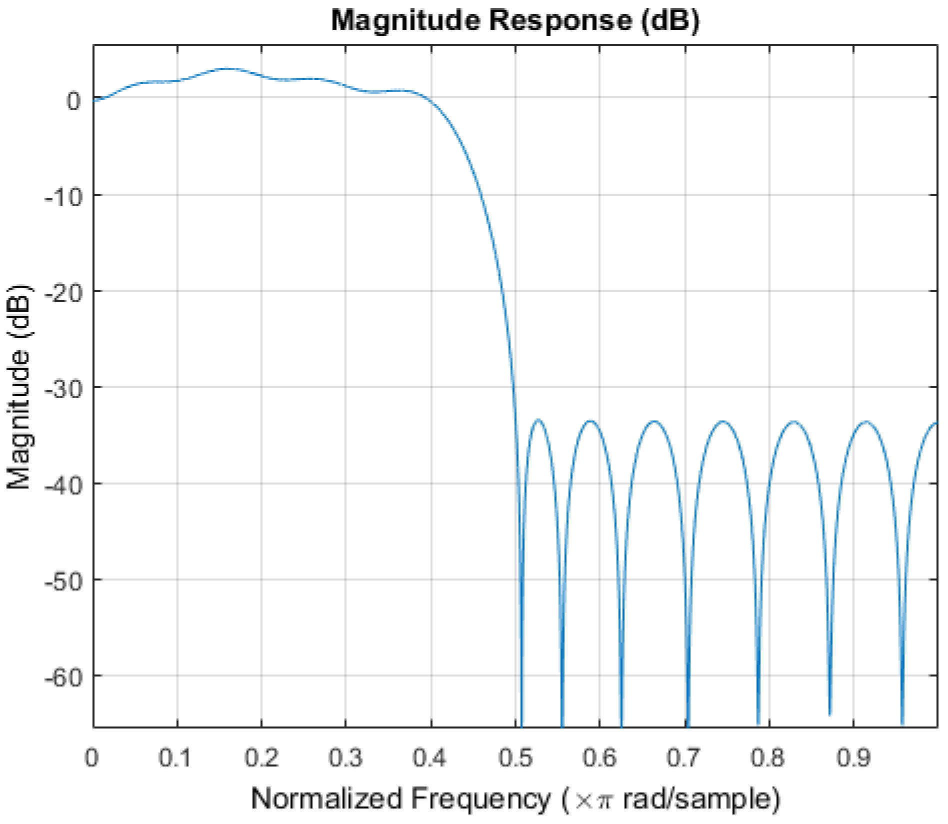
`[b,err] = firlpnorm(...)` returns the least-pth approximation error `err`.

Examples

Design a Lowpass and Highpass Filter Using firlpnorm

Lowpass filter with a peak of 1.4 in the passband.

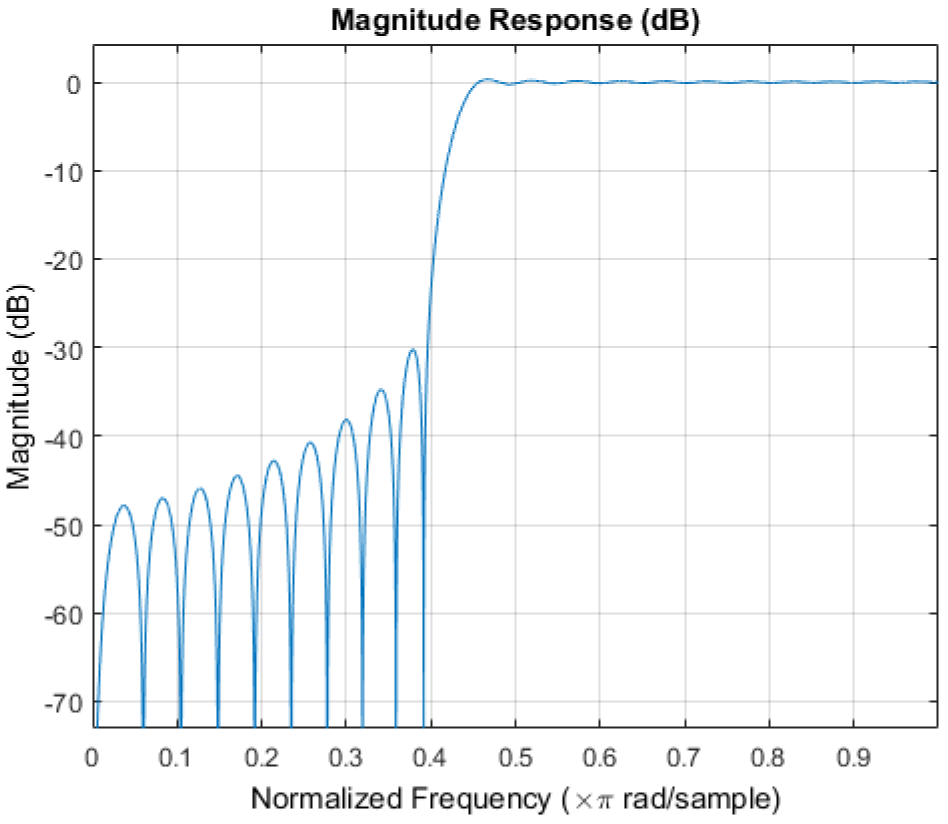
```
b = firlpnorm(22,[0 .15 .4 .5 1],[0 .4 .5 1],[1 1.4 1 0 0],...
[1 1 1 2 2]);
fvtool(b)
```



The resulting filter is lowpass, with the desired 1.4 peak in the passband (notice the 1.4 specified in vector a).

Highpass minimum-phase filter optimized for the 4-norm.

```
b = firlpnorm(44,[0 .4 .45 1],[0 .4 .45 1],[0 0 1 1],[5 1 1 1],...
[2 4],'minphase');
fvtool(b)
```



This is a minimum-phase, highpass filter.

The zero-pole plot shows the minimum phase nature more clearly.

```
fvtool(b,'polezero')
```

firls

Least-square linear-phase FIR filter design

Syntax

```
b = firls(n,f,a)
b = firls(n,f,a,w)
b = firls(n,f,a,ftype)
b = firls(n,f,a,w,ftype)
```

Description

`b = firls(n,f,a)` returns row vector `b` containing the `n+1` coefficients of the order `n` FIR filter. This filter has frequency-amplitude characteristics approximately matching those given by vectors, `f` and `a`.

`b = firls(n,f,a,w)` uses the weights in vector `w`, to weigh the error.

`b = firls(n,f,a,ftype)` specifies a filter type where `ftype` is:

- `'hilbert'`
- `'differentiator'`

`b = firls(n,f,a,w,ftype)` uses the weights in vector `w` to weigh the error. It also specifies a filter type where `ftype` is:

- `'hilbert'`
- `'differentiator'`

Examples

Design a Lowpass Filter with Transition Band

The following illustrates how to design a lowpass filter of order 225 with transition band.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.25 0.3 1]
a = [1 1 0 0]
```

```
f =

         0    0.2500    0.3000    1.0000

a =

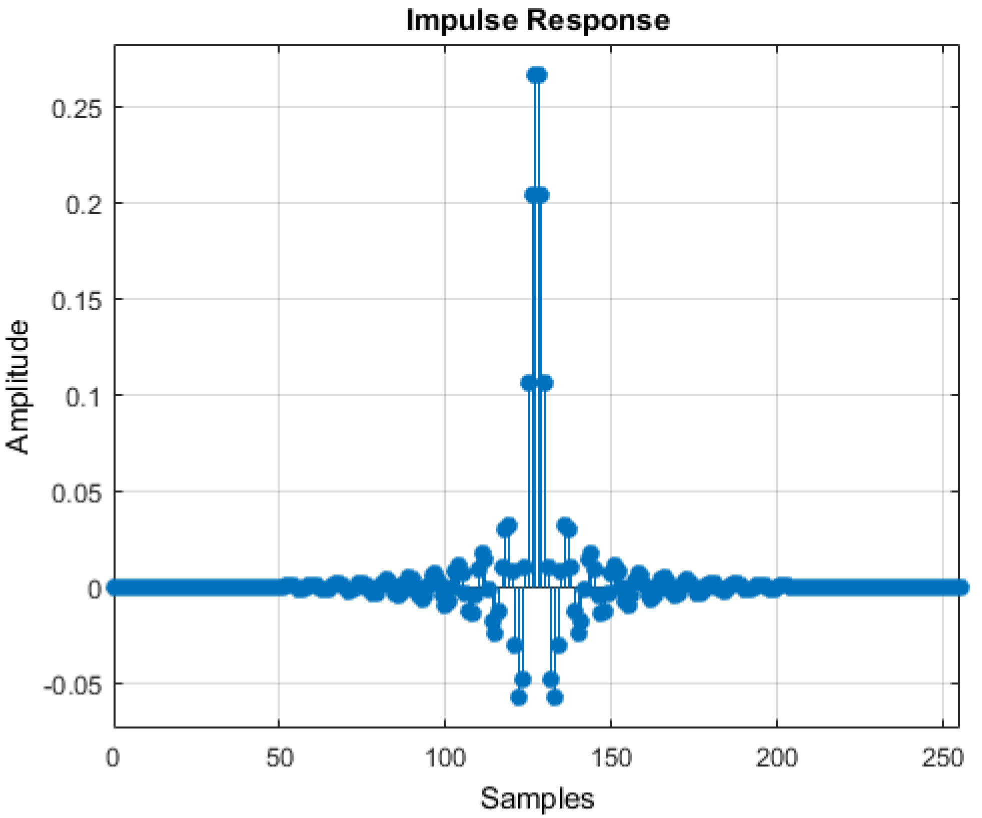
     1     1     0     0
```

Use `firls` to obtain the `n+1` coefficients of the order `n` lowpass FIR filter.

```
b = firls(255,f,a);
```

Show the impulse response of the filter

```
fvtool(b,'impulse')
```



Design an Antisymmetric Filter with Piecewise Linear Passbands

The following shows how to design a 24th-order anti-symmetric filter with piecewise linear passbands, and plot the desired and actual amplitude responses.

Create the frequency and amplitude vectors, `f` and `a`.

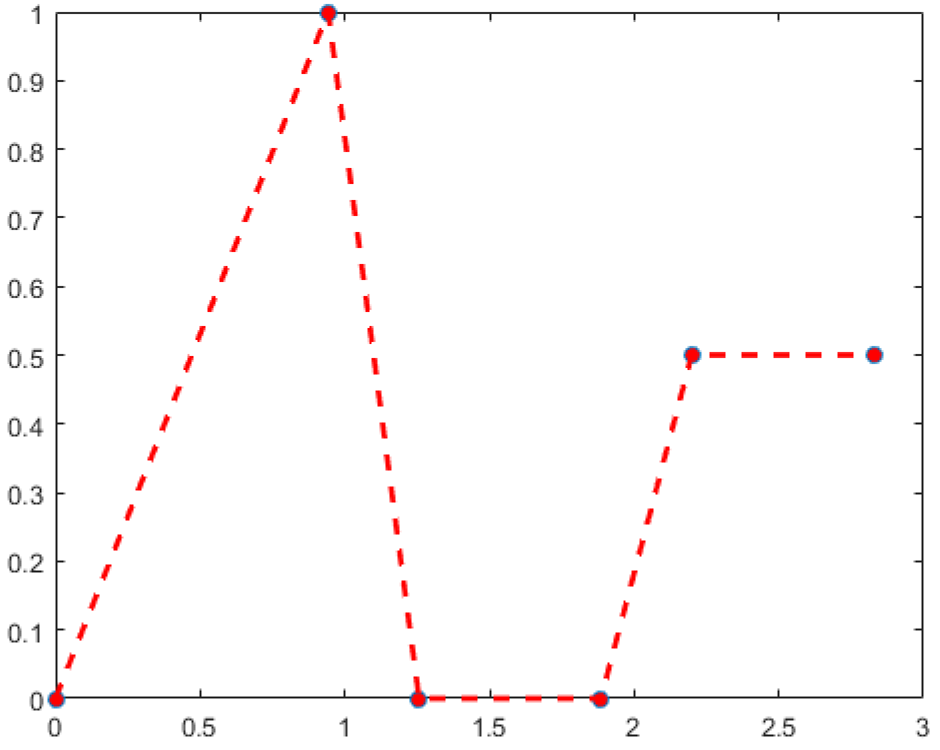
```
f = [0 0.3 0.4 0.6 0.7 0.9];
a = [0 1 0 0 0.5 0.5];
```

Use `firls` to obtain the 25 coefficients of the filter.

```
b = firls(24,f,a,'hilbert');
```

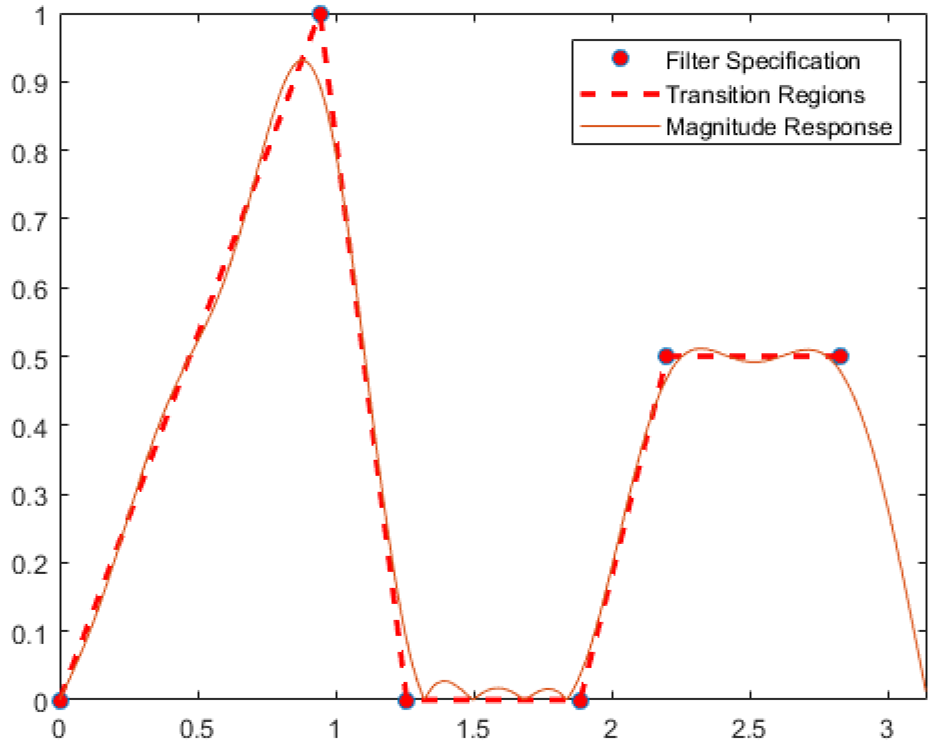
Plot the ideal amplitude response along with the transition regions.

```
plot(f.*pi,a,'o','markerfacecolor',[1 0 0]);
hold on;
plot(f.*pi,a,'r--','linewidth',2);
```



Use `freqz` to obtain the frequency response of the designed filter and plot the magnitude response of the filter.

```
[H,F] = freqz(b,1);
plot(F,abs(H));
set(gca,'xlim',[0 pi])
legend('Filter Specification','Transition Regions','Magnitude Response')
```



Input Arguments

n — Filter order

(default) | integer scalar

Order of the filter, specified as an integer scalar. For odd orders, the frequency response at the Nyquist frequency is necessarily 0. For this reason, `firls` always uses an even filter order for configurations with a passband at the Nyquist frequency. If you specify an odd-valued `n`, `firls` increments it by 1.

Example: 8

Data Types: `int8` | `int16` | `int32` | `int64`

`f` — Pairs of frequency points

vector of numeric values

Pairs of frequency points, specified as a vector of values ranging between 0 and 1, where 1 corresponds to the Nyquist frequency. The frequencies must be in increasing order, and duplicate frequency points are allowed. You can use duplicate frequency points to design filters exactly like those returned by the `fir1` and `fir2` functions with a rectangular (`rectwin`) window.

`f` and `a` are the same length. This length must be an even number.

Example: `[0 0.3 0.4 1]`

Data Types: `double` | `single`

`a` — Amplitude values

vector of numeric values

Amplitude values of the function at each frequency point, specified as a vector of the same length as `f`. This length must be an even number.

The desired amplitude at frequencies between pairs of points ($f(k)$, $f(k+1)$) for k odd, is the line segment connecting the points ($f(k)$, $a(k)$) and ($f(k+1)$, $a(k+1)$).

The desired amplitude at frequencies between pairs of points ($f(k)$, $f(k+1)$) for k even is unspecified. These are transition or “don't care” regions.

Example: `[1 1 0 0]`

Data Types: `double` | `single`

`w` — Weights

vector of numeric values

Weights to weigh the fit for each frequency band, specified as a vector of length half the length of `f` and `a`, so there is exactly one weight per band. `w` indicates how much emphasis to put on minimizing the integral squared error in each band, relative to the other bands.

Example: `[0.5 1]`

Data Types: `double` | `single`

ftype — Filter type
'hilbert' and 'differentiator'

Filter type, specified as either 'hilbert' or 'differentiator'.

Example: 'hilbert'

Data Types: char

Output Arguments

b — Filter coefficients
vector of numeric values

Filter coefficients, returned as a numeric vector of n+1 values, where n is the filter order.

b = firls(n,f,a) designs a linear-phase filter of type I (n odd) and type II (n) . The output coefficients, or "taps," in b obey the relation:
b(k) = b(n+2-k), k = 1, ... , n + 1

b = firls(n,f,a,'hilbert') designs a linear-phase filter with odd symmetry (type III and type IV). The output coefficients, or "taps," in b obey the relation:
b(k) = –b(n+2-k), k = 1, ... , n + 1

b = firls(n,f,a,'differentiator') designs type III and type IV filters, using a special weighting technique. For nonzero amplitude bands, the integrated squared error has a weight of $(1/f)^2$. This weighting causes the error at low frequencies to be much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, the filters minimize the relative integrated squared error. This value is the integral of the square of the ratio of the error to the desired amplitude.

Definitions

Diagnostics

Error and warning messages

One of the following diagnostic messages is displayed when an incorrect argument is used:

```
F must be even length.
F and A must be equal lengths.
Requires symmetry to be 'hilbert' or 'differentiator'.
Requires one weight per band.
Frequencies in F must be nondecreasing.
Frequencies in F must be in range [0,1].
```

A more serious warning message is

```
Warning: Matrix is close to singular or badly scaled.
```

This tends to happen when the product of the filter length and transition width grows large. In this case, the filter coefficients b might not represent the desired filter. You can check the filter by looking at its frequency response.

Algorithms

`firls` designs a linear-phase FIR filter. This filter minimizes the weighted, integrated squared error between an ideal piecewise linear function and the magnitude response of the filter over a set of desired frequency bands.

Reference [1] describes the theoretical approach behind `firls`. The function solves a system of linear equations involving an inner product matrix of size roughly `n/2` using the MATLAB \ operator.

This function designs type I, II, III, and IV linear-phase filters. Type I and II are the defaults for n even and odd respectively. The `'hilbert'` and `'differentiator'` flags produce type III (n even) and IV (n odd) filters. The various filter types have different symmetries and constraints on their frequency responses (see [2] for details).

Linear Phase Filter Type	Filter Order	Symmetry of Coefficients	Response H(f), f = 0	Response H(f), f = 1 (Nyquist)
Type I	Even	b(k) = b(n+2-k), k=1,..., n+1	No restriction	No restriction
Type II	Even	b(k) = b(n+2-k), k=1,..., n+1	No restriction	$H(1) = 0$
Type III	Odd	b(k) = –b(n+2-k), k=1,..., n+1	$H(0) = 0$	$H(1) = 0$
Type IV	Odd	b(k) = –b(n+2-k), k=1,..., n+1	$H(0) = 0$	No restriction

firminphase

Minimum-phase FIR spectral factor

Syntax

```
h = firminphase(b)
h = firminphase(b,nz)
```

Description

`h = firminphase(b)` computes the minimum-phase FIR spectral factor `h` of a linear-phase FIR filter `b`. Filter `b` must be real, have even order, and have nonnegative zero-phase response.

`h = firminphase(b,nz)` specifies the number of zeros, `nz`, of `b` that lie on the unit circle. You must specify `nz` as an even number to compute the minimum-phase spectral factor because every root on the unit circle must have even multiplicity. Including `nz` can help `firminphase` calculate the required FIR spectral factor. Zeros with multiplicity greater than two on the unit circle cause problems in the spectral factor determination.

Note You can find the maximum-phase spectral factor, `g`, by reversing `h`, such that *g = fliplr(h)*, and *b = conv(h, g)*.

Examples

Design a Constrained Least Squares Filter using firminphase

This example designs a constrained least squares filter with a nonnegative zero-phase response, and then uses `firminphase` to compute the minimum-phase spectral factor.

```
f   = [0 0.4 0.8 1];
a   = [0 1 0];
up  = [0.02 1.02  0.01];
lo  = [0 0.98 0]; % The zeros insure nonnegative zero-phase resp.
n   = 32;
```

```
b   = fircls(n,f,a,up,lo);
h   = firminphase(b)
```

```
h =

firnyquist

Lowpass Nyquist (Lth-band) FIR filter

Syntax

```
b = firnyquist(n,l,r)
b = firnyquist('minorder',l,r,dev)
b = firnyquist(n,l,r,decay)
b = firnyquist(n,l,r,'nonnegative')
b = firnyquist(n,l,r,'minphase')
```

Description

`b = firnyquist(n,l,r)` designs an Nth order, Lth band, Nyquist FIR filter with a rolloff factor `r` and an equiripple characteristic.

The rolloff factor `r` is related to the normalized transition width `tw` by $tw = 2\pi(r/l)$ (rad/sample). The order, `n`, must be even. `l` must be an integer greater than one. If `l` is not specified, it defaults to 4. `r` must satisfy `0< r < 1`. If `r` is not specified, it defaults to `0.5`.

`b = firnyquist('`**`minorder`**`',l,r,dev)` designs a minimum-order, Lth band Nyquist FIR filter with a rolloff factor `r` using the Kaiser window. The peak ripple is constrained by the scalar `dev`.

`b = firnyquist(n,l,r,decay)` designs an Nth order (`n`), Lth band (`l`), Nyquist FIR filter where the scalar `decay`, specifies the rate of decay in the stopband. `decay` must be nonnegative. If you omit or leave it empty, `decay` defaults to `0` which yields an equiripple stopband. A nonequiripple stopband (`decay` $\neq 0$) may be desirable for decimation purposes.

`b = firnyquist(n,l,r,'`**`nonnegative`**`')` returns an FIR filter with nonnegative zero-phase response. This filter can be spectrally factored into minimum-phase and maximum-phase “square-root” filters. This allows you to use the spectral factors in applications such as matched-filtering.

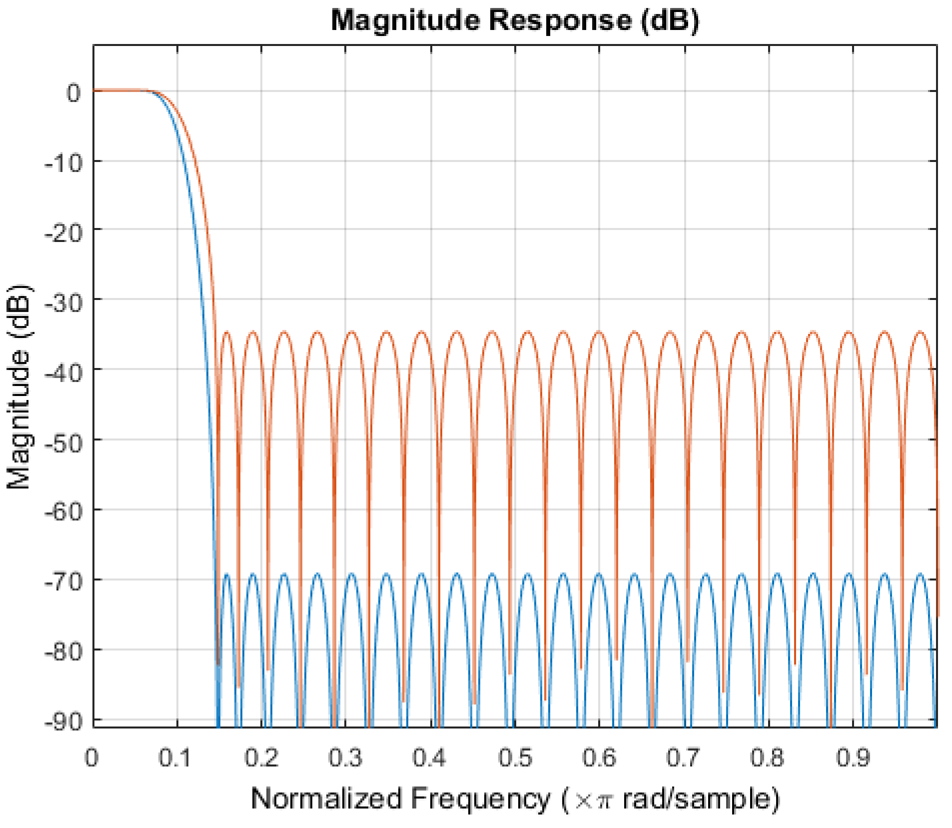
`b = firnyquist(n,l,r,'minphase')` returns the minimum-phase spectral factor `bmin` of order `n`. `bmin` meets the condition `b=conv(bmin,bmax)` so that `b` is an Lth band FIR Nyquist filter of order 2n with filter rolloff factor `r`. Obtain `bmax`, the maximum phase spectral factor by reversing the coefficients of `bmin`. For example, `bmax = bmin(end:-1:1)`.

Examples

Design a Nyquist Filter Using firnyquist

This example designs a minimum phase factor of a Nyquist filter.

```
bmin = firnyquist(47,10,.45,'minphase');
b = firnyquist(2*47,10,.45,'nonnegative');
[h,w,s] = freqz(b); hmin = freqz(bmin);
fvtool(b,1,bmin,1);
```



This example compares filters with different decay rates.

```
b1 = firnyquist(72,8,.3,0); % Equiripple
b2 = firnyquist(72,8,.3,15);
b3 = firnyquist(72,8,.3,25);
fvtool(b1,1,b2,1,b3,1);
```

firpr2chfb

Two-channel FIR filter bank for perfect reconstruction

Syntax

```
[h0,h1,g0,g1] = firpr2chfb(n,fp)
[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')
[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)
```

Description

`[h0,h1,g0,g1] = firpr2chfb(n,fp)` designs four FIR filters for the analysis sections (`h0` and `h1`) and synthesis section is (`g0` and `g1`) of a two-channel perfect reconstruction filter bank. The design corresponds to the orthogonal filter banks also known as power-symmetric filter banks.

`n` is the order of all four filters. It must be an odd integer. `fp` is the passband-edge for the lowpass filters `h0` and `g0`. The passband-edge argument `fp` must be less than 0.5. `h1` and `g1` are highpass filters with the passband-edge given by (1-`fp`).

`[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')` designs the four filters such that the maximum stopband ripple of `h0` is given by the scalar `dev`. Specify `dev` in linear units, not decibels. The stopband-ripple of `h1` is also be given by `dev`, while the maximum stopband-ripple for both `g0` and `g1` is (2*`dev`).

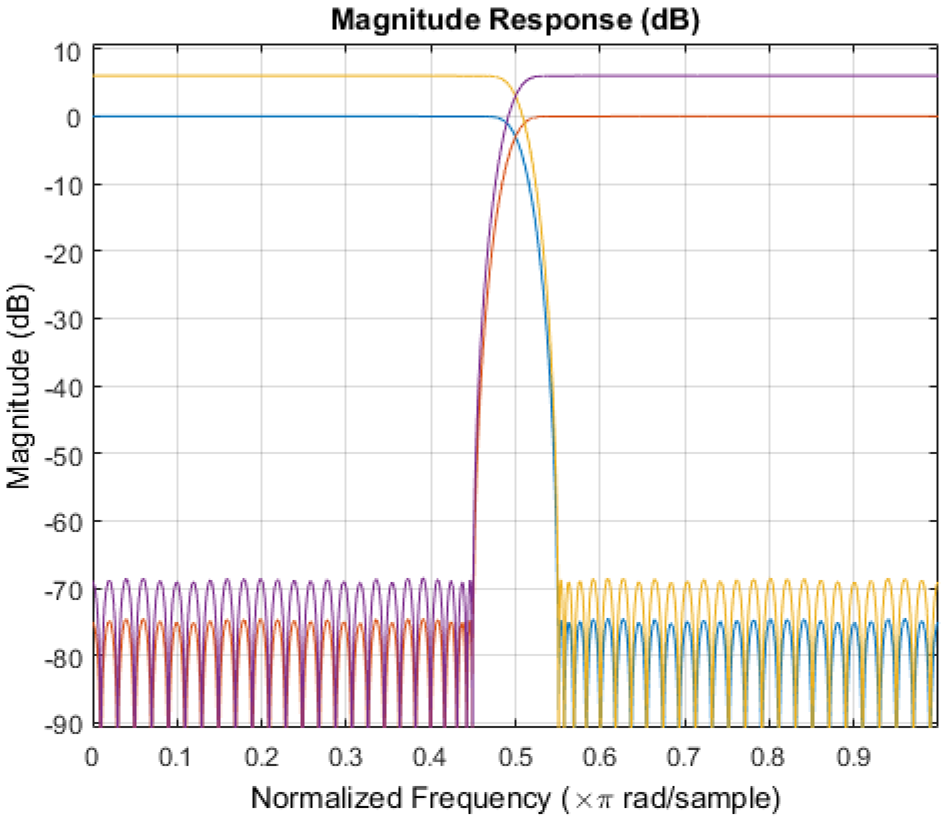
`[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)` designs the four filters such that `h0` meets the passband-edge specification `fp` and the stopband-ripple `dev` using minimum order filters to meet the specification.

Examples

Design a Filter Bank Using firpr2chfb

Design a filter bank with filters of order n equal to 99 and passband edges of 0.45 and 0.55.

```
n = 99;
[h0,h1,g0,g1] = firpr2chfb(n,.45);
fvtool(h0,1,h1,1,g0,1,g1,1);
```



Here are the filters, showing clearly the passband edges.

Use the following stem plots to verify perfect reconstruction using the filter bank created by firpr2chfb.

```
stem(1/2*conv(g0,h0)+1/2*conv(g1,h1))
n=0:n;
stem(1/2*conv((-1).^n.*h0,g0)+1/2*conv((-1).^n.*h1,g1))
stem(1/2*conv((-1).^n.*g0,h0)+1/2*conv((-1).^n.*g1,h1))
stem(1/2*conv((-1).^n.*g0,(-1).^n.*h0)+...
```

```
1/2*conv((-1).^n.*g1,(-1).^n.*h1))
stem(conv((-1).^n.*h1,h0)-conv((-1).^n.*h0,h1))
```

firtype

Type of linear phase FIR filter

Syntax

```
t = firtype(b)
t = firtype(d)
```

Description

`t = firtype(b)` determines the type, `t`, of an FIR filter with coefficients `b`. `t` can be 1, 2, 3, or 4. The filter must be real and have linear phase.

`t = firtype(d)` determines the type, `t`, of an FIR filter, `d`. `t` can be 1, 2, 3, or 4. The filter must be real and have linear phase.

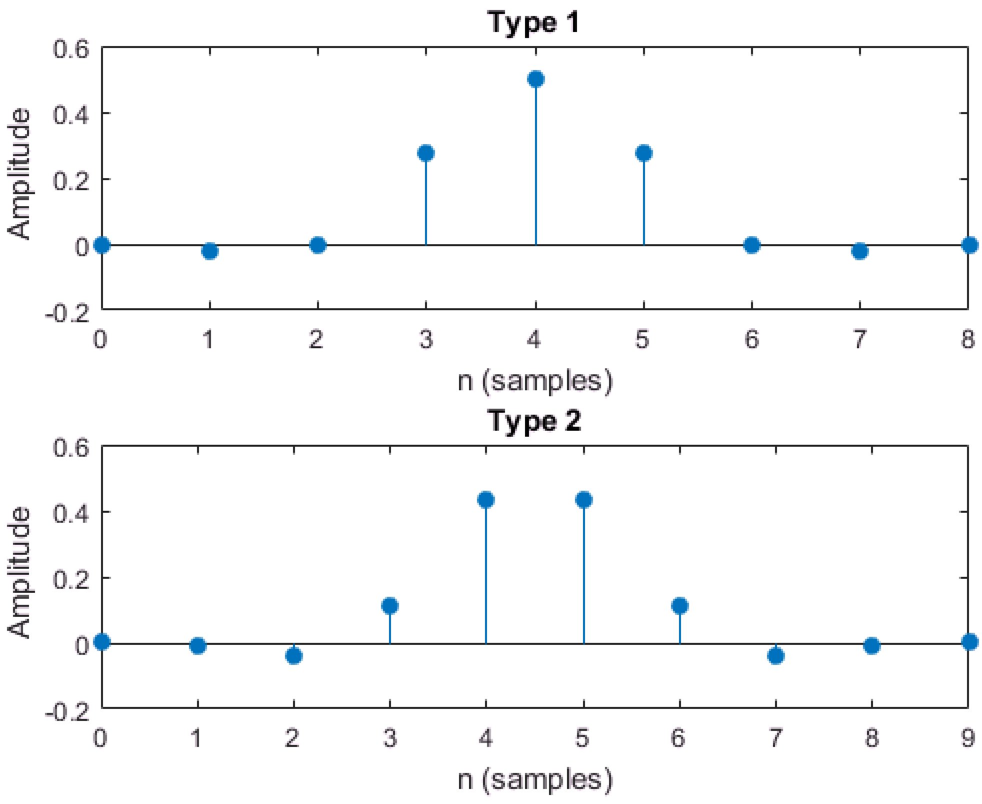
Examples

Types of Linear Phase Filters

Design two FIR filters using the window method, one of even order and the other of odd order. Determine their types and plot their impulse responses.

```
subplot(2,1,1)
b = fir1(8,0.5);
impz(b), title(['Type ' int2str(firtype(b))])

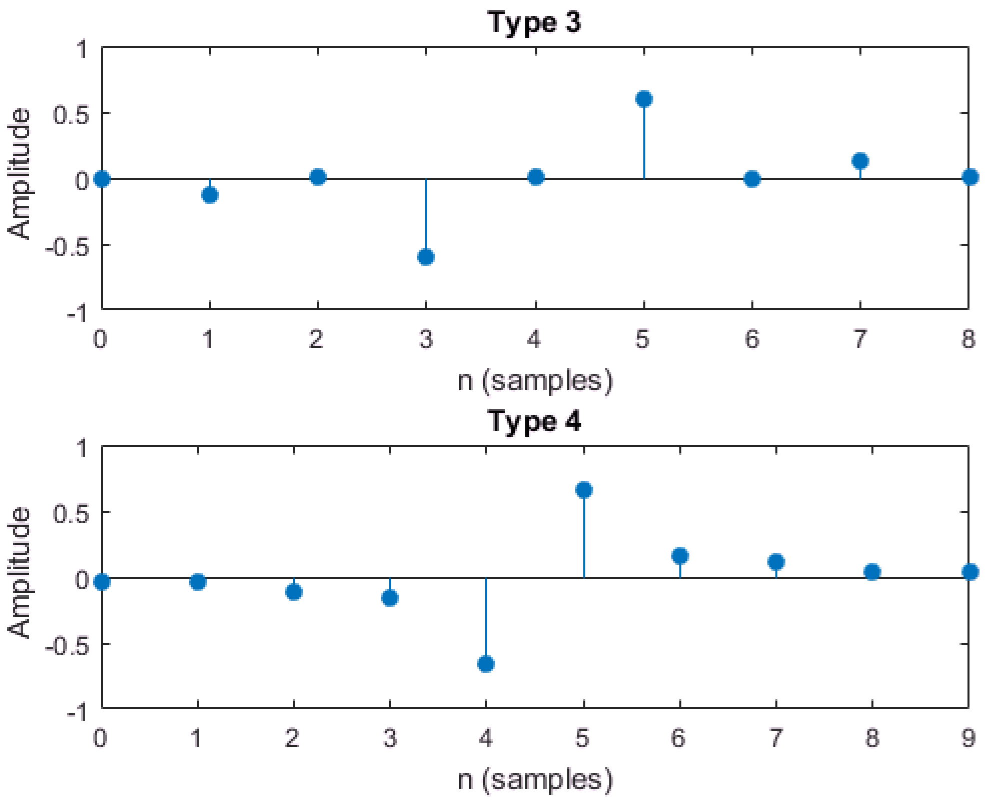
subplot(2,1,2)
b = fir1(9,0.5);
impz(b), title(['Type ' int2str(firtype(b))])
```



Design two equiripple Hilbert transformers, one of even order and the other of odd order. Determine their types and plot their impulse responses.

```
subplot(2,1,1)
b = firpm(8,[0.2 0.8],[1 1],'hilbert');
impz(b), title(['Type ' int2str(firtype(b))])

subplot(2,1,2)
b = firpm(9,[0.2 0.8],[1 1],'hilbert');
impz(b), title(['Type ' int2str(firtype(b))])
```



Types of FIR digitalFilter Objects

Use `designfilt` to design the filters from the previous example. Display their types.

```
d1 = designfilt('lowpassfir','DesignMethod','window', ...
                'FilterOrder',8,'CutoffFrequency',0.5);
disp(['d1 is of type ' int2str(firtype(d1))])
```

```
d1 is of type 1
```

```
d2 = designfilt('lowpassfir','DesignMethod','window', ...
                'FilterOrder',9,'CutoffFrequency',0.5);
disp(['d2 is of type ' int2str(firtype(d2))])
```

```
d2 is of type 2
```

```
d3 = designfilt('hilbertfir','DesignMethod','equiripple', ...
                'FilterOrder',8,'TransitionWidth',0.4);
disp(['d3 is of type ' int2str(firtype(d3))])
```

```
d3 is of type 3
```

```
d4 = designfilt('hilbertfir','DesignMethod','equiripple', ...
                'FilterOrder',9,'TransitionWidth',0.4);
disp(['d4 is of type ' int2str(firtype(d4))])
```

```
d4 is of type 4
```

Input Arguments

b — Filter coefficients
vector

Filter coefficients of the FIR filter, specified as a double- or single-precision real-valued row or column vector.

Data Types: `double` | `single`

d — FIR filter
`digitalFilter` object | filter System object

FIR filter, specified as any of the following:

- A digitalFilter object. Use `designfilt` to generate a digital filter based on frequency-response specifications.
- A Filter System object. You can use this input if you have a license for DSP System Toolbox software. `firtype` supports the following Filter System objects:

dsp.LowpassFilter
dsp.HighpassFilter
dsp.FIRFilter
dsp.FIRRateConverter
dsp.FIRDecimator

dsp.FIRInterpolator
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.VariableBandwidthFIRFilter

Output Arguments

t — Filter type

1 | 2 | 3 | 4

Filter type, returned as either 1, 2, 3, or 4. Filter types are defined as follows:

- Type 1 — Even-order symmetric coefficients
- Type 2 — Odd-order symmetric coefficients
- Type 3 — Even-order antisymmetric coefficients
- Type 4 — Odd-order antisymmetric coefficients

Introduced in R2013a

freqrespest

Frequency response estimate via filtering

Syntax

```
[h,w] = freqrespest(sysobj,L)
[h,w] = freqrespest(sysobj,L,param1,value1,param2,value2,...)
[h,w] = freqrespest(sysobj,L,opts)
freqrespest(sysobj,...)
```

Description

`[h,w] = freqrespest(sysobj,L)` estimates the frequency response of a filter System object, `sysobj`. A set of input data is filtered and then forming the ratio between output data and input data. The test input data comprises sinusoids with uniformly distributed random frequencies.

Use this technique for comparing the performance of fixed-point filters to that of another filter type. You can, for example, compare fixed—point frequency response estimate to that of a similar filter that uses quantized coefficients, but applies floating-point arithmetic internally. Such comparison determines whether the fixed-point filter performance closely matches the floating-point, quantized coefficients version of the filter.

`L` is the number of trials to use to compute the estimate. If you do not specify this value, `L` defaults to 10. More trials generates a more accurate estimate of the response, but require more time to compute the estimate.

`h` is the estimate of the complex frequency response. `w` contains the vector of frequencies at which `h` is estimated.

`[h,w] = freqrespest(sysobj,L,param1,value1,param2,value2,...)` uses parameter value (PV) pairs as input arguments to specify optional parameters for the test. These parameters are the valid PV pairs. Enter the parameter names as input arguments in single quotation marks. The following table provides valid parameters for `[h, w]`.

Parameter Name	Default Value	Description
NFFT	512	Number of FFT points to use.
NormalizedFrequency	true	Indicate whether to use normalized frequency or linear frequency. Values are true (use normalized frequency), or false (use linear frequency). When you specify false, you must supply the sampling frequency Fs.
Fs	normalized	Specify the sampling frequency when NormalizedFrequency is false. No default value. You must set NormalizedFrequency to false before setting a value for Fs.
SpectrumRange	half	Specify the spectrum range to be used as whole or half (default).
CenterDC	false	Specify whether to set the center of the spectrum to the DC value in the output plot. If you select true, both the negative and positive values appear in the plot. If you select false, DC appears at the origin of the axes.
Arithmetic	ARITH	Analyze the filter System object, based on the arithmetic specified in the ARITH input. ARITH can be set to double, single, or fixed. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

freqrespest requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the Arithmetic parameter, i.e., use the syntax [h,w] = freqrespest(sysobj) , then the following rules apply for this method:

- The System object state is Unlocked — freqrespest performs double precision analysis.

- The System object state is `Locked` — `freqrespest` performs analysis based on the locked input data type.

When you do specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = freqrespest(sysobj,'Arithmetic', ARITH)`, review the following rules for this method. Which rule applies depends on the value you set for the `Arithmetic` parameter.

Value	**System Object State**	**Rule**
`ARITH = ’double’`	`Unlocked`	`freqrespest` performs double-precision analysis.
	`Locked`	`freqrespest` performs double-precision analysis.
`ARITH = ‘single’`	`Unlocked`	`freqrespest` performs single-precision analysis.
	`Locked`	`freqrespest` performs single-precision analysis.
`ARITH = ‘fixed’`	`Unlocked`	`freqrespest` produces an error because the fixed-point input data type is unknown.
	`Locked`	If the input data type is double or single, then `freqrespest` produces an error because the fixed-point input data type is unknown.
		When the input data is of fixed-point type, `freqrespest` performs analysis based on the locked input data type.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.BiquadFilter

Filter System objects
dsp.CoupledAllpassFilter
dsp.FIRFilter
dsp.HighpassFilter
dsp.IIRFilter
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

`[h,w] = freqrespest(sysobj,L,opts)` uses an object, `opts`, to specify the optional input parameters. This specification is not done directly by specifying PV pairs as input arguments. Create `opts` with

```
opts = freqrespopts(sysobj);
```

Because `opts` is an object, you use `set` to change the parameter values in `opts` before you use it with `freqrespest`. For example, you could specify a new sample rate with

```
set(opts,'fs',48e3); % Same as opts.fs=48e3
```

`freqrespest(sysobj,...)` with no output argument launches FVTool.

`freqrespest` can also compute the frequency response of double-precision floating filters. Such filters cannot be converted to transfer-function form without introducing significant round off errors which affect the `freqz` frequency response computation. Examples of these kinds of filters include state-space or lattice filters, especially if they are high-order filters.

Examples

Estimate the Frequency Response of Fixed-Point FIR Filter

This example shows to how to estimate the frequency response of a fixed-point FIR filter.

```
firFilt = design(fdesign.lowpass(.4,.5,1,60),'equiripple','Systemobject',true);
```

```
dataIn = fi(randn(16,15),1,16,15);
dataOut = firFilt(dataIn);
[h,w] = freqrespest(firFilt); % This should be about the same as freqz.
release(firFilt);
```

Continuing with filter `firFilt`, change `FullPrecisionOverride` to `false` and then specify the word lengths and precision (the fraction lengths) applied to the output from internal addition and multiplication operations. After you set the word and fraction lengths, use `freqrespest` to compute the frequency response estimate for the fixed-point filter.

```
firFilt.FullPrecisionOverride = false;
firFilt.ProductDataType = 'Custom';
firFilt.CustomProductDataType = numerictype(1,16,15);
firFilt.AccumulatorDataType = 'Custom';
firFilt.CustomAccumulatorDataType = numerictype(1,16,15);
firFilt.OutputDataType = 'Same as accumulator';
dataOut = firFilt(dataIn);
[h,w] = freqrespest(firFilt,2);
[h2,w2] = freqz(firFilt,512);
plot(w/pi,20*log10(abs([h,h2])))
legend('Frequency response estimated by filtering',...
'Freq. response computed by quantizing coefficients only');
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude (dB)')
```

freqrespopts

Options for filter frequency response analysis

Syntax

```
opts = freqrespopts(H)
```

Description

`opts = freqrespopts(H)` uses the settings in the filter System object, `H`, to create an object, `opts`. This object contains parameters and values for estimating the filter frequency response. You pass `opts` as an input argument to `freqrespest` to specify values for the input parameters.

`freqrespopts` allows you to use the same settings for `freqrespest` with multiple filters without specifying all of the parameters as input arguments to `freqrespest`.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.BiquadFilter
dsp.CoupledAllpassFilter
dsp.FIRFilter
dsp.HighpassFilter
dsp.IIRFilter
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

In addition, dsp.FarrowRateConverter and dsp.FilterCascade support this analysis method.

Examples

Set the Frequency Response Options

This example shows freqrespopts in use for setting options for freqrespest. hd and hd2 are bandpass filters that use different design methods. The opts object makes it easier to set the same conditions for the frequency response estimate in freqrespest.

```
d = fdesign.bandpass('fst1,fp1,fp2,fst2,ast1,ap,ast2',...
0.25,0.3,0.45,0.5,60,0.1,60);
hd = design(d,'butter','SystemObject',true)
```

```
hd = 

  dsp.BiquadFilter with properties:

                 Structure: 'Direct form II'
           SOSMatrixSource: 'Property'
                 SOSMatrix: [18×6 double]
               ScaleValues: [19×1 double]
         InitialConditions: 0
    OptimizeUnityScaleValues: true

  Use get to show all properties
```

```
hd2 = design(d,'cheby2','SystemObject',true)
```

```
hd2 = 

  dsp.BiquadFilter with properties:

                 Structure: 'Direct form II'
           SOSMatrixSource: 'Property'
                 SOSMatrix: [9×6 double]
               ScaleValues: [10×1 double]
         InitialConditions: 0
    OptimizeUnityScaleValues: true
```

```
  Use get to show all properties

opts = freqrespopts(hd)

opts =

  <a href="matlab:helpPopup struct" style="font-weight:bold">struct</a> with fields:

             FreqPoints: 'All'
                   NFFT: 512
    NormalizedFrequency: true
                     Fs: 'Normalized'
          SpectrumRange: 'Half'
               CenterDC: false

opts.NFFT=256; % Same as set(opts,'nfft',256).
opts.NormalizedFrequency=false;
opts.fs=1.5e3;
opts.CenterDC=true

opts =

  <a href="matlab:helpPopup struct" style="font-weight:bold">struct</a> with fields:

             FreqPoints: 'All'
                   NFFT: 256
    NormalizedFrequency: false
                     Fs: 1500
          SpectrumRange: 'Whole'
               CenterDC: true
```

With opts configured as needed, use it as an input argument for freqrespest.

```
[h2,w2]=freqrespest(hd2,20,opts);
[h1,w1]=freqrespest(hd,20,opts);
```

hd = design(d,'freqsamp','SystemObject',true)
hd = design(...,'filterstructure',structure,'SystemObject',true)
hd = design(...,'window',window,'SystemObject',true)
```

Description

`hd = design(d,'freqsamp','SystemObject',true)` designs a frequency-sampled filter specified by the filter specifications object `d`.

`hd = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the filter structure you specify by the `structure` input argument. `structure` is `dffir` by default and can be any one of the following filter structures.

Structure	Description of Resulting Filter Structure
`dffir`	Direct-form FIR filter
`dffirt`	Transposed direct-form FIR filter
`dfsymfir`	Symmetrical direct-form FIR filter
`dfasymfir`	Asymmetrical direct-form FIR filter

`hd = design(...,'window',window,'SystemObject',true)` designs filters using the window specified by `window`. Provide the input argument `window` as

- A character vector for the window type. For example, use `'bartlett'`, or `'hamming'`. See `window` for the full list of windows available or refer to `window` in the *Signal Processing Toolbox User's Guide*.
- A function handle that references the `window` function. When the `window` function requires more than one input, use a cell array to hold the required arguments. The first example shows a cell array input argument.

- The window vector itself.

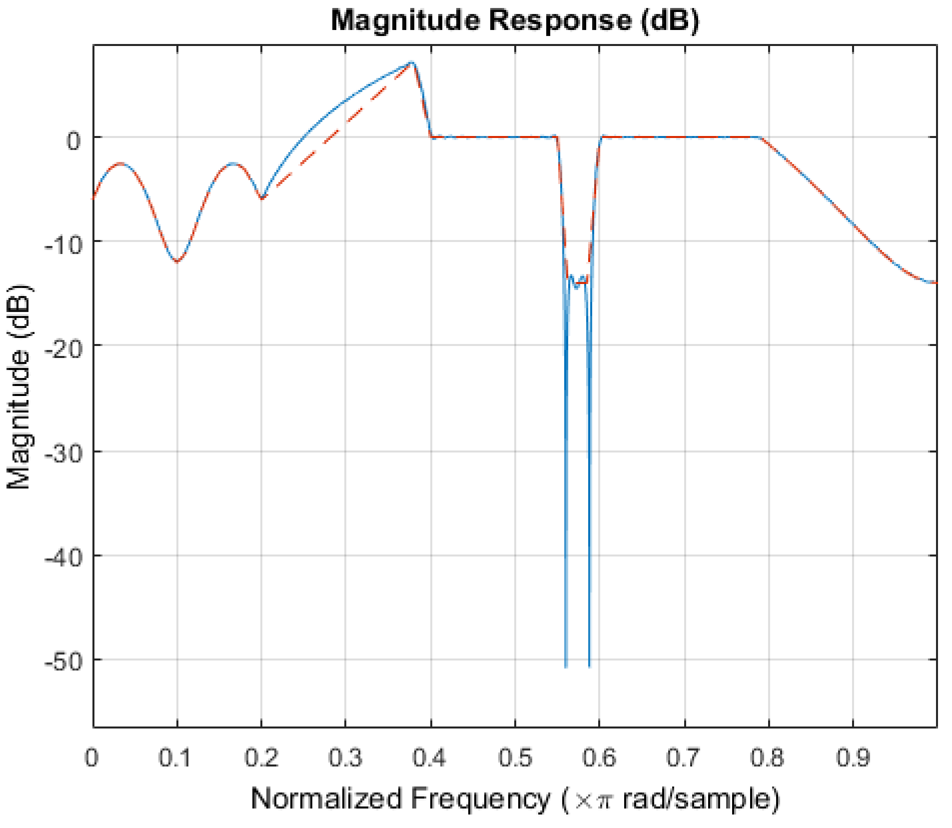
Examples

Design a Frequency Sampled FIR Filter

These examples design FIR filters that have arbitrary magnitude responses. In the first filter, the response has three distinct sections and the resulting filter is real.

The second example creates a complex filter.

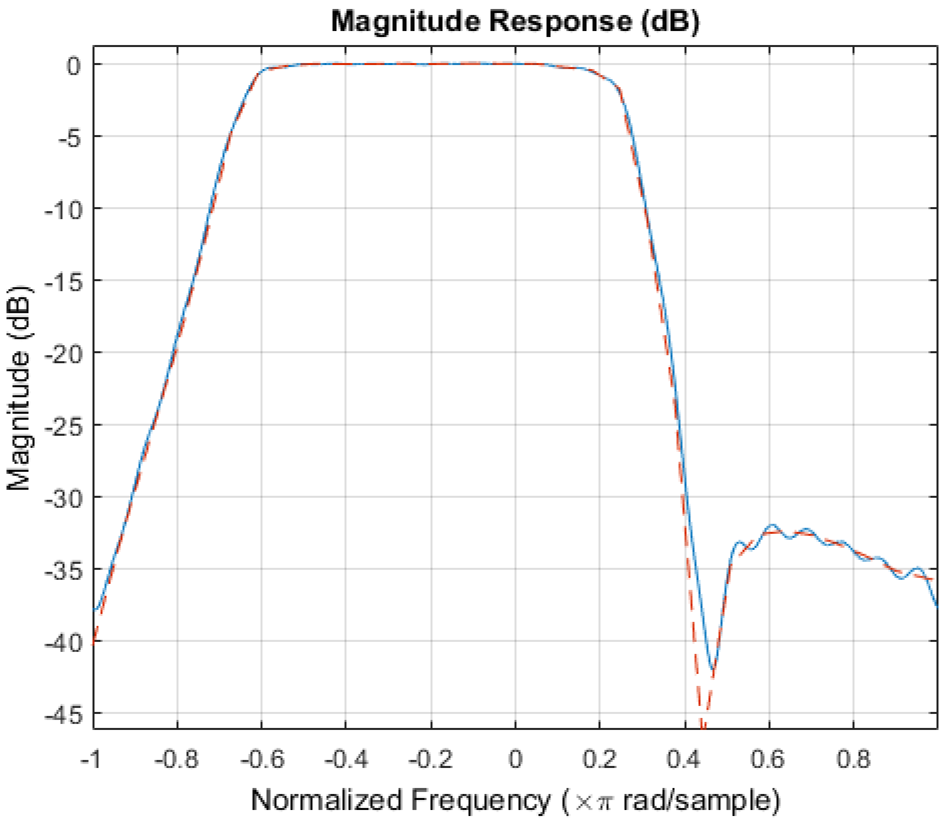
```
b1 = 0:0.01:0.18;
b2 = [.2 .38 .4 .55 .562 .585 .6 .78];
b3 = [0.79:0.01:1];
a1 = .5+sin(2*pi*7.5*b1)/4;    % Sinusoidal response section.
a2 = [.5 2.3 1 1 -.2 -.2 1 1]; % Piecewise linear response section.
a3 = .2+18*(1-b3).^2;          % Quadratic response section.
f = [b1 b2 b3];
a = [a1 a2 a3];
n = 300;
d = fdesign.arbmag('n,f,a',n,f,a); % First specifications object.
hd = design(d,'freqsamp','window',{@kaiser,.5},...
    'SystemObject',true); % Filter.
fvtool(hd)
```



Now design the arbitrary-magnitude complex FIR filter. Recall that vector f contains frequency locations and vector a contains the desired filter response values at the locations specified in f.

```
f = [-1 -.93443 -.86885 -.80328 -.7377 -.67213 -.60656 -.54098 ...
-.47541,-.40984 -.34426 -.27869 -.21311 -.14754 -.081967 ...
-.016393 .04918 .11475,.18033 .2459 .31148 .37705 .44262 ...
 .5082 .57377 .63934 .70492 .77049,.83607 .90164 1];
a = [.0095848 .021972 .047249 .099869 .23119 .57569 .94032 ...
.98084 .99707,.99565 .9958 .99899 .99402 .99978 .99995 .99733 ...
.99731 .96979 .94936,.8196 .28502 .065469 .0044517 .018164 ...
.023305 .02397 .023141 .021341,.019364 .017379 .016061];
n = 48;
d = fdesign.arbmag('n,f,a',n,f,a); % Second spec. object.
```

```
hdc = design(d,'freqsamp','window','rectwin','SystemObject',true); % Filter.
fvtool(hdc)
```



fvtool shows you the response for hdc from -1 to 1 in normalized frequency. design(d,...) returns a complex filter for hdc because the frequency vector includes negative frequency values.

Introduced in R2011a

freqz

Frequency response of filter

Syntax

```
[h,w] = freqz(sysobj)
[h,w] = freqz(sysobj,n)
[h,w] = freqz(sysobj,Name,Value)
freqz(sysobj)
```

Description

`[h,w] = freqz(sysobj)` returns the complex frequency response `h` of the filter System object, `sysobj`. The vector `w` contains the frequencies (in radians) at which the function evaluates the frequency response. The frequency response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[h,w] = freqz(sysobj,n)` returns the complex frequency response of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`freqz` uses the transfer function associated with the filter to calculate the frequency response of the filter with the current coefficient values.

`[h,w] = freqz(sysobj,Name,Value)` returns a frequency response with additional options specified by one or more `Name,Value` pair arguments.

`freqz(sysobj)` uses `fvtool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `sysobj`.

For more information about optional input arguments for `freqz`, refer to `freqz` in Signal Processing Toolbox documentation.

Input Arguments

`sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter

Filter System objects
dsp.VariableBandwidthIIRFilter

dsp.SampleRateConverter is also supported by `freqz`.

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`'double'` | `'single'` | `'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

System Object State	Coefficient Data Type	Rule
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

h

Complex `n`-element frequency response vector. If `n` is not specified, the function uses a default value of 8192.

w

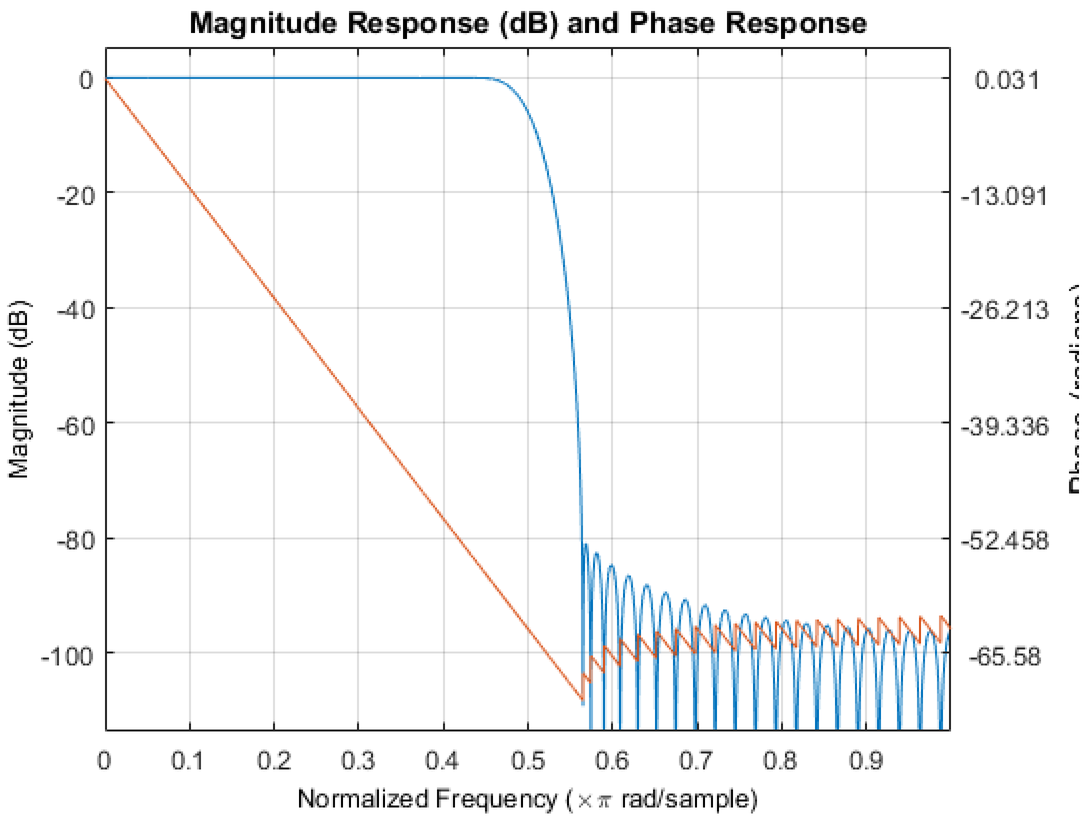
Frequency vector of length `n`, in radians/sample. `w` consists of `n` points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If `n` is not specified, the function uses a default value of 8192.

Examples

Frequency Response of the Filter

This examples plot the frequency response of the lowpass FIR filter using `freqz`.

```
b = fir1(80,0.5,kaiser(81,8));
firFilt = dsp.FIRFilter('Numerator',b);
freqz(firFilt);
```



Tips

There are several ways of analyzing the frequency response of filters. `freqz` accounts for quantization effects in the filter coefficients, but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, refer to function `noisepsd`.

Algorithms

freqz calculates the frequency response for a filter from the filter transfer function $Hq(z)$. The complex-valued frequency response is calculated by evaluating $Hq(e^{j\omega})$ at discrete values of w specified by the syntax you use. The integer input argument n determines the number of equally-spaced points around the upper half of the unit circle at which freqz evaluates the frequency response. The frequency ranges from 0 to π radians per sample when you do not supply a sampling frequency as an input argument. When you supply the scalar sampling frequency fs as an input argument to freqz, the frequency ranges from 0 to fs/2 Hz.

Functions
fvtool

Introduced in R2011a

gain

CIC filter gain

Syntax

```
gain(hs)
gain(hs,j)
```

Description

`gain(hs)` returns the gain of the filter System object `hs`. The function supports the `dsp.CICDecimator` and `dsp.CICInterpolator` filter structures.

When `hs` is a decimator, `gain` returns the gain for the overall CIC decimator.

When `hs` is an interpolator, the CIC interpolator inserts zeros into the input data stream, reducing the filter overall gain by $1/R$, where R is the interpolation factor, to account for the added zero valued samples. Therefore, the gain of a CIC interpolator is $(RM)^N/R$, where N is the number of filter sections and M is the filter differential delay. `gain(hs)` returns this value. The next example presents this case.

`gain(hs,j)` returns the gain of the `j`th section of a CIC interpolation filter. When you omit `j`, `gain` assumes that `j` is 2*N, where N is the number of sections, and returns the gain of the last section of the filter. This syntax does not apply when `hs` is a decimator.

Examples

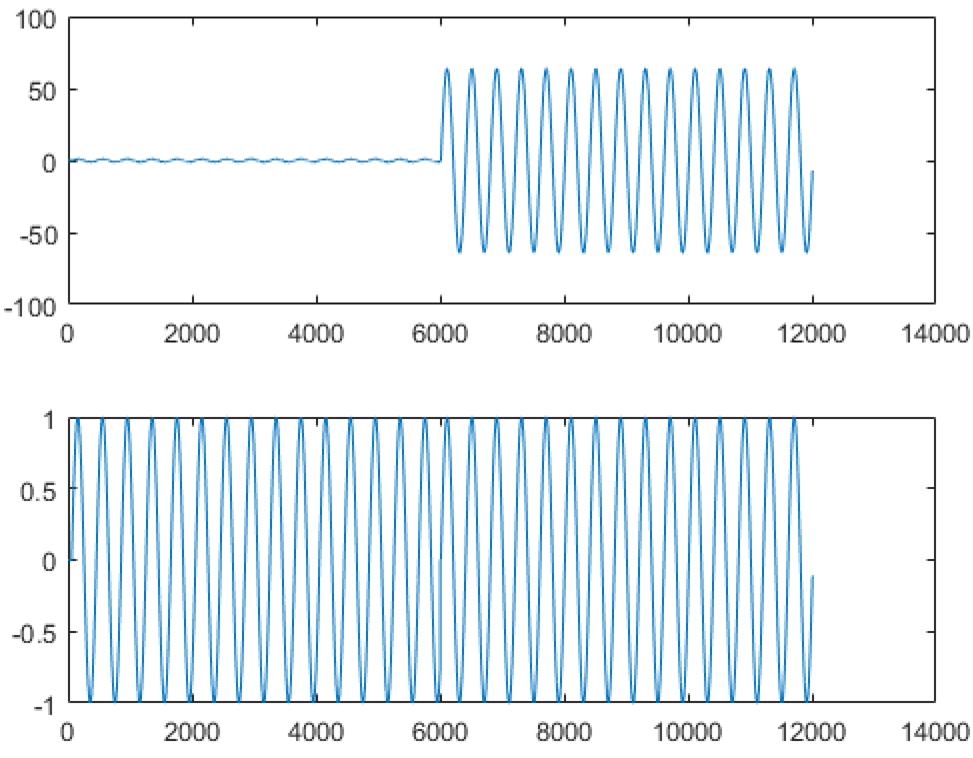
Compare the Performance of Interpolation Filters

To compare the performance of two interpolators, one a CIC filter and the other an FIR filter, use gain to adjust the CIC filter output amplitude to match the FIR filter output amplitude. Start by creating an input data set, a sinusoidal signal x.

```
fs = 1000;          % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
x = x';
```

```
l = 4; % Interpolation factor for FIR filter.
d = fdesign.interpolator(l);
firInterp = design(d,'multistage','SystemObject',true);
yfir = firInterp(x);

r = 4; % Interpolation factor for the CIC filter.
d = fdesign.interpolator(r,'cic');
cicInterp = design(d,'multisection','SystemObject',true);
ycic = cicInterp(x);
gaincic = gain(cicInterp);
subplot(211);
plot([yfir; double(ycic)]);
subplot(212)
plot([yfir; double(ycic)/gain(cicInterp)]);
```



After correcting for the gain induced by the CIC interpolator, the second subplot shows that the FIR filter and the CIC filter provide nearly identical interpolation.

`scale`

Introduced in R2011a

grpdelay

Group delay response of discrete-time filter System object

Syntax

```
[gd,w] = grpdelay(sysobj)
[gd,w] = grpdelay(sysobj,n)
[gd,w] = grpdelay(sysobj,Name,Value)
grpdelay(sysobj)
```

Description

`[gd,w] = grpdelay(sysobj)` returns the group delay `gd` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the group delay is evaluated. The group delay is defined as:

$$-\frac{d}{dw}(angle(w))$$

The group delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[gd,w] = grpdelay(sysobj,n)` returns the group delay of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[gd,w] = grpdelay(sysobj,Name,Value)` returns the group delay with additional options specified by one or more `Name,Value` pair arguments.

`grpdelay(sysobj)` plots the group delay of the filter System object `sysobj` in the `fvtool`.

For information on more input options, refer to `grpdelay` in Signal Processing Toolbox documentation.

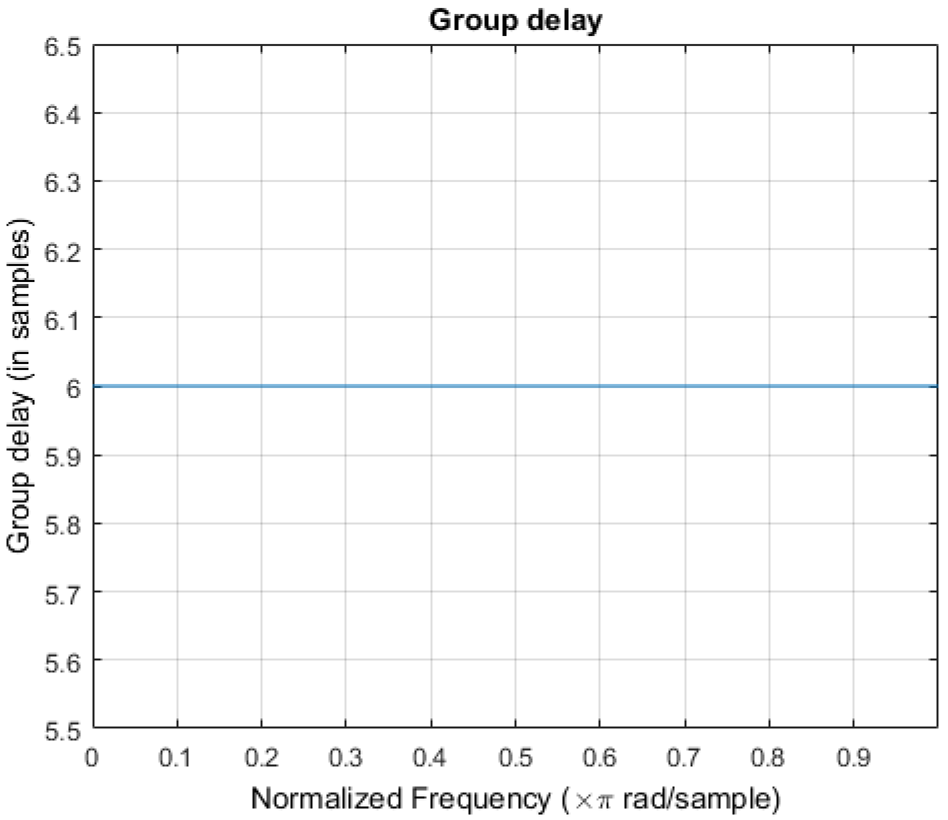
Examples

Group Delay of a Discrete-Time Multirate Filter

```
CICComp = dsp.CICCompensationDecimator;
```

`grpdelay` computes the group delay of the filter and displays it using fvtool

```
grpdelay(CICComp);
```



Input Arguments

sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter

Filter System objects
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:

`‘double’ | 'single' | 'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depend on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

gd

Group delay vector of length n. If n is not specified, the function uses a default value of 8192.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If n is not specified, the function uses a default value of 8192.

help

Help for design method with filter specification

Syntax

`help(d,'designmethod')`

Description

`help(d,'designmethod')` displays help in the command window for the design algorithm `designmethod` for the current specifications of the filter specification object `d`. `designmethod` must be one of the design algorithms returned by `designmethods` for `d`, the design object.

Examples

Get Help for Designing Butterworth Filters

Get specific help for designing lowpass Butterworth filters.

The first lowpass filter uses the default specification 'Fp,Fst,Ap,Ast' and returns help text specific to the specification.

```
d = fdesign.lowpass;
designmethods(d,'Systemobject',true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

```
help(d,'butter')

 DESIGN Design a Butterworth IIR filter.
    HD = DESIGN(D, 'butter') designs a Butterworth filter specified by the
    FDESIGN object D, and returns the DFILT/MFILT object HD.

    HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD,
    using a System object instead of a DFILT/MFILT object.

    HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
    structure STRUCTURE.  STRUCTURE is 'df2sos' by default and can be any of
    the following:

    'df1sos'
    'df2sos'
    'df1tsos'
    'df2tsos'
    'cascadeallpass'
    'cascadewdfallpass'

    Some of the listed structures may not be supported by System object
    filters. Type validstructures(D, 'butter', 'SystemObject', true) to
    get a list of structures supported by System objects.

    HD = DESIGN(..., 'MatchExactly', MATCH) designs a Butterworth filter
    and matches the frequency and magnitude specification for the band
    MATCH exactly.  The other band will exceed the specification.  MATCH
    can be 'stopband' or 'passband' and is 'stopband' by default.

    HD = DESIGN(..., 'SOSScaleNorm', NORM) designs an SOS filter and scales
    the coefficients using the P-Norm NORM. NORM can be either a
    discrete-time-domain norm or a frequency-domain norm. Valid time-domain
    norms are 'l1','l2', and 'linf'. Valid frequency-domain norms are
    'L1','L2', and 'Linf'. Note that L2-norm is equal to l2-norm
    (Parseval's theorem) but the same is not true for other norms.

    The different norms can be ordered in terms of how stringent they are
    as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'.
    Using the most stringent scaling, 'l1', the filter is the least prone
    to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is
    the most commonly used scaling in practice.

    Scaling is turned off by default, which is equivalent to setting
```

```
SOSScaleNorm = ''.

HD = DESIGN(..., 'SOSScaleOpts', OPTS) designs an SOS filter and scales
the coefficients using an FDOPTS.SOSSCALING object OPTS.  Scaling options
are:
Property                Default     Description/Valid values
---------               -------     ------------------------
'sosReorder'            'auto'      Reorder section prior to scaling.
                                    {'auto','none','up','down','lowpass',
                                     'highpass','bandpass','bandstop'}
'MaxNumerator'          2           Maximum value for numerator coefficients
'NumeratorConstraint'   'none'      {'none', 'unit', 'normalize','po2'}
'OverflowMode'          'wrap'      {'wrap','saturate'}
'ScaleValueConstraint'  'unit'      {'unit','none','po2'}
'MaxScaleValue'         'Not used'  Maximum value for scale values

When sosReorder is set to 'auto', the sections will be automatically
reordered depending on the response type of the design (lowpass,
highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint'
is set to something other than 'unit'. If 'MaxScaleValue' is set to a
number, the 'ScaleValueConstraint' will be changed to 'none'. Further,
if SOSScaleNorm is off (as it is by default), then all the SOSScaleOpts
will be ignored.

For more information about P-Norm and scaling options see help for DFILT\SCALE.

% Example #1 - Compare passband and stopband MatchExactly.
   h     = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
   Hd    = design(h, 'butter', 'MatchExactly', 'passband');
   Hd(2) = design(h, 'butter', 'MatchExactly', 'stopband');

   % Compare the passband edges in FVTool.
   fvtool(Hd);
   axis([.09 .11 -2 0]);
```

Note the discussion of the `MatchExactly` input option. When you use a design object that uses a different specification, such as 'N,F3dB', the help content for the butter design method changes.

In this case, the MatchExactly option does not appear in the help because it is not an available input argument for the specification 'N,F3dB'.

```
d = fdesign.lowpass('N,F3dB')
```

```
d = 

  lowpass with properties:

               Response: 'Lowpass'
          Specification: 'N,F3dB'
            Description: {2×1 cell}
    NormalizedFrequency: 1
            FilterOrder: 10
                   F3dB: 0.5000
```

```
designmethods(d,'Systemobject',true)
```

```
Design Methods that support System objects for class fdesign.lowpass (N,F3dB):

butter
maxflat
```

```
help(d,'butter')
```

```
 DESIGN Design a Butterworth IIR filter.
    HD = DESIGN(D, 'butter') designs a Butterworth filter specified by the
    FDESIGN object D, and returns the DFILT/MFILT object HD.

    HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD,
    using a System object instead of a DFILT/MFILT object.

    HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
    structure STRUCTURE.  STRUCTURE is 'df2sos' by default and can be any of
    the following:

    'df1sos'
    'df2sos'
    'df1tsos'
    'df2tsos'
    'cascadeallpass'
    'cascadewdfallpass'
```

```
Some of the listed structures may not be supported by System object
filters. Type validstructures(D, 'butter', 'SystemObject', true) to
get a list of structures supported by System objects.

HD = DESIGN(..., 'SOSScaleNorm', NORM) designs an SOS filter and scales
the coefficients using the P-Norm NORM. NORM can be either a
discrete-time-domain norm or a frequency-domain norm. Valid time-domain
norms are 'l1','l2', and 'linf'. Valid frequency-domain norms are
'L1','L2', and 'Linf'. Note that L2-norm is equal to l2-norm
(Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are
as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'.
Using the most stringent scaling, 'l1', the filter is the least prone
to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is
the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting
SOSScaleNorm = ''.

HD = DESIGN(..., 'SOSScaleOpts', OPTS) designs an SOS filter and scales
the coefficients using an FDOPTS.SOSSCALING object OPTS.  Scaling options
are:
Property                Default     Description/Valid values
---------               -------     ------------------------
'sosReorder'            'auto'      Reorder section prior to scaling.
                                    {'auto','none','up','down','lowpass',
                                     'highpass','bandpass','bandstop'}
'MaxNumerator'          2           Maximum value for numerator coefficients
'NumeratorConstraint'   'none'      {'none', 'unit', 'normalize','po2'}
'OverflowMode'          'wrap'      {'wrap','saturate'}
'ScaleValueConstraint'  'unit'      {'unit','none','po2'}
'MaxScaleValue'         'Not used'  Maximum value for scale values

When sosReorder is set to 'auto', the sections will be automatically
reordered depending on the response type of the design (lowpass,
highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint'
is set to something other than 'unit'. If 'MaxScaleValue' is set to a
number, the 'ScaleValueConstraint' will be changed to 'none'. Further,
if SOSScaleNorm is off (as it is by default), then all the SOSScaleOpts
will be ignored.
```

```
For more information about P-Norm and scaling options see help for DFILT\SCALE.

% Example #1 - Design a lowpass Butterworth filter in the DF2TSOS structure.

Introduced in R2011a

ifir

Interpolated FIR filter design

Syntax

```
[h,g] = ifir(l,type,f,dev)
[h,g,d] = ifir(l,type,f,dev)
[...] = ifir(...,str)
```

Description

`[h,g] = ifir(l,type,f,dev)` designs a periodic filter $h(z^{l})$, where `l` is the interpolation factor. It also finds an image-suppressor filter `g(z)`, such that the cascade of the two filters represents the optimal minimax FIR approximation of the desired response. This response is specified by `type`, with band edge frequencies contained in vector `f`. This is done while not exceeding the maximum deviations or ripples (linear) specified in vector `dev`.

When `type` is set to `'low'`, the filter design is a lowpass design. When `type` is set to `'high'`, the filter design is a highpass design. `f` is a two-element vector with passband and stopband edge frequency values. For narrowband lowpass filters and wideband highpass filters, `l×f(2)` is less than `1`. For wideband lowpass filters and narrowband highpass filters, specify `f` so that `l×(1–f(1))` is less than `1`.

`dev` is a two-element vector that contains the peak ripple or deviation (in linear units) allowed for both the passband and the stopband.

The `ifir` design algorithm achieves an efficient design in the sense that it reduces the total number of multipliers required. To do this, the design problem is broken into two stages. In the first stage, the filter is upsampled to achieve the stringent specifications without using many multipliers. In the second stage, the filter removes the images created when upsampling the previous filter.

`[h,g,d] = ifir(l,type,f,dev)` returns a delay `d` that is connected in parallel with the cascade of $h(z^{l})$ and `g(z)` for both wideband lowpass and highpass filters. This is necessary to obtain the desired response.

[...] = ifir(...,str) uses str to choose the algorithm level of optimization used. Possible values for str are 'simple', 'intermediate' (default) or 'advanced'. str provides for a tradeoff between design speed and filter order optimization. The 'advanced' option can result in substantial filter order reduction, especially for g(z).

Examples

Narrowband lowpass design using an interpolation factor of 6

This example shows how to use the function ifir to design a narrowband lowpass filter.

```
[h,g]=ifir(6,'low',[.12 .14],[.01 .001]);
H = dsp.FIRFilter('Numerator',h);

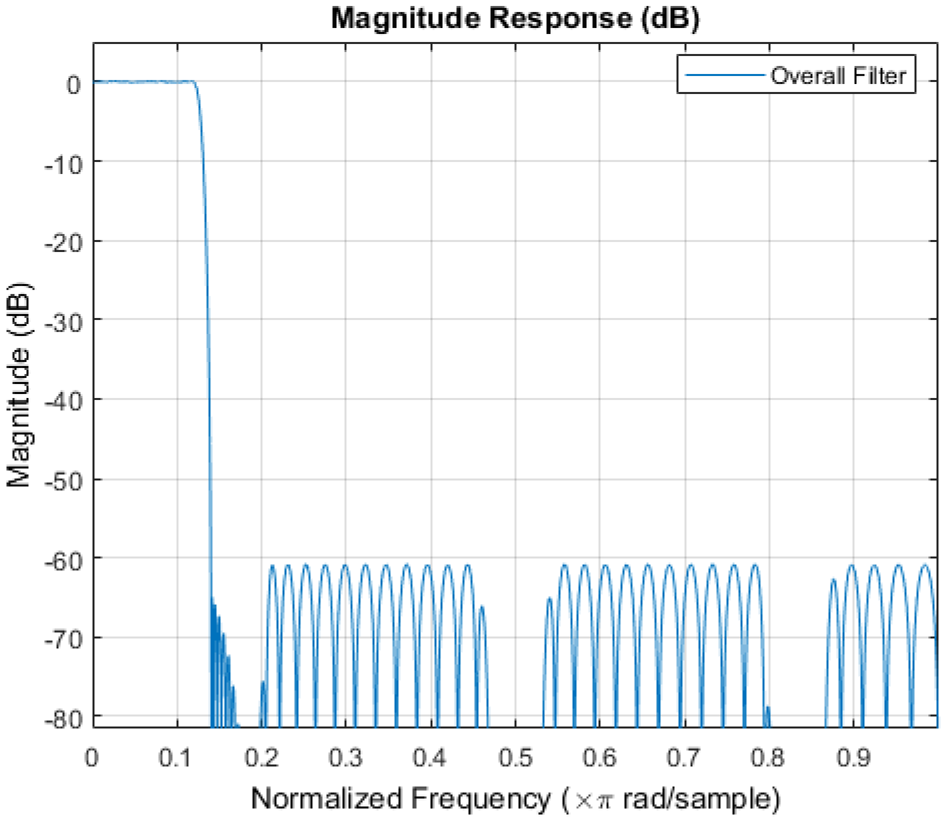
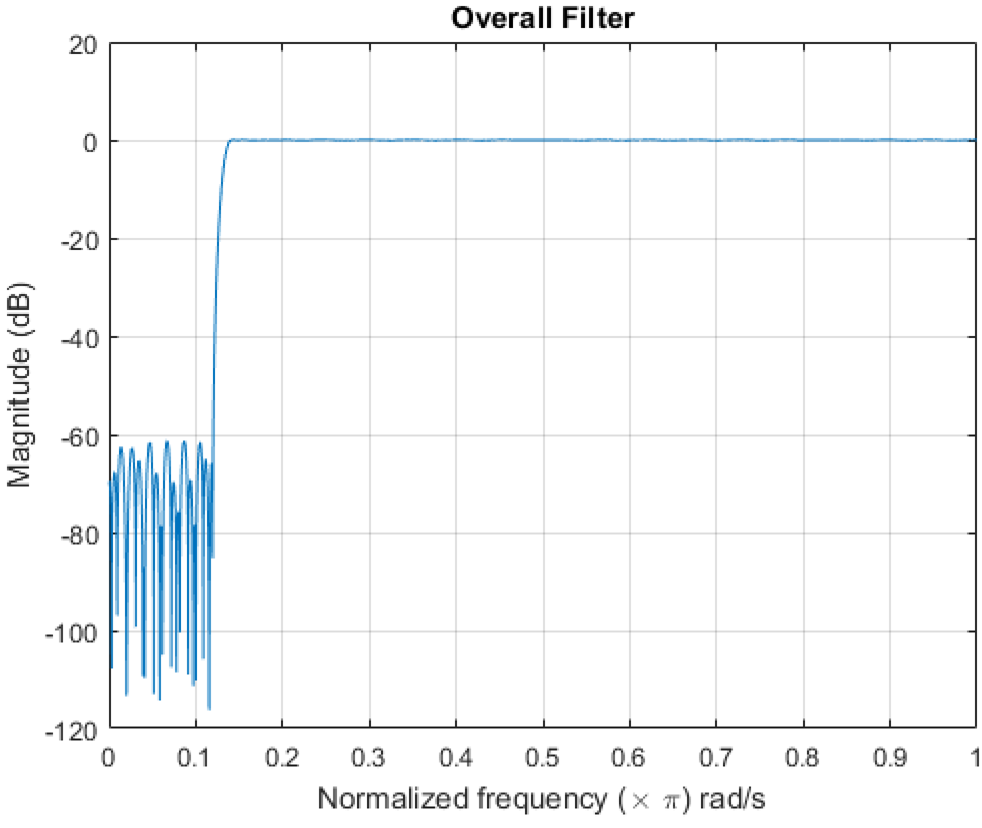
Normalized Frequency (×π rad/sample)



Wideband highpass design using an interpolation factor of 6

This example shows how to use `ifir` to design a wideband highpass filter.

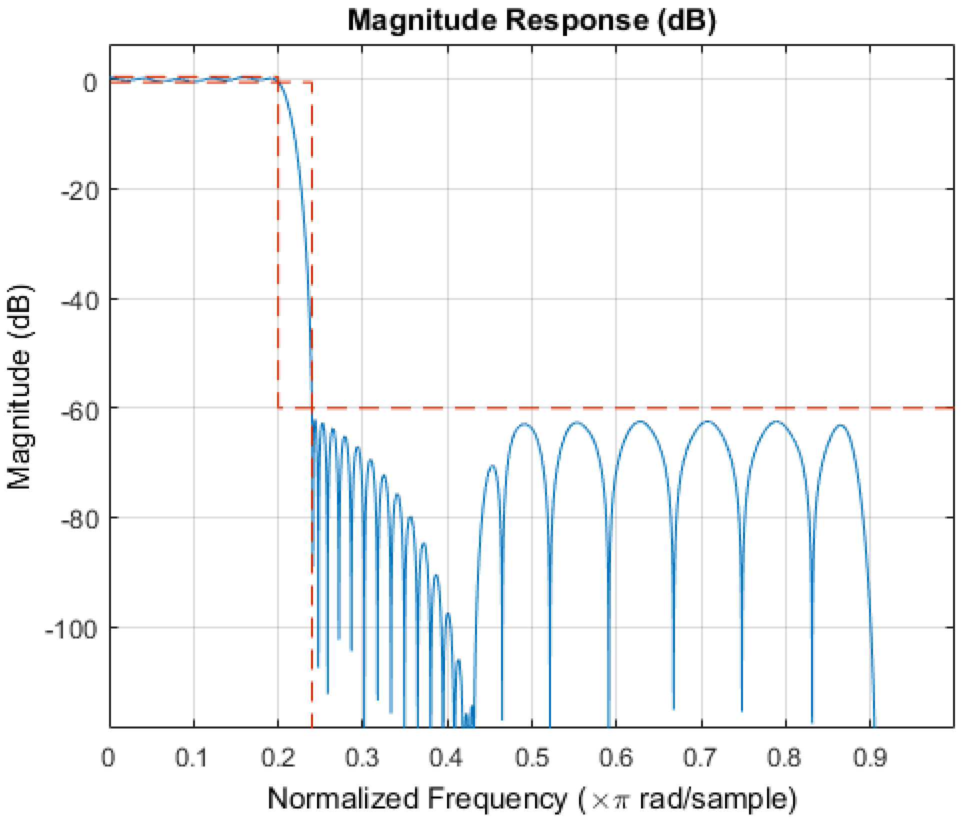
```
[h,g,d]=ifir(6,'high',[.12 .14],[.001 .01]);
H = dsp.FIRFilter('Numerator',h); G = dsp.FIRFilter('Numerator',g);
b1 = cascade(H,G);                % Branch 1
b2 = dsp.FIRFilter('Numerator',d); % Branch 2
Hoverall = freqz(b1) + freqz(b2); % Overall wideband highpass
plot(linspace(0,1,length(Hoverall)),20*log10(abs(Hoverall)))
xlabel('Normalized frequency (\times \pi) rad/s')
ylabel('Magnitude (dB)')
title('Overall Filter');
grid on
```



Design a cascade of lowpass filters

This example shows how to use `fdesign.lowpass` to design a cascade of lowpass filters. After designing the filter, use `fvtool` to plot the response curve.

```
fpass = 0.2;
fstop = 0.24;
d1 = fdesign.lowpass(fpass, fstop);
lowpassCascade = design(d1,'ifir','Systemobject',true);
fvtool(lowpassCascade)
```



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

Introduced in R2011a

iirbpc2bpc

Transform IIR complex bandpass filter to IIR complex bandpass filter with different characteristics

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations, W_{t1}, and W_{t2} respectively. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

Examples

Shift Complex Bandpass

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex passband from 0.25π to 0.75π.

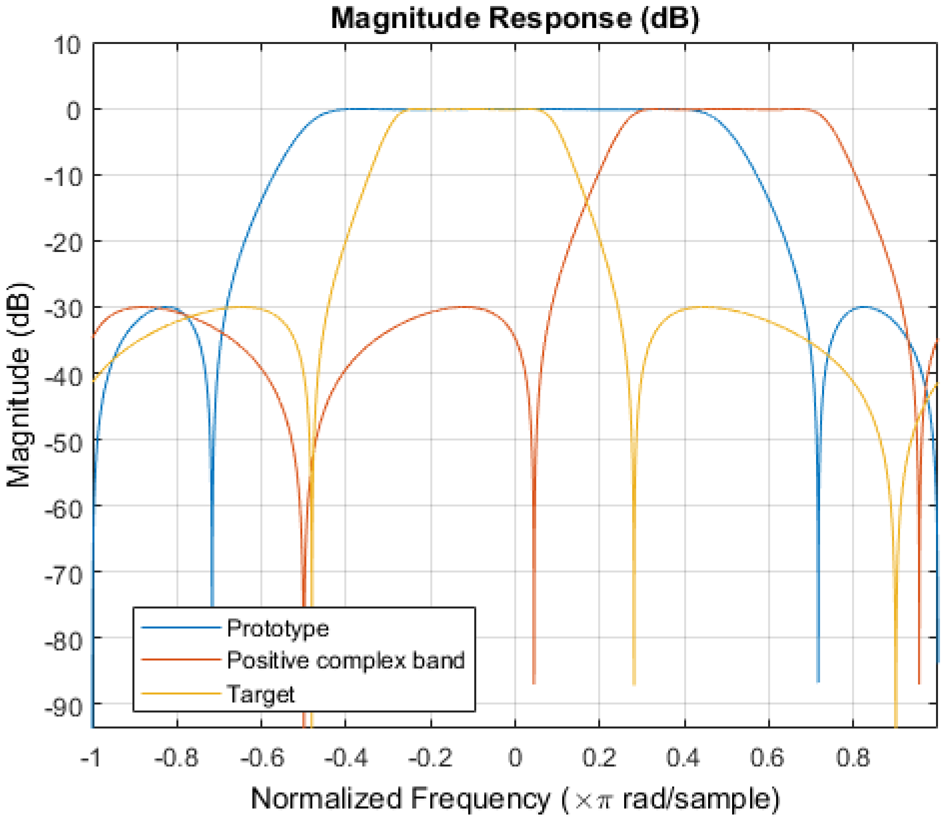
```
[bc,ac] = iirlp2bpc(b,a,0.5,[0.25 0.75]);
```

Move the bandpass to between –0.3π and 0.1π.

```
[num,den] = iirbpc2bpc(bc,ac,[0.25 0.75],[-0.3 0.1]);
```

Compare the three filters in FVTool.

```
hvft = fvtool(b,a,bc,ac,num,den);
legend(hvft,'Prototype','Positive complex band','Target')
```



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

iircomb

IIR comb notch or peak filter

Syntax

```
[num,den] = iircomb(n,bw)
[num,den] = iircomb(n,bw,ab)
[num,den] = iircomb(...,'type')
```

Description

`[num,den] = iircomb(n,bw)` returns a digital notching filter with order `n` and with the width of the filter notch at -3 dB set to `bw`, the filter bandwidth. The filter order must be a positive integer. `n` also defines the number of notches in the filter across the frequency range from 0 to 2π — the number of notches equals `n`+1.

For the notching filter, the transfer function takes the form

$$H(z) = b\frac{1-z^{-n}}{1-\alpha z^{-n}}$$

where a and b are the positive scalars and n is the filter order or the number of notches in the filter minus 1.

The quality factor (Q factor) q for the filter is related to the filter bandwidth by $q = \omega_0/bw$ where ω_0 is the frequency to remove from the signal.

`[num,den] = iircomb(n,bw,ab)` returns a digital notching filter whose bandwidth, `bw`, is specified at a level of -`ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

`[num,den] = iircomb(...,'type')` returns a digital filter of the specified type. The input argument `type` can be either

- `'notch'` to design an IIR notch filter. Notch filters attenuate the response at the specified frequencies. This is the default type. When you omit the `type` input argument, `iircomb` returns a notch filter.
- `'peak'` to design an IIR peaking filter. Peaking filters boost the signal at the specified frequencies.

The transfer function for peaking filters is

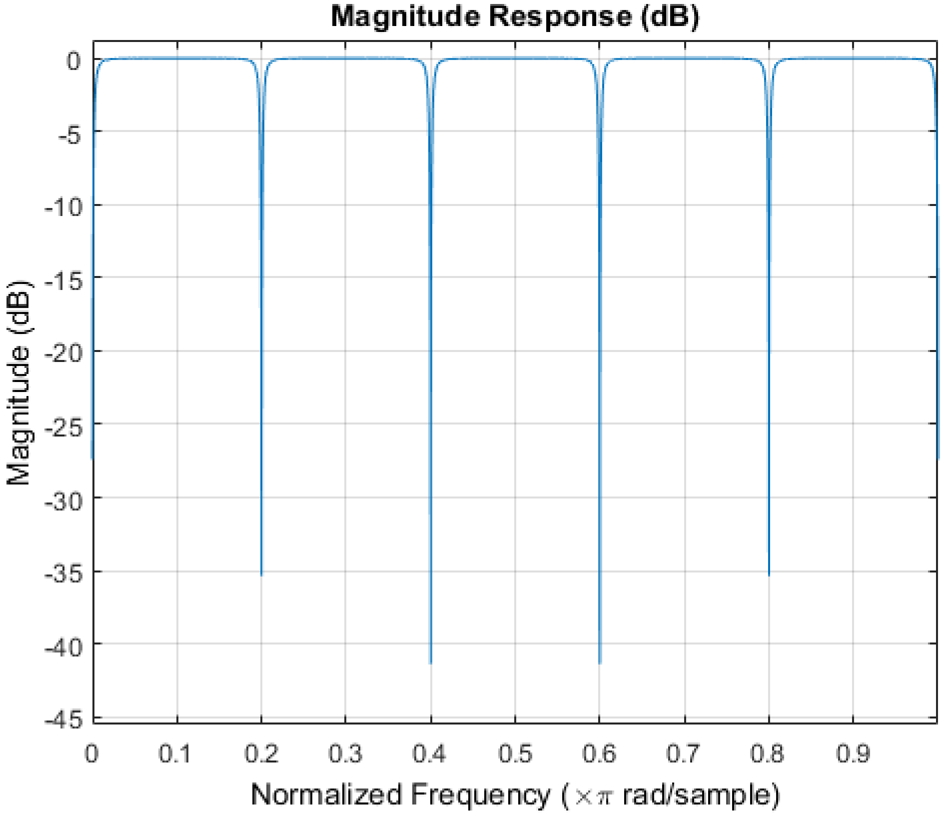
$$H(z) = b\frac{1 - z^{-n}}{1 + az^{-n}}$$

Examples

Design an IIR Notch Filter Using iircomb

Design and plot an IIR notch filter with 11 notches (equal to filter order plus 1) that removes a 60 Hz tone (f0) from a signal at 600 Hz(fs). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
fs = 600; fo = 60;  q = 35; bw = (fo/(fs/2))/q;
[b,a] = iircomb(fs/fo,bw,'notch'); % Note type flag 'notch'
fvtool(b,a);
```



Using the Filter Visualization Tool (FVTool) generates the following plot showing the filter notches. Note the notches are evenly spaced and one falls at exactly 60 Hz.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

Introduced in R2011a

iirftransf

IIR frequency transformation of filter

Syntax

```
[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)
```

Description

`[OutNum,OutDen] = iirftransf(OrigNum,OrigDen,FTFNum,FTFDen)` returns the numerator and denominator vectors, `OutNum` and `OutDen`, of the target filter, which is the result of transforming the prototype filter specified by the numerator, `OrigNum`, and denominator, `OrigDen`, with the mapping filter given by the numerator, `FTFNum`, and the denominator, `FTFDen`. If the allpass mapping filter is not specified, then the function returns an original filter.

Examples

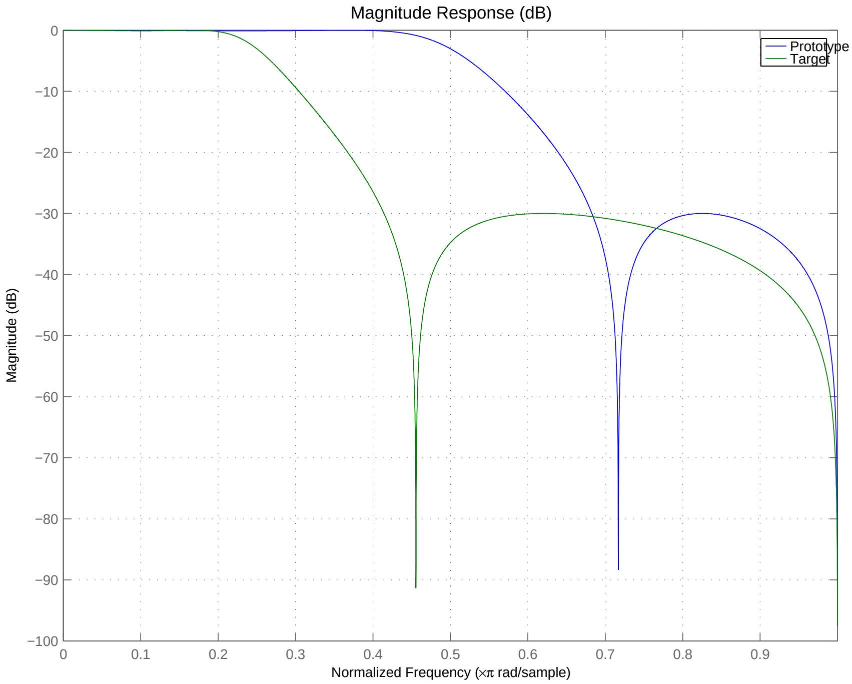
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[num, den] = iirftransf(b, a, AlpNum, AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Here's the comparison between the filters.



Arguments

Variable	Description
OrigNum	Numerator of the prototype lowpass filter
OrigDen	Denominator of the prototype lowpass filter
FTFNum	Numerator of the mapping filter
FTFDen	Denominator of the mapping filter
OutNum	Numerator of the target filter
OutDen	Denominator of the target filter

See Also

zpkftransf

Introduced in R2011a

iirgrpdelay

Optimal IIR filter with prescribed group-delay

Syntax

```
[num,den] = iirgrpdelay(n,f,edges,a)
[num,den] = iirgrpdelay(n,f,edges,a,w)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)
[num,den,tau] = iirgrpdelay(n,f,edges,a,w)
```

Description

`[num,den] = iirgrpdelay(n,f,edges,a)` returns an allpass IIR filter of order `n` (`n` must be even) which is the best approximation to the relative group-delay response described by `f` and `a` in the least-pth sense. `f` is a vector of frequencies between 0 and 1 and `a` is specified in samples. The vector `edges` specifies the band-edge frequencies for multi-band designs. `iirgrpdelay` uses a constrained Newton-type algorithm. Always check your resulting filter using `grpdelay` or `freqz`.

`[num,den] = iirgrpdelay(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point and must be the same length as `f` and `a`). Entries in `w` tell `iirgrpdelay` how much emphasis to put on minimizing the error in the vicinity of each specified frequency point relative to the other points.

`f` and `a` must have the same number of elements. `f` and `a` can contains more elements than the vector `edges` contains. This lets you use `f` and `a` to specify a filter that has any group-delay contour within each band.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius)` returns a filter having a maximum pole radius equal to `radius`, where 0<`radius`<1. `radius` defaults to 0.999999. Filters whose pole radius you constrain to be less than 1.0 can better retain transfer function accuracy after quantization.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p), where p is a two-element vector [pmin pmax], lets you determine the minimum and maximum values of p used in the least-pth algorithm. p defaults to [2 128] which yields filters very similar to the L-infinity, or Chebyshev, norm. pmin and pmax should be even. If p is 'inspect', no optimization occurs. You might use this feature to inspect the initial pole/zero placement.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens) specifies the grid density dens used in the optimization process. The number of grid points is (dens*(n+1)). The default is 20. dens can be specified as a single-element cell array. The grid is not equally spaced.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden) allows you to specify the initial estimate of the denominator coefficients in vector initden. This can be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating initden.

[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau) allows the initial estimate of the group delay offset to be specified by the value of tau, in samples.

[num,den,tau] = iirgrpdelay(n,f,edges,a,w) returns the resulting group delay offset. In all cases, the resulting filter has a group delay that approximates [a + tau]. Allpass filters can have only positive group delay and a non-zero value of tau accounts for any additional group delay that is needed to meet the shape of the contour specified by (f,a). The default for tau is max(a).

Hint: If the zeros or poles cluster together, your filter order may be too low or the pole radius may be too small (overly constrained). Try increasing n or radius.

For group-delay equalization of an IIR filter, compute a by subtracting the filter's group delay from its maximum group delay. For example,

```
[be,ae] = ellip(4,1,40,0.2);
f = 0:0.001:0.2;
g = grpdelay(be,ae,f,2);   % Equalize only the passband.
a = max(g)-g;
[num,den]=iirgrpdelay(8, f, [0 0.2], a);
```

iirlinphase

Quasi-linear phase IIR filter from halfband filter specification

Syntax

```
iirlinFilter= design(d,'iirlinphase','SystemObject',true)
hd = design(...,'filterstructure',structure,'SystemObject',true)
```

Description

`iirlinFilter= design(d,'iirlinphase','SystemObject',true)` designs a quasi-linear phase filter `iirlinFilter` specified by the filter specification object `d`.

`hd = design(...,'`**`filterstructure`**`',structure,'SystemObject',true)` returns a filter with the structure specified by `structure`. By default, the filter structure is a cascade structure. The following table lists all the structures `design` supports for the IIR linear phase response.

Structure	Filter Structure
`cascadeallpass`	Cascade of allpass filters
`cascadewdfallpass`	Cascade of allpass wave digital filters
`iirdecim`	IIR polyphase decimator
`iirwdfdecim`	IIR wave digital filter polyphase decimator
`iirinterp`	IIR polyphase interpolator
`iirwdfinterp`	IIR wave digital filter polyphase interpolator

To get a list of all the structures the specific `fdesign` method supports, type the following in the MATLAB command prompt.

```
d = fdesign.halfband;
strucs = validstructures(d,'SystemObject',true);
```

To get a list of structures `iirlinphase` supports, type the following in the MATLAB command prompt.

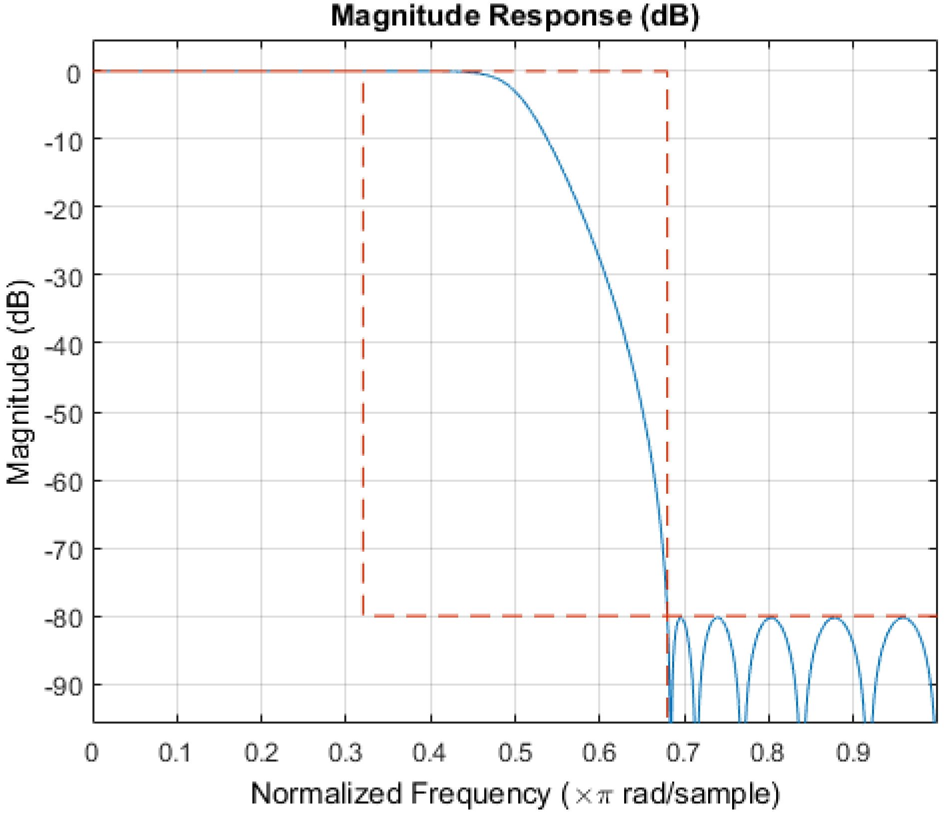
```
iirlinphaseStrucs = strucs.iirlinphase;
```

Examples

Design a Minimum-order Halfband IIR Filter

Design a quasi-linear phase, minimum-order halfband IIR filter with transition width of 0.36 and stopband attenuation of at least 80 dB.

```
tw = 0.36;
ast = 80;
d = fdesign.halfband('tw,ast',tw,ast); % Transition width,
                                       % stopband attenuation.
halfbandIIR = design(d,'iirlinphase','SystemObject',true);
fvtool(halfbandIIR)
```



Notice the characteristic halfband nature of the ripple in the stopband. If you measure the resulting filter, you see it meets the specifications.

```
measure(halfbandIIR)
```

```
ans =

Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.32
3-dB Point       : 0.5
6-dB Point       : 0.51911
Stopband Edge    : 0.68
Passband Ripple  : 4.0866e-08 dB
Stopband Atten.  : 80.2642 dB
Transition Width : 0.36
```

iirlp2bp

Transform IIR lowpass filter to IIR bandpass filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bp(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the “DC Mobility,” meaning that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_ts.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature: the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies.

Examples

Transform Lowpass Filter to Bandpass Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

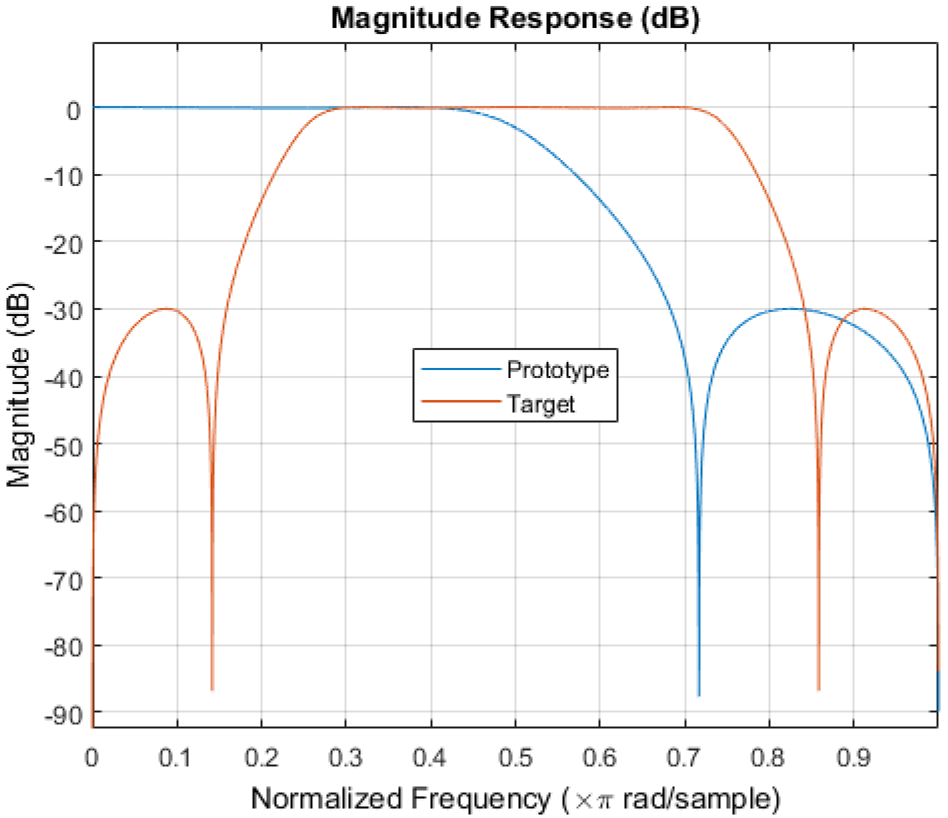
```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a real bandpass filter by placing the cutoff frequencies of the prototype filter at 0.25π and 0.75π.

```
[num,den] = iirlp2bp(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude responses of the filters using FVTool.

```
hvft = fvtool(b,a,num,den);
legend(hvft,'Prototype','Target')
```



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2bpc

IIR lowpass to complex bandpass transformation

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bpc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; for example real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

Examples

Transform Lowpass Filter to Complex Bandpass Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex bandpass filter by placing the cutoff frequencies of the prototype filter at 0.25π and 0.75π.

```

iirlp2bs

Transform IIR lowpass filter to IIR bandstop filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bs(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` of the bandstop digital filter. `AllpassNum` and `AllpassDen` are the vectors of numerator and denominator coefficients of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. It is assumed that W_{t2} is greater than W_{t1}. Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_ts.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

For more details on the lowpass to bandstop frequency transformation, see “Digital Frequency Transformations”.

Examples

Transform Lowpass Filter to Bandstop Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a bandstop filter by placing the cutoff frequencies of the prototype filter at 0.25π and 0.75π.

```
[num,den] = iirlp2bs(b,a,0.5,[0.25 0.75]);
```

```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2bsc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and the denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency -W_o, at the required target frequency location, W_{t1}, and the second feature, originally at +W_o, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

Examples

Transform Lowpass Filter to Complex Bandstop Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

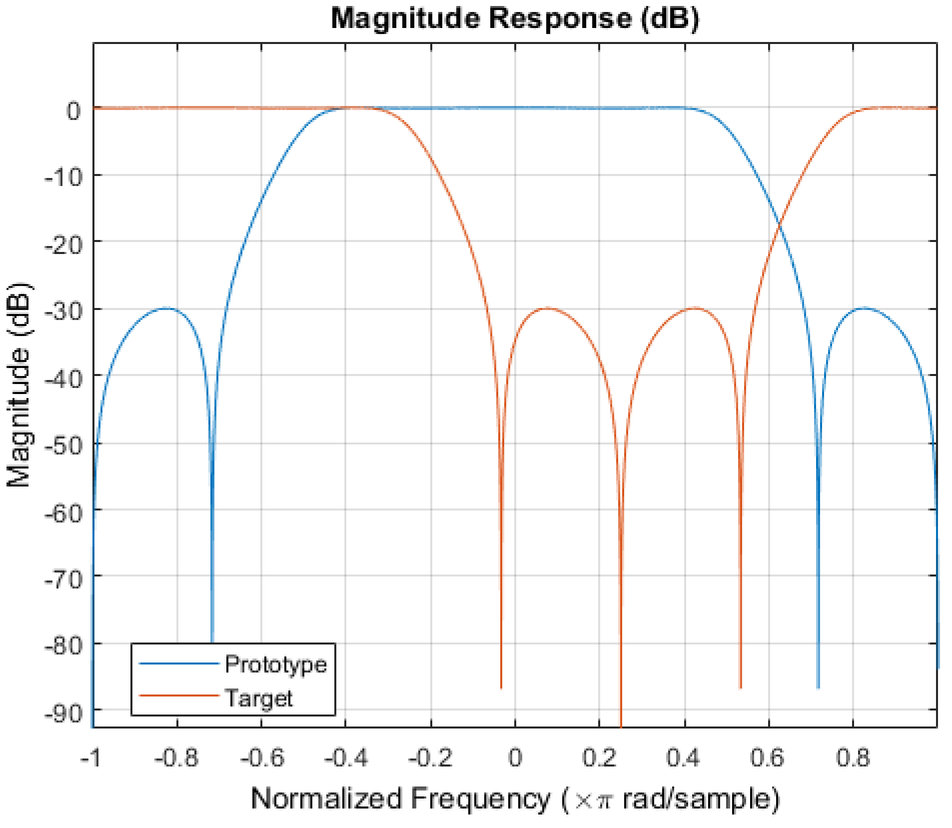
```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex bandstop filter by placing the cutoff frequencies of the prototype filter at –0.25π and 0.75π.

```
[num,den] = iirlp2bsc(b,a,0.5,[-0.25 0.75]);
```

Compare the magnitude responses of the filters using FVTool.

```
fvt = fvtool(b,a,num,den);
legend(fvt,'Prototype','Target')
```



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Variable	Description
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

iirlp2hp

Transform lowpass IIR filter to highpass filter

Syntax

```
[num,den] = iirlp2hp(b,a,wc,wd)
```

Description

`[num,den] = iirlp2hp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2bp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

Examples

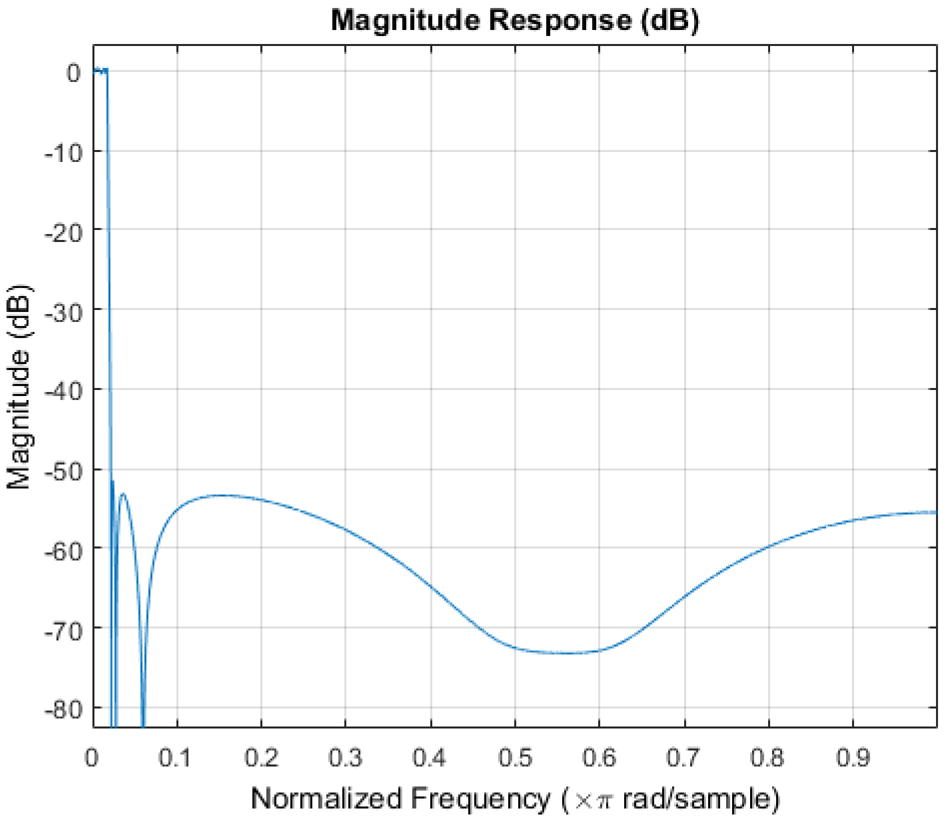
Transform Lowpass Filter to Highpass Filter

This example transforms an IIR filter from lowpass to highpass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter.

Generate a least P-norm optimal IIR lowpass filter with varying attenuation levels in the stopband. Specify a numerator order of 10 and a denominator order of 6. Visualize the magnitude response of the filter.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1], ...
    [0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0], ...
    [1 1 1 1 20 20]);

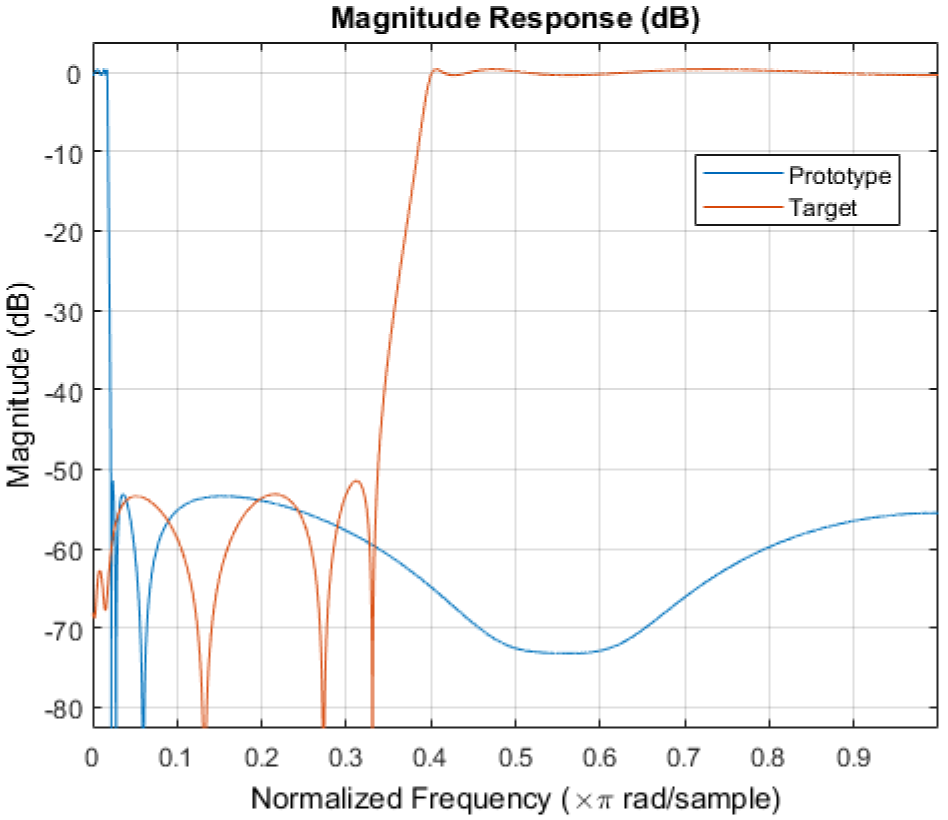
fvtool(b,a)
```



To generate a highpass filter whose passband flattens out at 0.4π rad/sample, select the frequency in the lowpass filter at 0.0175π, the frequency where the passband starts to roll off, and move it to the new location. Compare the magnitude responses of the filters using FVTool.

```
wc = 0.0175;
wd = 0.4;
[num,den] = iirlp2hp(b,a,wc,wd);

hvft = fvtool(b,a,num,den);
legend(hvft,'Prototype','Target')
```



The transition band for the highpass filter is essentially the mirror image of the transition for the lowpass filter from 0.0175π to 0.025π, stretched out over a wider frequency range. In the passbands, the filter share common ripple characteristics and magnitude.

Introduced in R2011a

iirlp2lp

Transform lowpass IIR filter to different lowpass filter

Syntax

```
[num,den] = iirlp2lp(b,a,wc,wd)
```

Description

`[num,den] = iirlp2lp(b,a,wc,wd)` with input arguments `b` and `a`, the numerator and denominator coefficients (zeros and poles) for a lowpass IIR filter, `iirlp2lp` transforms the magnitude response from lowpass to highpass. `num` and `den` return the coefficients for the transformed highpass filter. For `wc`, enter a selected frequency from your lowpass filter. You use the chosen frequency to define the magnitude response value you want in the highpass filter. Enter one frequency for the highpass filter — the value that defines the location of the transformed point — in `wd`. Note that all frequencies are normalized between zero and one. Notice also that the filter order does not change when you transform to a highpass filter.

When you select `wc` and designate `wd`, the transformation algorithm sets the magnitude response at the `wd` values of your bandstop filter to be the same as the magnitude response of your lowpass filter at `wc`. Filter performance between the values in `wd` is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as `wc`. Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version. Without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

Examples

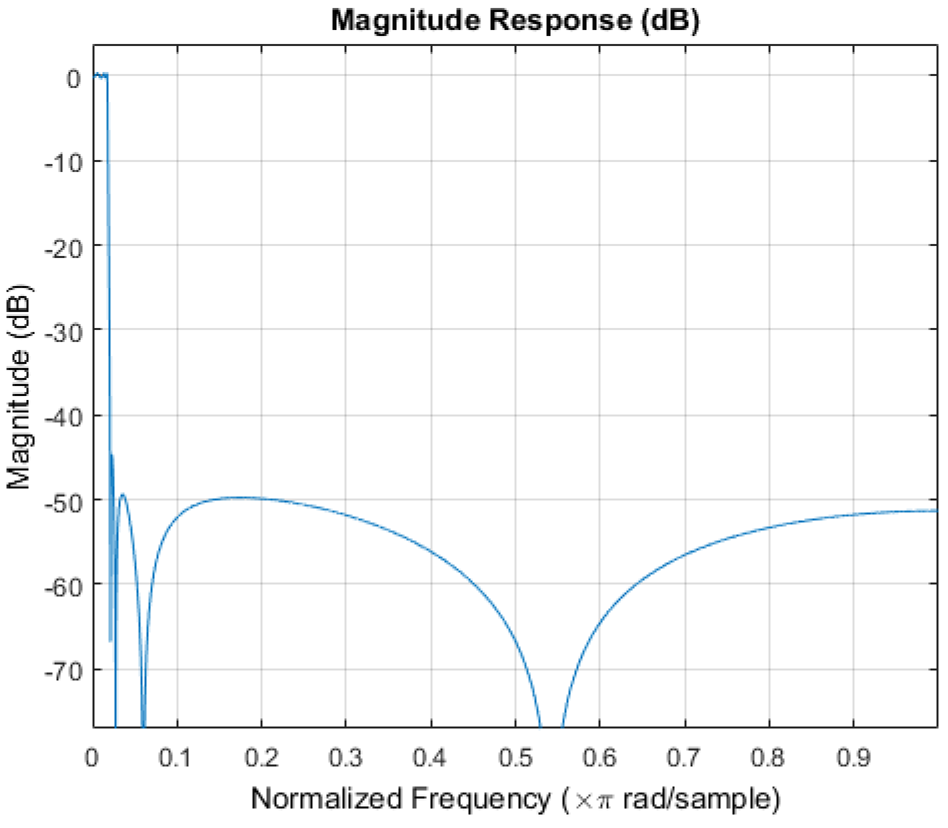
Extend Passband of Lowpass Filter

This example transforms the passband of a lowpass IIR filter by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter.

Generate a least P-norm optimal IIR lowpass filter with varying attenuation levels in the stopband. Specify a numerator order of 10 and a denominator order of 6. Visualize the magnitude response of the filter.

```
[b,a] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1], ...
    [0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0], ...
    [1 1 1 1 10 10]);

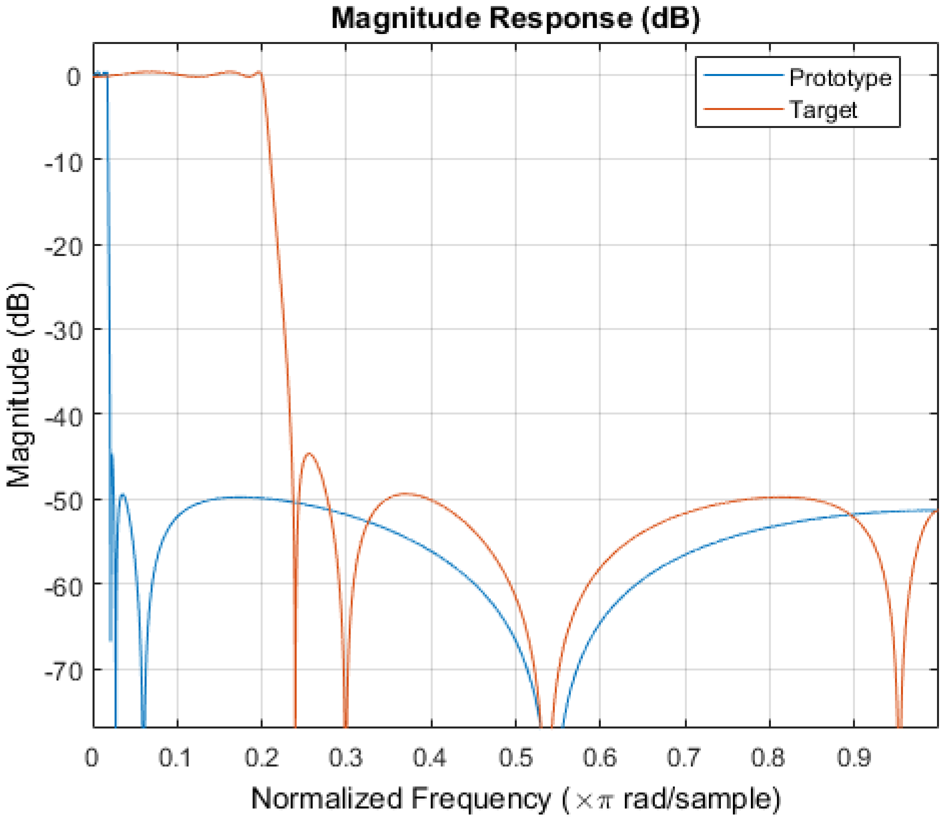
fvtool(b,a)
```



To generate a lowpass filter whose passband extends out to 0.2π rad/sample, select the frequency in the lowpass filter at 0.0175π, the frequency where the passband starts to roll off, and move it to the new location. Compare the magnitude responses of the filters using FVTool.

```
wc = 0.0175;
wd = 0.2;
[num,den] = iirlp2lp(b,a,wc,wd);

hvft = fvtool(b,a,num,den);
legend(hvft,'Prototype','Target')
```



Moving the edge of the passband from π to 0.2π results in a new lowpass filter whose peak response in-band is the same as in the original filter, with the same ripple and the same absolute magnitude. The rolloff is slightly less steep and the stopband profiles are the same for both filters. The new filter stopband is a "stretched" version of the original, as is the passband of the new filter.

`firlp2hp` | `firlp2lp` | `iirlp2bp` | `iirlp2bs` | `iirlp2hp`

Introduced in R2011a

iirlp2mb

Transform IIR lowpass filter to IIR M-band filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2mb(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to real multiple bandpass frequency mapping. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]=iirlp2mb(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter do not change in the target filter. It is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Transform Lowpass Filter to Multiband Filters

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a real multiband filter with two passbands.

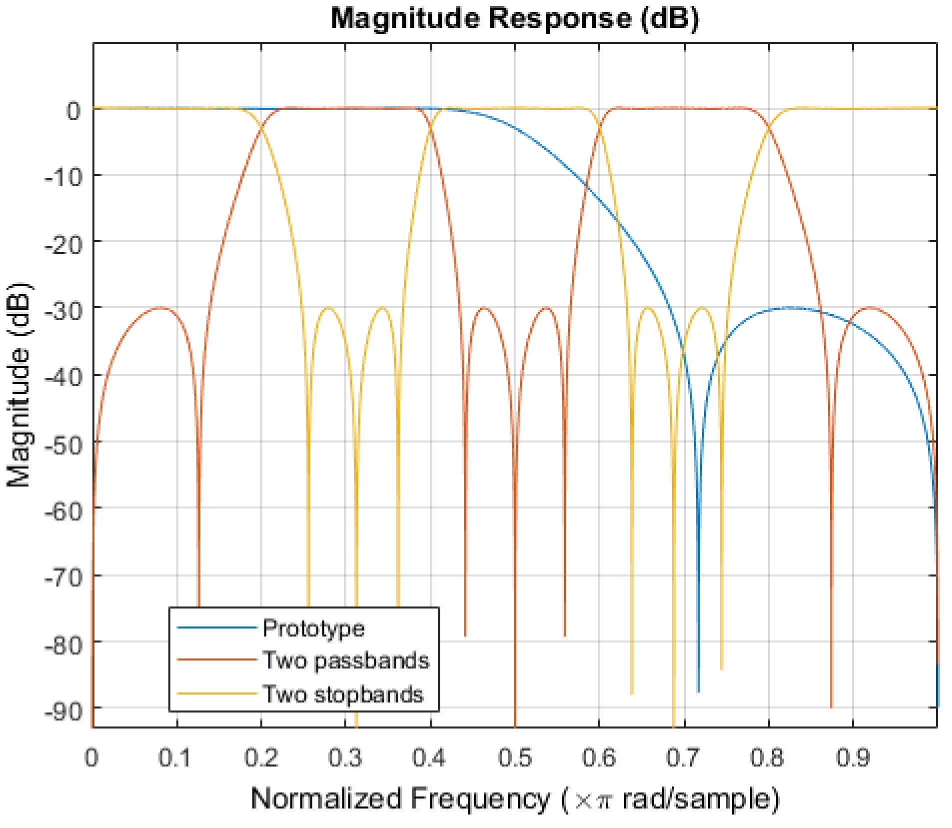
```
[num1,den1] = iirlp2mb(b,a,0.5,[2 4 6 8]/10);
```

Create a real multiband filter with two stopbands.

```
[num2,den2] = iirlp2mb(b,a,0.5,[2 4 6 8]/10, 'stop');
```

Compare the magnitude responses of the filters using FVTool.

```
hvft = fvtool(b,a,num1,den1,num2,den2);
legend(hvft,'Prototype','Two passbands','Two stopbands')
```



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default

Variable	Description
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

iirlp2xc

Transform IIR lowpass filter to IIR complex N-point filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xc(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., a stopband edge, DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Transform Lowpass Filter to IIR Complex N-Point Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about –3 dB at 0.5π rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Transform the lowpass filter to an IIR complex N-point filter. Compare the magnitude responses of the filters using FVTool.

```
[num,den] = iirlp2xc(b,a,[-0.5 0.5],[-0.25 0.25])

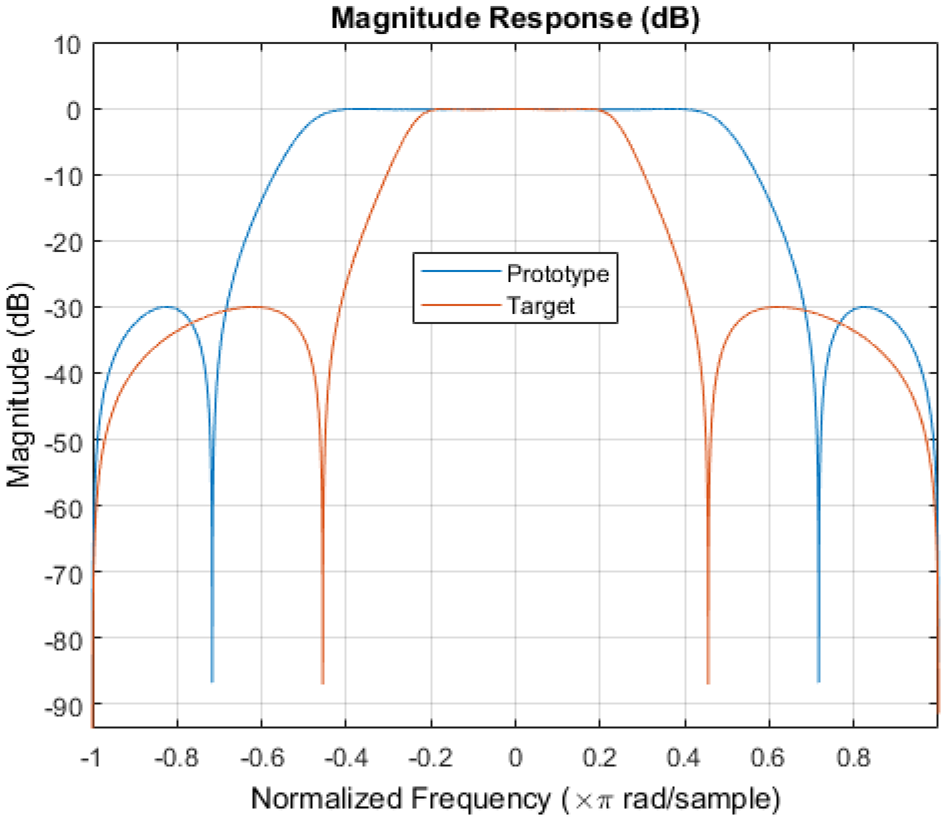
fvt = fvtool(b,a,num,den);
legend(fvt,'Prototype','Target')
```

```
num =

   0.0643 - 0.0000i   0.0464 + 0.0000i   0.0464 + 0.0000i   0.0643 + 0.0000i

den =

   1.0000 + 0.0000i  -1.6918 - 0.0000i   1.2340 + 0.0000i  -0.3207 - 0.0000i
```



The target filter has complex coefficients and is indeed a bandpass filter.

Arguments

Variable	Description
B	Numerator of the prototype lowpass filter.
A	Denominator of the prototype lowpass filter.
Wo	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Variable	Description
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Num	Numerator of the target filter.
Den	Denominator of the target filter.
AllpassNum	Numerator of the mapping filter.
AllpassDen	Denominator of the mapping filter.

iirlp2xn

Transform IIR lowpass filter to IIR real N-point filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirlp2xn(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to real multipoint frequency transformation, where `N` is the number of features being mapped. By default the DC feature is kept at its original location.

`[Num,Den,AllpassNum,AllpassDen]= iirlp2xn(B,A,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Transform Lowpass Filter to IIR Real N-Point Filter

`allpasslp2xn` | `iirftransf` | `zpklp2xn`

Introduced in R2011a

iirlpnorm

Least P-norm optimal IIR filter

Syntax

```
[num,den] = iirlpnorm(n,d,f,edges,a)
[num,den] = iirlpnorm(n,d,f,edges,a,w)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)
[num,den,err] = iirlpnorm(...)
[num,den,err,sos,g] = iirlpnorm(...)
```

Description

`[num,den] = iirlpnorm(n,d,f,edges,a)` returns a filter having a numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-pth sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. An unconstrained quasi-Newton algorithm is employed and any poles or zeros that lie outside of the unit circle are reflected back inside. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the "Hints" on page 5-983 section. Always use `freqz` to check the resulting filter.

`[num,den] = iirlpnorm(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which may exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

is a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p)` where `p` is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `Pmin` and `pmax` should be even. If `p` is `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `(dens*(n+d+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. `initnum` should be of length n+1, and `initden` should be of length d+1. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnorm(...)` returns the least-pth approximation error, `err`.

`[num,den,err,sos,g] = iirlpnorm(...)` returns the second-order section representation in the matrix `sos` and gain `g`. For numerical reasons it may be beneficial to use `sos` and `g` in some cases.

Examples

"Least Pth-Norm Optimal IIR Filter Design"

Design a Lowpass Filter with a Peak of 4.015 dB in Passband

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])

num =

   -0.0128    0.0041   -0.0068    0.0048    0.0056   -0.0001

den =
```

```
  Columns 1 through 7

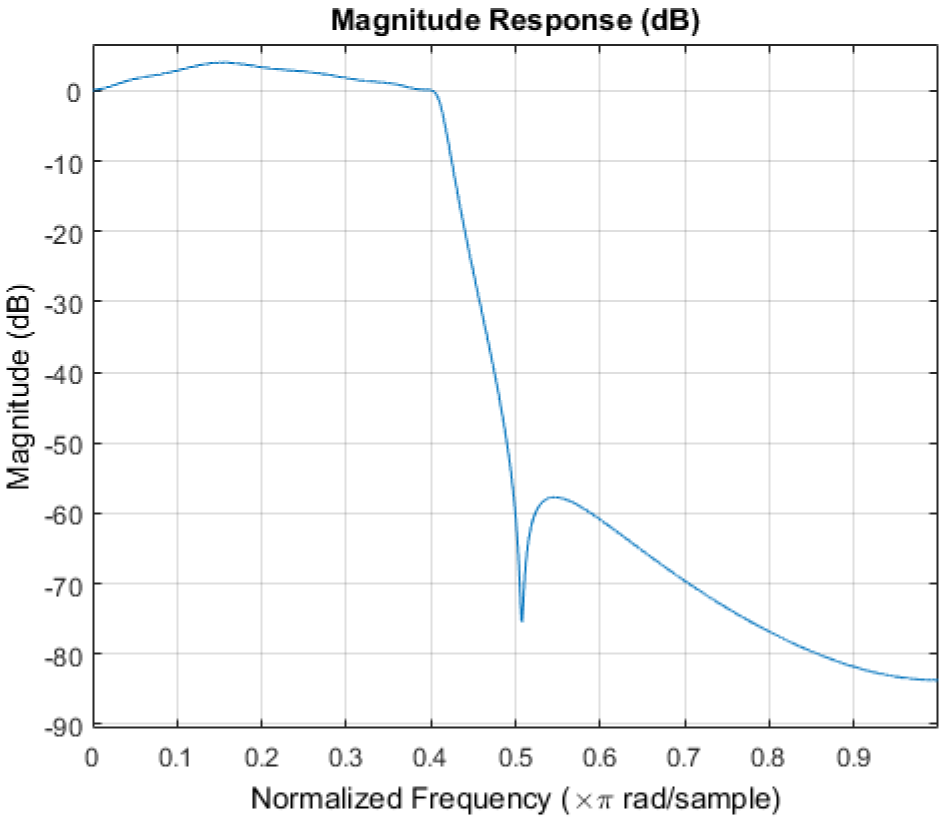
    1.0000   -6.0264   18.6845  -38.7635   59.2365  -69.7345   64.5556

  Columns 8 through 13

  -47.2403   27.1100  -11.9198    3.8290   -0.8143    0.0882
```

Display the magnitude response in fvtool

```
fvtool(num,den)
```



Hints

- This is a weighted least-pth optimization.
- Check the radii and locations of the poles and zeros for your filter. If the zeros are on the unit circle and the poles are well inside the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radii and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weighting in the passband.

`iirlpnormc` | `zplane` | `filter` | `freqz` | `iirgrpdelay`

Introduced in R2011a

iirlpnormc

Constrained least Pth-norm optimal IIR filter

Syntax

```
[num,den] = iirlpnormc(n,d,f,edges,a)
[num,den] = iirlpnormc(n,d,f,edges,a,w)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)
[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)
[num,den] =
iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)
[num,den,err] = iirlpnormc(...)
[num,den,err,sos,g] = iirlpnormc(...)
```

Description

`[num,den] = iirlpnormc(n,d,f,edges,a)` returns a filter having numerator order `n` and denominator order `d` which is the best approximation to the desired frequency response described by `f` and `a` in the least-pth sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. A constrained Newton-type algorithm is employed. `n` and `d` should be chosen so that the zeros and poles are used effectively. See the Hints section. Always check the resulting filter using `fvtool`.

`[num,den] = iirlpnormc(n,d,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `iirlpnormc` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. `f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector `f`. For example,

```
[num,den] = iirlpnormc(5,5,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)` returns a filter having a maximum pole radius of `radius` where 0<`radius`<1. `radius` defaults to 0.999999. Filters that have a reduced pole radius may retain better transfer function accuracy after you quantize them.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)` where `p` is a two-element vector [`pmin pmax`] allows for the specification of the minimum and maximum values of `p` used in the least-pth algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If `p` is `'inspect'`, no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is `(dens*(n+d+1))`. The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnormc(...)` returns the least-Pth approximation error `err`.

`[num,den,err,sos,g] = iirlpnormc(...)` returns the second-order section representation in the matrix SOS and gain G. For numerical reasons you may find SOS and G beneficial in some cases.

Hints

- This is a weighted least-pth optimization.
- Check the radii and location of the resulting poles and zeros.
- If the zeros are all on the unit circle and the poles are well inside of the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radius and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weight in the passband.

- If you reduce the pole radius, you might need to increase the order of the denominator.

The message

```
Poorly conditioned matrix. See the "help" file.
```

indicates that `iirlpnormc` cannot accurately compute the optimization because either:

a The approximation error is extremely small (try reducing the number of poles or zeros — refer to the hints above).

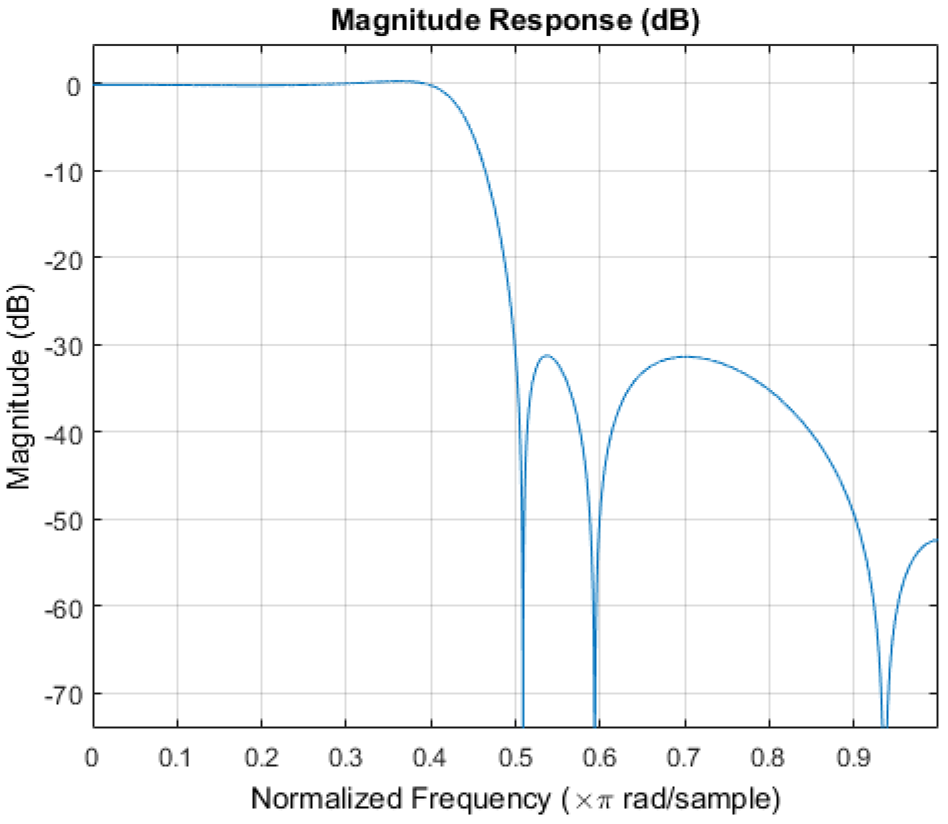
b The filter specifications have huge variation, such as `a=[1 1e9 0 0]`.

Examples

Magnitude Response of Constrained Least Pth-norm Optimal IIR Filter

This example returns a lowpass filter whose pole radius is constrained to 0.8.

```
[b,a,err,s,g] = iirlpnormc(6,6,[0 .4 .5 1],[0 .4 .5 1],...
[1 1 0 0],[1 1 1 1],.8);
fvtool(b,a);
```



The magnitude response shows the lowpass nature of the filter. The pole/zero plot following shows that the poles are constrained to 0.8 as specified in the command.

```
fvtool(b,a,'polezero');
```

iirls

Least-squares IIR filter from specification object

Syntax

```
hd = design(d,'iirls','SystemObject',true)
hd =
design(d,'iirls',designoption,value,designoption,value,...,'SystemObject',true
```

Description

`hd = design(d,'iirls','SystemObject',true)` designs a least-squares filter specified by the filter specification object `d`.

Note The `iirls` algorithm might not be well behaved in all cases. Experience is your best guide to determining if the resulting filter meets your needs. When you use `iirls` to design a filter, review the filter carefully to ensure that it is appropriate for your use.

`hd =`
`design(d,'iirls',designoption,value,designoption,value,...,'SystemObject',true`
returns a least-squares IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `iirls`, refer to the command line help system. For example, to get specific information about using `iirls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'iirls')
```

Examples

Design a Complex Bandpass Filter

Starting from an arbitrary magnitude and phase design object d, generate a complex bandpass filter of order = 5. To make the example a little easier to do, use the default values for F, and H, the frequency vector and the complex desired frequency response.

```
d = fdesign.arbmagnphase('N,F,H',5)
```

```
d = 

  arbmagnphase with properties:

               Response: 'Arbitrary Magnitude and Phase'
          Specification: 'N,F,H'
            Description: {3×1 cell}
    NormalizedFrequency: 1
            FilterOrder: 5
            Frequencies: [1×655 double]
           FreqResponse: [1×655 double]
```

```
fvt = design(d,'iirls','SystemObject',true);
fvtool(fvt,'freq');
legend('Magnitude','phase');
```

iirnotch

Second-order IIR notch filter

Syntax

```
[num,den] = iirnotch(w0,bw)
[num,den] = iirnotch(w0,bw,ab)
```

Description

`[num,den] = iirnotch(w0,bw)` turns a digital notching filter with the notch located at `w0`, and with the bandwidth at the -3 dB point set to `bw`. To design the filter, `w0` must meet the condition 0.0 `w0` 1.0, where 1.0 corresponds to π radians per sample in the frequency range.

The quality factor (Q factor) `q` for the filter is related to the filter bandwidth by `q` `w0/bw` where ω_0 is `w0`, the frequency to remove from the signal.

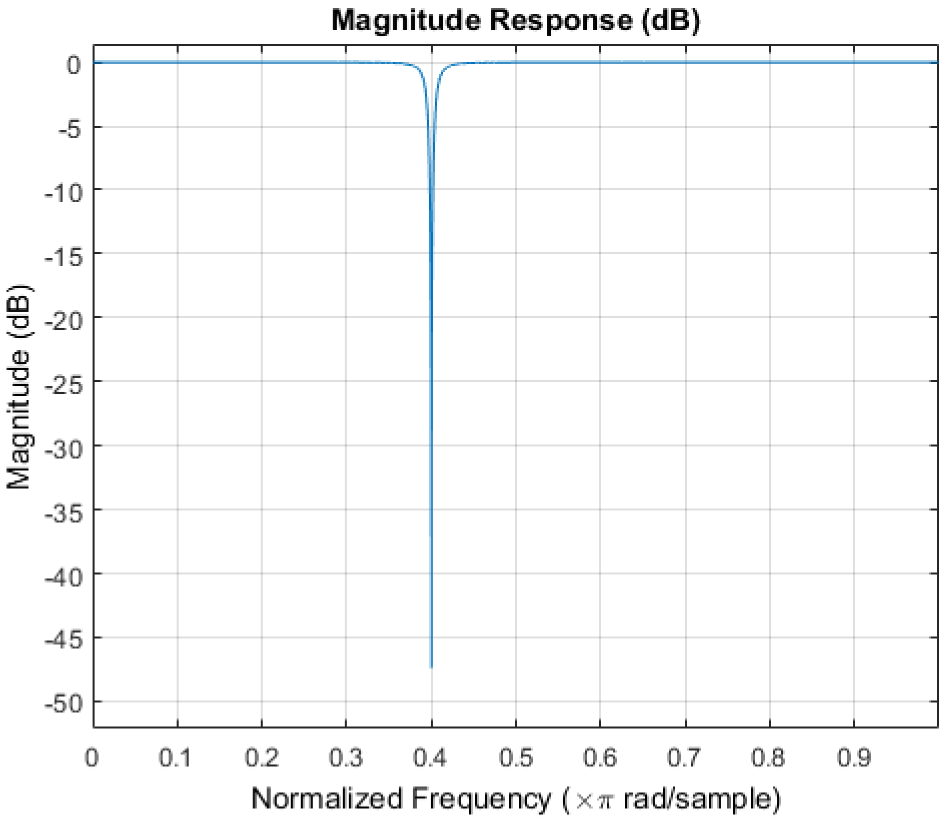
`[num,den] = iirnotch(w0,bw,ab)` returns a digital notching filter whose bandwidth, `bw`, is specified at a level of -`ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB.

Examples

Design an IIR Notch Filter Using iirnotch

Design and plot an IIR notch filter that removes a 60 Hz tone (f0) from a signal at 300 Hz (fs). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth:

```
wo = 60/(300/2);  bw = wo/35;
[b,a] = iirnotch(wo,bw);
fvtool(b,a);
```



The notch filter has the desired bandwidth with the notch located at 60 Hz, or 0.4? radians per sample. Compare this plot to the comb filter plot shown on the reference page for iircomb.

iirparameq

IIR biquad digital parametric equalizer filter

Compatibility

`iirparameq` function will be removed in a future release. Existing code using the function continues to run. For new code, use the `designParamEQ` function from Audio System Toolbox instead.

Syntax

```
[SOS,SV] = iirparameq(N,G,Wo,BW)
```

```
[SOS,SV,B,A] = iirparameq(N,G,Wo,BW)
```

Description

`[SOS,SV] = iirparameq(N,G,Wo,BW)` returns the coefficients of an `Nth` order IIR biquad digital parametric equalizer with gain `G`, center frequency `Wo`, and bandwidth `BW`. The coefficients are returned in a second-order section matrix, `SOS`, and a vector of scale values between each biquad stage, `SV`.

`[SOS,SV,B,A] = iirparameq(N,G,Wo,BW)` additionally returns a matrix of numerator fourth-order sections, B, and a matrix `A` of denominator fourth-order sections, A. These can be used in lieu of a biquad implementation and are useful for the case `Wo = 0.5`.

Examples

Second-order section matrices of the parametric equalizer

Compute the second-order section matrix and scale values of a parametric equalizer.

```
[SOS,SV] = iirparameq(6,5,0.0042,0.0028)
```

```
SOS =
```

```

```

Two Equalizers Centered at Different Frequencies

Design two equalizers centered at 100 Hz and 1000 Hz respectively, both with a gain of 5 dB and a Q-factor of 1.5, for a system running at 48 kHz.

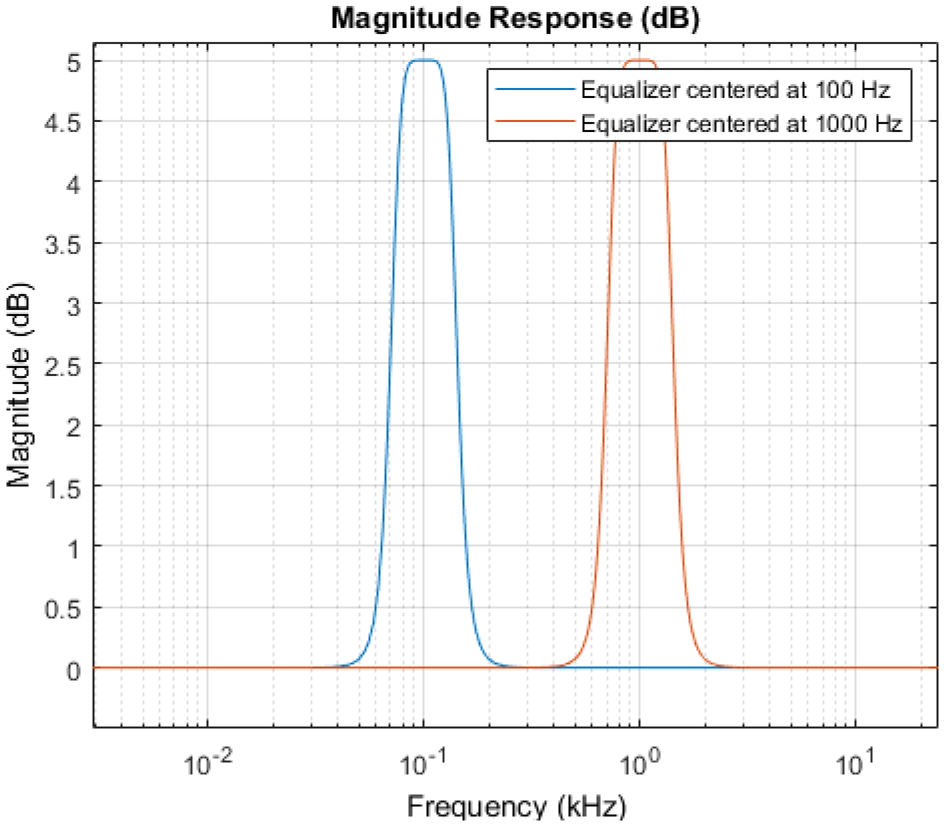
```
Fs  = 48e3;
N   = 6;
G   = 5;
Q   = 1.5;
Wo1 = 100/(Fs/2);
Wo2 = 1000/(Fs/2);
% Obtain the bandwidth of the equalizers from the center frequencies and
% Q-factors.
BW1 = Wo1/Q;
BW2 = Wo2/Q;
% Design the equalizers and obtain their SOS and SV values.
[SOS1,SV1] = iirparameq(N,G,Wo1,BW1);
[SOS2,SV2] = iirparameq(N,G,Wo2,BW2);
```

Design biquad filters using the obtained SOS and SV values.

```
BQ1 = dsp.BiquadFilter('SOSMatrix',SOS1,'ScaleValues',SV1);
BQ2 = dsp.BiquadFilter('SOSMatrix',SOS2,'ScaleValues',SV2);
```

Plot the magnitude response of both filters using a log scale.

```
fvtool(BQ1,BQ2,'Fs',Fs,'FrequencyScale','Log');
legend('Equalizer centered at 100 Hz','Equalizer centered at 1000 Hz');
```



Compare Notch Filters Designed with Different Orders

Design an eighth-order notch filter and compare it to a traditional second-order notch filter designed with `IIRNOTCH`.

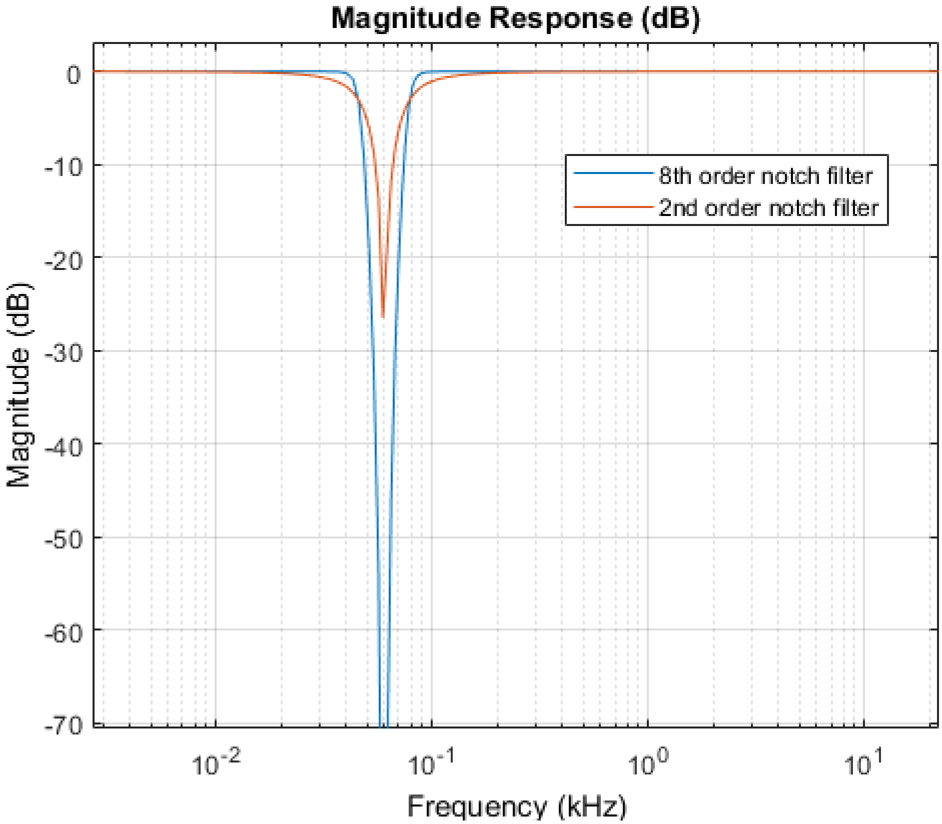
```
Fs  = 44.1e3;
N   = 8;
G   = -inf;
Q   = 1.8;
Wo  = 60/(Fs/2); % Notch at 60 Hz
BW  = Wo/Q; % Bandwidth occurs at -3 dB for this special case
[SOS1,SV1] = iirparameq(N,G,Wo,BW);
[NUM,DEN]  = iirnotch(Wo,BW);
SOS2 = [NUM,DEN];
```

Design the notch filters using the SOS and SV values.

```
BQ1 = dsp.BiquadFilter('SOSMatrix',SOS1,'ScaleValues',SV1);
BQ2 = dsp.BiquadFilter('SOSMatrix',SOS2);
```

Plot the magnitude response of both filters. The filters intersect at -3 dB point.

```
FVT = fvtool(BQ1,BQ2,'Fs',Fs,'FrequencyScale','Log');
legend(FVT,'8th order notch filter','2nd order notch filter');
```



Input Arguments

N — Order of the parametric equalizer

even positive integer

Order of the parametric equalizer, specified as an even positive integer.

Example: 6

Example: 10

Data Types: `single` | `double`

G — Gain of the parametric equalizer

real scalar

Gain of the parametric equalizer in dB, specified as a real scalar.

Example: 2

Example: -2.2

Data Types: single | double

Wo — Center frequency of the parametric equalizer

real scalar

Center frequency of the parametric equalizer, specified as a real scalar in the range [0.0 1.0]. A value of 1.0 corresponds to π radians/sample.

Example: 0.0

Example: 1.0

Data Types: single | double

BW — Bandwidth of the parametric equalizer

real scalar

Bandwidth of the parametric equalizer, specified as a real scalar in the range [0.0 1.0]. A value of 1.0 corresponds to π radians/sample.

Example: 0.0

Example: 1.0

Data Types: single | double

Output Arguments

SOS — Second-order section matrix

real-valued matrix

Second-order section matrix, returned as a real-valued L-by-6 matrix, where L is the number of second-order sections of the filter.

SV — Scale values between each biquad stage

real-valued vector

Scale values between each biquad stage, returned as a real-valued vector of length $L + 1$.

B — Numerator coefficients of the fourth-order sections of the parametric equalizer
real-valued matrix

Numerator coefficients of the fourth-order sections of the parametric equalizer, returned as a real-valued M-by-5 matrix. M is the number of fourth-order sections of the filter.

A — Denominator coefficients of the fourth-order sections of the parametric equalizer
real-valued matrix

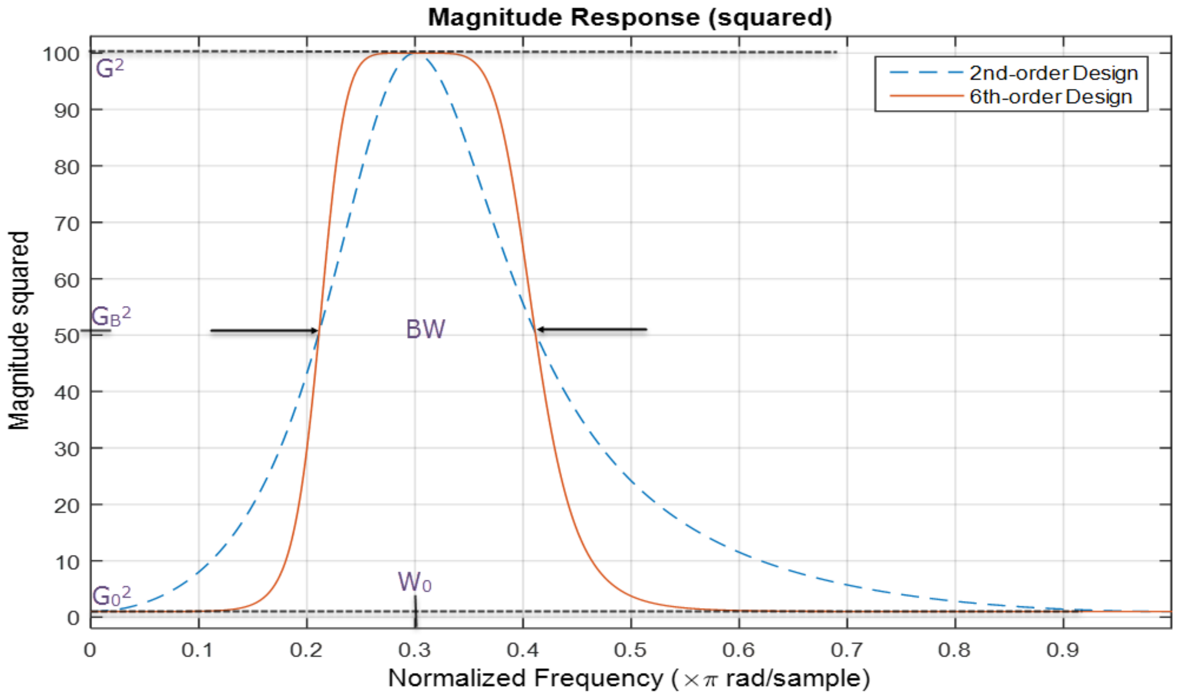
Denominator coefficients of the fourth-order sections of the parametric equalizer, returned as a real-valued M-by-5 matrix. M is the number of fourth-order sections of the filter.

More About

High-order Parametric Equalizer

Parametric equalizers are digital filters used in audio processing for adjusting the frequency content of a sound signal. Parametric equalizers provide capabilities beyond those of graphic equalizers by allowing the adjustment of gain, center frequency, and bandwidth of each filter. In contrast, graphic equalizers allow for the adjustment of the gain of each filter only. Digital parametric audio equalizers are commonly implemented as biquadratic (second-order IIR) filters. Due to low order, biquadratic filters can present relatively large ripple or transition regions. When several filters are connected in cascade, they can overlap with each other. In such circumstances, high-order filters are preferred. High-order filters provide flatter passbands, sharper band edges, and more control over the shape of each filter. In addition, if the order of the filter is set to two, the design changes to a special case: a traditional second-order parametric equalizer.

The figure shows the magnitude response of a second-order parametric equalizer compared with a high-order parametric equalizer.



$W_0 = 0.3 \times \pi$ radians/sample is the center frequency of the equalizer, $BW = 0.2$ radians/sample is the bandwidth of the equalizer, $G = 10$ is the peak gain of the equalizer, $G_0 = 1$, and $G_B = (G_0^2 + G^2) / 2$.

Algorithm

The first step in the filter design is to design a high-order analog lowpass shelving filter that meets the specified gain and bandwidth. A high-order Butterworth filter is used for this purpose. The analog Butterworth filter is then transformed into a digital lowpass shelving filter, and finally into a peaking equalizer that is centered at the specified peak frequency.

The design specifications for the digital equalizer are the order of the equalizer, N, the gain of the equalizer, G, the center frequency of the equalizer, W_0, and the bandwidth of the equalizer, BW.

The transfer function of the high-order parametric equalizer is given by:

$$H(z) = [\frac{b_{00} + b_{01}z^{-1} + b_{02}z^{-2}}{1 + a_{01}z^{-1} + a_{02}z^{-2}}]^r \times \prod_{i=1}^{L} [\frac{b_{i0} + b_{i1}z^{-1} + b_{i2}z^{-2} + b_{i3}z^{-3} + b_{i4}z^{-4}}{1 + a_{i1}z^{-1} + a_{i2}z^{-2} + a_{i3}z^{-3} + a_{i4}z^{-4}}]$$

where b_{00}, b_{01}, b_{02}, a_{01}, and a_{02} are coefficients of the second-order section of the equalizer. b_{i0}, b_{i1}, b_{i2}, b_{i3}, b_{i4}, a_{i1}, a_{i2}, and a_{i3} are coefficients of the fourth-order sections of the equalizer. $L = (N - r) / 2$, where $r = 1$ when N is odd, and $r = 0$ when N is even. The fourth-order sections are factored into second-order sections so that you can implement them using biquad filters.

For more information on how coefficients are computed in terms of the design specifications, see the "Butterworth Designs" section in [1].

dsp.ParametricEQFilter | `iircomb` | `iirnotch` | `iirpeak`

Introduced in R2015a

iirpeak

Second-order IIR peak or resonator filter

Syntax

```
[num,den] = iirpeak(w0,bw)
[num,den] = iirpeak(w0,bw,ab)
```

Description

`[num,den] = iirpeak(w0,bw)` turns a second-order digital peaking filter with the peak located at `w0`, and with the bandwidth at the +3 dB point set to `bw`. To design the filter, `w0` must meet the condition 0.0 < `w0` < 1.0, where 1.0 corresponds to π radians per sample in the frequency range.

The quality factor (Q factor) q for the filter is related to the filter bandwidth by `q` = `w0/bw` where ω_0 is `w0` the signal frequency to boost.

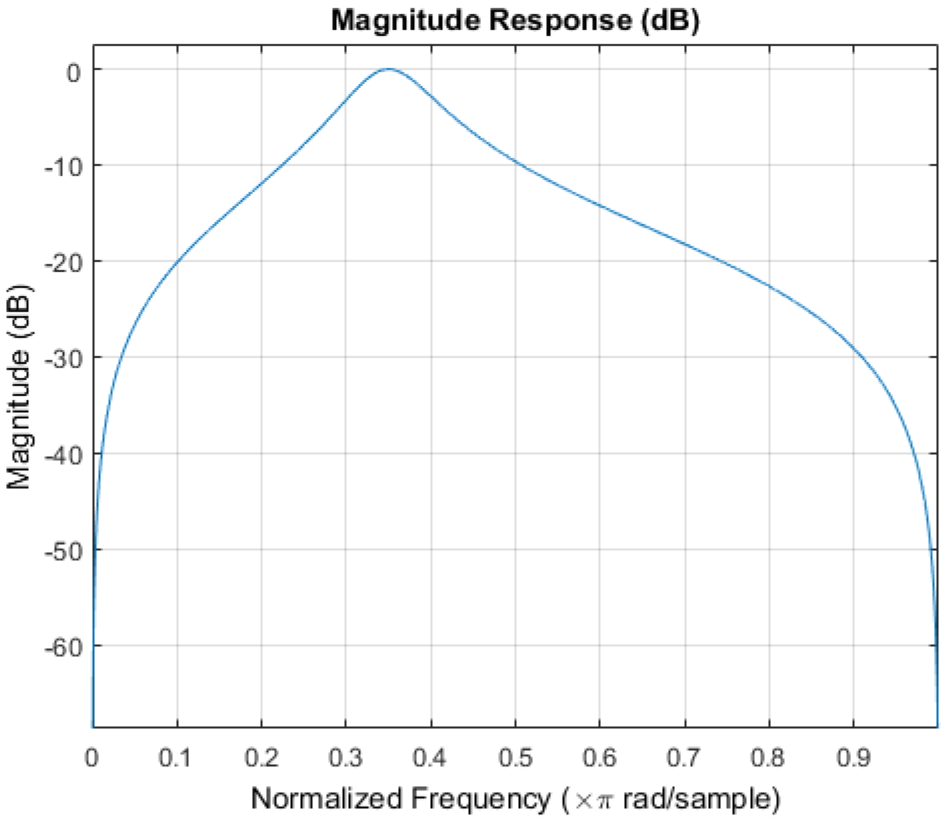
`[num,den] = iirpeak(w0,bw,ab)` returns a digital peaking filter whose bandwidth, `bw`, is specified at a level of `+ab` decibels. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default +3 dB point, such as +6 dB or 0 dB.

Examples

Design an IIR Peaking Filter Using iirpeak

Design and plot an IIR peaking filter that boosts the frequency at 1.75 Khz in a signal and has bandwidth of 500 Hz at the -3 dB point:

```
fs = 10000; wo = 1750/(fs/2);  bw = 500/(fs/2);
[b,a] = iirpeak(wo,bw);
fvtool(b,a);
```



The peak filter has the desired gain and bandwidth at 1.75 KHz.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

See Also

`firgr` | `iircomb` | `iirparameq` | `iirnotch`

Introduced in R2011a

iirpowcomp

Power complementary IIR filter

Syntax

```
[bp,ap] = iirpowcomp(b,a)
[bp,ap] = iirpowcomp(b,a,c)
```

Description

`[bp,ap] = iirpowcomp(b,a)` returns the coefficients of the power complementary IIR filter g(z) = `bp`(z)/`ap`(z) in vectors `bp` and `ap`, given the coefficients of the IIR filter h(z) = `b`(z)/`a`(z) in vectors `b` and `a`. `b` must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as `a`. The two power complementary filters satisfy the relation

$|H(w)|^2 + |G(w)|^2 = 1.$

`[bp,ap] = iirpowcomp(b,a,c)` where `c` is a complex scalar of unity magnitude, forces `bp` to satisfy the generalized hermitian property:

`conj(bp(end:-1:1)) = c*bp`.

When `c` is omitted, the function chooses `c` as follows:

- When `b` is real, the function chooses `c` as 1 or -1, whichever yields `bp` as real.
- When `b` is complex, `c` defaults to 1.

`ap` is always equal to `a`.

Examples

Power Complementary IIR Filter

```
[b,a]=cheby1(10,.5,.4);
[bp,ap]=iirpowcomp(b,a);
```

```
fvtool(b,a,bp,ap,'MagnitudeDisplay','Magnitude squared');
legend('Original Filter','Power Complementary Version');
```

Introduced in R2011a

iirrateup

Upsample IIR filter by integer factor

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter being transformed from any prototype by applying an `N`th-order rateup frequency transformation, where `N` is the upsample ratio. Transformation creates `N` equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

The relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

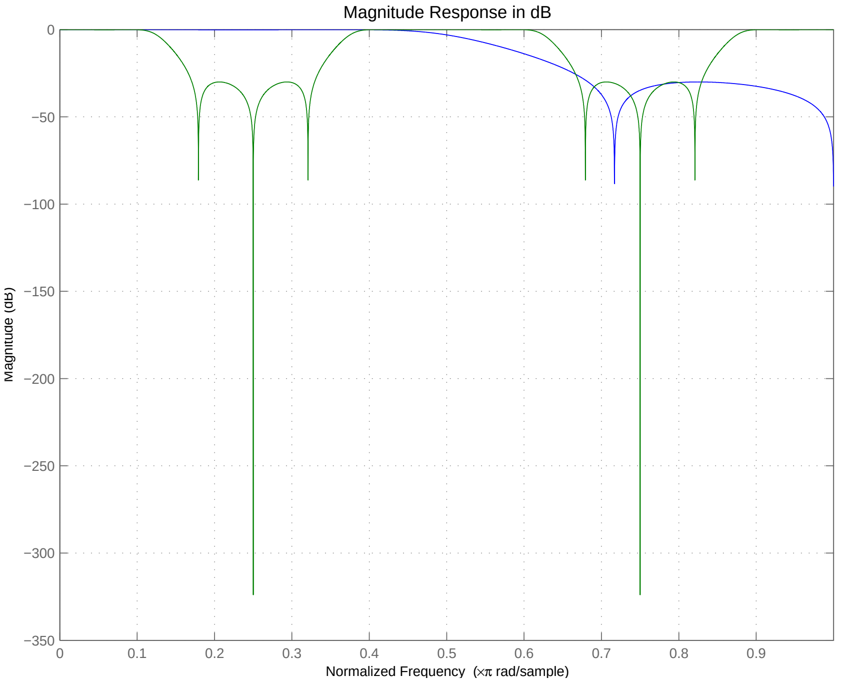
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
[num, den] = iirrateup(b, a, 4);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

As shown in the figure produced by FVTool, the transformed filter appears as expected.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
N	Frequency multiplication ratio
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Introduced in R2011a

iirshift

Shift frequency response of IIR filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real shift frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator of the allpass mapping filter, `AllpassDen`. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation places one selected feature of an original filter located at frequency W_o to the required target frequency location, W_t. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them from the beginning.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

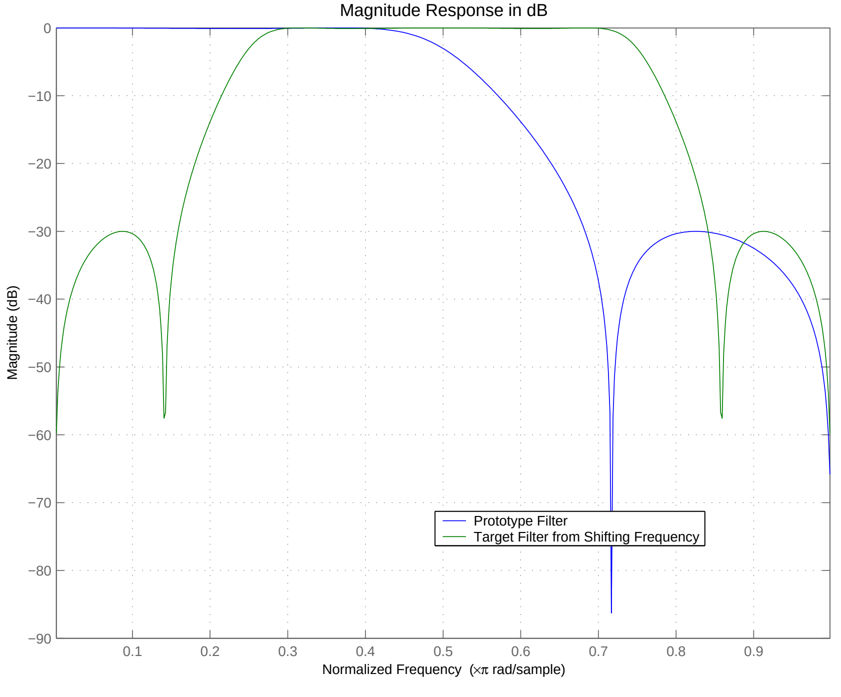
Perform the real frequency shift by defining where the selected feature of the prototype filter, originally at W_o=`0.5`, should be placed in the target filter, W_t=`0.75`:

```
Wo = 0.5; Wt = 0.75;
[num, den] = iirshift(b, a, Wo, Wt);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Shifting the specified feature from the prototype to the target generates the response shown in the figure.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

iirshiftc

Shift frequency response of IIR complex filter

Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)
```

Description

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at W_o, placed at W_t in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)` calculates the allpass filter for doing the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

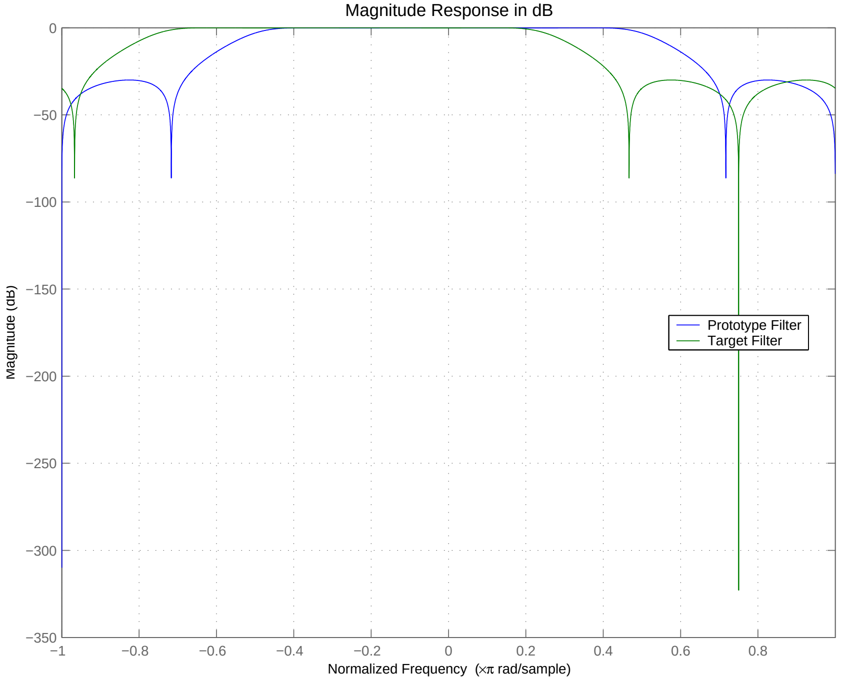
Rotate all features of the prototype filter in the frequency domain by the same amount by specifying where the selected feature of an original filter, W_o= `0.5`, should appear in the target filter, W_t= `0.25`:

```
[num, den] = iirshiftc(b, a, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

After applying the shift, the selected feature from the original filter is just where it should be, at W_t = `0.25`.



Arguments

Variable	Description
B	Numerator of the prototype lowpass filter

Variable	Description
A	Denominator of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Num	Numerator of the target filter
Den	Denominator of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

impz

Impulse response of discrete-time filter System object

Syntax

```
[impResp,t] = impz(sysobj)
[impResp,t] = impz(sysobj,n)
[impResp,t] = impz(sysobj,n,fs)
[impResp,t] = impz(sysobj,[],fs)
[impResp,t] = impz(sysobj,Name,Value)
impz(sysobj)
```

Description

`[impResp,t] = impz(sysobj)` computes the impulse response of the filter System object, `sysobj`, and returns the response in column vector `impResp`, and a vector of times (or sample intervals) in `t`, where `t = [0 1 2 ...k-1]'`. `k` is the number of filter coefficients.

`[impResp,t] = impz(sysobj,n)` computes the impulse response at `floor(n)` 1-second intervals. The time vector `t` equals `(0:floor(n)-1)'`.

`[impResp,t] = impz(sysobj,n,fs)` computes the impulse response at `floor(n)` 1/`fs`-second intervals. The time vector `t` equals `(0:floor(n)-1)'/fs`.

`[impResp,t] = impz(sysobj,[],fs)` computes the impulse response at `k` 1/`fs`-second intervals. `k` is the number of filter coefficients. The time vector `t` equals `(0:k-1)'/fs`.

`[impResp,t] = impz(sysobj,Name,Value)` returns an impulse response with additional options specified by one or more `Name,Value` pair arguments.

`impz(sysobj)` uses `fvtool` to plot the impulse response of the filter System object `sysobj`.

For more input options, refer to `impz` in Signal Processing Toolbox documentation.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Input Arguments

`sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator

Filter System objects
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

n

Length of the impulse response vector.

Default: Number of filter coefficients

fs

Sampling frequency.

Default: 1

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Arithmetic' — Value types:
'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data

System Object State	Coefficient Data Type	Rule
		type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

`impResp`

`n`-element impulse response vector. If `n` is not specified, the length of the impulse response vector equals the number of coefficients in the filter.

t

Time vector of length `n`, in seconds. `t` consists of `n` equally spaced points in the range `(0:floor(n)-1)'/fs`. If `n` is not specified, the function uses the number of coefficients of the filter.

Examples

Plot the Impulse Response of a Lowpass Elliptic Filter

Create a discrete-time filter for a fourth-order, lowpass elliptic filter with a cutoff frequency of 0.4 times the Nyquist frequency. Use a second-order sections structure to resist quantization errors. Plot the first 50 samples of the impulse response, along with the reference impulse response.

```
d = fdesign.lowpass(.4,.5,1,80);
```

Create a design object for the prototype filter. Use `ellip` to design a minimum order discrete-time biquad filter.

```
biquad = design(d,'ellip','Systemobject',true);
```

Plot the impulse response.

```
impz(biquad);
axis([1 75 -0.2 0.35])
```

`filter` | `stepz`

Introduced in R2011a

impzlength

Impulse response length

Syntax

```
len = impzlength(b,a)
len = impzlength(sos)
len = impzlength(d)

len = impzlength(hs)

len = impzlength( ___ ,tol)
```

Description

`len = impzlength(b,a)` returns the impulse response length for the causal discrete-time filter with the rational system function specified by the numerator, `b`, and denominator, `a`, polynomials in z^{-1}. For stable IIR filters, `len` is the effective impulse response sequence length. Terms in the IIR filter's impulse response after the `len`-th term are essentially zero.

`len = impzlength(sos)` returns the effective impulse response length for the IIR filter specified by the second order sections matrix, `sos`. `sos` is a K-by-6 matrix, where the number of sections, K, must be greater than or equal to 2. If the number of sections is less than 2, `impzlength` considers the input to be the numerator vector, `b`. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The ith row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`len = impzlength(d)` returns the impulse response length for the digital filter, `d`. Use `designfilt` to generate `d` based on frequency-response specifications.

`len = impzlength(hs)` returns the impulse response length for the filter System object, `hs`. You must have the DSP System Toolbox software to use `impzlength` with a filter System object.

`len = impzlength( ___ ,tol)` specifies a tolerance for estimating the effective length of an IIR filter's impulse response. By default, `tol` is `5e-5`. Increasing the value of `tol` estimates a shorter effective length for an IIR filter's impulse response. Decreasing the value of `tol` produces a longer effective length for an IIR filter's impulse response.

Examples

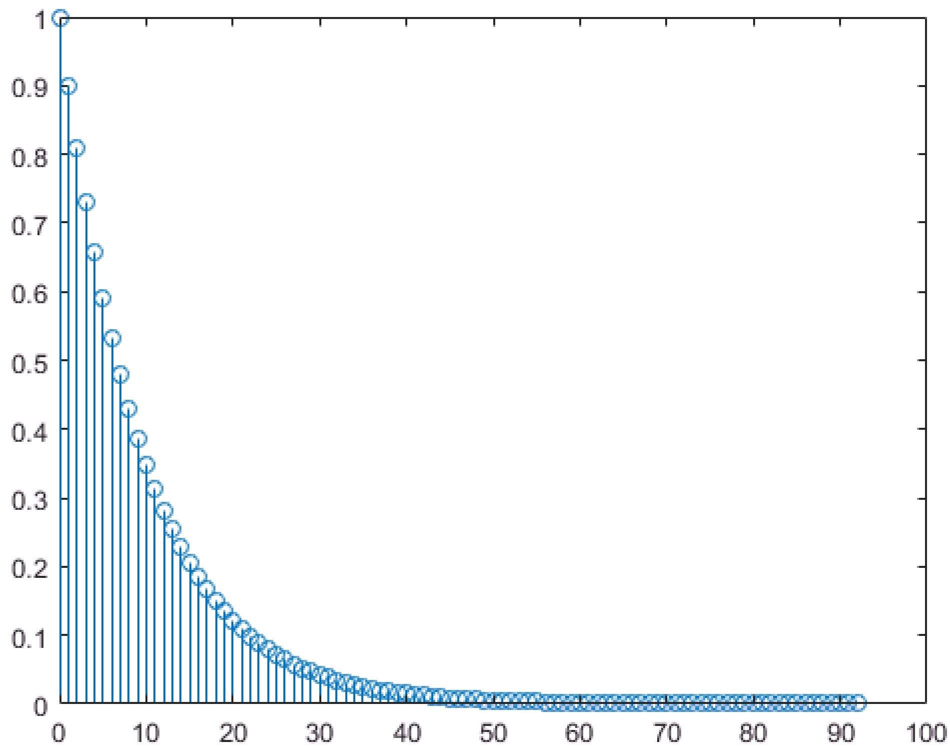
IIR Filter Effective Impulse Response Length — Coefficients

Create a lowpass allpole IIR filter with a pole at 0.9. Calculate the effective impulse response length. Obtain the impulse response. Plot the result.

```
b = 1;
a = [1 -0.9];
len = impzlength(b,a)
```

```
len = 93
```

```
[h,t] = impz(b,a);
stem(t,h)
```



```
h(len)
```

```
ans = 6.1704e-05
```

IIR Filter Effective Impulse Response Length — Second-Order Sections

Design a 4th-order lowpass elliptic filter with a cutoff frequency of 0.4π rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second-order section matrix using `zp2sos`. Determine the effective impulse response sequence length from the second-order section matrix.

```
[z,p,k] = ellip(4,1,60,.4);
```

```
[sos,g] = zp2sos(z,p,k);
len = impzlength(sos)
```

```
len = 80
```

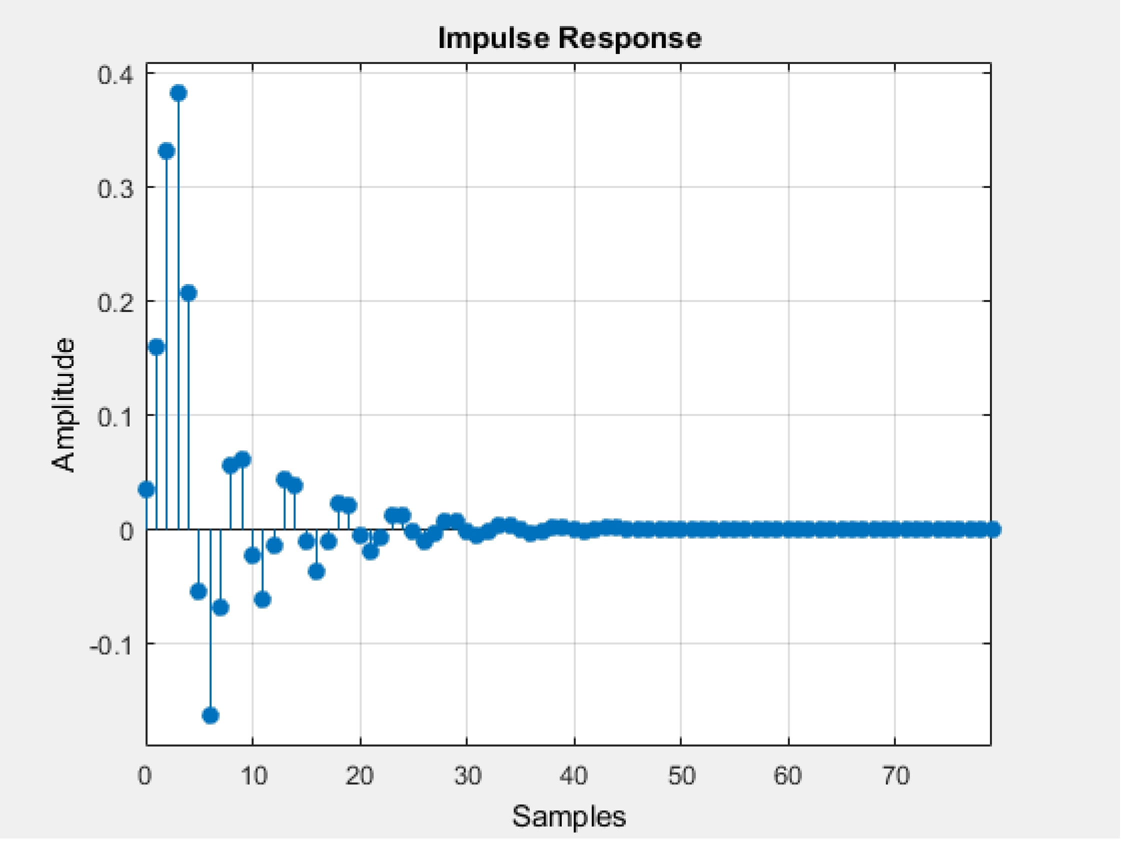
IIR Filter Effective Impulse Response Length — Digital Filter

Use `designfilt` to design a 4th-order lowpass elliptic filter with normalized passband frequency 0.4π rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Determine the effective impulse response sequence length and visualize it.

```
d = designfilt('lowpassiir','FilterOrder',4,'PassbandFrequency',0.4, ...
               'PassbandRipple',1,'StopbandAttenuation',60, ...
               'DesignMethod','ellip');
len = impzlength(d)
```

```
len = 80
```

```
impz(d)
```



Impulse Response Length of Filter System object

This example requires DSP System Toolbox™ software.

Design a 4th-order lowpass elliptic filter with a cutoff frequency of 0.4*pi rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second order section matrix using `zp2sos`. Create a biquad filter System object™ and input the System object to `impzlength`.

```
[z,p,k] = ellip(4,1,60,.4);
[sos,g] = zp2sos(z,p,k);
hBqdFilt = dsp.BiquadFilter('Structure','Direct form I',...
                                              'SOSMatrix', sos,...
```

```
                                              'ScaleValues',g);
len = impzlength(hBqdFilt)

len =

    80
```

Impulse Response Length — Filter System Objects

Design IIR Butterworth and FIR equiripple filters for data sampled at 1 kHz. The passband frequency is 100 Hz and the stopband frequency is 150 Hz. The passband ripple is 0.5 dB and there is 60 dB of stopband attenuation. Obtain System objects for the filters and compare the filter impulse response sequence lengths.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',100,150,0.5,60,1000);
Hd1 = design(d,'butter','SystemObject',true);
Hd2 = design(d,'equiripple','SystemObject',true);
len = [impzlength(Hd1) impzlength(Hd2)]

len =

   183    49
```

Input Arguments

b — Numerator coefficients

vector | scalar

Numerator coefficients, specified as a scalar (allpole filter) or a vector.

Example: `b = fir1(20,0.25)`

Data Types: `single` | `double`
Complex Number Support: Yes

a — Denominator coefficients

vector | scalar

Denominator coefficients, specified as a scalar (FIR filter) or vector.

Data Types: `single` | `double`
Complex Number Support: Yes

`sos` — Matrix of second order sections

matrix

Matrix of second order sections, specified as a K-by-6 matrix. The system function of the K-th biquad filter has the rational Z-transform

$$H_k(z) = \frac{B_k(1) + B_k(2)z^{-1} + B_k(3)z^{-2}}{A_k(1) + A_k(2)z^{-1} + A_k(3)z^{-2}}.$$

The coefficients in the Kth row of the matrix, `sos`, are ordered as follows.

$$\begin{bmatrix} B_k(1) & B_k(2) & B_k(3) & A_k(1) & A_k(2) & A_k(3) \end{bmatrix}$$

The frequency response of the filter is the system function evaluated on the unit circle with

$$z = e^{j2\pi f}.$$

`d` — Digital filter

`digitalFilter` object

Digital filter, specified as a digitalFilter object. Use `designfilt` to generate a digital filter based on frequency-response specifications.

Example: `d = designfilt('lowpassiir','FilterOrder',3,'HalfPowerFrequency',0.5)` specifies a third-order Butterworth filter with normalized 3-dB frequency 0.5π rad/sample.

`hs` — Filter System object

filter System object

Filter System object, specified as one of the following:

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

Using `impzlength` with a filter System object requires the DSP System Toolbox software.

`tol` — Tolerance for IIR filter effective impulse response length

`5e-5` (default) | positive scalar

Tolerance for IIR filter effective impulse response length, specified as a positive number. The tolerance determines the term in the absolutely summable sequence after which subsequent terms are considered to be 0. The default tolerance is `5e-5`. Increasing the tolerance returns a shorter effective impulse response sequence length. Decreasing the tolerance returns a longer effective impulse response sequence length.

Output Arguments

`len` — Length of impulse response

positive integer

Length of the impulse response, specified as a positive integer. For stable IIR filters with absolutely summable impulse responses, `impzlength` returns an effective length for the impulse response beyond which the coefficients are essentially zero. You can control this cutoff point by specifying the optional `tol` input argument.

Introduced in R2013a

info

Information about filter

Syntax

```
info(obj)
info(obj,'short')
info(obj,'long')
s = info(obj)
```

Description

`info(obj)` returns very basic information about the filter System object, `obj`. The particulars depend on the filter type and structure.

`info(obj,'short')` returns the same information as `info(obj)`.

`info(obj,'long')` returns the following information about the filter:

- Specifications such as the filter structure and filter order
- Information about the design method and options
- Performance measurements for the filter response, such as the passband cutoff or stopband attenuation, included in the `measure` method
- Cost of implementing the filter in terms of operations required to apply the filter to data, included in the `cost` method

When the filter uses fixed-point arithmetic, the function returns additional information about the filter, including the arithmetic setting and details about the filter internals.

`s = info(obj)` returns filter information in the variable `s`. You can also provide the optional arguments `'short'` and `'long'` with this syntax.

Input Arguments

`obj`

One of the following types of filter System objects:

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter

dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

'short'

Input argument that instructs the function to return basic information about the filter.

'long'

Input argument that instructs the function to return in-depth information about the filter.

Output Arguments

s

Variable for storing filter information.

Examples

Obtain Filter Information

Obtain short-format and long-format information about a filter.

Introduced in R2011a

int

States from CIC filter

Compatibility

`mfilt` will be removed in a future release. Refer to the reference page for a specific `mfilt` object to see its recommended replacement.

Syntax

`integerstates = int(hm.states)`

Description

`integerstates = int(hm.states)` returns the states of a CIC filter in matrix form, rather than as the native `filtstates` object. An important point about `int` is that it quantizes the state values to the smallest number of bits possible while maintaining the values accurately.

Examples

For many users, the states of multirate filters are most useful as a matrix, but the CIC filters store the states as objects. Here is how you get the states from you CIC filter as a matrix.

```
hm = mfilt.cicinterp;
hs = hm.states; % Returns a FILTSTATES.CIC object hs.
states = int(hs); % Convert object hs to a signed integer matrix.
```

After using int to convert the states object to a matrix, here is what you get.

Before converting:

```
hm.states

ans =
```

```
    Integrator: [2x1 States]
          Comb: [2x1 States]
```

After the conversion and assigning the states to `states`:

```
states

states =

           0            0
           0            0
```

`filtstates.cic` | dsp.CICInterpolator | dsp.CICDecimator

Introduced in R2011a

isallpass

Determine whether filter is allpass

Syntax

```
flag = isallpass(b,a)
flag = isallpass(sos)
flag = isallpass(d)
flag = isallpass(...,tol)
flag = isallpass(hs,...)
flag = isallpass(hs,'Arithmetic',arithtype)
```

Description

`flag = isallpass(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is an allpass filter. If the filter is not an allpass filter, `flag` is equal to `false`.

`flag = isallpass(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is an allpass filter. `sos` is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isallpass(d)` returns `true` if the digital filter, `d`, is an allpass filter. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = isallpass(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`. Specifying a tolerance may be most helpful in fixed-point allpass filters.

`flag = isallpass(hs,...)` returns `true` if the filter System object, `hs`, is an allpass filter. You must have the DSP System Toolbox software to use this syntax.

`flag = isallpass(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

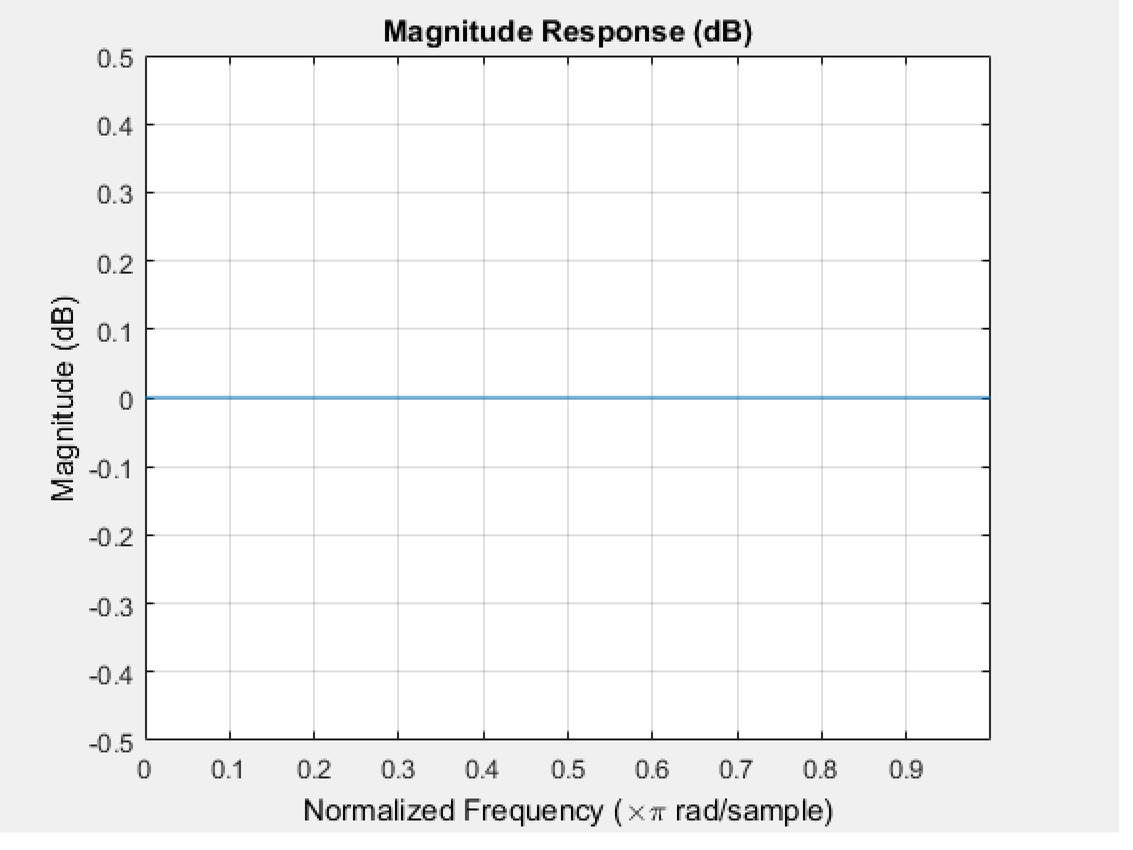
Allpass Filters

Create an allpass filter and verify that the frequency response is allpass.

```
b = [1/3 1/4 1/5 1];
a = fliplr(b);
flag = isallpass(b,a)
```

```
flag = logical
   1
```

```
fvtool(b,a)
```



Create a lattice allpass filter and verify that the filter is allpass.

```
k = [1/2 1/3 1/4 1/5];
[b,a] = latc2tf(k,'allpass');
flag_isallpass = isallpass(b,a)

flag_isallpass = logical
   1
```

```
fvtool(b,a)
```

Introduced in R2013a

isfir

Determine whether filter System object is FIR

Syntax

```
isfir(sysobj)
```

Description

`isfir(sysobj)` determines whether the filter System object `sysobj` is an FIR filter. If the filter is FIR, `isfir` returns `1`.

To determine whether `sysobj` is an FIR filter, `isfir(sysobj)` inspects if the filter in the transfer function form has a scalar denominator. If it does, it is an FIR filter.

Examples

Determine Whether an FIR Filter

Design a Lowpass FIR Filter.

```
d = fdesign.lowpass;
h = design(d,'Systemobject',true)
```

```
h =

  dsp.FIRFilter with properties:

            Structure: 'Direct form'
      NumeratorSource: 'Property'
            Numerator: [1×43 double]
    InitialConditions: 0

  Use get to show all properties
```

Determine if the filter is an FIR filter using `isfir`.

```
isfir(h)
```

```
ans =

  logical

   1
```

`isfir` returns 1 to indicate that the filter is an FIR filter.

islinphase

Determine whether filter has linear phase

Syntax

```
flag = islinphase(b,a)
flag = islinphase(sos)
flag = islinphase(d)
flag = islinphase(...,tol)
flag = islinphase(hs,...)
flag = islinphase(hs,'Arithmetic',arithtype)
```

Description

`flag = islinphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter coefficients in `b` and `a` define a linear phase filter. `flag` is equal to `false` if the filter does not have linear phase.

`flag = islinphase(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, has linear phase. `sos` is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = islinphase(d)` returns `true` if the digital filter, `d`, has linear phase. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = islinphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`.

`flag = islinphase(hs,...)` determines whether the filter System object, `hs`, has linear phase. You must have the DSP System Toolbox to use `islinphase` with a System object.

`flag = islinphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be one of `'double'`, 'single', or 'fixed'. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked. You must have the DSP System Toolbox to use islinphase with a System object.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

Linear and Nonlinear Phase

Use the window method to design a tenth-order lowpass FIR filter with normalized cutoff frequency 0.55. Verify that the filter has linear phase.

```
firSpecs = fdesign.lowpass('N,Fc',10,0.55);
lpFIR = design(firSpecs,'window','SystemObject',true);

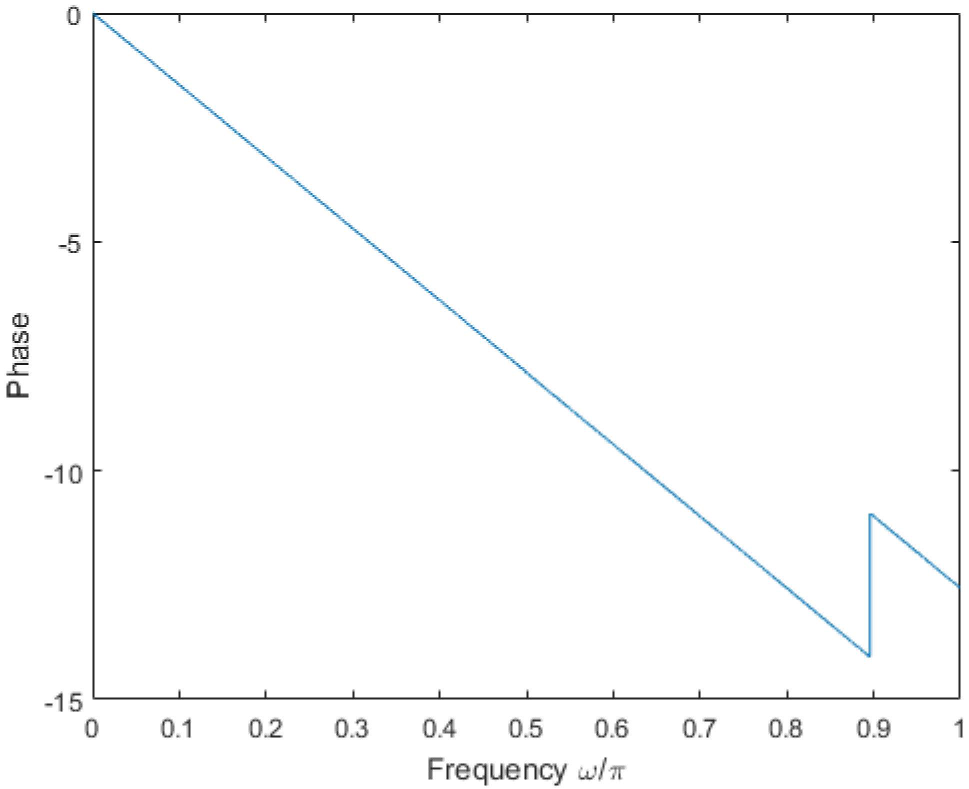
flag = islinphase(lpFIR)
[phs,w] = phasez(lpFIR);

plot(w/pi,phs)
xlabel('Frequency \omega/\pi')
ylabel('Phase')
```

```
flag =

  logical

   1
```



IIR filters in general do not have linear phase. Verify the statement by constructing eighth-order Butterworth, Chebyshev, and elliptic filters with similar specifications.

```
ord = 4;

Wp = 0.35;
Wst = 0.4;
atten = 20;
rippl = 1;

buttSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
buttIIR = design(buttSpecs,'butter','SystemObject',true);

chb1Specs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
```

```
chb1IIR = design(chb1Specs,'cheby1','SystemObject',true);

chb2Specs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
chb2IIR = design(chb2Specs,'cheby2','SystemObject',true);

ellpSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
ellpIIR = design(ellpSpecs,'ellip','SystemObject',true);
```

Plot the phase responses of the filters. Determine whether they have linear phase.

```
fv = fvtool(buttIIR,chb1IIR,chb2IIR,ellpIIR,'Analysis','phase');
legend(fv,'Butterworth','Chebyshev I','Chebyshev II','Elliptic')

phs = [islinphase(buttIIR) islinphase(chb1IIR) ...
       islinphase(chb2IIR) islinphase(ellpIIR)]
```

```
phs =

  1×4 logical array

   0   0   0   0
```

Introduced in R2013a

ismaxphase

Determine whether filter is maximum phase

Syntax

```
flag = ismaxphase(b,a)
flag = ismaxphase(sos)
flag = ismaxphase(d)
flag = ismaxphase(...,tol)
flag = ismaxphase(hs,...)
flag = ismaxphase(hs,'Arithmetic',arithtype)
```

Description

`flag = ismaxphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a maximum phase filter.

`flag = ismaxphase(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is a maximum phase filter. `sos` is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = ismaxphase(d)` returns `true` if the digital filter, `d`, has maximum phase. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = ismaxphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`.

`flag = ismaxphase(hs,...)` returns `true`if the filter System object `hs` is a maximum phase filter. You must have the DSP System Toolbox software to use this syntax.

`flag = ismaxphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

Maximum- and Minimum-Phase Filters

Design maximum-phase and minimum-phase lattice filters and verify their phase type.

```
k = [1/6 1/1.4];
bmax = latc2tf(k,'max');
bmin = latc2tf(k,'min');
max_flag = ismaxphase(bmax)
```

```
max_flag = logical
   1
```

```
min_flag = isminphase(bmin)
```

```
min_flag = logical
   1
```

Given a filter defined with a set of single precision numerator and denominator coefficients, check if it is maximum phase for different values of the tolerance.

```
b = single([1 -0.9999]);
a = single([1 0.45]);
max_flag1 = ismaxphase(b,a)
```

```
max_flag1 = logical
   0
```

```
max_flag2 = ismaxphase(b,a,1e-3)
```

```
max_flag2 = logical
   1
```

designfilt | digitalFilter | isallpass | islinphase | isminphase | isstable

Introduced in R2013a

isminphase

Determine whether filter is minimum phase

Syntax

```
flag = isminphase(b,a)
flag = isminphase(sos)
flag = isminphase(d)
flag = isminphase(...,tol)
flag = isminphase(hs,...)
isminphase(hs,'Arithmetic',arithtype)
```

Description

A filter is *minimum phase* when all the zeros of its transfer function are on or inside the unit circle, or the numerator is a scalar. An equivalent definition for a minimum phase filter is a causal and stable system with a causal and stable inverse.

`flag = isminphase(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a minimum phase filter.

`flag = isminphase(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is minimum phase. `sos` is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isminphase(d)` returns `true` if the digital filter, `d`, has minimum phase. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = isminphase(...,tol)` uses the tolerance, `tol`, to determine when two numbers are close enough to be considered equal. If not specified, `tol`, defaults to `eps^(2/3)`.

`flag = isminphase(hs,...)` determines whether the filter System object `hs` is minimum phase, returning `1` if true and `0` if false. You must have the DSP System Toolbox software to use this syntax.

`isminphase(hs,'Arithmetic',arithtype)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

Minimum Phase Filters

Design a sixth-order lowpass Butterworth IIR filter using second order sections. Specify a normalized 3-dB frequency of 0.15. Check if the filter has minimum phase.

```
[z,p,k] = butter(6,0.15);
SOS = zp2sos(z,p,k);
min_flag = isminphase(SOS)
```

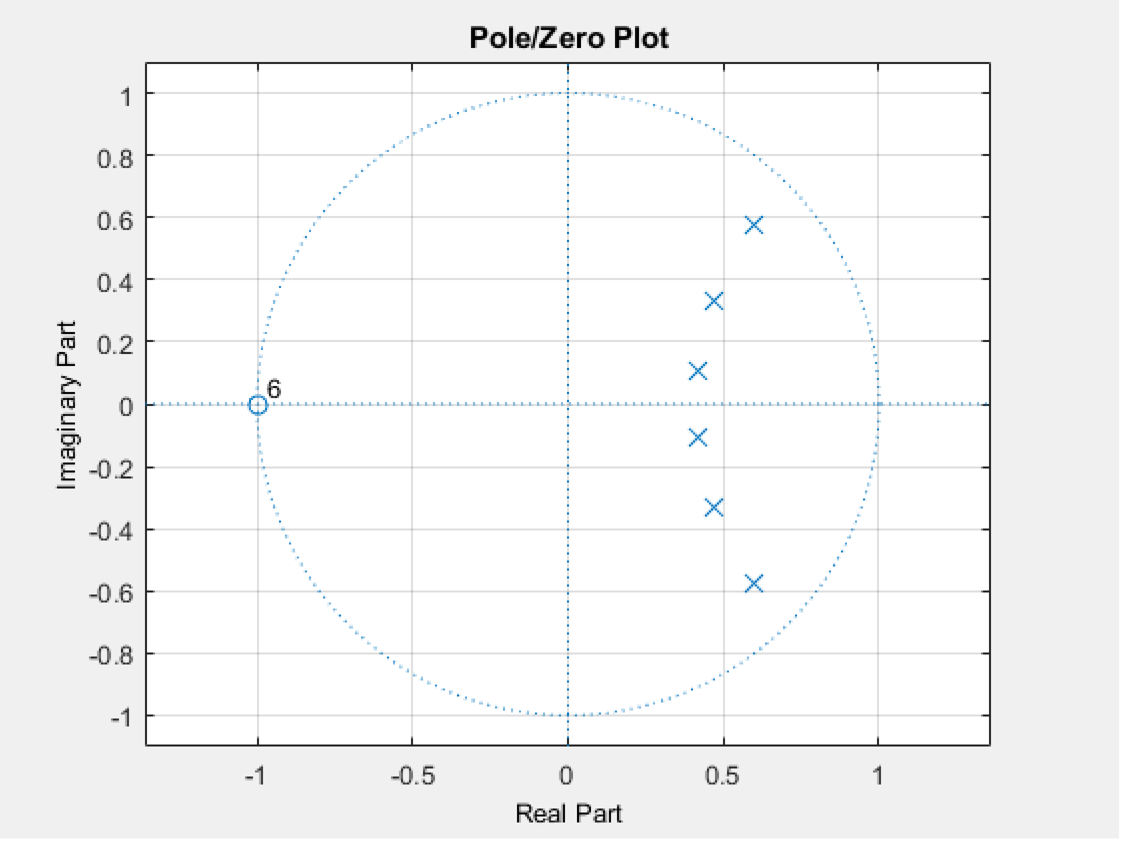
```
min_flag = logical
   1
```

Redesign the filter using `designfilt`. Check that the zeros and poles of the transfer function are on or within the unit circle.

```
d = designfilt('lowpassiir','DesignMethod','butter','FilterOrder',6, ...
               'HalfPowerFrequency',0.25);
d_flag = isminphase(d)
```

```
d_flag = logical
   1
```

```
zplane(d)
```



Given a filter defined with a set of single-precision numerator and denominator coefficients, check if it has minimum phase for different tolerance values.

```
b = single([1 1.00001]);
a = single([1 0.45]);
min_flag1 = isminphase(b,a)
```

```
min_flag1 = logical
   0
```

```
min_flag2 = isminphase(b,a,1e-3)
```

```
min_flag2 = logical
   1
```

Introduced in R2013a

isreal

Determine whether filter uses real coefficients

Syntax

```
isreal(hd)
isreal(hs)
```

Description

`isreal(hd)` returns `1` (or true) if all filter coefficients for the filter `hd` are real, and returns `0` (or false) otherwise. Complex filters have one or more coefficients with nonzero imaginary parts.

`isreal(hs)` determines whether the filter coefficients of the filter System object `hs` are real, returning `1` if true and `0` if false.

Note Quantizing a filter cannot make a real filter into a complex filter.

Examples

Check If the Filter Coefficients are Real

Create a `dsp.BiquadFilter` System object™. Pass a fixed-point input to the object. Test the coefficients of the fixed-point filter to see if they are strictly real.

```
d = fdesign.lowpass('n,fp,ap,ast',5,0.4,0.5,20);
biquadFilter = design(d,'ellip','SystemObject',true);
IsRealBefore = isreal(biquadFilter)
```

```
IsRealBefore =

  logical
```

```
   1
```

Pass a fixed-point input to the object.

```
fiInput = fi(randn(1000,2),1,32,16);
fiOutput = biquadFilter(fiInput);
IsRealAfter = isreal(biquadFilter)
```

```
IsRealAfter =

  logical

   1
```

`isreal` returns a 1, indicating that the filter coefficients are real.

Introduced in R2011a

issos

Determine whether filter is SOS form

Syntax

```
issos(hd)
issoss(hs)
```

Description

`issos(hd)` determines whether quantized filter `hq` consists of second-order sections. Returns `1` if all sections of quantized filter `hq` have order less than or equal to two, and `0` otherwise.

`issoss(hs)` determines whether the filter System object `hs` consists of second-order sections, returning `1` if true and `0` if false.

Examples

Design a Lowpass SOS Filter

By default, fdesign and design return SOS filters when possible. This example designs a lowpass SOS filter that uses fixed-point arithmetic.

```
d = fdesign.lowpass('n,fp,ap,ast',40,0.55,0.1,60);
hd = design(d,'ellip','SystemObject',true);
IsSOS=issos(hd)
```

```
IsSOS =

  logical

   1
```

The filter is in second-order section form.

See Also

Introduced in R2011a

isstable

Determine whether filter is stable

Syntax

```
flag = isstable(b,a)
flag = isstable(sos)
flag = isstable(d)
flag = isstable(hs)
flag = isstable(hs,'Arithmetic',arithtype)
```

Description

`flag = isstable(b,a)` returns a logical output, `flag`, equal to `true` if the filter specified by numerator coefficients, `b`, and denominator coefficients, `a`, is a stable filter. If the poles lie on or outside the circle, `isstable` returns `false`. If the poles are inside the circle, `isstable` returns `true`.

`flag = isstable(sos)` returns `true` if the filter specified by second order sections matrix, `sos`, is stable. `sos` is a *K*-by-6 matrix, where the number of sections, *K*, must be greater than or equal to 2. Each row of `sos` corresponds to the coefficients of a second order (biquad) filter. The *i*th row of the `sos` matrix corresponds to `[bi(1) bi(2) bi(3) ai(1) ai(2) ai(3)]`.

`flag = isstable(d)` returns `true` if the digital filter, `d`, is stable. Use `designfilt` to generate `d` based on frequency-response specifications.

`flag = isstable(hs)` returns `true` if the filter System object `hs` is stable. You must have the DSP System Toolbox software to use this syntax.

`flag = isstable(hs,'Arithmetic',`*`arithtype`*`)` analyzes the filter System object `hs` based on the specified *`arithtype`*. *`arithtype`* can be `'double'`, `'single'`, or `'fixed'`. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked. You must have the DSP System Toolbox software to use this syntax.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

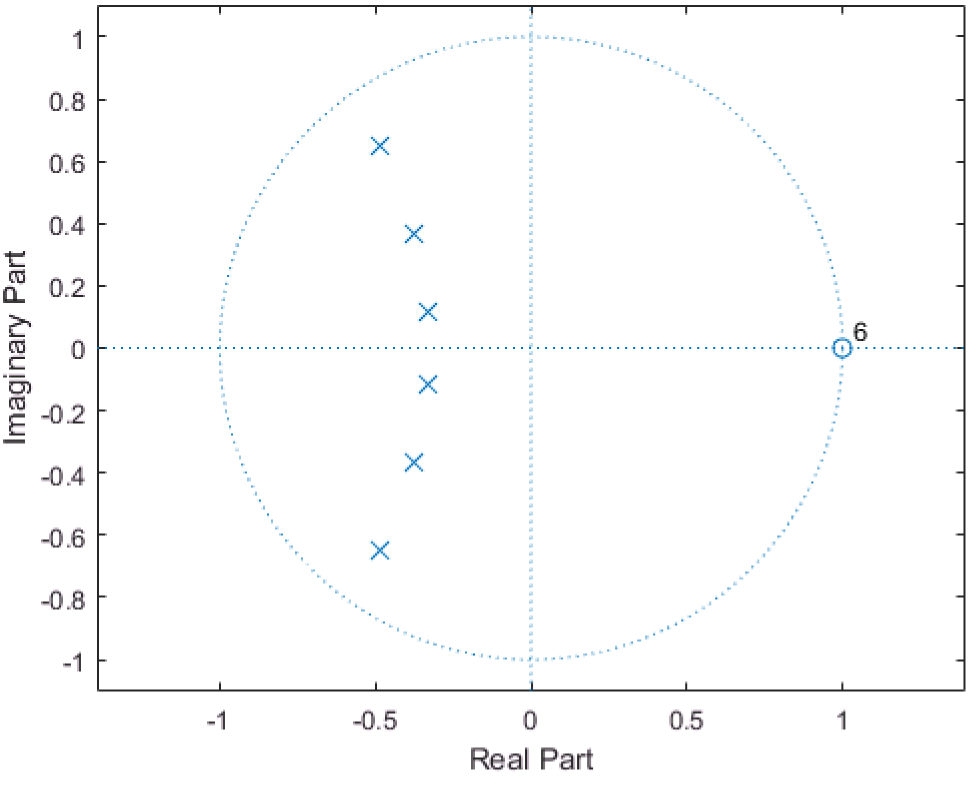
Filter Stability

Design a sixth-order Butterworth highpass IIR filter using second order sections. Specify a normalized 3-dB frequency of 0.7. Determine if the filter is stable.

```
[z,p,k] = butter(6,0.7,'high');
SOS = zp2sos(z,p,k);
flag = isstable(SOS)
```

```
flag = logical
   1
```

```
zplane(z,p)
```

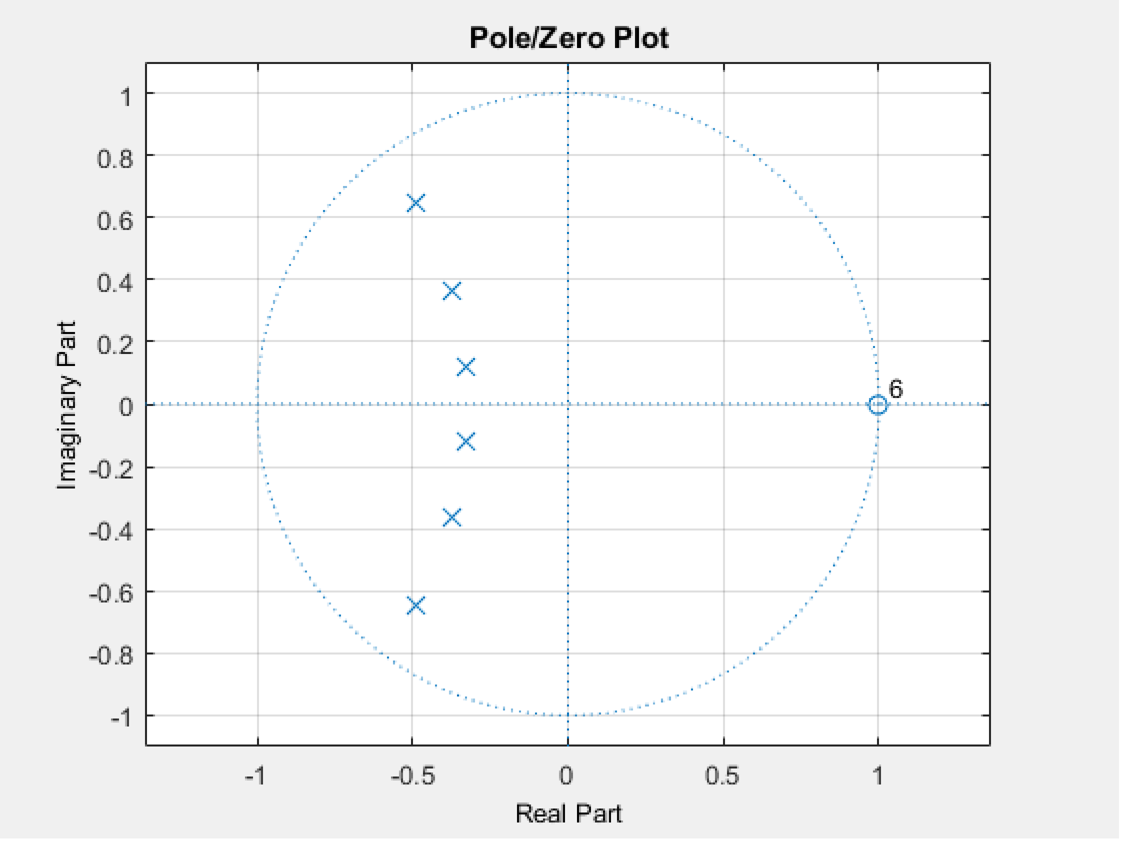


Redesign the filter using `designfilt` and check it for stability.

```
d = designfilt('highpassiir','DesignMethod','butter','FilterOrder',6, ...
                 'HalfPowerFrequency',0.7);
dflg = isstable(d)
```

```
dflg = logical
   1
```

```
zplane(d)
```



Create a filter and determine its stability at double and single precision.

```
b = [1 -0.5];
a = [1 -0.999999999];
act_flag1 = isstable(b,a)
```

```
act_flag1 = logical
   1
```

```
act_flag2 = isstable(single(b),single(a))
```

```
act_flag2 = logical
   0
```

Introduced in R2013a

kaiserwin

Kaiser window filter from specification object

Syntax

```
kFilter = design(d,'kaiserwin','SystemObject',true)
kFilter = design(d,'kaiserwin',designoption,value,designoption,...
value,'SystemObject',true)
```

Description

`kFilter = design(d,'kaiserwin','SystemObject',true)` designs a digital filter `kFilter` that uses a Kaiser window. For `kaiserwin` to work properly, the filter order in the specifications object must be even. In addition, higher order filters (filter order greater than 120) tend to be more accurate for smaller transition widths. `kaiserwin` returns a warning when your filter order may be too low to design your filter accurately.

`kFilter = design(d,'kaiserwin',designoption,value,designoption,... value,'SystemObject',true)` returns a filter where you specify design options as input arguments and the design process uses the Kaiser window technique.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `kaiserwin`, refer to the command line help system. For example, to get specific information about using `kaiserwin` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'kaiserwin')
```

Examples

Design a Direct Form FIR Filter

This example designs a direct form FIR filter from a halfband filter specification object.

```
d = fdesign.halfband('n,tw',200,0.01);
hbFilter = design(d,'kaiserwin','filterstructure','dffir',...
    'SystemObject',true)
```

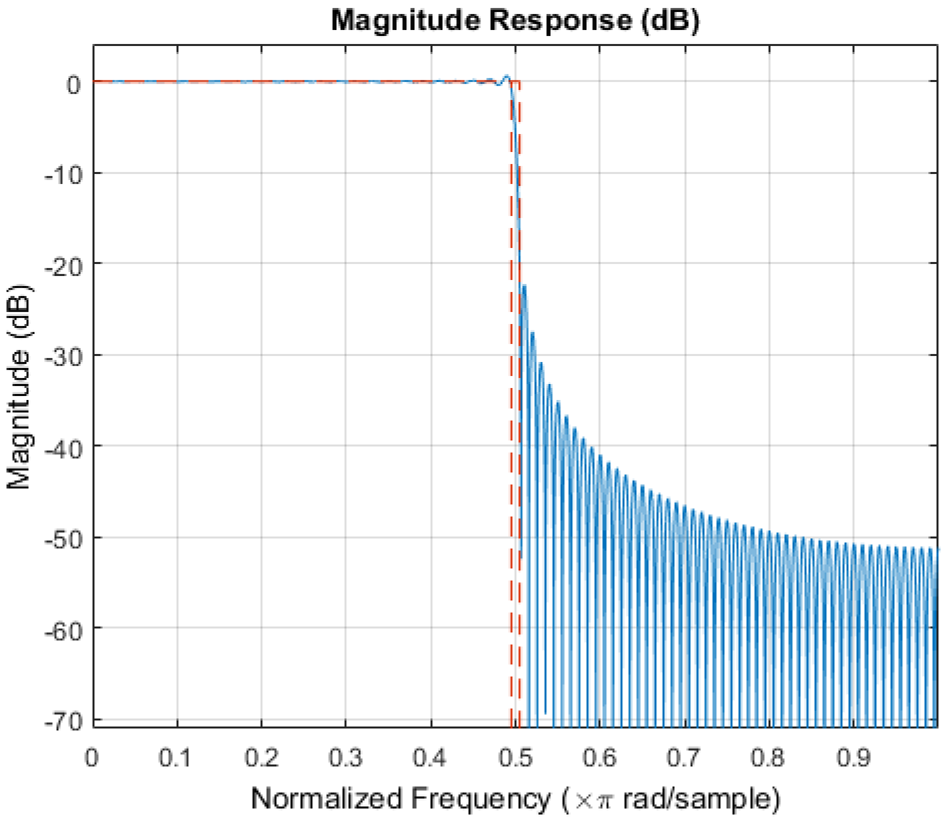
```
hbFilter = 

  dsp.FIRFilter with properties:

            Structure: 'Direct form'
      NumeratorSource: 'Property'
            Numerator: [1×201 double]
    InitialConditions: 0

  Use get to show all properties
```

```
fvtool(hbFilter);
```



In this example, `kaiserwin` uses an interpolating filter specification object.

```
d = fdesign.interpolator(4,'lowpass');
interpFilter= design(d,'kaiserwin','SystemObject',true)
```

```
interpFilter = 

  dsp.FIRInterpolator with properties:

        NumeratorSource: 'Property'
              Numerator: [1×147 double]
    InterpolationFactor: 4
```

```
  Use get to show all properties
```

```
fvtool(interpFilter);
```

Introduced in R2011a

lagrange

Fractional delay filter from `fdesign.fracdelay` specification object

Syntax

```
Hd = design(d,'lagrange')
hd = design(d,'lagrange',FilterStructure,structure)
```

Description

`Hd = design(d,'lagrange')` designs a fractional delay filter using the Lagrange method based on the specifications in `d`.

`hd = design(d,'lagrange',FilterStructure,`*`structure`*`)` specifies the Lagrange design method and the *`structure`* filter structure for `hd`. The sole valid filter structure string for `structure` is `fd`, describing the fractional delay structure.

Examples

This example uses a fractional delay of 0.30 samples. The `help` and `designopts` commands provide the details about designing fractional delay filters.

```
d=fdesign.fracdelay(.30)

d =

               Response: 'Fractional Delay'
          Specification: 'N'
            Description: {'Filter Order'}
              FracDelay: 0.3
    NormalizedFrequency: true
            FilterOrder: 3

designmethods(d)

Design Methods for class fdesign.fracdelay (N):
```

```
lagrange

help(d,'lagrange')

DESIGN Design a Lagrange fractional delay filter.
HD = DESIGN(D, 'lagrange') designs a Lagrange filter specified by the
  FDESIGN object D, and returns the DFILT object HD.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
 structure STRUCTURE.  STRUCTURE is 'farrowfd' by default and can be any of
 the following:

'farrowfd'
'fd'

 % Example #1 - Design a linear Lagrange fractional delay filter of 0.2 samples.
 h = fdesign.fracdelay(0.2,'N',2);
 Hd = design(h, 'lagrange', 'FilterStructure', 'farrowfd')

 % Example #2 - Design a cubic Lagrange fractional delay filter
 Fs = 8000;      % Sampling frequency of 8kHz
 fdelay = 50e-6; % Fractional delay of 50 microseconds.
 h  = fdesign.fracdelay(fdelay,'N',3,Fs);
 Hd = design(h, 'lagrange', 'FilterStructure', 'farrowfd');
```

This example designs a linear Lagrange fractional delay filter where you set the delay to 0.2 seconds and the filter order N to 2.

```
h = fdesign.fracdelay(0.2,'N',2);
hd = design(h,'lagrange','FilterStructure','farrowfd')
```

Design a cubic Lagrange fractional delay filter with filter order equal to 3.

```
Fs = 8000;      % Sampling frequency of 8 kHz.
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h  = fdesign.fracdelay(fdelay,'N',3,Fs);
hd = design(h,'lagrange','FilterStructure','farrowfd');
```

Introduced in R2011a

liblinks

Check model for blocks from specific DSP System Toolbox libraries

Syntax

```
liblinks(lib)
liblinks(lib,sys)
liblinks(lib,sys,c)
```

Description

`liblinks(lib)` returns a cell array of character vectors that lists the blocks in the current model that are linked to the specified libraries. The input `lib` provides a cell array of character vectors with the library names. Use the library name visible in the title bar when you open a library model.

`liblinks(lib,sys)` acts on the named model `sys`.

`liblinks(lib,sys,c)` changes the foreground color of the returned blocks to the color `c`. Possible values of `c` are `'blue'`, `'green'`, `'red'`, `'cyan'`, `'magenta'`, `'yellow'`, or `'black'`.

Examples

Check for blocks from the Sources library in the specified model:

```
rlsdemo
liblinks('dspsrcs4',gcs)
```

`dsp_links`

Introduced before R2006a

limitcycle

Response of single-rate, fixed-point IIR filter

Syntax

```
report = limitcycle(hd)
report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)
```

Description

`report = limitcycle(hd)` returns the structure `report` that contains information about how filter `hd` responds to a zero-valued input vector. By default, the input vector has length equal to twice the impulse response length of the filter.

`limitcycle` returns a structure whose elements contain the details about the limit cycle testing. As shown in this table, the report includes the following details.

Output Object Property	Description
`LimitCycleType`	Contains one of the following results: • `Granular` — indicates that a granular overflow occurred. • `Overflow` — indicates that an overflow limit cycle occurred. • `None` — indicates that the test did not find any limit cycles.
`Zi`	Contains the initial condition value(s) that caused the detected limit cycle to occur.
`Output`	Contains the output of the filter in the steady state.
`Trial`	Returns the number of the Monte Carlo trial on which the limit cycle testing stopped. For example, `Trial = 10` indicates that testing stopped on the tenth Monte Carlo trial.

Using an input vector longer than the filter impulse response ensures that the filter is in steady-state operation during the limit cycle testing. `limitcycle` ignores output that occurs before the filter reaches the steady state. For example, if the filter impulse length is 500 samples, `limitcycle` ignores the filter output from the first 500 input samples.

To perform limit cycle testing on your IIR filter, you must set the filter `Arithmetic` property to `fixed` and `hd` must be a fixed-point IIR filter of one of the following forms:

- `df1` — direct-form I
- `df1t` — direct-form I transposed
- `df1sos` — direct-form I with second-order sections
- `df1tsos` — direct-form I transposed with second-order sections
- `df2` — direct-form II
- `df2t` — direct-form II transposed
- `df2sos` — direct-form II with second-order sections
- `df2tsos` — direct-form II transposed with second-order sections

When you use `limitcycle` without optional input arguments, the default settings are

- Run 20 Monte Carlo trials
- Use an input vector twice the length of the filter impulse response
- Stop testing if the simulation process encounters either a granular or overflow limit cycle

To determine the length of the filter impulse response, use `impzlength`:

```
impzlength(hd)
```

During limit cycle testing, if the simulation runs reveal both overflow and granular limit cycles, the overflow limit cycle takes precedence and is the limit cycle that appears in the report.

Each time you run `limitcycle`, it uses a different sequence of random initial conditions, so the results can differ from run to run.

Each Monte Carlo trial uses a new set of randomly determined initial states for the filter. Test processing stops when `limitcycle` detects a zero-input limit cycle in filter `hd`.

`report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)` returns a report of how filter `hd` responds to a zero-valued input vector, using the following optional input arguments:

- `ntrials` — Number of Monte Carlo trials (default is 20).
- `inputlengthfactor` — integer factor used to calculate the length of the input vector. The length of the input vector comes from (`impzlength(hd) * inputlengthfactor`), where `inputlengthfactor` = 2 is the default value.
- `stopcriterion` — the criterion for stopping the Monte Carlo trial processing. `stopcriterion` can be set to **`either`** (the default), **`granular`**, **`overflow`**. This table describes the results of each stop criterion.

stopcriterion Setting	Description
`either`	Stop the Monte Carlo trials when `limitcycle` detects either a granular or overflow limit cycle.
`granular`	Stop the Monte Carlo trials when `limitcycle` detects a granular limit cycle.
`overflow`	Stop the Monte Carlo trials when `limitcycle` detects an overflow limit cycle.

Note An important feature is that if you specify a specific limit cycle stop criterion, such as `overflow`, the Monte Carlo trials do not stop when testing encounters a granular limit cycle. You receive a warning that no `overflow` limit cycle occurred, but consider that a `granular` limit cycle might have occurred.

Examples

In this example, there is a region of initial conditions in which no limit cycles occur and a region where they do. If no limit cycles are detected before the Monte Carlo trials are over, the state sequence converges to zero. When a limit cycle is found, the states do not end at zero. Each time you run this example, it uses a different sequence of random initial conditions, so the plot you get can differ from the one displayed in the following figure.

```
s = [1 0 0 1 0.9606 0.9849];
hd = dfilt.df2sos(s);
hd.arithmetic = 'fixed';
```

```
greport = limitcycle(hd,20,2,'granular')
oreport = limitcycle(hd,20,2,'overflow')
figure,
subplot(211),plot(greport.Output(1:20)), title('Granular Limit Cycle');
subplot(212),plot(oreport.Output(1:20)), title('Overflow Limit Cycle');

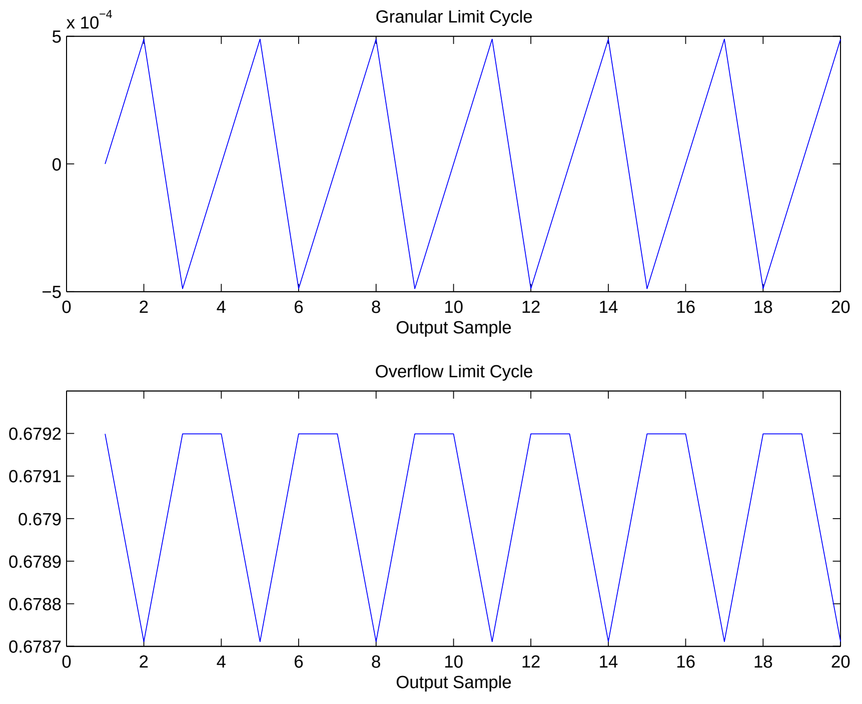
greport =

    LimitCycle: 'granular'
            Zi: [2x1 double]
        Output: [1303x1 embedded.fi]
         Trial: 1

oreport =

    LimitCycle: 'overflow'
            Zi: [2x1 double]
        Output: [1303x1 embedded.fi]
         Trial: 2
```

The plots shown in this figure present both limit cycle types — the first displays the small amplitude granular limit cycle, the second the larger amplitude overflow limit cycle.



As you see from the plots, and as is generally true, overflow limit cycles are much greater magnitude than granular limit cycles. This is why `limitcycle` favors overflow limit cycle detection and reporting.

Introduced in R2011a

maxflat

Maxflat FIR filter

Syntax

```
maxflatFilter = design(d,'maxflat','SystemObject',true)
maxflatFilter =
design(d,'maxflat','FilterStructure',structure,'SystemObject',true)
```

Description

`maxflatFilter = design(d,'maxflat','SystemObject',true)` designs a maximally flat filter, `maxflatFilter`, from a filter specification object, `d`.

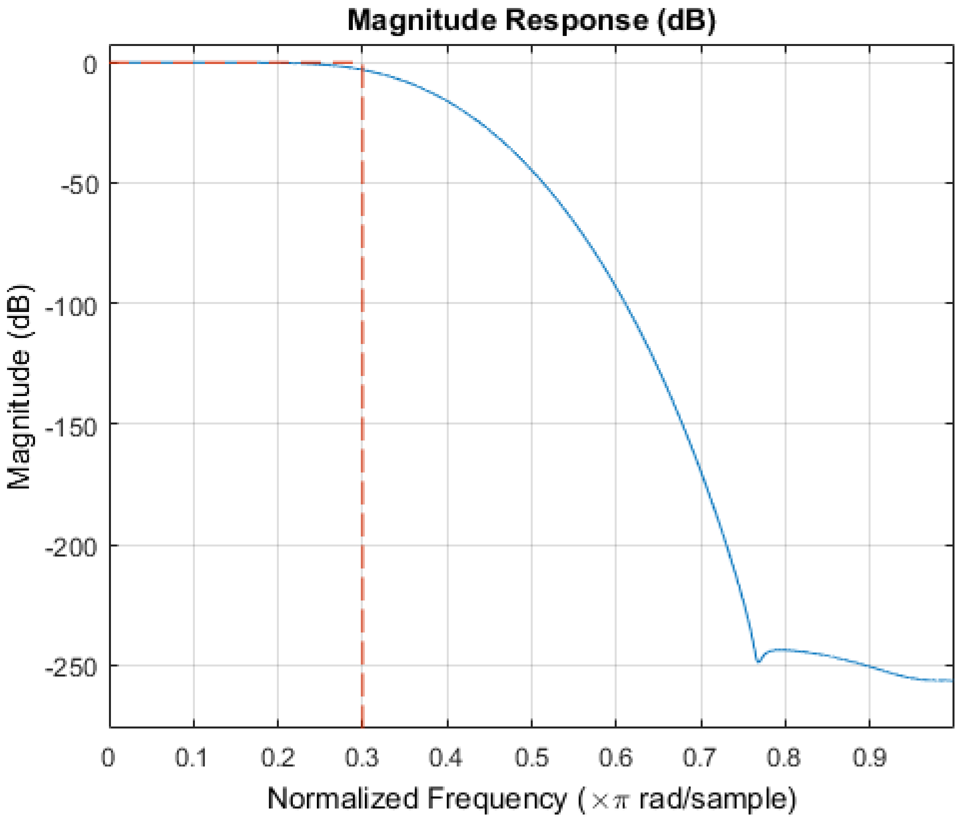
`maxflatFilter =`
`design(d,'maxflat','FilterStructure',structure,'SystemObject',true)` designs a maximally flat filter where `structure` is one of the following:

- `'dffir'`, a discrete-time, direct-form FIR filter (the default value)
- `'dffirt'`, a discrete-time, direct-form FIR transposed filter
- `'dfsymfir'`, a discrete-time, direct-form symmetric FIR filter

Examples

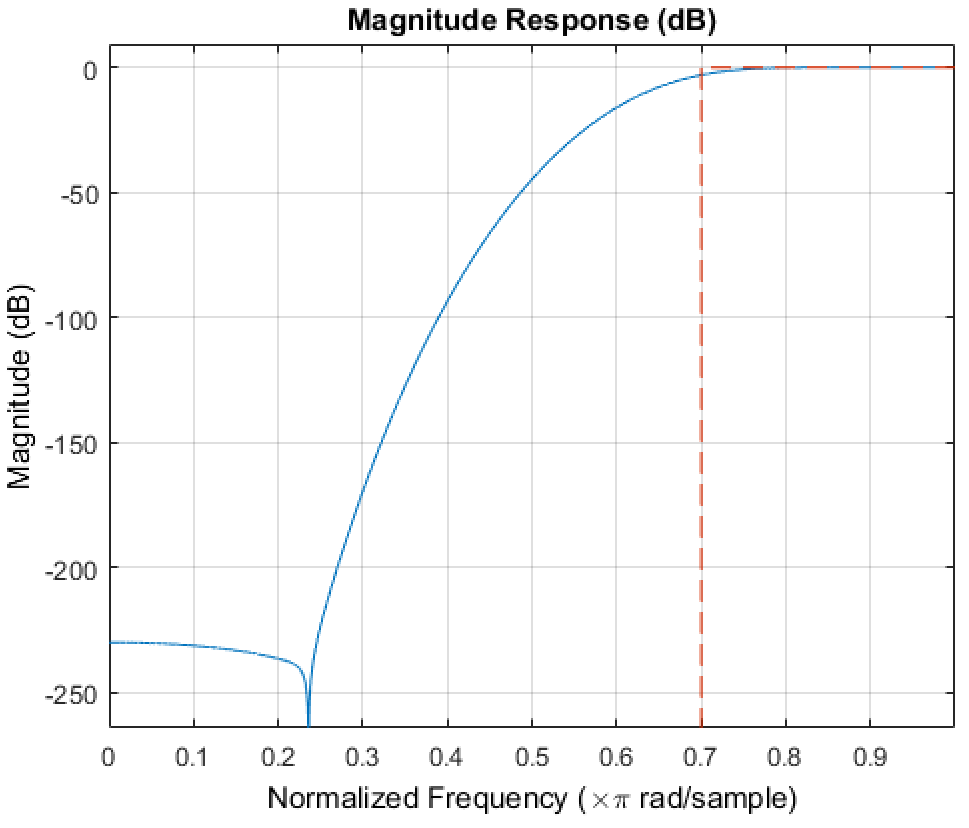
Design a Lowpass Filter with a Maximally Flat FIR Structure

```
d  = fdesign.lowpass('N,F3dB', 50, 0.3);
flatLowpass = design(d, 'maxflat','SystemObject',true);
fvtool(flatLowpass);
```



Design a Highpass Filter With a Maximally Flat Symmetric FIR Structure

```
d  = fdesign.highpass('N,F3dB', 50, 0.7);
flatHighpass = design(d,'maxflat','FilterStructure','dfsymfir',...
    'SystemObject',true);
fvtool(flatHighpass)
```



Introduced in R2011a

maximizestopband

Maximize stopband attenuation of fixed-point filter

Syntax

```
Hq = maximizestopband(Hd,Wordlength)
Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)
```

Description

`Hq = maximizestopband(Hd,Wordlength)` quantizes the single-stage or multistage FIR filter `Hd` and returns the fixed-point filter `Hq` with wordlength `wordlength` that maximizes the stopband attenuation. `Hd` must be generated using `fdesign` and `design`. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `maximizestopband` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use in the maximization. `Hq` is the fixed-point filter with the largest stopband attenuation among the trials. The number of Monte Carlo trials `N` defaults to 1.

You must have the Fixed-Point Designer software installed to use this function.

Examples

Maximize Stopband Attenuation

Maximize stopband attenuation for 16-bit fixed-point filter.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',0.4,0.45,0.5,60);
```

```
Hd = design(Hf,'equiripple');
```

Use 16 bits to represent coefficients.

```
WL = 16;
Hq = maximizestopband(Hd,WL);
```

Compare stopband attenuation

```
md = measure(Hd)

md =

Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.41178
6-dB Point       : 0.41845
Stopband Edge    : 0.45
Passband Ripple  : 0.49369 dB
Stopband Atten.  : 60.0697 dB
Transition Width : 0.05
```

```
mq = measure(Hq)

mq =

Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.41178
6-dB Point       : 0.41845
Stopband Edge    : 0.45
Passband Ripple  : 0.49773 dB
Stopband Atten.  : 59.9728 dB
Transition Width : 0.05
```

```
hfvt=fvtool(Hd,Hq,'ShowReference','off');
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

Introduced in R2011a

maxstep

Maximum step size for adaptive filter convergence

Compatibility

`maxstep` will be removed in a future release. Use dsp.LMSFilter or dsp.BlockLmsFilter instead.

Syntax

```
mumax = maxstep(ha,x)
[mumax,mumaxmse] = maxstep(ha,x)
```

Description

`mumax = maxstep(ha,x)` predicts a bound on the step size to provide convergence of the mean values of the adaptive filter coefficients. The columns of the matrix `x` contain individual input signal sequences. The signal set is assumed to have zero mean or nearly so.

`[mumax,mumaxmse] = maxstep(ha,x)` predicts a bound on the adaptive filter step size to provide convergence of the LMS adaptive filter coefficients in the mean-square sense. `maxstep` issues a warning when `ha.stepsize` is outside of the range 0 < `ha.stepsize` < `mumaxmse`/2.

`maxstep` is available for the following adaptive filter objects:

- `adaptfilt.blms`
- `adaptfilt.blmsfft`
- `adaptfilt.lms`
- `adaptfilt.nlms` (uses a different syntax. Refer to the text below.)
- `adaptfilt.se`

Note With `adaptfilt.nlms` filter objects, `maxstep` uses the following slightly different syntax:

```
mumax = maxstep(ha)
[mumax,mumaxmse] = maxstep(ha)
```

The maximum step size for convergence is fully defined by the filter object `ha`. Matrix `x` is not necessary. If you include an `x` input matrix, MATLAB returns an error.

Examples

Analyze and simulate a 32-coefficient (31st-order) LMS adaptive filter object. To demonstrate the adaptation process, run 2000 iterations and 50 trials.

```
% Specify [numiterations,numexamples] = size(x);
x = zeros(2000,50);
d = x;
obj = fdesign.lowpass('n,fc',31,0.5);
hd = design(obj,'window'); % FIR filter to identified.
coef = cell2mat(hd.coefficients); % Convert cell array to matrix.

for k=1:size(x,2);   % Create input and desired response signal
                     % matrices.
% Set the (k)th input to the filter.
  x(:,k) = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x,1),1)));
  n = 0.1*randn(size(x,1),1);  % (k)th observation noise signal.
  d(:,k) = filter(coef,1,x(:,k))+n; % (k)th desired signal end.
end
mu = 0.1;                      % LMS step size.
ha = adaptfilt.lms(32,mu);
[mumax,mumaxmse] = maxstep(ha,x);

Warning: Step size is not in the range 0 < mu < mumaxmse/2:
Erratic behavior might result.

mumax

mumax =

    0.0623

mumaxmse

mumaxmse =

    0.0530
```

Introduced in R2011a

measure

Measure frequency response characteristics of filter System object

Syntax

```
measure(sysobj)
M = measure(sysobj)
M = measure(sysobj,'Arithmetic',ARITH,...)
M = measure(sysobj,'freqspec', freqspecvalue,...)
```

Description

`measure(sysobj)` displays measurements of various quantities from the frequency response of the filter System object, `sysobj`. Measurements include the actual passband ripple, the minimum stopband attenuation, the frequency point at which the filter's gain is 3 dB below the nominal passband gain, etc. You must construct `sysobj` using `fdesign` and `design` with the name-value pair argument `'SystemObject', true`. You can optionally specify additional options by one or more `Name,Value` pair arguments.

`M = measure(sysobj)` returns the measurements, *M*, such that the measurements can be queried programmatically. For example, to query the 3 dB point, type `M.F3dB`. Type `get(M)` to see the full list of properties that can be queried. Note that different filter responses generate different measurements.

`M = measure(sysobj,'Arithmetic',ARITH,...)` analyzes the filter System object, `sysobj`, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to one of `'double'`, `'single'`, or `'fixed'`. When the arithmetic input is not specified and the filter System object is in an unlocked state, the analysis tool assumes a double precision filter.

`M = measure(sysobj,'freqspec', freqspecvalue,...)` passes the frequency value as an input to `measure` in order to determine the corresponding magnitude measurements. For designs that do not specify some of the frequency constraints, you can determine the corresponding magnitude measurements using this option.

In the following example, the passband edge, passband ripple, and the transition width of the IIR filter are unknown.

```
designLowpass = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
chebFilter = design(designLowpass,'cheby2');
measure(chebFilter)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : Unknown
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : Unknown
Stopband Atten.  : 79.9994 dB
Transition Width : Unknown
```

Specify the passband edge to be `0.4`, and measure the passband ripple and the transition width of this filter.

```
measure(chebFilter,'Fpass',0.4)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : 0.013644 dB
Stopband Atten.  : 79.9994 dB
Transition Width : 0.28727
```

When `sysobj` is a generic discrete-time filter, for example, a single-rate lowpass filter, `measure(sysobj)` returns the following filter specifications.

Lowpass Filter Specification	Description
`Sample Rate`	Filter sampling frequency.
`Passband Edge`	Location of the edge of the passband as it enters transition.
`3-dB Point`	Location of the –3 dB point on the response curve.
`6-dB Point`	Location of the –6 dB point on the response curve.
`Stopband Edge`	Location of the edge of the transition band as it enters the stopband.
`Passband Ripple`	Ripple in the passband.

Lowpass Filter Specification	Description
`Stopband Atten`	Attenuation in the stopband.
`Transition Width`	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between `Fpass` and `Fstop`.

When `sysobj` is a bandstop filter, `measure(sysobj)` returns these specifications for the resulting bandstop filter.

Bandstop Filter Specification	Description
`Sample Rate`	Filter sampling frequency.
`First Passband Edge`	Location of the edge of the first passband.
`First 3-dB Point`	Location of the edge of the –3 dB point in the first transition band.
`First 6-dB Point`	Location of the edge of the –6 dB point in the first transition band.
`First Stopband Edge`	Location of the start of the stopband.
`Second Stopband Edge`	Location of the end of the stopband.
`Second 6-dB Point`	Location of the edge of the –6 dB point in the second transition band.
`Second 3-dB Point`	Location of the edge of the –3 dB point in the second transition band.
`Second Passband Edge`	Location of the start of the second passband.
`First Passband Ripple`	Ripple in the first passband.
`Stopband Atten`	Attenuation in the stopband.
`Second Passband Ripple`	Ripple in the second passband.
`First Transition Width`	Width of the first transition region. Measured between the –3 and –6 dB points.
`Second Transition Width`	Width of the second transition region. Measured between the –6 and –3 dB points.

When `sysobj` is an interpolator, decimator, or a rate converter, `measure(sysobj)` returns these specifications for the resulting filter.

Interpolator Filter Specification	Description
`Sample Rate`	Filter sampling frequency.
`First Passband Edge`	Location of the edge of the passband as it enters transition.
`3-dB Point`	Location of the –3 dB point on the response curve.
`6-dB Point`	Location of the –6 dB point on the response curve.
`Stopband Edge`	Location of the edge of the transition band as it enters the stopband.
`Passband Ripple`	Ripple in the passband.
`Stopband Atten`	Attenuation in the stopband.
`Transition Width`	Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between `Fpass` and `Fstop`.

Input Arguments

`sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter

Filter System objects
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	'Same as input'	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Examples

Measure the Filter Specifications

Create a lowpass filter and check whether the actual filter meets the specifications. For this case, use normalized frequency for Fs, the default setting.

```
desigLowpass = fdesign.lowpass('Fp,Fst,Ap,Ast',0.45,0.55,0.1,80)
```

```
desigLowpass = 

  lowpass with properties:

               Response: 'Lowpass'
          Specification: 'Fp,Fst,Ap,Ast'
            Description: {4×1 cell}
    NormalizedFrequency: 1
                  Fpass: 0.4500
                  Fstop: 0.5500
                  Apass: 0.1000
                  Astop: 80
```

```
designmethods(desigLowpass,'SystemObject',true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Use the default equiripple design method.

```
equiFilter = design(desigLowpass,'SystemObject',true)
```

```
equiFilter =

  dsp.FIRFilter with properties:

            Structure: 'Direct form'

                 Astop1: 60
                  Apass: 1
                 Astop2: 60
```

Convert to Linear Frequency.

```
normalizefreq(designBandpass,false,1.5e3)
```

```
bpFilter = design(designBandpass,'cheby2','SystemObject',true);
```

Measure the specifications of the designed bandpass filter.

```
measure(bpFilter)
```

```
ans =

Sample Rate              : 1.5 kHz
First Stopband Edge      : 262.5 Hz
First 6-dB Point         : 319.9585 Hz
First 3-dB Point         : 324.9744 Hz
First Passband Edge      : 337.5 Hz
Second Passband Edge     : 412.5 Hz
Second 3-dB Point        : 425.0256 Hz
Second 6-dB Point        : 430.0415 Hz
Second Stopband Edge     : 487.5 Hz
First Stopband Atten.    : 60 dB
Passband Ripple          : 0.17985 dB
Second Stopband Atten.   : 60 dB
First Transition Width   : 75 Hz
Second Transition Width  : 75 Hz
```

Tips

For designs that do not specify some of the frequency constraints, the function may not be able to determine corresponding magnitude measurements. In these cases, a constraint can be passed in to `measure` to determine such measurements. For example:

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H)
```

returns values of `Unknown` for the passband edge, passband ripple, and transition width measurements, but

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
H = design(f,'cheby2','SystemObject',true);
measure(H,'Fpass',0.4)
```

provides measurements for all returned values.

Introduced in R2011a

mfilt

Multirate filter

Compatibility

`mfilt` will be removed in a future release. See dsp.CICDecimator, dsp.CICInterpolator, dsp.FIRDecimator, dsp.FIRInterpolator, dsp.FilterCascade, dsp.FarrowRateConverter, dsp.FIRRateConverter, dsp.IIRHalfbandDecimator, or dsp.IIRHalfbandInterpolator instead.

Syntax

`hm = mfilt.`*`structure`*`(input1,input2,...)`

Description

`hm = mfilt.`*`structure`*`(input1,input2,...)` returns the object `hm` of type *`structure`*. As with `dfilt` objects, you must include the *`structure`* string to construct a multirate filter object. You can, however, construct a default multirate filter object of a given structure by not including input arguments in your calling syntax.

Multirate filters include decimators and interpolators, and fractional decimators and fractional interpolators where the resulting interpolation or decimation factor is not an integer.

Structures

Each of the following multirate filter structures has a reference page of its own.

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in `realizemdl` and `block`
`mfilt.cascade`	Cascade multirate filters to form another filter	Supported

Filter Structure String	Description of Resulting Multirate Filter	Coefficient Mapping Support in `realizemdl` and `block`
`mfilt.cicdecim`	Cascaded integrator-comb decimator	Not supported
`mfilt.cicinterp`	Cascaded integrator-comb interpolator	Not supported
`mfilt.farrowsrc`	Multirate Farrow filter	Supported.
`mfilt.fftfirinterp`	Overlap-add FIR polyphase interpolator	Not supported
`mfilt.firdecim`	Direct-form FIR polyphase decimator	Supported
`mfilt.firinterp`	Direct-form FIR polyphase interpolator	Supported
`mfilt.firsrc`	Direct-form FIR polyphase sample rate converter	Supported
`mfilt.firtdecim`	Direct-form transposed FIR polyphase decimator	Supported
`mfilt.holdinterp`	FIR hold interpolator	Not supported
`mfilt.iirdecim`	IIR decimator	Supported
`mfilt.iirinterp`	IIR interpolator	Supported
`mfilt.linearinterp`	FIR Linear interpolator	Supported
`mfilt.iirwdfdecim`	IIR wave digital filter decimator	Supported
`mfilt.iirwdfinterp`	IIR wave digital filter interpolator	Supported

Copying mfilt Objects

To create a copy of an `mfilt` object, use the `copy` method.

```
h2 = copy(hd)
```

Note The syntax `hd2 = hd` copies only the object handle. It does not create a new object. `hd2` and `hd` are not independent. If you change the property value for one of the two, such as `hd2`, you are changing the property for both.

Examples

Decimation by a factor of two. Convert input sampled at 48 kHz to 24 kHz:

```
Fs = 4.8e4;
t =0:1/Fs:1-(1/Fs);
x = cos(2*pi*4000*t);
Hm=mfilt.firdecim(2);
% Note cutoff frequency of 1/2 normalized frequency
fvtool(Hm);
% Note the group delay of 34 samples
fvtool(Hm,'analysis','grpdelay');
y = filter(Hm,x);
% Note delay in output is consistent with 36/2
stem(y(1:48),'markerfacecolor',[0 0 1]);
```

Using existing coefficients to decimate a signal by a factor of two:

```
M = 2; % Decimation factor
  b = firhalfband('minorder',.45,0.0001);
  Hm = mfilt.firdecim(M,b);
  % Decimate a signal which consists of the sum of 2 sinusoids.
  N = 160;
  x = sin(2*pi*.05*[0:N-1]+pi/3)+cos(2*pi*.03*[0:N-1]+pi/3);
  y = filter(Hm,x);
```

Note Multirate filters can also have complex coefficients. For example, you can specify complex coefficients in the argument `num` passed to the filter structure. This works for all multirate filter structures.

```
m = 2;
num = [0.5 0.5+1j*0.2];
Hm = mfilt.firdecim(m, num);
y = filter(Hm, [1:10]);
```

`mfilt.firinterp` | `mfilt.firsrc` | `mfilt.firtdecim`

Introduced in R2011a

mfilt.cascade

Cascade filter objects

Compatibility

`mfilt.cascade` will be removed in a future release. Use dsp.FilterCascade instead.

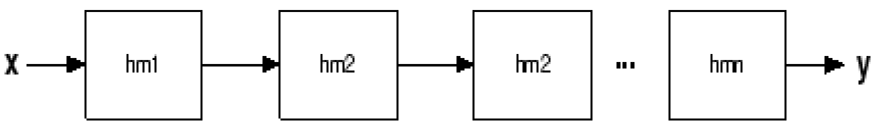
Syntax

```
hm = cascade(hm1,hm2,...,hmn)
```

Description

`hm = cascade(hm1,hm2,...,hmn)` creates filter object `hm` by cascading (connecting in series) the individual filter objects `hm1`, `hm2`, and so on to `hmn`.

In block diagram form, the cascade looks like this, with x as the input to the filter `hm` and y the output from the cascade filter `hm`:



`mfilt.cascade` accepts any combination of `mfilt` and `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

Examples

Create a variety of `mfilt` objects and cascade them together.

```
hm(1) = mfilt.firdecim(12);
hm(2) = mfilt.firdecim(4);
h1 = mfilt.cascade(hm(1),hm(2));
hm(3) = mfilt.firinterp(4);
```

```
hm(4) = mfilt.firinterp(12);
h2 = mfilt.cascade(hm(3),hm(4));
% Cascade h1 and h2 together
h3 = mfilt.cascade(h1,h2,9600);
```

See Also

`dfilt.cascade`

Introduced in R2011a

mfilt.cicdecim

Fixed-point CIC decimator

Compatibility

`mfilt.cicdecim` will be removed in a future release. Use dsp.CICDecimator instead.

Syntax

```
hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)
```

Description

`hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)` returns a cascaded integrator-comb (CIC) decimation filter object.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
`r`	Decimation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. `r` must be an integer value greater than or equal to 1. The default value is 2.
`m`	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing `m` increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. `m` must be an integer value greater than or equal to 1. The default value is 1.

Input Arguments	Description
`n`	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. 2 is the default value.
`iwl`	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.
`owl`	Word length of the output signal. It can be any positive integer number of bits. By default, `owl` is 16 bits.
`wlps`	Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter `wlps` as a scalar or vector of length `2*n`, where `n` is the number of sections. When `wlps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator. When you elect to specify `wlps` as an input argument, the `FilterInternals` property automatically switches from the default value of `'FullPrecision'` to `'SpecifyWordLengths'`.

Constraints and Word Length Considerations

CIC decimators have the following constraint — the word lengths of the filter section must be monotonically decreasing. The word length of each filter section must be the same size as, or smaller than, the word length of the previous filter section.

The formula for B_{max}, the most significant bit at the filter output, is given in the Hogenauer paper in the References below.

$$B_{\max} = (N \log_2 RM + B_{in} - 1)$$

where B_{in} is the number of bits of the input.

The cast operations shown in the diagram in “Algorithms” on page 5-1124 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints above, the constructor returns an error.

When you specify the word lengths correctly, the most significant bit B_{max} stays the same throughout the filter, while the word length of each section either decreases or stays the same. This can cause the fraction length to change throughout the filter as least significant bits are truncated to decrease the word length, as shown in “Algorithms” on page 5-1124.

Properties of the Object

Objects have properties that control the way the object behaves. This table lists all the properties for the filter, with a description of each.

Name	Values	Default	Description
`Arithmetic`	`fixed`	`fixed`	Reports the kind of arithmetic the filter uses. CIC decimators are always fixed-point filters.
`DecimationFactor`	Any positive integer	2	Amount to reduce the input sampling rate.
`DifferentialDelay`	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
`FilterStructure`	`mfilt` structure string	None	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` objects.
`FilterInternals`	`FullPrecision`, `MinWordLengths`, `SpecifyPrecision`, `SpecifyWordLengths`	`FullPrecision`	Set the usage mode for the filter. Refer to “Usage Modes” on page 5-1117 below for details.
`InputFracLength`	Any positive integer	15	The number of bits applied to the fraction length to interpret the input data to the filter.

Name	Values	Default	Description
`InputOffset`	Integers in the range 0 ≤ **`InputOffset`** ≤ **`r-1`**	0	Contains a value derived from the number of input samples and the decimation factor — `InputOffset = mod(length(nx),m)` where `nx` is the number of input samples that have been processed so far and `m` is the decimation factor. The `InputOffset` property applies only when you set the `PersistentMemory` property to `true`. See "InputOffset" on page 6-113 for more information.
`InputWordLength`	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
`NumberOfSections`	Any positive integer	2	Number of sections used in the decimator. Generally called `n`. Reflects either the number of decimator or comb sections, not the total number of sections in the filter.
`OutputFracLength`	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.

Name	Values	Default	Description
`OutputWordLength`	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
`PersistentMemory`	`false` or `true`	`false`	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When `PersistentMemory` is `false`, you cannot access the filter states. Setting `PersistentMemory` to `true` reveals the `States` property so you can modify the filter states.

Name	Values	Default	Description
`SectionWord Lengths`	Any integer or a vector of length 2*`n`.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter `SectionWordLengths`

Name	Values	Default	Description
			as a scalar or vector of length 2*n, where n is the number of sections. When SectionWordLengths is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the decimator. Available when FilterInternals is 'SpecifyWordLengths'.
States	filtstates.cic object	m+1-by-n matrix of zeros, after you call function int.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. m is the differential delay of the comb section and n is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when PersistentMemory is true. Refer to the filtstates object in Signal Processing Toolbox documentation for more general information about the filtstates object.

Usage Modes

There are four modes of usage for this which are set using the `FilterInternals` property

- `FullPrecision` — All word and fraction lengths set to B_{max} + 1, called B_{accum} by Fred Harris in [3]. Full Precision is the default setting.
- `MinWordLengths` — Automatically set the sections for minimum word lengths.
- `SpecifyWordLengths` — Specify the word lengths for each section.
- `SpecifyPrecision` — Specify precision by providing values for the word and fraction lengths for each section.

Full Precision

In full precision mode, the word lengths of all sections and the output are set to B_{accum} as defined by

$$B_{accum} = ceil(N_{\mathrm{secs}}(Log_2(D \times M)) + InputWordLength)$$

where N_{secs} is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'FullPrecision'
```

Minimum Wordlengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than B_{accum}, roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [1]) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than B_{accum} as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from B_{accum} to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output wordlength for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'MinWordLengths'

OutputWordLength: 16
```

Specify word lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length 2*(`NumberOfSections`), where each vector element represents the word length for a section. If you specify a scalar, such as B_{accum}, the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display for the `SpecifyWordLengths` mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]

OutputWordLength: 16
```

Specify precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the word length for each section. When you enter a scalar such as B_{accum}, `mfilt.cicdecim` expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the fraction length for each section as well. When you enter a scalar such as B_{accum}, `mfilt.cicdecim` applies scalar expansion as done for the word lengths.

Here is the SpecifyPrecision display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]

OutputWordLength: 16
OutputFracLength: 11
```

About the States of the Filter

In the states property you find the states for both the integrator and comb portions of the filter. states is a matrix of dimensions m + 1-by-n, with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use int to assign the states to a variable in MATLAB. As an example, here are the states for a CIC decimator hm before and after filtering a data set.

```
x = fi(ones(1,10),true,16,0); % Fixed-point input data.
hm = mfilt.cicdecim(2,1,2,16,16,16);
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified.
y=filter(hm,x);
sts=int(hm.states)
```

STS is an integer matrix that int returns from the contents of the filtstates.cic object in hm.

Design Considerations

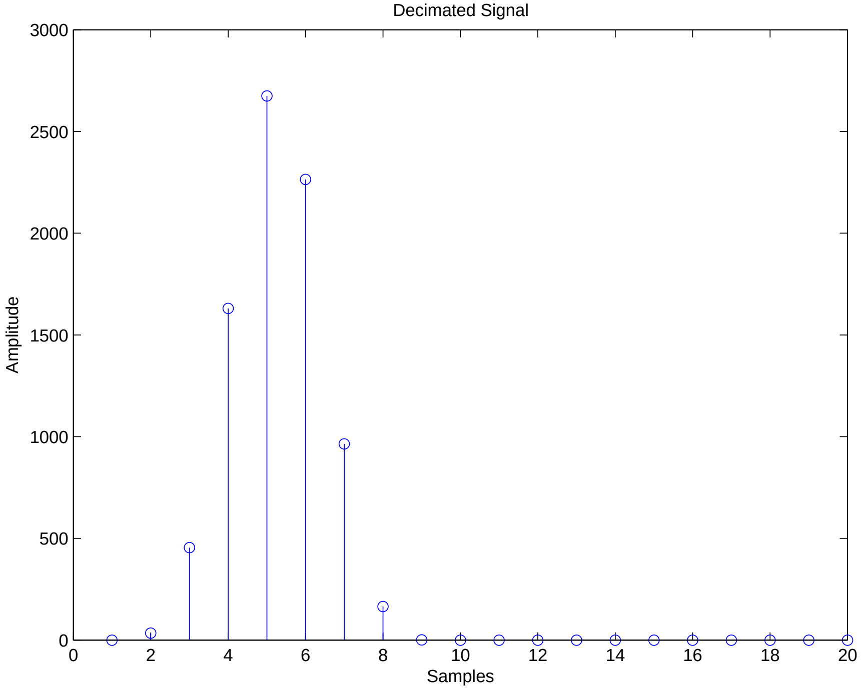
When you design your CIC decimation filter, remember the following general points:

- The filter output spectrum has nulls at $\omega = k * 2\pi/rm$ radians, $k = 1,2,3....$
- Aliasing and imaging occur in the vicinity of the nulls.
- n, the number of sections in the filter, determines the passband attenuation. Increasing n improves the filter ability to reject aliasing and imaging, but it also increases the droop (or rolloff) in the filter passband. Using an appropriate FIR filter in series after the CIC decimation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the decimation factor. Raising the decimation factor increases the DC gain.

Examples

This example applies a decimation factor r equal to 8 to a 160-point impulse signal. The signal output from the filter has 160/r, or 20, points or samples. Choosing 10 bits for the word length represents a fairly common setting for analog to digital converters. The plot shown after the code presents the stem plot of the decimated signal, with 20 samples remaining after decimation:

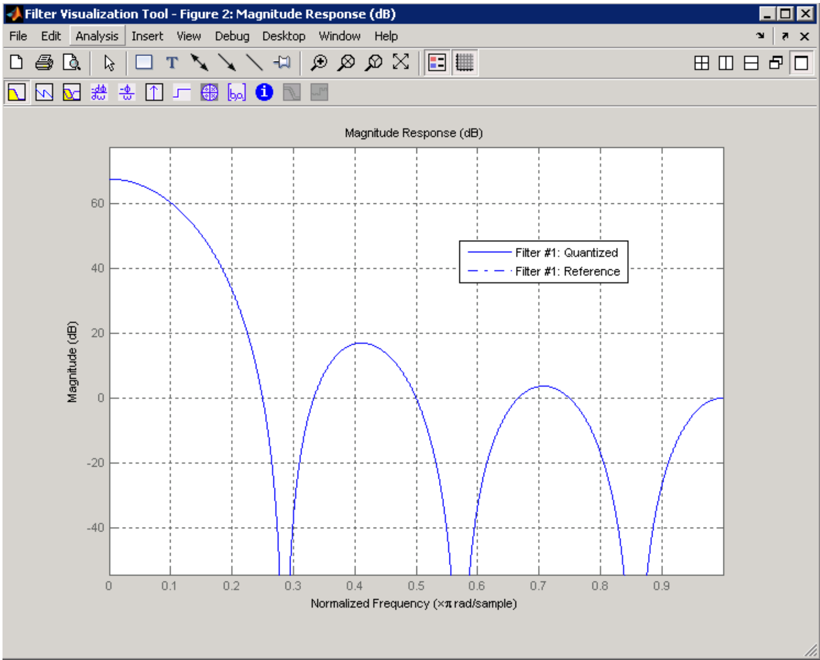
```
m = 2;  % Differential delays in the filter.
n = 4;  % Filter sections
r = 8;   % Decimation factor
x = int16(zeros(160,1)); x(1) = 1;    % Create a 160-point
                                      % impulse signal.
hm = mfilt.cicdecim(r,m,n); % Expects 16-bit input
                            % by default.
y = filter(hm,x);
stem(double(y));    % Plot output as a stem plot.
xlabel('Samples'); ylabel('Amplitude');
title('Decimated Signal');
```



The next example demonstrates one way to compute the filter frequency response, using a 4-section decimation filter with the decimation factor set to 7:

```
hm = mfilt.cicdecim(7,1,4);
fvtool(hm)
```

FVTool provides ways for you to change the title and x labels to match the figure shown. Here's the frequency response plot for the filter. For details about the transfer function used to produce the frequency response, refer to [1] in the References section.

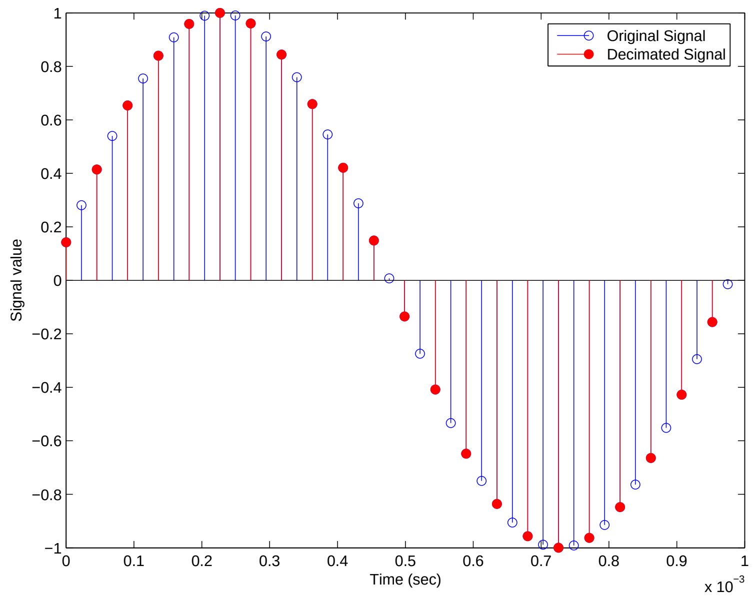


This final example demonstrates the decimator for converting from 44.1 kHz audio to 22.05 kHz — decimation by two. To overlay the before and after signals, scale the output and plot the signals on a stem plot.

```
r = 2;                  % Decimation factor.
hm = mfilt.cicdecim(r); % Use default NumberOfSections &
                        % DifferentialDelay property values.
fs = 44.1e3;            % Original sampling frequency: 44.1kHz.
n = 0:10239;            % 10240 samples, 0.232 second long signal.
x  = sin(2*pi*1e3/fs*n);% Original signal, sinusoid at 1kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

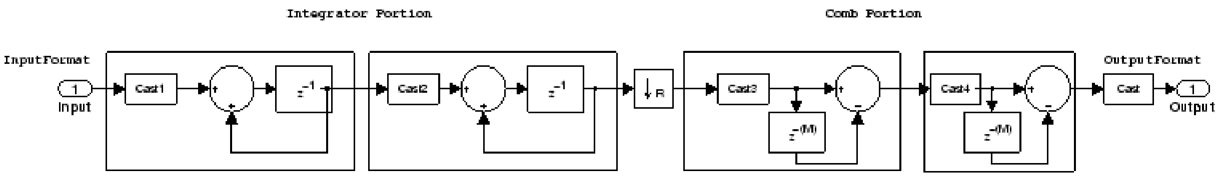
% Scale the output to overlay the stem plots.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:44)/fs,x(2:45)); hold on;  % Plot original signal
                                     % sampled at 44.1kHz.
stem(n(1:22)/(fs/r),y(3:24),'r','filled'); % Plot decimated
                                           % signal (22.05kHz)
                                           % in red.
xlabel('Time (seconds)');ylabel('Signal Value');
```



Algorithms

To show how the CIC decimation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC decimation filter (n = 2). *fs* is the high sampling rate, the input to the decimation process.

For details about the bits that are removed in the Comb section, refer to [1] in References.



`mfilt.cicdecim` calculates the fraction length at each section of the decimator to avoid overflows at the output of the filter.

`mfilt` | `mfilt.cicinterp`

Introduced in R2011a

mfilt.cicinterp

Fixed-point CIC interpolator

Compatibility

`mfilt.cicinterp` will be removed in a future release. Use dsp.CICInterpolator instead.

Syntax

```
hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)
hm = mfilt.cicinterp
hm = mfilt.cicinterp(R,...)
```

Description

`hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)` constructs a cascaded integrator-comb (CIC) interpolation filter object that uses fixed-point arithmetic.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

Input Arguments	Description
R	Interpolation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. R must be an integer value greater than or equal to 1. The default value is 2.
M	Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing M increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. M must be an integer value greater than or equal to 1. The default value is 1.

Input Arguments	Description
N	Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. By default, the filter has two sections.
IWL	Word length of the input signal. Use any integer number of bits. The default value is 16 bits.
OWL	Word length of the output signal. It can be any positive integer number of bits. By default, OWL is 16 bits.
WLPS	Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WLPS as a scalar or vector of length 2*N, where N is the number of sections. When WLPS is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the integrator. When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.

hm = mfilt.cicinterp constructs the CIC interpolator using the default values for the optional input arguments.

hm = mfilt.cicinterp(R,...) constructs the CIC interpolator applying the values you provide for R and any other values you specify as input arguments.

Constraints and Conversions

In Hogenauer [1], the author describes the constraints on CIC interpolator filters. mfilt.cicinterp enforces a constraint—the word lengths of the filter sections must be non-decreasing. That is, the word length of each filter section must be the same size as, or greater than, the word length of the previous filter section.

The formula for W_j, the minimum register width, is derived in [1]. The formula for W_j is given by

$$W_j = ceil(B_{in} + \log_2 G_j)$$

where G_j, the maximum register growth up to the jth section, is given by

$$G_j = \begin{cases} 2^j, & j = 1,2,\ldots,N \\ \dfrac{2^{2N-j}(RM)^{j-N}}{R}, & j = N+1,\ldots,2N \end{cases}$$

When the differential delay, M, is 1, there is also a special condition for the register width of the last comb, W_N, that is given by

$$W_N = B_{in} + N - 1 \quad if \quad M = 1$$

The conversions denoted by the cast blocks in the integrator diagrams in "Algorithms" on page 5-1135 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints described in this section, `mfilt.cicinterp` returns an error.

The fraction lengths and scalings of the filter sections do not change. At each section the word length is either staying the same or increasing. The signal scaling can change at the output after the final filter section if you choose the output word length to be less than the word length of the final filter section.

Properties of the Object

The following table lists the properties for the filter with a description of each.

Name	Values	Default	Description
`Arithmetic`	`fixed`	`fixed`	Reports the kind of arithmetic the filter uses. CIC interpolators are always fixed-point filters.
`InterpolationFactor`	Any positive integer	2	Amount to increase the input sampling rate.
`DifferentialDelay`	Any positive integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
`FilterStructure`	`mfilt` structure string	None	Reports the type of filter object, such as a interpolator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` objects.
`FilterInternals`	`FullPrecision`, `MinWordLengths`, `SpecifyWordLengths`, `SpecifyPrecision`	`FullPrecision`	Set the usage mode for the filter. Refer to "Usage Modes" on page 5-1132 below for details.
`InputFracLength`	Any positive integer	16	The number of bits applied as the fraction length to interpret the input data to the filter.
`InputWordLength`	Any positive integer	16	The number of bits applied to the word length to interpret the input data to the filter.
`NumberOfSections`	Any positive integer	2	Number of sections used in the interpolator. Generally

Name	Values	Default	Description
			called `n`. Reflects either the number of interpolator or comb sections, not the total number of sections in the filter.
`OutputFracLength`	Any positive integer	15	The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.
`OutputWordLength`	Any positive integer	16	The number of bits applied to the word length to interpret the output data from the filter.
`PersistentMemory`	`false` or `true`	`false`	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When `PersistentMemory` is `false`, you cannot access the filter states. Setting `PersistentMemory` to `true` reveals the `States` property so you can modify the filter states.

Name	Values	Default	Description
SectionWordLengths	Any integer or a vector of length 2^N, where N is a positive integer. This property only applies when the FilterInternals is SpecifyWordLengths.	16	Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter SectionWordLengths as a scalar or vector of length 2*n, where n is the number of sections. When SectionWordLengths is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the interpolator. Available when FilterInternals is 'SpecifyWordLengths'.

Name	Values	Default	Description
States	filtstates.cic object	m+1-by-n matrix of zeros, after you call function int.	Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. m is the differential delay of the comb section and n is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when PersistentMemory is true. Refer to the filtstates object in Signal Processing Toolbox documentation for more general information about the filtstates object.

Usage Modes

There are usage modes which are set using the FilterInternals property:

- FullPrecision — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to:

  $$\text{wordlength} = \text{ceil}(\log_2((RM)^N \,/\, R)) + I,$$

  where R is the interpolation factor, M is the differential delay, N is the number of filter sections, and I denotes the input word length.
- MinWordLengths — In this mode, you specify the word length of the filter output in the OutputWordLength property. The word lengths of the filter sections are automatically set in the same way as in the FullPrecision mode. The section fraction lengths are set to the input fraction length. The output fraction length is set

to the input fraction length minus the difference between the last section and output word lengths.

- SpecifyWordLengths — In this mode, you specify the word lengths of the filter sections and output in the SectionWordLengths and OutputWordLength properties. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- SpecifyPrecision — In this mode, you specify the word and fraction lengths of the filter sections and output in the SectionWordLengths, SectionFracLengths, OutputWordLength, and OutputFracLength properties.

About the States of the Filter

In the states property you find the states for both the integrator and comb portions of the filter. states is a matrix of dimensions m+1-by-n, with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use the int method to assign the states. As an example, here are the states for a CIC interpolator hm before and after filtering data:

```
x = fi(cos(pi/4*[0:99]),true,16,0); % Fixed-point input data
hm = mfilt.cicinterp(2,1,2,16,16,16);
% get initial states-all zero
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified
y=filter(hm,x);
sts=int(hm.states)
%sts =
%
%     -1     -1
%     -1     -1
```

Design Considerations

When you design your CIC interpolation filter, remember the following general points:

- The filter output spectrum has nulls at $\omega = k * 2\pi/\mathtt{rm}$ radians, $k = 1,2,3....$
- Aliasing and imaging occur in the vicinity of the nulls.
- n, the number of sections in the filter, determines the passband attenuation. Increasing n improves the filter ability to reject aliasing and imaging, but it also increases the droop or rolloff in the filter passband. Using an appropriate FIR filter in series after the CIC interpolation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the interpolation factor. Raising the interpolation factor increases the DC gain.

Examples

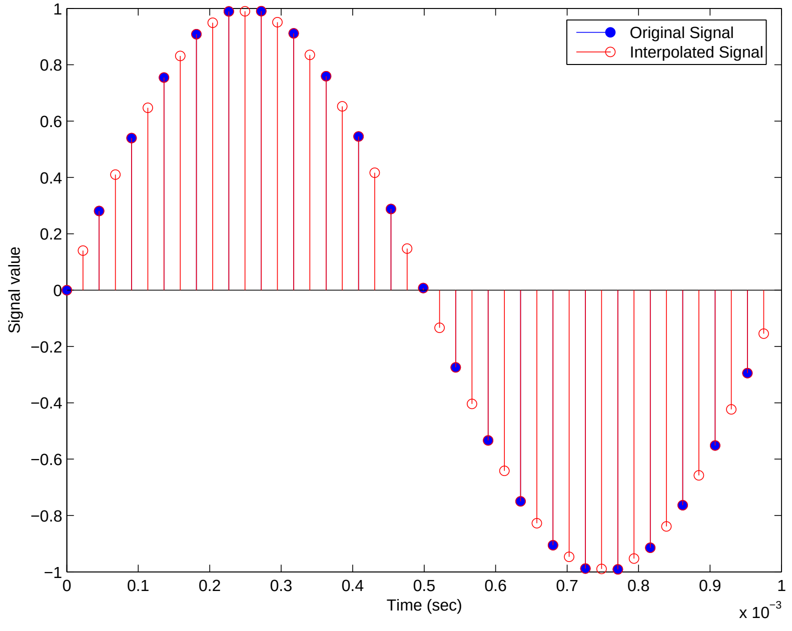
Demonstrate interpolation by a factor of two, in this case from 22.05 kHz to 44.1 kHz. Note the scaling required to see the results in the stem plot and to use the full range of the int16 data type.

```
R = 2;                      % Interpolation factor.
hm = mfilt.cicinterp(R);    % Use default NumberOfSections and
                            % DifferentialDelay property values.
fs = 22.05e3;               % Original sample frequency:22.05 kHz.
n = 0:5119;                % 5120 samples, .232 second long signal.
x = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay stem plots correctly.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:22)/fs,x(1:22),'filled'); % Plot original signal sampled
                                   % at 22.05 kHz.
hold on;
stem(n(1:44)/(fs*R),y(4:47),'r');  % Plot interpolated signal
                                   % (44.1 kHz) in red.
xlabel('Time (sec)');ylabel('Signal Value');
```

As you expect, the plot shows that the interpolated signal matches the input sine shape, with additional samples between each original sample.



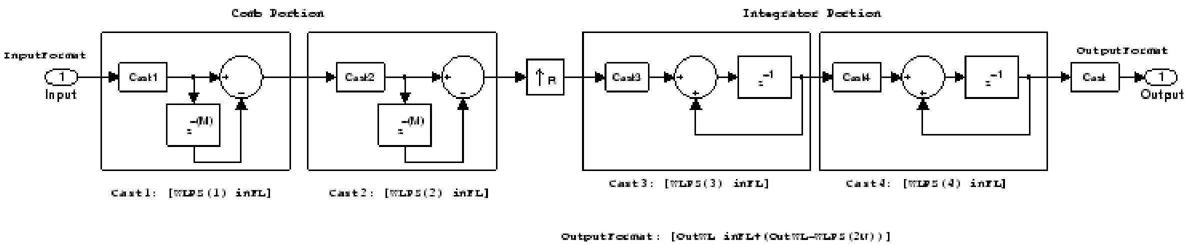
Use the filter visualization tool (FVTool) to plot the response of the interpolator object. For example, to plot the response of an interpolator with an interpolation factor of 7, 4 sections, and 1 differential delay, do something like the following:

```
hm = mfilt.cicinterp(7,1,4)
fvtool(hm)
```

Algorithms

To show how the CIC interpolation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC interpolation filter (`n` = 2). *fs* is the high sampling rate, the output from the interpolation process.

For details about the bits that are removed in the integrator section, refer to [1] in References.



When you select `MinWordLengths`, the filter section word lengths are automatically set to the minimum number of bits possible in a valid CIC interpolator. `mfilt.cicinterp` computes the wordlength for each section so the roundoff noise introduced by all sections is less than the roundoff noise introduced by the quantization at the output.

Introduced in R2011a

mfilt.farrowsrc

Sample rate converter with arbitrary conversion factor

Compatibility

`mfilt.farrowsrc` will be removed in a future release. Use dsp.FarrowRateConverter instead.

Syntax

```
hm = mfilt.farrowsrc(L,M,C)
hm = mfilt.farrowsrc
hm = mfilt.farrowsrc(l,...)
```

Description

`hm = mfilt.farrowsrc(L,M,C)` returns a filter object that is a natural extension of `dfilt.farrowfd` with a time-varying fractional delay. It provides a economical implementation of a sample rate converter with an arbitrary conversion factor. This filter works well in the interpolation case, but may exhibit poor anti-aliasing properties in the decimation case.

Note: You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.farrowsrc`.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. The default value of `l` is 3.

Input Argument	Description
`m`	Decimation factor for the filter. `m` specifies the amount to decrease the input sampling rate. The default value for `m` is 2.
`c`	Coefficients for the filter. When no input arguments are specified, the default coefficients are `[-1 1; 1, 0]`

`hm = mfilt.farrowsrc` constructs the filter using the default values for `l`, `m`, and `c`.

`hm = mfilt.farrowsrc(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

mfilt.farrowsrc Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.farrowsrc` objects. The next table describes each property for an `mfilt.farrowsrc` filter object.

Name	Values	Description
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`Arithmetic`	String	Reports the arithmetic precision used by the filter.
`Coefficients`	Vector	Vector containing the coefficients of the FIR lowpass filter
`InterpolationFactor`	Integer	Interpolation factor for the filter. It specifies the amount to increase the input sampling rate.
`DecimationFactor`	Integer	Decimation factor for the filter. It specifies the amount to increase the input sampling rate.
`PersistentMemory`	`false` or `true`	Determines whether the filter states are restored to their starting values for each filtering operation. The starting

Name	Values	Description
		values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
[L,M] = rat(48/44.1);
Hm = mfilt.farrowsrc(L,M);            % We use the default filter
Fs = 44.1e3;                          % Original sampling frequency
n = 0:9407;                           % 9408 samples, 0.213 seconds long
x  = sin(2*pi*1e3/Fs*n);              % Original signal, sinusoid at 1kHz
y = filter(Hm,x);                     % 10241 samples, still 0.213 seconds
stem(n(1:45)/Fs,x(1:45))              % Plot original sampled at 44.1kHz
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(2:50)-1)/(Fs*L/M),y(2:50),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48kHz sample rate')
```

The results of the example are shown in the following figure:

dsp.FarrowRateConverter

Introduced in R2011a

mfilt.fftfirinterp

Overlap-add FIR polyphase interpolator

Compatibility

`mfilt.fftfirinterp` will be removed in a future release. Use dsp.FIRInterpolator instead.

Syntax

```
hm = mfilt.fftfirinterp(l,num,bl)
hm = mfilt.fftfirinterp
hm = mfilt.fftfirinterp(l,...)
```

Description

`hm = mfilt.fftfirinterp(l,num,bl)` returns a discrete-time FIR filter object that uses the overlap-add method for filtering input data.

The input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The number of FFT points is given by `[bl+ceil(length(num)/l)-1]`. It is to your advantage to choose `bl` such that the number of FFT points is a power of two—using powers of two can improve the efficiency of the FFT and the associated interpolation process.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When `num` is not provided as an input, `fftfirinterp` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to `π/l` by default.
`bl`	Length of each block of input data used in the filtering. `bl` must be an integer. When you omit input `bl`, it defaults to 100

`hm = mfilt.fftfirinterp` constructs the filter using the default values for `l`, `num`, and `bl`.

`hm = mfilt.fftfirinterp(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

mfilt.fftfirinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.fftfirinterp` objects. The next table describes each property for an `mfilt.fftfirinterp` filter object.

Name	Values	Description
`FilterStructure`		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`Numerator`		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
`InterpolationFactor`		Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer.
`BlockLength`		Length of each block of input data used in the filtering.

Name	Values	Description
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
States		Stored conditions for the filter, including values for the interpolator states.

Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
l = 8;                        % Interpolation factor
hm = mfilt.fftfirinterp(l);   % We use the default filter
n = 8192;                     % Number of points
hm.blocklength = n;           % Set block length to number of points
fs = 44.1e3;                  % Original sample freq: 44.1 kHz.
n = 0:n-1;                    % 0.1858 secs of data
x = sin(2*pi*n*22e3/fs);      % Original signal, sinusoid at 22 kHz
y = filter(hm,x);             % Interpolated sinusoid
xu = l*upsample(x,8);         % Upsample to compare--the spectrum
                              % does not change
[px,f]=periodogram(xu,[],65536,l*fs);% Power spectrum of original
                                     % signal
[py,f]=periodogram(y,[],65536,l*fs); % Power spectrum of
                                     % interpolated signal
plot(f,10*log10(([fs*px,l*fs*py])))
legend('22  kHz sinusoid sampled at 44.1  kHz',...
'22  kHz sinusoid sampled at 352.8  kHz')
xlabel('Frequency (Hz)'); ylabel('Power Spectrum');
```

To see the results of the example, look at this figure.

`mfilt.firinterp` | `mfilt.holdinterp` | `mfilt.linearinterp` | `mfilt.firsrc` | `mfilt.cicinterp`

Introduced in R2011a

mfilt.firdecim

Direct-form FIR polyphase decimator

Compatibility

`mfilt.firdecim` will be removed in a future release. Use dsp.FIRDecimator instead.

Syntax

```
hm = mfilt.firdecim(m)
hm = mfilt.firdecim(m,num)
```

Description

`hm = mfilt.firdecim(m)` returns a direct-form FIR polyphase decimator object `hm` with a decimation factor of `m`. A lowpass Nyquist filter of gain 1 and cutoff frequency of `π/m` is designed by default. This filter allows some aliasing in the transition band but it very efficient because the first polyphase component is a pure delay.

`hm = mfilt.firdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. This lets you specify more completely the FIR filter to use for the decimator.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.
num	Vector containing the coefficients of the FIR lowpass filter used for decimation. When num is not provided as an input, mfilt.firdecim constructs a lowpass Nyquist filter with gain of 1 and cutoff frequency equal to π/m by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firdecim objects. The next table describes each property for an mfilt.firdecim filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice

Name	Values	Description
		of `mfilt` object. Describes the signal flow for the filter object.
`InputOffset`	Integers	Contains a value derived from the number of input samples and the decimation factor — `InputOffset = mod(length(nx),m)` where `nx` is the number of input samples that have been processed so far and `m` is the decimation factor.
`Numerator`	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
`PersistentMemory`	`false`, `true`	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` set to `false` returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to `true` allows you to modify the `States`, `InputOffset`, and `PolyphaseAccum` properties.
`PolyphaseAccum`	0 in `double`, `single`, or `fixed` for the different filter arithmetic settings.	Differentiates between the adders in the filter that work in full precision at all times (`PolyphaseAccum`) and the adders in the filter that the user controls and that may introduce quantization effects when `FilterInternals` is set to `SpecifyPrecision`.

Name	Values	Description
`States`	`Double`, `single`, or `fi` matching the filter arithmetic setting.	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Double is the default setting for floating-point filters in double arithmetic.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the filter. You see one or more of these properties when you set Arithmetic to fixed. Some of the properties have different default values when they refer fixed point filters. One example is the property `PolyphaseAccum` which stores data as doubles when you use your filter in double-precision mode, but stores a `fi` object in fixed-point mode.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use `info(hm)` where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 6-104.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
`AccumWordLength`	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by

Name	Values	Description
		setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits[16]	Specifies the word length applied to interpret input data.
`OutputFracLength`	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilterInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.

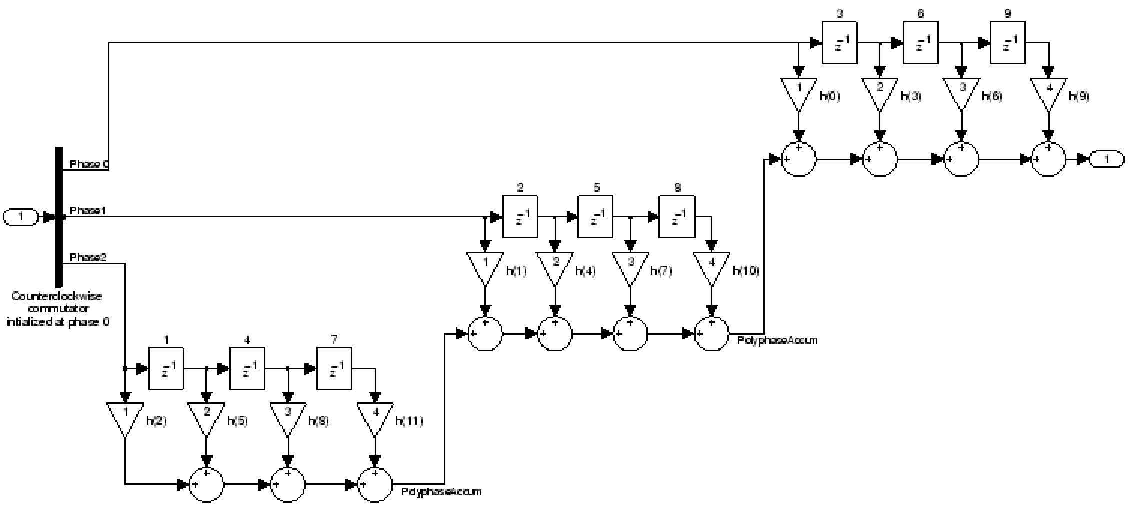
Name	Values	Description
`OverflowMode`	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`RoundMode`	`[convergent]`, `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Name	Values	Description
`States`	`fi` object	This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

Filter Structure

To provide decimation, `mfilt.firdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firdecim`.



Notice the order of the states in the filter flow diagram. States 1 through 9 appear in the diagram above each delay element. State 1 applies to the first delay element in phase

2. State 2 applies to the first delay element in phase 1. State 3 applies to the first delay element in phase 0. State 4 applies to the second delay in phase 2, and so on. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:9];
```

Examples

Convert an input signal from 44.1 kHz to 22.05 kHz using decimation by a factor of 2. In the figure that appears after the example code, you see the results of the decimation.

```
m = 2;                          % Decimation factor.
hm = mfilt.firdecim(m);         % Use the default filter.
fs = 44.1e3;                    % Original sample freq: 44.1kHz.
n = 0:10239;                    % 10240 samples, 0.232 second long
                                % signal.
x  = sin(2*pi*1e3/fs*n);        % Original signal--sinusoid at 1kHz.
y = filter(hm,x);               % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44))        % Plot original sampled at 44.1 kHz.
hold on                         % Plot decimated signal (22.05 kHz)
                                % in red.
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

`mfilt.firtdecim` | `mfilt.firsrc` | `mfilt.cicdecim`

Introduced in R2011a

mfilt.firfracdecim (Obsolete)

Direct-form FIR polyphase fractional decimator

Syntax

```
hm = mfilt.firfracdecim(l,m,num)
```

Description

`mfilt.firfracdecim` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracdecim(l,m,num)` returns a direct-form FIR polyphase fractional decimator. Input argument `l` is the interpolation factor. `l` must be an integer. When you omit `l` in the calling syntax, it defaults to 2. `m` is the decimation factor. It must be an integer. If not specified, it defaults to l+1.

`num` is a vector containing the coefficients of the FIR lowpass filter used for decimation. If you omit `num`, a lowpass Nyquist filter of gain l and cutoff frequency of π/`max(l,m)` is used by default.

By specifying both a decimation factor and an interpolation factor, you can decimate your input signal by noninteger amounts. The fractional decimator first interpolates the input, then decimates to result in an output signal whose sample rate is `l/m` of the input rate. By default, the resulting decimation factor is 2/3 when you do not provide `l` and `m` in the calling syntax. Specify `l` smaller than `m` for proper decimation.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. It must be an integer. When you do not specify a value for `l` it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for decimation. When `num` is not provided as an input, `firfracdecim` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to π/`max(l,m)` by default.

Input Argument	Description
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to l + 1.

mfilt.firfracdecim Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firfracdecim objects. The next table describes each property for an mfilt.firfracdecim filter object.

Name	Values	Description
FilterStructure	String	Reports the type of filter object, such as a decimator or fractional decimator. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputOffset	Integers	Contains the number of input data samples processed without generating an output sample. The default value is 0.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for interpolation.
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Name	Values	Description
`States`	Matrix	Stored conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter. The number of states is (`lh`-1)*`m`+(l-1)*(`lo`+`mo`) where `lh` is the length of each subfilter, and `l` and `m` are the interpolation and decimation factors. `lo` and `mo`, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that `lo`*l-`mo`*`m` = -1 (refer to the reference for more details). Use `euclidfactors` to get `lo` and `mo` for an `mfilt.firfracdecim` object

Examples

To demonstrate `firfracdecim`, perform a fractional decimation by a factor of 2/3. This is one way to downsample a 48 kHz signal to 32 kHz, commonly done in audio processing.

```
l  = 2; m = 3;               % Interpolation/decimation factors.
hm = mfilt.firfracdecim(l,m); % We use the default
fs = 48e3;                   % Original sample freq: 48 kHz.
n  = 0:10239;                % 10240 samples, 0.213 second long
                             % signal
x  = sin(2*pi*1e3/fs*n);     % Original signal, sinusoid at 1 kHz
y  = filter(hm,x);           % 9408 samples, still 0.213 seconds
stem(n(1:49)/fs,x(1:49)); hold on; % Plot original signal sampled
                                   % at 48 kHz
stem(n(1:32)/(fs*l/m),y(13:44),'r','filled') % Plot decimated
                                             % signal at 32 kHz
xlabel('Time (sec)');
```

As shown, the plot clearly demonstrates the reduced sampling frequency of 32 kHz.

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

Introduced in R2011a

mfilt.firfracinterp (Obsolete)

Direct-form FIR polyphase fractional interpolator

Syntax

```
hm = mfilt.firfracinterp(l,m,num)
```

Description

`mfilt.firfracinterp` will be removed in a future release. Use `mfilt.firsrc` instead.

`hm = mfilt.firfracinterp(l,m,num)` returns a direct-form FIR polyphase fractional interpolator mfilt object. `l` is the interpolation factor. It must be an integer. If not specified, `l` defaults to 3.

`m` is the decimation factor. Like `l`, it must be an integer. If you do not specify `m` in the calling syntax, it defaults to 1. If you also do not specify a value for `l`, `m` defaults to 2.

`num` is a vector containing the coefficients of the FIR lowpass filter used for interpolation. If omitted, a lowpass Nyquist filter of gain `l` and cutoff frequency of π/`max(l,m)` is used by default.

By specifying both a decimation factor and an interpolation factor, you can interpolate your input signal by noninteger amounts. The fractional interpolator first interpolates the input, then decimates to result in an output signal whose sample rate is `l/m` of the input rate. For proper interpolation, you specify `l` to be greater than `m`. By default, the resulting interpolation factor is 3/2 when you do not provide `l` and `m` in the calling syntax.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
l	Interpolation factor for the filter. l specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for l it defaults to 3.
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firfracinterp uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/max(l,m) by default.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 1. When you do not specify l as well, m defaults to 2.

mfilt.firfracinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firfracinterp` objects. The next table describes each property for an `mfilt.firfracinterp` filter object.

Name	Values	Description
FilterStructure		Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
Numerator		Vector containing the coefficients of the FIR lowpass filter used for interpolation.
RateChangeFactors	[l,m]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal.
PersistentMemory	false or true	Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when

Name	Values	Description
		you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to the default values any state that the filter changes during processing. States that the filter does not change are not affected.
`States`	Matrix	Stored conditions for the filter, including values for the interpolator and comb states.

Examples

To convert a signal from 32 kHz to 48 kHz requires fractional interpolation. This example uses the `mfilt.firfracinterp` object to upsample an input signal. Setting `l` = 3 and `m` = 2 returns the same `mfilt` object as the default `mfilt.firfracinterp` object.

```
l  = 3; m = 2;               % Interpolation/decimation factors.
hm = mfilt.firfracinterp(l,m);    % We use the default filter
fs = 32e3;                   % Original sample freq: 32 kHz.
n = 0:6799;                  % 6800 samples, 0.212 second long signal
x  = sin(2*pi*1e3/fs*n);     % Original signal, sinusoid at 1 kHz
y = filter(hm,x);            % 10200 samples, still 0.212 seconds
stem(n(1:32)/fs,x(1:32),'filled') % Plot original sampled at
                                  % 32 kHz
hold on;
% Plot fractionally interpolated signal (48 kHz) in red
stem(n(1:48)/(fs*l/m),y(20:67),'r')
xlabel('Time (sec)');ylabel('Signal Value')
```

The ability to interpolate by fractional amounts lets you raise the sampling rate from 32 to 48 kHz, something you cannot do with integral interpolators. Both signals appear in the following figure.

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

Introduced in R2011a

mfilt.firinterp

FIR filter-based interpolator

Compatibility

`mfilt.firinterp` will be removed in a future release. Use dsp.FIRInterpolator instead.

Syntax

```
Hm = mfilt.firinterp(L)
Hm = mfilt.firinterp(L,num)
```

Description

`Hm = mfilt.firinterp(L)` returns a FIR polyphase interpolator object `Hm` with an interpolation factor of `L` and gain equal to `L`. `L` defaults to 2 if unspecified.

`Hm = mfilt.firinterp(L,num)` uses the values in the vector `num` as the coefficients of the interpolation filter.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `Hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When `num` is not provided as an input, `firinterp` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to `π/l` by default. The default length for the Nyquist filter is 24*`l`. Therefore, each polyphase filter component has length 24.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firinterp` objects. The next table describes each property for an `mfilt.firinterp` filter object.

Name	Values	Description
`Arithmetic`	`Double`, `single`, `fixed`	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operation mode for your filter.
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Describes the signal flow for the filter object.
`InterpolationFactor`	Integer	Interpolation factor for the filter. `l` specifies the amount to increase the sampling rate of the input signal. It must be an integer.

Name	Values	Description
`Numerator`	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
`PersistentMemory`	`[false]`, `true`	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` set to `false` returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to `true` allows you to modify the `States` property.
`States`	`Double`, `single`, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firinterp` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 6-104.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and

Name	Values	Description
		lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.
AccumWordLength	Any integer number of bits[39]	Sets the word length used to store data in the accumulator.
Arithmetic	fixed for fixed-point filters	Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.
CoeffAutoScale	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.

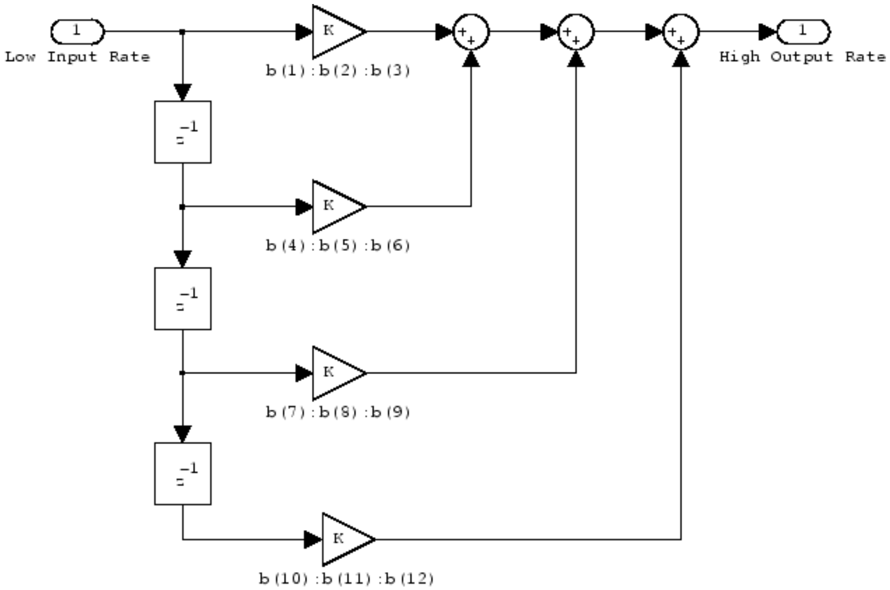
Name	Values	Description
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.
OverflowMode	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
`RoundMode`	[`convergent`], `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object to match the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Filter Structure

To provide interpolation, `mfilt.firinterp` uses the following structure.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firinterp`. In the figure, the delay line updates happen at the lower input rate. The remainder of the filter — the sums and coefficients — operate at the higher output rate.



Examples

This example uses `mfilt.firinterp` to double the sample rate of a 22.05 kHz input signal. The output signal ends up at 44.1 kHz. Although `l` is set explicitly to `2`, this represents the default interpolation value for `mfilt.firinterp` objects.

```
L = 2;                      % Interpolation factor.
Hm = mfilt.firinterp(L);    % Use the default filter.
fs = 22.05e3;                % Original sample freq: 22.05 kHz.
n = 0:5119;                   % 5120 samples, 0.232s long signal.
x  = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.
y = filter(Hm,x);           % 10240 samples, still 0.232s.
```

```
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
                                  % 22.05 kHz.
hold on;

% Plot interpolated signal (44.1 kHz) in red
stem(n(1:44)/(fs*L),y(25:68),'r')
xlabel('Time (sec)');ylabel('Signal Value')
legend('Original Signal','Interpolated Signal');
```

With interpolation by 2, the resulting signal perfectly matches the original, but with twice as many samples — one between each original sample, as shown in the following figure.

mfilt.holdinterp | mfilt.linearinterp | mfilt.fftfirinterp | mfilt.firsrc | mfilt.cicinterp

Introduced in R2011a

mfilt.firsrc

Direct-form FIR polyphase sample rate converter

Compatibility

`mfilt.firsrc` will be removed in a future release. Use dsp.FIRRateConverter instead.

Syntax

```
hm = mfilt.firsrc(l,m,num)
```

Description

`hm = mfilt.firsrc(l,m,num)` returns a direct-form FIR polyphase sample rate converter. `l` specifies the interpolation factor. It must be an integer and when omitted in the calling syntax, it defaults to 2.

`m` is the decimation factor. It must be an integer. If not specified, `m` defaults to 1. If `l` is also not specified, `m` defaults to 3 and the overall rate change factor is 2/3.

You specify the coefficients of the FIR lowpass filter used for sample rate conversion in `num`. If omitted, a lowpass Nyquist filter with gain `l` and cutoff frequency of π/`max`(`l`,`m`) is the default.

Combining an interpolation factor and a decimation factor lets you use `mfilt.firsrc` to perform fractional interpolation or decimation on an input signal. Using an `mfilt.firsrc` object applies a rate change factor defined by `l/m` to the input signal. For proper rate changing to occur, `l` and `m` must be relatively prime — meaning the ratio `l/m` cannot be reduced to a ratio of smaller integers.

When you are doing sample-rate conversion with large values of `l` or `m`, such as `l` or `m` greater than 20, using the `mfilt.firsrc` structure is the most effective approach.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

Note: You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.firsrc`.

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l`, it defaults to 2.
`num`	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When `num` is not provided as an input, `mfilt.firsrc` uses a lowpass Nyquist filter with gain equal to `l` and cutoff frequency equal to `π/max(l,m)` by default. The default length for the Nyquist filter is 24*`max(1,m)`. Therefore, each polyphase filter component has length 24.
`m`	Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for `m`, it defaults to 1. When `l` is unspecified as well, `m` defaults to 3.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firsrc objects. The next table describes each property for an mfilt.firsrc filter object.

Name	Values	Description
Arithmetic	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operation mode for your filter.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where nx is the number of input samples and m is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	false, true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States, InputOffset, and PolyphaseAccum properties.
RateChangeFactors	Positive integers. [2 3]	Specifies the interpolation and decimation factors [l m] (the rate change factors) for changing the input sample rate by nonintegral amounts.
States	Double, single, matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firsrc` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 6-104.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.
`AccumWordLength`	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best

Name	Values	Description
		precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
`OutputFracLength`	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilterInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.
`OverflowMode`	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`RateChangeFactors`	Positive integers [2 3]	Specifies the interpolation and decimation factors `[l m]` (the rate change factors) for changing the input sample rate by nonintegral amounts.

Name	Values	Description
`RoundMode`	[`convergent`], `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

Examples

This is an example of a common audio rate change process — changing the sample rate of a high end audio (48 kHz) signal to the compact disc sample rate (44.1 kHz). This conversion requires a rate change factor of 0.91875, or `l` = 147 and `m` = 160.

```
l  = 147; m = 160;          % Interpolation/decimation factors.
hm = mfilt.firsrc(l,m);     % Use the default FIR filter.
fs = 48e3;                  % Original sample freq: 48 kHz.
n = 0:10239;                % 10240 samples, 0.213 seconds long.
x  = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.
y = filter(hm,x);           % 9408 samples, still 0.213 seconds.
stem(n(1:49)/fs,x(1:49))    % Plot original sampled at 48 kHz.
hold on

% Plot fractionally decimated signal (44.1 kHz) in red
stem(n(1:45)/(fs*l/m),y(13:57),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

Fractional decimation provides you the flexibility to pick and choose the sample rates you want by carefully selecting `l` and `m`, the interpolation and decimation factors, that result in the final fractional decimation. The following figure shows the signal after applying the rate change filter `hm` to the original signal.

`mfilt.firsrc` | `mfilt.firinterp` | `mfilt.firdecim`

Introduced in R2011a

mfilt.firtdecim

Direct-form transposed FIR filter

Compatibility

`mfilt.firtdecim` will be removed in a future release. Use dsp.FIRDecimator instead.

Syntax

```
hm = mfilt.firtdecim(m)
hm = mfilt.firtdecim(m,num)
```

Description

`hm = mfilt.firtdecim(m)` returns a polyphase decimator `mfilt` object `hm` based on a direct-form transposed FIR structure with a decimation factor of `m`. A lowpass Nyquist filter of gain 1 and cutoff frequency of π/`m` is the default.

`hm = mfilt.firtdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. `num` is a vector containing the coefficients of the transposed FIR lowpass filter used for decimation. If omitted, a lowpass Nyquist filter with gain of 1 and cutoff frequency of π/`m` is the default.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
num	Vector containing the coefficients of the FIR lowpass filter used for interpolation. When num is not provided as an input, firtdecim uses a lowpass Nyquist filter with gain equal to l and cutoff frequency equal to π/m by default. The default length for the Nyquist filter is 24*m. Therefore, each polyphase filter component has length 24.
m	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for m it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating mfilt.firtdecim objects. The next table describes each property for an mfilt.firtdecim filter object.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
DecimationFactor	Integer	Decimation factor for the filter. m specifies the amount to reduce the sampling rate of the input signal. It must be an integer.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object. Also describes the signal flow for the filter object.
InputOffset	Integers	Contains a value derived from the number of input samples and the decimation factor — InputOffset = mod(length(nx),m) where

Name	Values	Description
		nx is the number of input samples that have been processed so far and m is the decimation factor.
Numerator	Vector	Vector containing the coefficients of the FIR lowpass filter used for decimation.
PersistentMemory	[false], true	Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory set to false returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to true allows you to modify the States, InputOffset, and PolyphaseAccum properties.
PolyphaseAccum	Double, single [0]	The idea behind having both PolyphaseAccum and Accum is to differentiate between the adders in the filter that work in full precision at all times (PolyphaseAccum) from the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.
States	Double, single matching the filter arithmetic setting.	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.firtdecim filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 6-104.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. [32]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
`AccumWordLength`	Any integer number of bits [39]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` property value to specify the precision used.
`CoeffWordLength`	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`FilterInternals`	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.

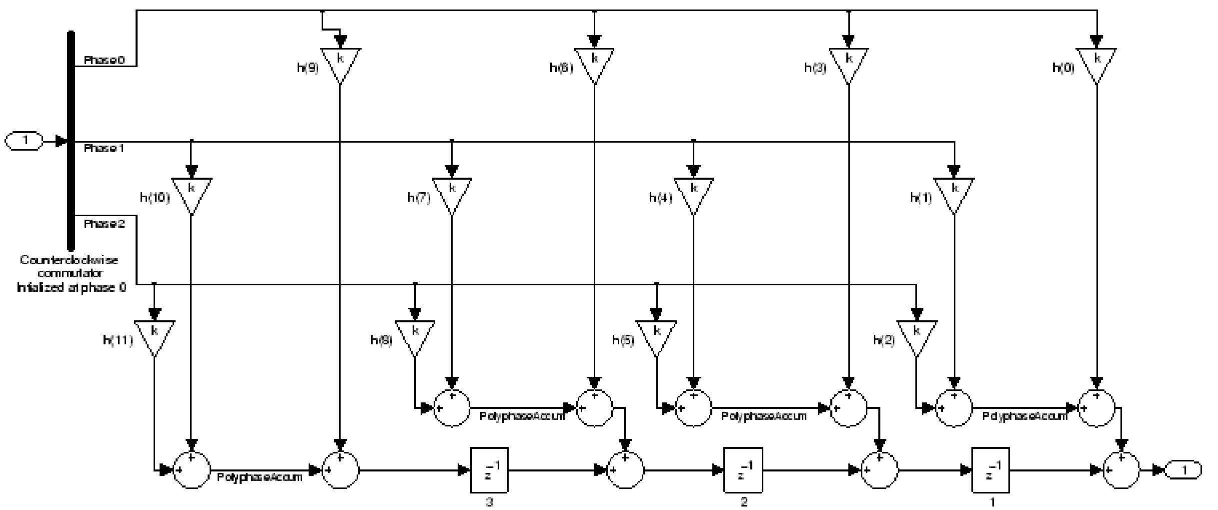
Name	Values	Description
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
`InputWordLength`	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
`OutputFracLength`	Any positive or negative integer number of bits [32]	Determines how the filter interprets the filter output data. You can change the value of `OutputFracLength` when you set `FilterInternals` to `SpecifyPrecision`.
`OutputWordLength`	Any integer number of bits [39]	Determines the word length used for the output data. You make this property editable by setting `FilterInternals` to `SpecifyPrecision`.
`OverflowMode`	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.
`PolyphaseAccum`	`fi` object with zeros to start	Differentiates between the adders in the filter that work in full precision at all times (`PolyphaseAccum`) and the adders in the filter that the user controls and that may introduce quantization effects when `FilterInternals` is set to `SpecifyPrecision`.

Name	Values	Description
`RoundMode`	[`convergent`], `ceil`, `fix`, `floor`, `nearest`, `round`	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
`Signed`	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`States`	`fi` object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.

Filter Structure

To provide sample rate changes, `mfilt.firtdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter. To keep track of the position of the commutator, the `mfilt` object uses the property `InputOffset` which reports the current position of the commutator in the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firtdecim`.



Notice the order of the states in the filter flow diagram. States 1 through 3 appear in the following diagram at each delay element. State 1 applies to the third delay element in phase 2. State 2 applies to the second delay element in phase 2. State 3 applies to the first delay element in phase 2. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

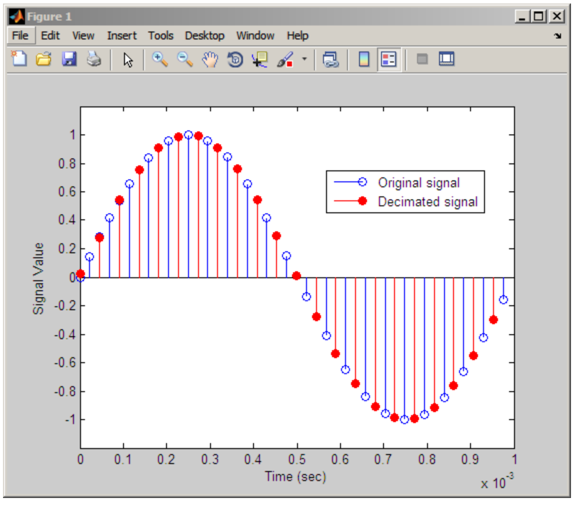
In property value form, the states for a filter `hm` are

```
hm.states=[1:3];
```

Examples

Demonstrate decimating an input signal by a factor of 2, in this case converting from 44.1 kHz down to 22.05 kHz. In the figure shown following the code, you see the results of decimating the signal.

```
m = 2;                    % Decimation factor.
hm = mfilt.firtdecim(m); % Use the default filter coeffs.
fs = 44.1e3;              % Original sample freq: 44.1 kHz.
n = 0:10239;              % 10240 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1 kHz.
y = filter(hm,x);         % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
axis([0 0.001 -1.2 1.2]);
hold on                   % Plot decimated signal (22.05 kHz) in red
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value');
legend('Original signal','Decimated signal','location','best');
```



See Also

`mfilt.firdecim` | `mfilt.firsrc` | `mfilt.cicdecim`

Introduced in R2011a

mfilt.holdinterp

FIR hold interpolator

Compatibility

`mfilt.holdinterp` will be removed in a future release. Use dsp.CICInterpolator (with `NumSections` = 1) instead.

Syntax

```
hm = mfilt.holdinterp(l)
```

Description

`hm = mfilt.holdinterp(l)` returns the object `hm` that represents a hold interpolator with the interpolation factor `l`. To work, `l` must be an integer. When you do not include `l` in the calling syntax, it defaults to 2. To perform interpolation by noninteger amounts, use one of the fractional interpolator objects, such as `mfilt.firsrc`.

When you use this hold interpolator, each sample added to the input signal between existing samples has the value of the most recent sample from the original signal. Thus you see something like a staircase profile where the interpolated samples form a plateau between the previous and next original samples. The example demonstrates this profile clearly. Compare this to the interpolation process for other interpolators in the toolbox, such as `mfilt.linearinterp`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input arguments for creating `hm`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.holdinterp` objects. The next table describes each property for an `mfilt.interp` filter object.

Name	Values	Description
`Arithmetic`	`Double`, `single`, `fixed`	Specifies the arithmetic the filter uses to process data while filtering.
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`InterpolationFactor`	Integer	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer.
`PersistentMemory`	'`false`' or '`true`'	Determines whether the filter states are restored to zero for each filtering operation.

Name	Values	Description
States	Double or single array	Filter states. states defaults to a vector of zeros that has length equal to nstates (hm). Always available, but visible in the display only when PersistentMemory is true.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the mfilt.holdinterp filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where hm is a filter.

For further information about the properties of this filter or any mfilt object, refer to "Multirate Filter Properties" on page 6-104.

Name	Values	Description
Arithmetic	Double, single, fixed	Specifies the arithmetic the filter uses to process data while filtering.
FilterStructure	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt object.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.

Name	Values	Description
`InterpolationFactor`	Integer	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer.
`PersistentMemory`	`'false'` or `'true'`	Determine whether the filter states get restored to zero for each filtering operation
`States`	`fi` object	Contains the filter states before, during, and after filter operations. For hold interpolators, the states are always empty — hold interpolators do not have states. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.

Filter Structure

Hold interpolators do not have filter coefficients and their filter structure is trivial.

Examples

To see the effects of hold-based interpolation, interpolate an input sine wave from 22.05 to 44.1 kHz. Note that each added sample retains the value of the most recent original sample.

```
l = 2;                              % Interpolation factor
hm = mfilt.holdinterp(l);
fs = 22.05e3;                       % Original sample freq: 22.05 kHz.
n = 0:5119;                         % 5120 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n);            % Original signal, sinusoid at 1 kHz
y = filter(hm,x);                   % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled')   % Plot original sampled at
                                    % 22.05 kHz
hold on                             % Plot interpolated signal (44.1 kHz)
stem(n(1:44)/(fs*l),y(1:44),'r')
legend('Original Signal','Interpolated Signal','Location','best');
xlabel('Time (sec)');ylabel('Signal Value')
```

The following figure shows clearly the step nature of the signal that comes from interpolating the signal using the hold algorithm approach. Compare the output to the linear interpolation used in `mfilt.linearinterp`.

`mfilt.linearinterp` | `mfilt.firinterp` | `mfilt.firsrc` | `mfilt.cicinterp`

Introduced in R2011a

mfilt.iirdecim

IIR decimator

Note: `mfilt.iirdecim` will be removed in a future release. Use dsp.IIRHalfbandDecimator instead.

Syntax

```
hm = mfilt.iirdecim(c1,c2,...)
```

Description

`hm = mfilt.iirdecim(c1,c2,...)` constructs an IIR decimator filter given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The resulting IIR decimator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR decimators.

Although the first example shows how to construct an IIR decimators explicitly, one usually constructs an IIR decimators filter as a result of designing an decimators, as shown in the subsequent examples.

Examples

When the coefficients are known, you can construct the IIR decimator directly using `mfilt.iirdecim`. For example, if the filter's coefficients are [0.6 0.5] for the first phase in the first stage, 0.7 for the second phase in the first stage and 0.8 for the third phase in the first stage; as well as 0.5 for the first phase in the second stage and 0.4 for the second phase in the second stage, construct the filter as shown here.

```
Hm = mfilt.iirdecim({[0.6 0.5] 0.7 0.8},{0.5 0.4})
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, iirallpassdemo example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband decimator with a decimation factor of 2. The example specifies the optional sampling frequency argument.

```
tw = 100;   % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000;  % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

`hm` contains the specifications for a decimator defined by `tw`, `ast`, `m`, and `fs`.

Use the specification object `hm` to design a `mfilt.iirdecim` filter object.

```
d = design(hm,'ellip','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d)     % Build model of the filter.
```

Designing a linear phase decimator is similar to the previous example. In this case, design a halfband linear phase decimator with decimation factor of 2.

```
tw  = 100;  % Transition width of filter.
ast = 60;   % Stopband attenuation of filter.
fs  = 2000; % Sampling frequency of signal to filter.
m = 2;      % Decimation factor.
```

Create a specification object for the decimator.

```
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

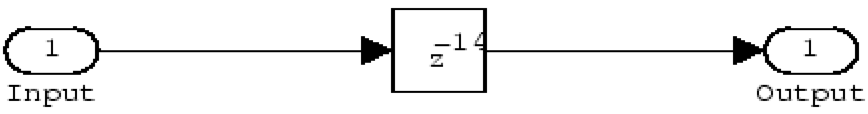
Finally, design the filter d.

```
d = design(hm,'iirlinphase','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d)  % Build model of the filter.
```

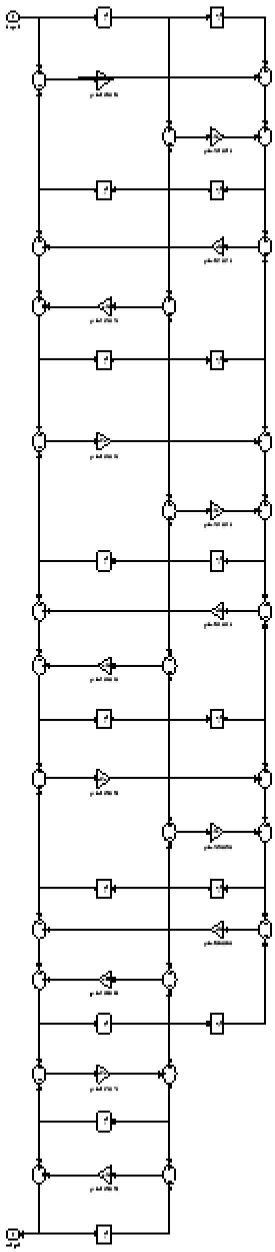
The filter implementation appears in this model, generated by `realizemdl` and Simulink.

Given the design specifications shown here

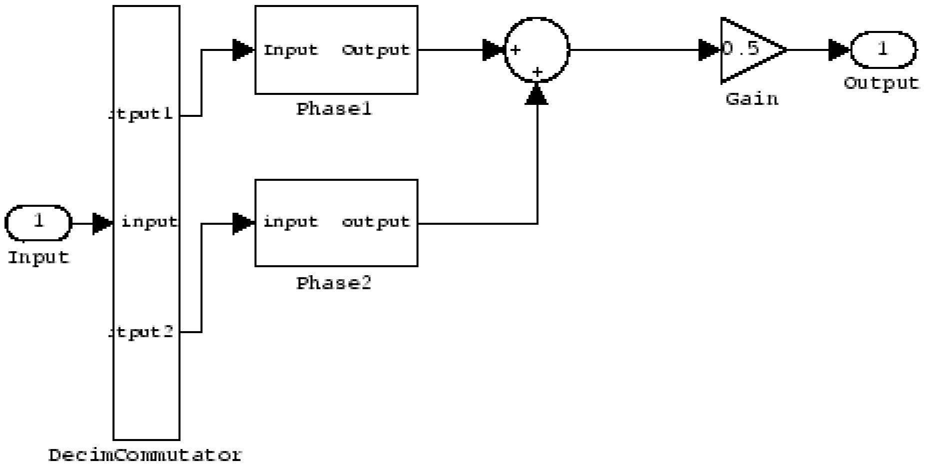
the first phase is a delay section with 0s and a 1 for coefficients and the second phase is a linear phase decimator, shown in the next models.



Phase 1 model



Phase 2 model



Overall model

For more information about Multirate Filter Constructors see the “Getting Started with Multirate Filter (MFILT) Objects” example, mfiltgettingstarteddemo.

See Also

`dfilt.cascadeallpass` | `mfilt` | `mfilt.iirinterp` | `mfilt.iirwdfdecim`

Introduced in R2011a

mfilt.iirinterp

IIR interpolator

Note: `mfilt.iirinterp` will be removed in a future release. Use dsp.IIRHalfbandInterpolator instead.

Syntax

```
hm = mfilt.iirinterp(c1,c2,...)
```

Description

`hm = mfilt.iirinterp(c1,c2,...)` constructs an IIR interpolator filter given the coefficients specified in the cell arrays C1, C2, etc.

The IIR interpolator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array—if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and a unique element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR interpolators.

Although the first example shows how to construct an IIR interpolator explicitly, one usually constructs an IIR interpolator filter as a result of designing an interpolator, as shown in the subsequent examples.

Examples

When the coefficients are known, you can construct the IIR interpolator directly using `mfilt.iirinterp`. In the following example, a cascaded polyphase IIR interpolator filter is constructed using 2 phases for each of three stages. The coefficients are given below:

```
Phase1Sect1=0.0603;Phase1Sect2=0.4126; Phase1Sect3=0.7727;
Phase2Sect1=0.2160; Phase2Sect2=0.6044; Phase2Sect3=0.9239;
```

Next the filter is implemented by passing the above coefficients to `mfilt.iirinterp` as cell arrays, where each cell array represents a different phase.

```
Hm = mfilt.iirinterp({Phase1Sect1,Phase1Sect2,Phase1Sect3},...
{Phase2Sect1,Phase2Sect2,Phase2Sect3})

Hm =

        FilterStructure: 'IIR Polyphase Interpolator'
              Polyphase: Phase1: Section1: 0.0603
                                 Section2: 0.4126
                                 Section3: 0.7727
                         Phase2: Section1: 0.216
                                 Section2: 0.6044
                                 Section3: 0.9239
    InterpolationFactor: 2
       PersistentMemory: false
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, iirallpassdemo example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband interpolator with a interpolation factor of 2.

```
tw = 100;  % Transition width of filter.
ast = 80;   % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l  = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Specification object `d` stores the interpolator design specifics. With the details in `d`, design the filter, returning `hm`, an `mfilt.iirinterp` object. Use `hm` to realize the filter if you have Simulink installed.

```
hm = design(d,'ellip','filterstructure','iirinterp');
```

```
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

Designing a linear phase halfband interpolator follows the same pattern.

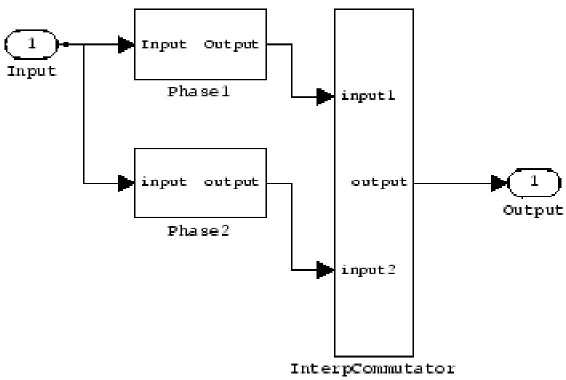
```
tw = 100;  % Transition width of filter.
ast= 60;   % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2;     % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

`fdesign.interpolator` returns a specification object that stores the design features for an interpolator.

Now perform the actual design that results in an `mfilt.iirinterp` filter, `hm`.

```
hm = design(d,'iirlinphase','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

The toolbox creates a Simulink model for `hm`, shown here. Phase1, Phase2, and InterpCommutator are all subsystem blocks.



For more information about Multirate Filter Constructors see the “Getting Started with Multirate Filter (MFILT) Objects” example, mfiltgettingstarteddemo.

`dfilt.cascadeallpass` | `mfilt` | `mfilt.iirdecim` | `mfilt.iirwdfinterp`

Introduced in R2011a

mfilt.iirwdfdecim

IIR wave digital filter decimator

Compatibility

`mfilt.iirwdfdecim` will be removed in a future release. Use dsp.IIRHalfbandDecimator instead.

Syntax

```
hm = mfilt.iirwdfdecim(c1,c2,...)
```

Description

`hm = mfilt.iirwdfdecim(c1,c2,...)` constructs an IIR wave digital decimator given the coefficients specified in the cell arrays c1, c2, and so on. The IIR decimator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfdecim` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR decimators.

Usually you do not construct IIR wave digital filter decimators explicitly. Instead, you obtain an IIR wave digital filter decimator as a result of designing a halfband decimator. The first example in the following section illustrates this case.

Examples

Design an elliptic halfband decimator with a decimation factor equal to 2. Both examples use the `iirwdfdecim` filter structure (an input argument to the `design` method) to design the final decimator.

The first portion of this example generates a filter specification object `d` that stores the specifications for the decimator.

```
tw  = 100;  % Transition width of filter to design, 100 Hz.
ast = 80;   % Stopband attenuation of filter 80 dB.
fs  = 2000; % Sampling frequency of the input signal.
m   = 2;    % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design using `d`. Filter object `hm` is an `mfilt.iirwdfdecim` filter.

```
Hm = design(d,'ellip','FilterStructure','iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

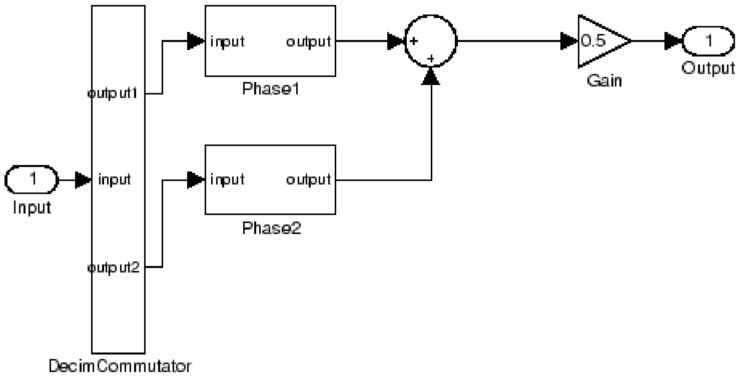
Design a linear phase halfband decimator for decimating a signal by a factor of 2.

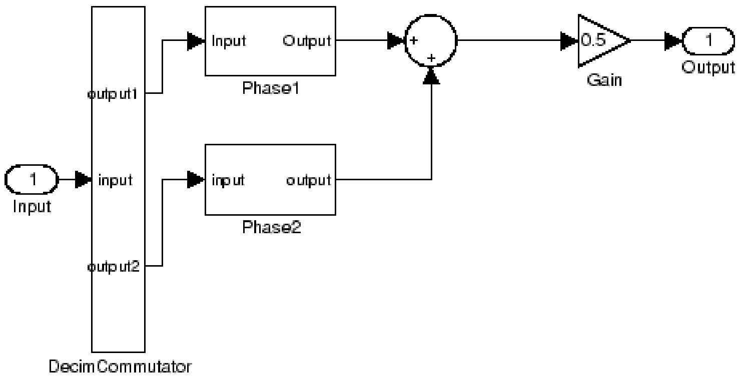
```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 60;   % Filter stopband attenuation = 80 dB
fs  = 2000; % Input signal sampling frequency.
m   = 2;    % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Use `d` to design the final filter `hm`, an `mfilt.iirwdfdecim` object.

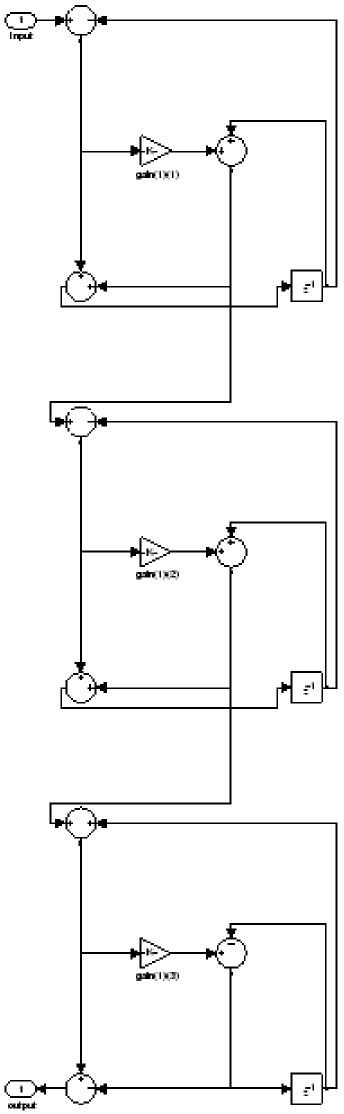
```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

The models that `realizemdl` returns for each example appear below. At this level, the realizations of the filters are identical. The differences appear in the subsystem blocks Phase1 and Phase2.





This is the Phase1 subsystem from the halfband model.



Phase1 subsystem from the linear phase model is less revealing—an allpass filter.

`dfilt.cascadewdfallpass` | `mfilt` | `mfilt.iirdecim` | `mfilt.iirwdfinterp`

Introduced in R2011a

mfilt.iirwdfinterp

IIR wave digital filter interpolator

Compatibility

`mfilt.iirwdfinterp` will be removed in a future release. Use dsp.IIRHalfbandInterpolator instead.

Syntax

```
hm = mfilt.iirwdfinterp(c1,c2,...)
```

Description

`hm = mfilt.iirwdfinterp(c1,c2,...)` constructs an IIR wave digital interpolator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR interpolator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfinterp` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR interpolators.

Usually you do not construct IIR wave digital filter interpolators explicitly. Rather, you obtain an IIR wave digital interpolator as a result of designing a halfband interpolator. The first example in the following section illustrates this case.

Examples

Design an elliptic halfband interpolator with interpolation factor equal to 2. At the end of the design process, hm is an IIR wave digital filter interpolator.

```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 80;   % Stopband attenuation of filter, 80 dB.
fs  = 2000; % Sampling frequency after interpolation.
l   = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

The specification object `d` stores the interpolator design requirements. Now use `d` to design the actual filter `hm`.

```
hm = design(d,'ellip','filterstructure','iirwdfinterp');
```

If you have Simulink installed, you can realize your filter as a model built from DSP System Toolbox blocks.

```
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

For variety, design a linear phase halfband interpolator with an interpolation factor of 2.

```
tw  = 100;  % Transition width of filter, 100 Hz.
ast = 80;   % Stopband attenuation of filter, 80 dB.
fs  = 2000; % Sampling frequency after interpolation.
l   = 2;    % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design process with `d`. Filter `hm` is an IIR wave digital filter interpolator. As in the previous example, `realizemdl` returns a Simulink model of the filter if you have Simulink installed.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)     % Build model of the filter.
```

See Also

`dfilt.cascadewdfallpass` | `mfilt.iirinterp` | `mfilt.iirwdfdecim`

Introduced in R2011a

mfilt.linearinterp

Linear interpolator

Compatibility

`mfilt.linearinterp` will be removed in a future release. Use idsp.CICInterpolator (with `NumSections` = 2) instead.

Syntax

```
hm = mfilt.linearinterp(l)
```

Description

`hm = mfilt.linearinterp(l)` returns an FIR linear interpolator `hm` with an integer interpolation factor `l`. Provide `l` as a positive integer. The default value for the interpolation factor is 2 when you do not include the input argument `l`.

When you use this linear interpolator, the samples added to the input signal have values between the values of adjacent samples in the original signal. Thus you see something like a smooth profile where the interpolated samples continue a line between the previous and next original samples. The example demonstrates this smooth profile clearly. Compare this to the interpolation process for `mfilt.holdinterp`, which creates a stairstep profile.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

  ```
  set(hm,'arithmetic','single');
  ```
- To change to fixed-point filtering, enter

  ```
  set(hm,'arithmetic','fixed');
  ```

Input Arguments

The following table describes the input argument for `mfilt.linearinterp`.

Input Argument	Description
`l`	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for `l` it defaults to 2.

Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.linearinterp` objects. The next table describes each property for an `mfilt.linearinterp` filter object.

Name	Values	Description
`Arithmetic`	`Double`, `single`, `fixed`	Specifies the arithmetic the filter uses to process data while filtering.
`FilterStructure`	String	Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`InterpolationFactor`	Integer	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate. It must be an integer.
`PersistentMemory`	'`false`' or '`true`'	Determine whether the filter states get restored to zero for each filtering operation

Name	Values	Description
`States`	Double or single array	Filter states. `states` defaults to a vector of zeros that has length equal to `nstates(hm)`. Always available, but visible in the display only when `PersistentMemory` is `true`.

Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

Note The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to "Multirate Filter Properties" on page 6-104.

Name	Values	Description
`AccumFracLength`	Any positive or negative integer number of bits. Depends on L. [29 when L=2]	Specifies the fraction length used to interpret data output by the accumulator.
`AccumWordLength`	Any integer number of bits [33]	Sets the word length used to store data in the accumulator.
`Arithmetic`	fixed for fixed-point filters	Setting this to `fixed` allows you to modify other filter properties to customize your fixed-point filter.
`CoeffAutoScale`	[true], false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change

Name	Values	Description
		the NumFracLength property value to specify the precision used.
CoeffWordLength	Any integer number of bits [16]	Specifies the word length to apply to filter coefficients.
FilterInternals	[FullPrecision], SpecifyPrecision	Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them.
InputFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret input data.
InputWordLength	Any integer number of bits [16]	Specifies the word length applied to interpret input data.
NumFracLength	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
OutputFracLength	Any positive or negative integer number of bits [29]	Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.
OutputWordLength	Any integer number of bits [33]	Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.

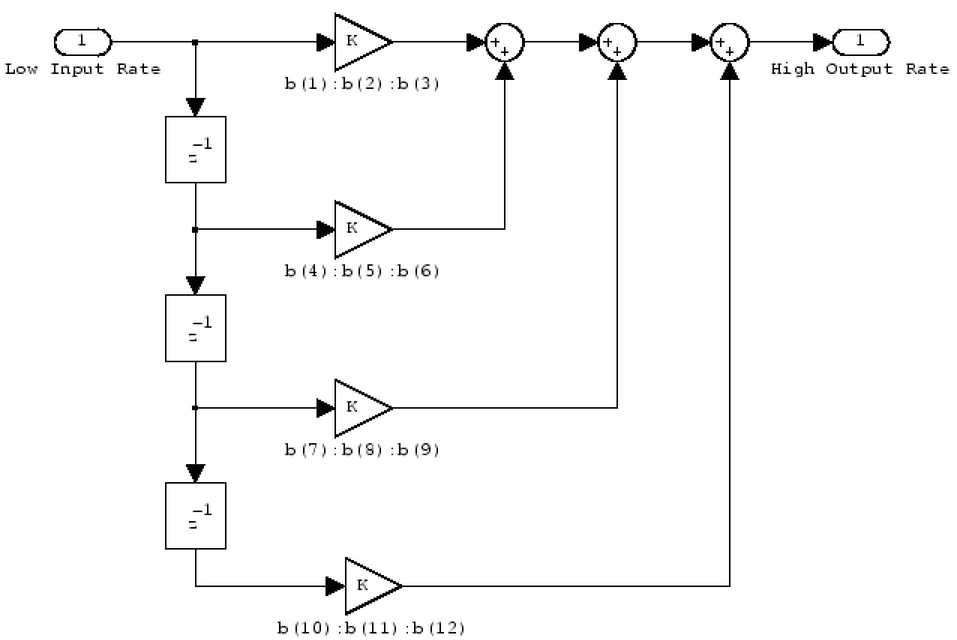
Name	Values	Description
`OverflowMode`	saturate, [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Description
RoundMode	[convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • ceil - Round toward positive infinity. • convergent - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • fix - Round toward zero. • floor - Round toward negative infinity. • nearest - Round toward nearest. Ties round toward positive infinity. • round - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.
Signed	[true], false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.

Name	Values	Description
`States`	`fi` object	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use `fi` objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure in the following section.

Filter Structure

Linear interpolator structures depend on the FIR filter you use to implement the filter. By default, the structure is direct-form FIR.



Examples

Interpolation by a factor of 2 (used to convert the input signal sampling rate from 22.05 kHz to 44.1 kHz).

```
l = 2;                          % Interpolation factor
hm = mfilt.linearinterp(l);
fs = 22.05e3;                   % Original sample freq: 22.05 kHz.
n = 0:5119;                     % 5120 samples, 0.232 second long signal
x  = sin(2*pi*1e3/fs*n);        % Original signal, sinusoid at 1 kHz
y = filter(hm,x);               % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
                                  % 22.05 kHz
hold on                         % Plot interpolated signal (44.1
                                % kHz) in red
stem(n(1:44)/(fs*l),y(2:45),'r')
xlabel('Time (s)');ylabel('Signal Value')
```

Using linear interpolation, as compared to the hold approach of `mfilt.holdinterp`, provides greater fidelity to the original signal.

Introduced in R2011a

midicallback

Call function handle when MIDI controls change value

Compatibility

The `midicallback` function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the `midicallback` function from Audio System Toolbox instead.

Syntax

```
oldfh = midicallback(h,newfh)
oldfh = midicallback(h,[])
fh= midicallback(h)
```

Description

`oldfh = midicallback(h,newfh)` sets `newfh` as the function handle to be called when `h` changes value, and returns the previous function handle, `oldfh`.

`oldfh = midicallback(h,[])` clears the function handle.

`fh= midicallback(h)` returns the current function handle.

Examples

Interactively Read MIDI Controls

Use the `midicallback` command with an anonymous function to interactively read MIDI controls.

```
h = midicontrols;
midicallback(h,@(h)disp(midiread(h)));
```

```
% Now move any control on the default MIDI device.
   0.6587
   0.6429
   0.6349
   0.6270
   0.6190
   0.6111
   0.6032
   0.5952
clear h
```

Input Arguments

h — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

newfh — new function handle

function handle

The new function handle, which is set as the function handle to be called when h changes value. For information on what function handles are, see “Function Handles” (MATLAB).

Example: @myFunction

Output Arguments

oldfh — Old function handle

function handle

The function handle set by the previous call to midicallback.

Example: @myFunction

fh — Current function handle

function handle

The function handle set by the current call to midicallback.

Example: @myFunction

See Also

See Also

`midicontrols` | `midiid` | `midiread` | `midisync` | `setpref`

Introduced in R2013b

midicontrols

Open a group of MIDI controls for reading

Compatibility

The `midicontrols` function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the `midicontrols` function from Audio System Toolbox instead.

Syntax

```
h = midicontrols
h = midicontrols(ControlNumbers)
h = midicontrols(ControlNumbers,InitialValues)
h = midicontrols( ___ ,'MIDIDevice',devicename)
h = midicontrols( ___ ,'OutputMode',mode)
```

Description

`h = midicontrols` returns an object that responds to any control on the default MIDI device. Calling `midiread` with the object, returns the double scalar value of the MIDI control that recently moved after the object was created. The value is normally in the range [0 1]. See `OutputMode` for an alternative. This object can only determine a control's value if the control is moved after the `midicontrols` object is created. If `midiread` is called before the control is moved, `midiread` returns a default initial value of `0`.

`h = midicontrols(ControlNumbers)` returns an object that responds to the MIDI controls specified by `ControlNumbers`. Calling `midiread` with the object, returns a double array of the same shape as `ControlNumbers`. Use `midiid` to interactively identify the control number of individual MIDI controls.

`h = midicontrols(ControlNumbers,InitialValues)` returns an object that uses the specified `InitialValues` when controls are not moved after the object is created.

Because initial values are quantized for the underlying MIDI protocol, sometimes `midiread` returns an initial value that is slightly different from `InitialValues`.

`h = midicontrols(___,'MIDIDevice',devicename)` specifies the MIDI device to which the object responds. Use `midiid` to interactively identify the name of a specific MIDI device. If you do not specify the `'MIDIDevice'` name-value pair, the default MIDI device is used. The MATLAB preference 'midi' `'DefaultDevice'` determines the default device.

`h = midicontrols(___,'OutputMode',mode)` specifies the range of values returned by `midiread` and accepted as `InitialValues`. This name-value pair is optional, and you can insert it only at the end of the argument list.

Examples

Respond to any Control on the Default Device

Create the object, and read from it:

```
h =midicontrols
midiread(h)
```

Move one of the controls, and read the data:

```
midiread(h)
```

Respond to a Specific Control

Make the object respond to a specific control:

```
h = midicontrols(1081);
```

Use Control Numbers and an Initial Value

Return a square array, with initial value of 0.5:

```
h = midicontrols([1081 1083; 1082 1084], 0.5);
```

Set Mode to raw, and Set an Initial Value

Return a square array, with the raw initial value of 63:

```
h = midicontrols([1081 1083; 1082 1084], 63, 'OutputMode', 'rawmidi');
```

Set the Default MIDI Device

Assume your MIDI device is a Behringer BCF2000. Set the default device this way:

```
setpref midi DefaultDevice BCF2000
```

This preference persists across MATLAB sessions, so you do not need to set it again unless you want to change devices.

Use Both ControlNumbers and DeviceName

Respond to control 1001 on a Behringer BCF2000:

```
h = midicontrols(1001, 'MIDIDevice', 'BCF2000');
```

Input Arguments

`ControlNumbers` — Identifying MIDI controls

integer values

`ControlNumbers` are integer-valued double-precision numbers. Each control on the MIDI device has a specific integer assigned to it by the device manufacturer. If `ControlNumbers` is [ ], then the `midicontrols` object responds to any control on the MIDI device. As a result, `midiread` returns a double scalar.

Example: `1081`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`InitialValues` — Initial value of MIDI control

any numeric value within range

`InitialValues` must either be an array of the same size as `ControlNumbers` or a scalar. If you do not specify `InitialValues`, the default initial value is `0`. Typically, initial values must be in the range [0 1]. However, if you specify `'rawmidi'` as `OutputMode`, the `InitialValues` range is between 0 and 127. Because the initial values are quantized for the underlying MIDI protocol, sometimes `midiread` returns an initial value that is slightly different from `InitialValues`.

Example: `0.3 or [0 0.3 0.6]`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`devicename` — Name of device

character string

`devicename` is a character string assigned by the device manufacturer or the host operating system. The specified `devicename` can be a substring of the device's exact name. If you do not specify the '`MIDIDevice`' name-value pair, the default MIDI device is used. The MATLAB preference '`midi`', '`DefaultDevice`' determines the default device.

If you do not set the MATLAB preference, the host operating system chooses the default device in an unspecified way. Some systems have virtual (ie, software) MIDI devices installed. Even if you have only one hardware MIDI device attached to your system, the system may not choose it, which can cause confusion. As a best practice, use `midiid` to identify the name of the device you want. Then use `setpref` to set it as the default device.

Example: `'BCF2000 MIDI 1'`

Data Types: `char`

`mode` — Mode of output

character string

`mode` is a string and must be one of `'normalized'` or `'rawmidi'`. In normalized mode, values are in the range [0 1]. Also, initial values are quantized for the underlying MIDI protocol. In the raw MIDI mode, values are integers in the range [0 127], and the quantization of the initial values is not performed. The default of this name-value pair is '`normalized`'.

Example: `'rawmidi'`

Data Types: `char`

Output Arguments

`h` — Object that listens to the controls on a MIDI device

object

`h` is an object that listens to the controls on a MIDI device.

`midicallback` | `midiid` | `midiread` | `midisync` | `setpref`

Introduced in R2013b

midiid

Interactively identify MIDI control

Compatibility

The midiid function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the midiid function from Audio System Toolbox instead.

Syntax

```
[ctl device] = midiid
```

Description

`[ctl device] = midiid` returns the control number and device name of the MIDI control moved by the user. Call the function at the MATLAB command prompt and then move the control you want to identify on the MIDI control surface. The function detects which control you move and returns the corresponding control number and device name that specify that control.

Examples

Retrieve Control Number and Device Name

Call `midiid`.

```
[ctl,dev] = midiid;
Move the control you wish to identify; type ^C to abort.
Waiting for control message...

ctl =
1002
dev =
```

`nanoKONTROL`

Output Arguments

`ctl` — Number associated with control being moved

integer values

`ctl` is an integer-valued double-precision number. Each control on the MIDI device has a specific integer assigned to it by the device manufacturer.

Example: `1003`

Data Types: `double`

`device` — Name of device

character string

`device` is a character string assigned by the device manufacturer or the host operating system.

Example: `'nanoKontrol'`

Data Types: `char`

See Also

`midicallback` | `midicontrols` | `midiread` | `midisync` | `setpref`

Introduced in R2013b

midiread

Return most recent value of MIDI controls

Compatibility

The `midiread` function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the `midiread` function from Audio System Toolbox instead.

Syntax

```
v = midiread(h)
```

Description

`v = midiread(h)` returns the most recent value of the MIDI controls associated with `midicontrols` object, `h`. You must create `h` first before it can determine the values of its MIDI controls if they are moved. Calling `midiread` before the controls are moved, returns the initial values specified to `midicontrols`. In this case, when `h` is created. (or `0` if no initial values are specified).

Examples

Read Control Values

```
h = midicontrols;
v = midiread(h);
```

Input Arguments

h — Object that listens to the controls on a MIDI device

object

h is an object that listens to the controls on a MIDI device.

Output Arguments

v — Most recent value of MIDI controls

any numeric value

The output value depends on the OutputMode specified by midicontrols when h is created. If you specify that the OutputMode is normalized, then the midiread returns output values in the range [0 1]. Also, initial values are quantized and may be slightly different from those specified by midicontrols.

If you specify the mode as rawmidi, then midiread returns integer values in the range [0 127], and no quantization is required. If you do not specify the OutputMode, the default is normalized.

Example: 0.3 or [0 0.3 0.6]

Data Types: double | uint8

midicallback | midicontrols | midiid | midisync | setpref

Introduced in R2013b

midisync

Send values to MIDI controls to synchronize

Compatibility

The `midisync` function will be removed from DSP System Toolbox in a future release. Existing instances of the function continue to run. For new code, use the `midisync` function from Audio System Toolbox instead.

Syntax

```
midisync(h)
midisync(h,Values)
```

Description

`midisync(h)` sends the initial values specified by `midicontrols`. `h` is created by the MIDI controls associated with the `midicontrols` object, `h`. You can use `midisync` with bidirectional MIDI devices that can both send and receive messages, and move a control in response to a received message. For example, when a `midicontrols` object is first created, it is often helpful to move the MIDI control to match the initial value of the object. Many MIDI devices are not bidirectional, and calling `midisync` with a unidirectional device has no effect. `midisync` cannot tell whether a value is successfully sent to a device or even whether the device is bidirectional. Therefore, no errors or warnings are generated if sending a value fails.

`midisync(h,Values)` sends `Values` to the MIDI controls associated with the `midicontrols` object, `h`. `Values` must follow the same rules as `InitialValue` arguments of `midicontrols`.

Examples

Send a Slider Change to MIDI Control

```
midisync(h, get(slider, 'Value'))
```

Create a GUI with a Single Slider, and Synchronize it with a MIDI Control

When you move either control, the other control tracks it. The resulting value appears on the command prompt.

```
function trivialmidigui(controlnum,DEVICENAME)
    slider = uicontrol('Style','slider');
    mc = midicontrols(controlnum,'MIDIDevice',DEVICENAME);
    midisync(mc);
    set(slider,'Callback',@slidercb);
    midicallback(mc, @mccb);

    function slidercb(slider,~)
        val = get(slider,'Value');
        midisync(mc, val);
        disp(val);
    end

    function mccb(mc)
        val = midiread(mc);
        set(slider,'Value',val);
        disp(val);
    end
end
```

Input Arguments

`h` — Object that listens to the controls on a MIDI device

object

`h` is an object that listens to the controls on a MIDI device.

`Values` — Values sent to select MIDI control

any numeric value in range

`Values` must either be an array the same size as `ControlNumbers` from `midicontrols` or a scalar. If you do not specify `Values`, the default value is whatever the

InitialValues is from midicontrols. Typically, values must normally be in the range [0 1]. However, if you specify 'rawmidi' as OutputMode of midicontrols, the Values range is between 0 and 127.

Example: 0.3 or [0 0.3 0.6]

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Introduced in R2013b

minimizecoeffwl

Minimum wordlength fixed-point filter

Syntax

```
Hq = minimizecoeffwl(Hd)
Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)
Hq = inimizecoeffwl(Hd,...,'NTrials',N)
Hq = minimizecoeffwl(Hd,...'Apasstol',Apasstol)
Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)
Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)
```

Description

`Hq = minimizecoeffwl(Hd)` returns the minimum wordlength fixed-point filter object `Hq` that meets the design specifications of the single-stage or multistage FIR filter object `Hd`. `Hd` must be generated using `fdesign` and `design`. If `Hd` is a multistage filter object, the procedure minimizes the wordlength for each stage separately. `minimizecoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`.

`Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the minimization of the wordlength. By default `NSFlag` is `true`. Setting `NSFlag` to `false` minimizes the wordlength without using noise-shaping.

`Hq = inimizecoeffwl(Hd,...,'NTrials',N)` specifies the number of Monte Carlo trials to use in the minimization. `Hq` is the filter with the minimum wordlength among the `N` trials that meets the specifications in `Hd`. `'NTrials'` defaults to one.

`Hq = minimizecoeffwl(Hd,...'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`.

`Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)` determines whether the fixed-point filter matches the filter order and transition width of the floating-point design. Setting `'MatchRefFilter'` to `true` returns a fixed-point filter with the same order and transition width as `Hd`. The `'MatchRefFilter'` property defaults to `false` and the resulting fixed-point filter may have a different order and transition width than the floating-point design `Hd`.

You must have the Fixed-Point Designer software installed to use this function.

Examples

Minimize wordlength for lowpass FIR equiripple filter:

```
f=fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.3,1,60);
% Design filter with double-precision floating point
Hd=design(f,'equiripple');
% Find minimum wordlength fixed-point filter
% with 0.15 dB stopband tolerance
Hq=minimizecoeffwl(Hd,'MatchRefFilter',true,'Astoptol',0.15);
Hq1=minimizecoeffwl(Hd,'Astoptol',0.15);
% Hq.coeffwordlength is 14 bits.
% Hq1.coeffwordlength is 11 bits
hfvt=fvtool(Hd,Hq,Hq1,'showreference','off');
legend(hfvt,'44 coefficients floating-point',...
'44 coefficients 14 bits','48 coefficients 11 bits');
```

msepred

Predicted mean-squared error for adaptive filter

Compatibility

msepred will be removed in a future release. Use dsp.LMSFilter instead.

Syntax

```
[mmse,emse] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d)
[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m)
```

Description

[mmse,emse] = msepred(ha,x,d) predicts the steady-state values at convergence of the minimum mean-squared error (mmse) and the excess mean-squared error (emse) given the input and desired response signal sequences in x and d and the property values in the adaptfilt object ha.

[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d) calculates three sequences corresponding to the analytical behavior of the LMS adaptive filter defined by ha:

- meanw — contains the sequence of coefficient vector means. The columns of matrix meanw contain predictions of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of meanw are (size(x,1))-by-(ha.length).
- mse — contains the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the LMS adaptive filter at each time instant. The length of mse is equal to size(x,1).
- tracek — contains the sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the LMS adaptive filter at each time instant. The length of tracek is equal to size(x,1).

[mmse,emse,meanw,mse,tracek] = msepred(ha,x,d,m) specifies an optional input argument m that is the decimation factor for computing meanw, mse, and tracek. When m > 1, msepred saves every mth predicted value of each of these sequences. When you omit the optional argument m, it defaults to one.

Note msepred is available for the following adaptive filters only: — adaptfilt.blms — adaptfilt.blmsfft — adaptfilt.lms — adaptfilt.nlms — adaptfilt.se Using msepred is the same for any adaptfilt object constructed by the supported filters.

Examples

Analyze and simulate a 32-coefficient adaptive filter using 25 trials of 2000 iterations each.

```
x = zeros(2000,25); d = x;     % Initialize variables
ha = fir1(31,0.5);             % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));        % observation noise signal
d = filter(ha,1,x)+n;          % desired signal
l = 32;                        % Filter length
mu = 0.008;                    % LMS step size.
m  = 5;                        % Decimation factor for analysis
                               % and simulation results
ha = adaptfilt.lms(l,mu);
[mmse,emse,meanW,mse,traceK] = msepred(ha,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
(emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse]);
title('Mean-Square Error Performance');
axis([0 size(x,1) 0.001 10]);
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim,nn,traceK,'r');
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
legend('Simulation','Theory');
xlabel('Time Index'); ylabel('Squared Error Value');
```

Viewing the plots in this figure you see the various error values plotted in both simulation and theory. Each subplot reveals more information about the results as the simulation converges with the theoretical performance.

`filter` | `maxstep` | `msesim`

Introduced in R2011a

msesim

Measured mean-squared error for adaptive filter

Compatibility

msesim will be removed in a future release. Use dsp.LMSFilter, dsp.BlockLMSFilter, dsp.RLSFilter, dsp.FilteredXLMSFilter, dsp.AdaptiveLatticeFilter, or dsp.LMSFilter instead.

Syntax

```
mse = msesim(ha,x,d)
[mse,meanw,w,tracek] = msesim(ha,x,d)
[mse,meanw,w,tracek] = msesim(ha,x,d,m)
```

Description

`mse = msesim(ha,x,d)` returns the sequence of mean-square errors in column vector `mse`. The vector contains estimates of the mean-square error of the adaptive filter at each time instant during adaptation. The length of `mse` is equal to `size(x,1)`. The columns of matrix `x` contain individual input signal sequences, and the columns of the matrix `d` contain corresponding desired response signal sequences.

`[mse,meanw,w,tracek] = msesim(ha,x,d)` calculates three parameters that correspond to the simulated behavior of the adaptive filter defined by `ha`:

- `meanw` — sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the LMS adaptive filter coefficients at each time instant. The dimensions of `meanw` are (`size(x,1)`)-by-(`ha.length`).
- `w` — estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `ha`.
- `tracek` — sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the LMS adaptive filter at each time instant. The length of `tracek` is equal to `size(X,1)`.

[mse,meanw,w,tracek] = msesim(ha,x,d,m) specifies an optional input argument m that is the decimation factor for computing meanw, mse, and tracek. When m > 1, msepsim saves every mth predicted value of each of these sequences. When you omit the optional argument m, it defaults to one.

Examples

Simulation of a 32-coefficient FIR filter using 25 trials, each trial having 2000 iterations of the adaptation process.

```
x = zeros(2000,25); d = x;          % Initialize variables
ha = fir1(31,0.5);                  % FIR system to be identified
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));             % Observation noise signal
d = filter(ha,1,x)+n;               % Desired signal
l = 32;                             % Filter length
mu = 0.008;                         % LMS Step size.
m  = 5;                             % Decimation factor for analysis
                                    % and simulation results
ha = adaptfilt.lms(l,mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanWsim(:,13:15),'b');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
xlabel('Time Index'); ylabel('Coefficient Value');
subplot(2,2,3);
semilogy(nn,simmse);
title('Mean-Square Error Performance'); axis([0 size(x,1) 0.001...
10]);
legend('Measured MSE');
xlabel('Time Index'); ylabel('Squared Error Value');
subplot(2,2,4);
semilogy(nn,traceKsim);
title('Sum-of-Squared Coefficient Errors'); axis([0 size(x,1)...
0.0001 1]);
xlabel('Time Index'); ylabel('Squared Error Value');
```

Calculating the mean squared error for an adaptive filter is one measure of the performance of the adapting algorithm. In this figure, you see a variety of measures of the filter, including the error values.

filter | msepred

Introduced in R2011a

multistage

Multistage filter from specification object

Syntax

```
msFilter = design(d,'multistage','SystemObject',true)
msFilter =
design(...,'filterstructure',structure,'SystemObject',true)
msFilter = design(...,'nstages',nstages,'SystemObject',true)
msFilter = design(...,'usehalfbands',hb,'SystemObject',true)
```

Description

`msFilter = design(d,'multistage','SystemObject',true)` designs a multistage filter whose response you specified by the filter specification object `d`.

`msFilter = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the structure specified by `structure`. Input argument `structure` is `dffir` by default and can also be one of the following options.

structure	Valid with These Responses
`firdecim`	Lowpass or Nyquist response
`firtdecim`	Lowpass or Nyquist response
`firinterp`	Lowpass or Nyquist response
`lowpass`	Default lowpass only

Multistage design applies to the default lowpass filter specification object and to decimators and interpolators that use either lowpass or Nyquist responses.

`msFilter = design(...,'nstages',nstages,'SystemObject',true)` specifies `nstages`, the number of stages to be used in the design. `nstages` must be an integer or `auto`. To allow the design algorithm to use the optimal number of stages while minimizing the cost of using the resulting filter, `nstages` is `auto` by default. When you specify an integer for `nstages`, the design algorithm minimizes the cost for the number of stages you specify.

`msFilter = design(...,'`**`usehalfbands`**`',hb,'SystemObject',true)` uses halfband filters when you set `hb` to `true`. The default value for `hb` is `false`.

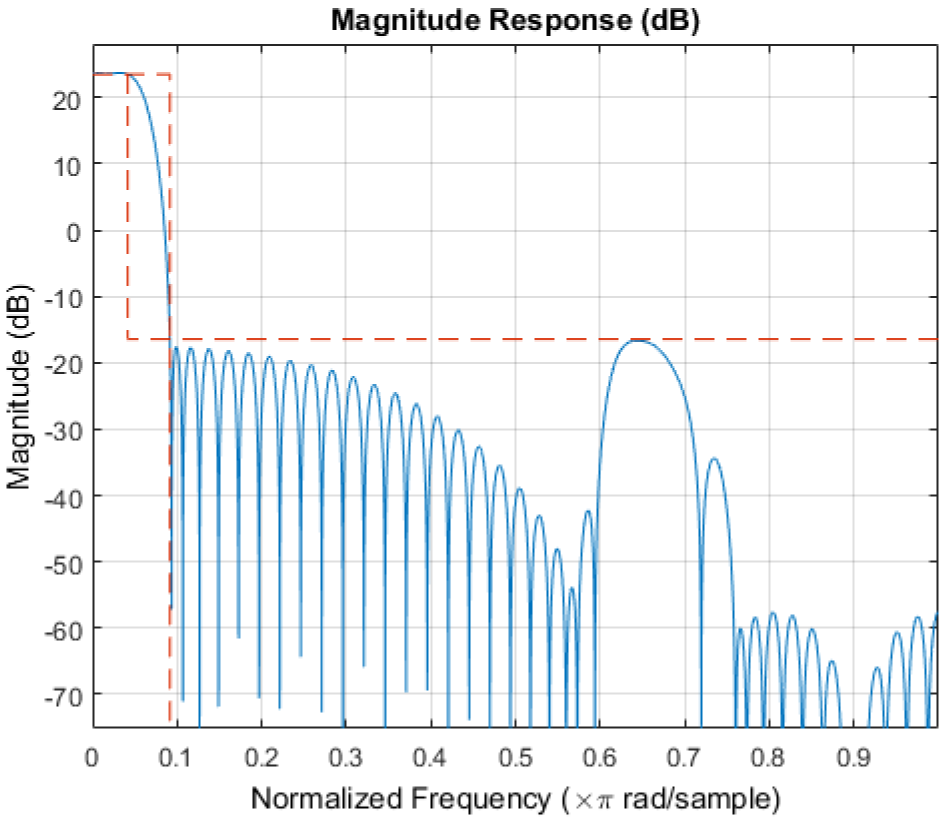
Note: To see a list of the design methods available for your filter, use `designmethods(hd)`.

Examples

Design a Multistage Interpolator

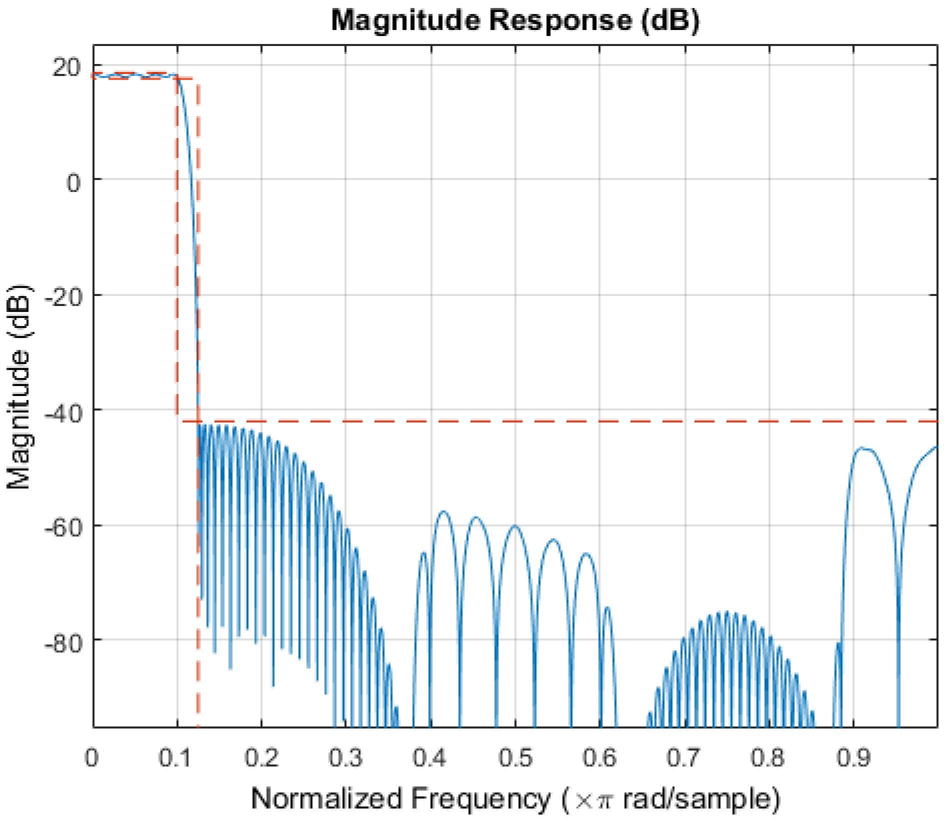
This example designs a minimum-order, multistage Nyquist interpolator.

```
l = 15;   % Interpolation factor. Also the Nyquist band.
tw = 0.05; % Normalized transition width
ast = 40;   % Minimum stopband attenuation in dB
d = fdesign.interpolator(l,'nyquist',l,'tw,ast',tw,ast);
msMinInterp = design(d,'multistage','SystemObject',true);
fvtool(msMinInterp);
```



Design a multistage lowpass interpolator with an interpolation factor of 8.

```
m = 8;
d = fdesign.interpolator(m,'lowpass');
% Use halfband filters if possible.
msInterp = design(d,'multistage','Usehalfbands',true,'SystemObject',true);
fvtool(msInterp);
```



See Also

`design` | `designopts`

Introduced in R2011a

noisepsd

Power spectral density of filter output due to roundoff noise

Syntax

```
hpsd = noisepsd(sysobj,L)
hpsd = noisepsd(sysobj,L,param1,value1,param2,value2,...)
hpsd = noisepsd(sysobj,L,opts)
noisepsd(sysobj,...)
```

Description

`hpsd = noisepsd(sysobj,L)` computes the power spectral density (PSD) at the output of filter System object, `sysobj`, occurring because of roundoff noise. This noise is produced by quantization errors within the filter. `L` is the number of trials used to compute the average. The PSD is computed from the average over the `L` trials. The more trials you specify, the better the estimate, but at the expense of longer computation time. When you do not explicitly specify `L`, the default is 10 trials.

`hpsd` is a `psd` data object. To extract the PSD vector (the data from the PSD) from `hpsd`, enter

```
get(hpsd,'data')
```

at the prompt. Plot the PSD data with `plot(hpsd)`. The average power of the output noise (the integral of the PSD) can be computed with `avgpower`, a method of `dspdata` objects:

```
avgpwr = avgpower(hpsd).
```

`hpsd = noisepsd(sysobj,L,param1,value1,param2,value2,...)` where `sysobj` is a filter System object, specifies optional parameters via propertyname/propertyvalue pairs. Valid `psd` object property values are:

Property Name	Default Value	Description and Valid Entries
`Nfft`	512	Specify the number of FFT points to use to calculate the PSD.

Property Name	Default Value	Description and Valid Entries
NormalizedFrequency	true	Determine whether to use normalized frequency. Enter a logical value of true or false. Because this property is a logical value, do not enclose the single quotation marks.
Fs	normalized	Specify the sampling frequency to use when you set NormalizedFrequency to false. Use any integer value greater than 1. Enter the value in Hz.
SpectrumType	onesided	Specify how noisepsd should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose CenterDC = true. Otherwise, CenterDC must be false. • onesided converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically. • twosided converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.
CenterDC	false	Shift the zero-frequency component to the center of a two-sided spectrum. • When you set SpectrumType to onesided, it is changed to twosided and the data is converted to a two-sided spectrum. • Setting CenterDC to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not affect the SpectrumType property setting.

Property Name	Default Value	Description and Valid Entries
`Arithmetic`	`ARITH`	Analyze the filter System object, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to `double`, `single`, or `fixed`. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

Note If the spectrum data you specify is calculated over half the Nyquist interval and you do not specify a corresponding frequency vector, the default frequency vector assumes that the number of points in the whole FFT was even. Also, the plot option to convert to a whole or two-sided spectrum assumes the original whole FFT length is even.

`noisepsd` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(sysobj)` , then the following rules apply to this method:

- The System object state is `Unlocked` — `noisepsd` performs double-precision analysis.
- The System object state is `Locked` — `noisepsd` performs analysis based on the locked input data type.

If you do specify the `Arithmetic` parameter, i.e., use the syntax `[h,w] = noisepsd(sysobj,'Arithmetic', ARITH)`, review the following rules for this method. Which rule applies depends on the value you set for the `Arithmetic` parameter.

Value	System Object State	Rule
`ARITH = ’double’`	`Unlocked`	`noisepsd` performs double-precision analysis.
	`Locked`	`noisepsd` performs double-precision analysis.
`ARITH = ‘single’`	`Unlocked`	`noisepsd` performs single-precision analysis.
	`Locked`	`noisepsd` performs single-precision analysis.

Value	System Object State	Rule
ARITH = 'fixed'	Unlocked	noisepsd produces an error because the fixed-point input data type is unknown.
	Locked	When the input data type is double or single, then noisepsd produces an error because since the fixed-point input data type is unknown.
		When the input data is of fixed-point type, noisepsd performs analysis based on the locked input data type.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpoleFilter
dsp.AllpassFilter
dsp.BiquadFilter
dsp.CoupledAllpassFilter
dsp.FIRFilter
dsp.HighpassFilter
dsp.IIRFilter
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

`hpsd = noisepsd(sysobj,L,opts)` uses an options object, `opts`, to specify the optional input arguments. This specification is not made using property-value pairs in the command. Use `opts = noisepsdopts(sysobj)` to create the object. `opts` then has the `noisepsd` settings from `sysobj`. After creating `opts`, you change the property values before calling `noisepsd`:

```
set(opts,'fs',48e3); % Set Fs to 48 kHz.
```

`noisepsd(sysobj,...)` with no output argument launches fvtool.

Examples

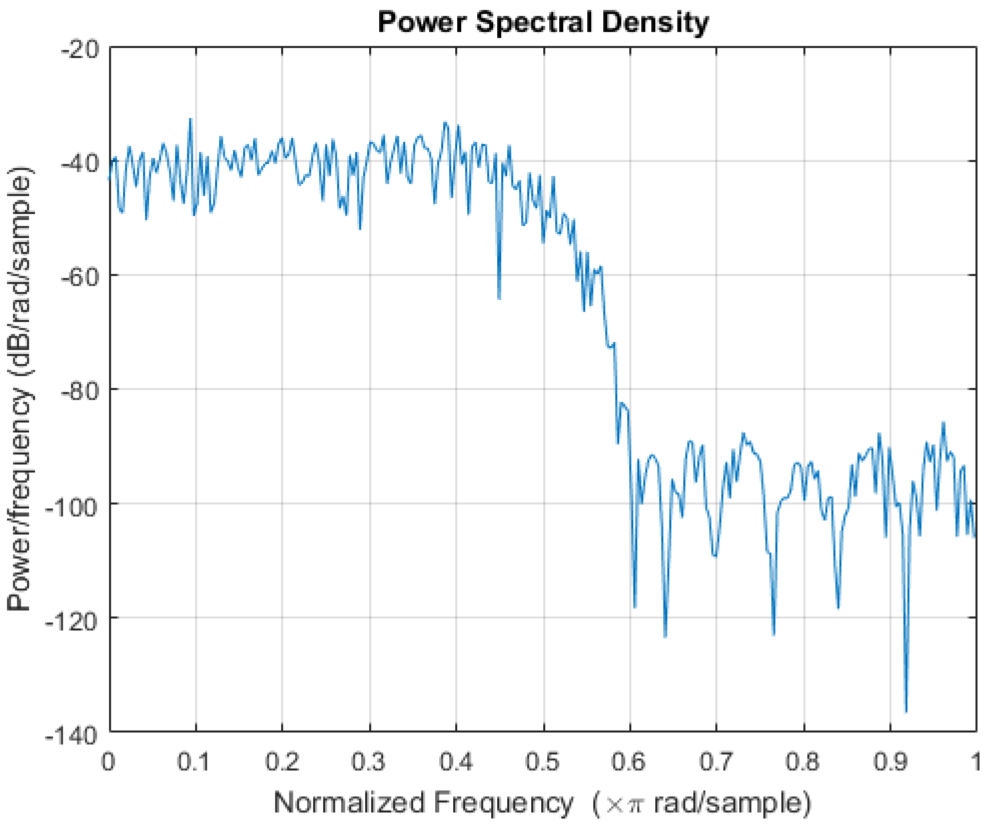
Compute the PSD of Output Noise

Compute the PSD of the output noise caused by the quantization processes in a fixed-point, direct form FIR filter. The input is of fixed-point type. `noisepsd` performs analysis based on the locked input data type.

```
b = firgr(27,[0 .4 .6 1],[1 1 0 0]);
firfilt = dsp.FIRFilter('Numerator',b); % Create the filter object.
data = fi(randn(15,16),1,16,3);
output = firfilt(data);
```

Quantize the filter to fixed-point.

```
hpsd = noisepsd(firfilt,'Arithmetic','fixed');
plot(hpsd)
```



`hpsd` looks similar to the following figure - the data resulting from the noise PSD calculation. You can review the data in hpsd.data.

Functions
`filter` | `noisepsdopts` | `norm` | `reorder` | `scale`

Introduced in R2011a

noisepsdopts

Options for running filter output noise PSD

Syntax

```
opts = noisepsdopts(sysobj)
```

Description

`opts = noisepsdopts(sysobj)` uses the current settings in the filter System object, `sysobj`, to create an options object, `opts`, that contains specified options for computing the output noise PSD. You can pass `opts` to the `noisepsd` method as an input argument.

Using `opts`, you can set the following properties for `noisepsd`:

Property Name	Default Value	Description and Valid Entries
`Nfft`	`512`	Specify the number of FFT points to use to calculate the PSD.
`NormalizedFrequency`	`true`	Determine whether to use normalized frequency. Enter a logical value of the logical `true` or `false`. Because this property is a logical value, do not enclose with single quotation marks.
`Fs`	`normalized`	Specify the sampling frequency to use when you set `NormalizedFrequency` to `false`. Use any integer value greater than 1. Enter the value in Hz.
`SpectrumType`	`onesided`	Specify how `noisepsd` should generate the PSD. Options are onesided or twosided. If you choose a two-sided computation, you can also choose `centerdc` = `true`. Otherwise, `centerdc` must be `false`.

Property Name	Default Value	Description and Valid Entries
		• `onesided` converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically. • `twosided` converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.
`CenterDC`	`false`	Shift the zero-frequency component to the center of a two-sided spectrum. • When you set `SpectrumType` to `onesided`, it is changed to `twosided` and the data is converted to a two-sided spectrum. • Setting `CenterDC` to `false` shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not effect the `SpectrumType` property setting.
`Arithmetic`	`ARITH`	Analyze the filter System object, based on the arithmetic specified in the `ARITH` input. `ARITH` can be set to `double`, `single`, or `fixed`. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

Functions
`noisepsd`

Introduced in R2011a

norm

P-norm of filter

Syntax

```
l = norm(hd)
l = norm(hd,pnorm)
```

Description

All of the variants of `norm` return the filter p-norm for the object in the syntax, a digital filter. When you omit the `pnorm` argument, `norm` returns the L2-norm for the object.

Note that by Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

For dfilt Objects

`l = norm(hd)` returns the L2-norm of a discrete-time filter.

`l = norm(hd,pnorm)` includes input argument `pnorm` that lets you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

By Parseval's theorem, the L2-norm of a filter is equal to the l2 norm. This equality is not true for the other norm variants.

IIR filters respond slightly differently to `norm`. When you compute the l2, linf, L1, and L2 norms for an IIR filter, `norm(...,L2,tol)` lets you specify the tolerance for the accuracy in the computation. For l1, l2, L2, and linf, `norm` uses the tolerance to truncate the infinite impulse response that it uses to calculate the norm. For L1, `norm` passes the tolerance to the numerical integration algorithm. Refer to Examples to see this in use. You cannot specify `Linf` for the norm and include the `tol` option.

Examples

Norm of an IIR Filter

This example shows how to compute the L2 norm of an IIR filter. A tolerance of 1e-10 is used.

```
spec = fdesign.lowpass('n,fc',5,0.4);
filter = butter(spec);
filternorm = norm(filter,'l2',1e-10)
```

```
filternorm =

    0.6336
```

See Also

reorder | scale | scalecheck

Introduced in R2011a

normalize

Normalize filter numerator or feed-forward coefficients

Syntax

```
normalize(hq)
g = normalize(hd)
```

Description

`normalize(hq)` normalizes the filter numerator coefficients for a quantized filter to have values between -1 and 1. The coefficients of `hq` change — `normalize` does not copy `hq` and return the copy. To restore the coefficients of `hq` to the original values, use `denormalize`.

Note that for lattice filters, the feed-forward coefficients stored in the property `lattice` are normalized.

`g = normalize(hd)` normalizes the numerator coefficients for the filter `hq` to between -1 and 1 and returns the gain `g` due to the normalization operation. Calling `normalize` again does not change the coefficients. `g` always returns the gain returned by the first call to normalize the filter.

Examples

Normalize the Coefficients of a Direct Form II Filter

Create a direct form II quantized filter that uses second-order sections. Then use normalize to maximize the use of the range of representable coefficients.

```
d = fdesign.lowpass('n,fp,ap,ast',8,.5,2,40);
hd = design(d,'ellip');
hd.arithmetic ='fixed';
```

Check the filter coefficients. Note that InitialSOSMatrix(3,2)>1

```
InitialSOSMatrix = hd.sosMatrix;
```

Use normalize to modify the coefficients into the range between -1 and 1. The output g contains the gains applied to each section of the SOS filter.

```
g = normalize(hd);
```

None of the numerator coefficients exceed -1 or 1.

See Also

`denormalize`

Introduced in R2011a

normalizefreq

Switch filter specification between normalized frequency and absolute frequency

Syntax

```
normalizefreq(d)
normalizefreq(d,flag)
normalizefreq(d,false,fs)
```

Description

`normalizefreq(d)` normalizes the frequency specifications in filter specifications object `d`. By default, the `NormalizedFrequency` property is set to `true` when you create a design object. You provide the design specifications in normalized frequency units. `normalizefreq` does not affect filters that already use normalized frequency.

If you use this syntax when `d` does not use normalized frequency specifications, all of the frequency specifications are normalized by `fs`/2 so they lie between 0 and 1, where `fs` is specified in the object. Included in the normalization are the filter properties that define the filter pass and stopband edge locations by frequency:

- `F3 dB` — Used by IIR filter specifications objects to describe the passband cutoff frequency
- `Fcutoff` — Used by FIR filter specifications objects to describe the passband cutoff frequency
- `Fpass` — Describes the passband edges
- `Fstop` — Describes the stopband edges

In this syntax, `normalizefreq(d)` assumes you specified `fs` when you created `d` or changed `d` to use absolute frequency specifications.

`normalizefreq(d,flag)` where `flag` is either **`true`** or **`false`**, specifies whether the `NormalizedFrequency` property value is `true` or `false` and therefore whether the filter normalizes the sampling frequency `fs` and other related frequency specifications. `fs` defaults to 1 for this syntax.

When you do not provide the input argument `flag`, it defaults to `true`. If you set `flag` to `false`, affected frequency specifications are multiplied by `fs`/2 to remove the normalization. Use this syntax to switch your filter between using normalized frequency specifications and not using normalized frequency specifications.

`normalizefreq(d,`**`false`**`,fs)` lets you specify a new sampling frequency `fs` when you set the `NormalizedFrequency` property to `false`.

Examples

Normalize the Frequency Specifications of a Filter

These examples demonstrate using `normalizefreq` in both of the major syntax applications-setting the design object frequency specifications to use absolute frequency (normalizefreq(hd,false,fs)) and resetting a design object to using normalized frequencies (normalizefreq(d)).

Construct a highpass filter specifications object by specifying the passband and stopband edges and the desired attenuations in the bands. By default, provide the frequency specifications in normalized values between 0 and 1.

```
d = fdesign.highpass(0.35, 0.45, 60, 40);
```

`Fstop` and `Fpass` are in normalized form, and the property `NormalizedFrequency` is true.

Now use normalizedfreq to convert to absolute frequency specifications, with a sampling frequency of 1000 Hz.

```
normalizefreq(d,false,1e3);
```

Both of the attenuation specifications remain the same. The passband and stopband edge definitions now appear in Hz, where the new value represents the normalized values multiplied by Fs/2, or 500 Hz.

Converting to using normalized frequencies consists of using `normalizefreq` with the design object d.

```
normalizefreq(d)
```

For bandstop, bandpass, and multiple band filter specifications objects, normalizefreq works the same way for all band edge definitions. When you do not provide the sampling frequency Fs as an input argument and you are converting to absolute frequency specifications, normalizefreq sets Fs to 1, as shown in this example.

```
d=fdesign.bandstop(0.25,0.35,0.55,0.65,50,60);
normalizefreq(d,false)
```

Introduced in R2011a

nstates

Number of filter states

Syntax

```
n = nstates(hd)
```

Description

Discrete-Time Filters

`n = nstates(hd)` returns the number of states `n` in the discrete-time filter `hd`. The number of states depends on the filter structure and the coefficients.

Examples

Number of States of a Filter

Determine the number of states of a direct form FIR filter.

```
FIRFilter = firls(30,[0 .1 .2 .5]*2,[1 1 0 0]);
DiscFilter = dfilt.dffir(FIRFilter);
NstateDF = nstates(DiscFilter)
```

```
NstateDF =

    30
```

Introduced in R2011a

order

Order of discrete-time filter System object

Syntax

```
n = order(sysobj)
```

Description

`n = order(sysobj)` returns the order `n` of the filter System object `sysobj`. The order depends on the filter structure and the reference double-precision floating-point coefficients.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator

Filter System objects
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

Examples

Determine the Order of a Filter

Design a compensation decimator for a CIC decimator using the `dsp.FilterCascade` object. Determine the order of the overall filter.

```
cicdecim = dsp.CICDecimator('DecimationFactor', 6, ...
    'NumSections', 6);

fs = 16e3;     % Sampling frequency of input of compensation decimator
fPass = 4e3;   % Passband frequency
fStop = 4.5e3; % Stopband frequency
ciccomp = dsp.CICCompensationDecimator(cicdecim, ...
    'DecimationFactor', 2, ...
    'PassbandFrequency', fPass, ...
    'StopbandFrequency', fStop, ...
    'SampleRate', fs);

filtchain = dsp.FilterCascade(cicdecim, ciccomp);

order(filtchain)
```

```
ans =
```

```
    648
```

Introduced in R2011a

phasedelay

Phase delay response of discrete-time filter System object

Syntax

```
[phi,w] = phasedelay(sysobj)
[phi,w] = phasedelay(sysobj,n)
[phi,w] = phasedelay(sysobj,Name,Value)
phasedelay(sysobj)
```

Description

`[phi,w] = phasedelay(sysobj)` returns the phase delay `phi` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the phase delay is evaluated.

The phase delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w] = phasedelay(sysobj,n)` returns the phase delay of the filter System object at `n` points equally spaced around the upper half of the unit circle.

`[phi,w] = phasedelay(sysobj,Name,Value)` returns the phase delay with additional options specified by one or more `Name,Value` pair arguments.

`phasedelay(sysobj)` plots the phase delay of the filter System object `sysobj` in the `fvtool`.

For information on more input options, refer to `phasedelay` in Signal Processing Toolbox documentation.

Examples

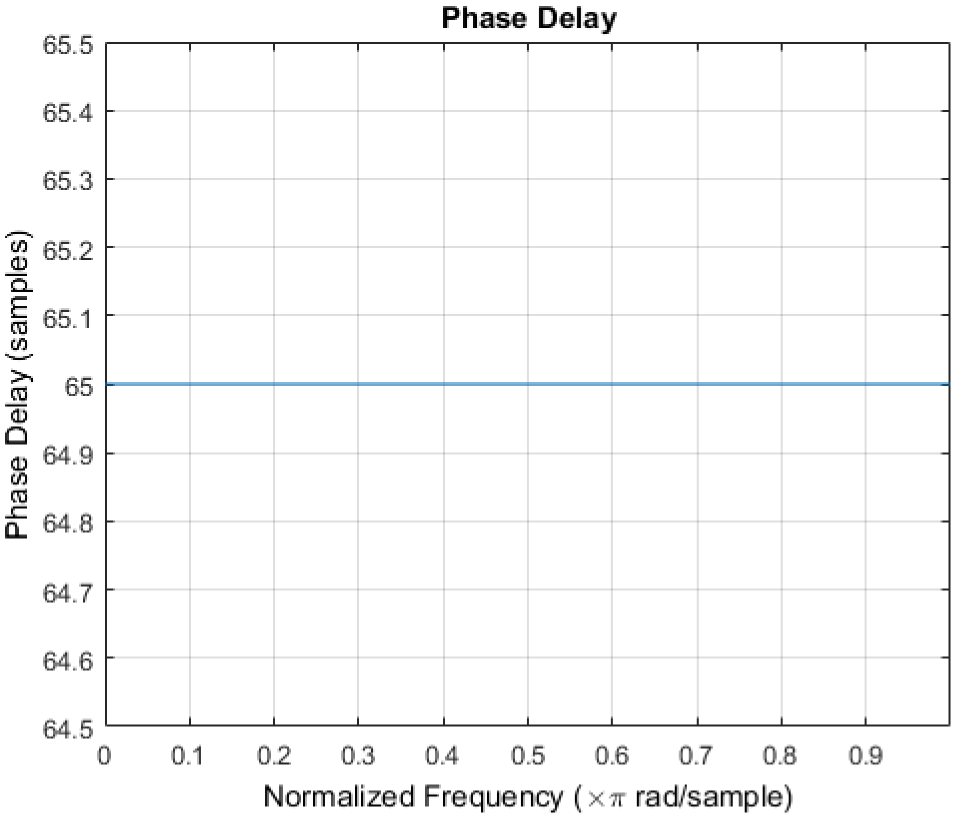
Phase Delay of a Discrete-Time Filter

```
Fs = 8000; Fcutoff = 2000;
```

```
FIRFilt = dsp.FIRFilter('Numerator', fir1(130,Fcutoff/(Fs/2)));
```

`phasedelay` computes the phase delay of the filter and displays it using fvtool

```
phasedelay(FIRFilt);
```



Input Arguments

`sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

n

Number of samples. For an FIR filter where n is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

phi

Phase delay vector of length n. If n is not specified, the function uses a default value of 8192.

w

Frequency vector of length n, in radians/sample. w consists of n points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If n is not specified, the function uses a default value of 8192.

Algorithms

You can provide fs, the sampling frequency, as an input as well. phasedelay uses fs to calculate the delay response and plots the response to fs/2.

Functions
freqz | freqz | fvtool | grpdelay | phasez | phasez | zerophase | zerophase | zplane

Introduced in R2011a

phasez

Unwrapped phase response for filter

Syntax

```
[phi,w] = phasez(sysobj)
[phi,w] = phasez(sysobj,n)
[phi,w] = phasez(sysobj,Name,Value)
phasez(sysobj)
```

Description

`[phi,w] = phasez(sysobj)` returns the unwrapped phase response `phi` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the function evaluates the phase response. The phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w] = phasez(sysobj,n)` returns the phase response of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[phi,w] = phasez(sysobj,Name,Value)` returns the phase response with additional options specified by one or more `Name,Value` pair arguments.

`phasez(sysobj)` displays the phase response of the filter System object `sysobj` in the `fvtool`.

For more information about optional input arguments for `phasez`, refer to `phasez` in Signal Processing Toolbox documentation.

Examples

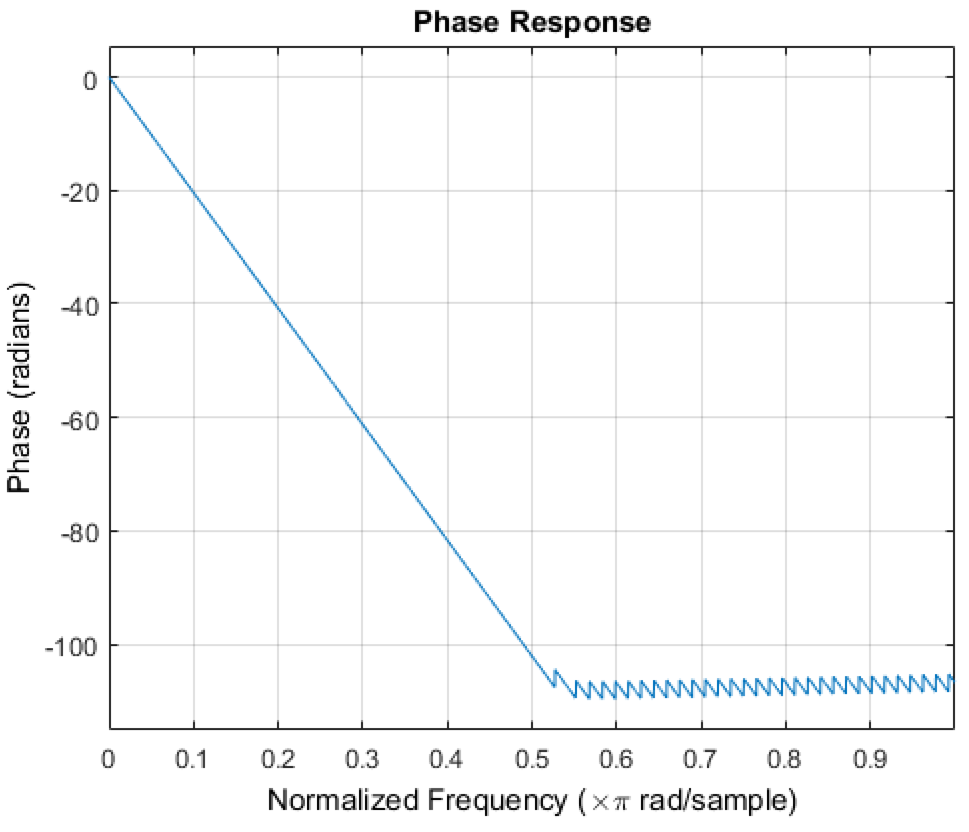
Unwrapped Phase Response of a Discrete-Time Filter

```
Fs = 8000; Fcutoff = 2000;
```

```
FIRFilt = dsp.FIRFilter('Numerator', fir1(130,Fcutoff/(Fs/2)));
```

`phasez` computes the unwrapped phase response of the filter and displays it using fvtool

```
phasez(FIRFilt);
```



Input Arguments

Introduced in R2011a

polyphase

Polyphase decomposition of multirate filter

Syntax

```
p = polyphase(hs)
p = polyphase(hs,Name,Value)
polyphase(hs)
```

Description

`p = polyphase(hs)` returns the polyphase matrix `p` of the multirate filter System object `hs`.

`p = polyphase(hs,Name,Value)` returns the polyphase matrix `p` of the multirate filter System object `hs`.

`polyphase(hs)` launches the Filter Visualization Tool (FVTool) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

Input Arguments

hs

Filter System object.

dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.FIRRateConverter
dsp.FIRDecimator
dsp.FIRInterpolator

dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`'double'` | `'single'` | `'fixed'`

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`,

System Object State	Coefficient Data Type	Rule
		the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

p

Polyphase matrix `p` of the multirate filter. Each row in the matrix represents one subfilter of the multirate filter. The first row of matrix `p` represents the first subfilter, the second row the second subfilter, and so on to the last subfilter.

Examples

Polyphase Matrix of an FIR Interpolator

When you create a multirate filter that uses polyphase decomposition, polyphase lets you analyze the component filters individually by returning the components as rows in a matrix. First, create an interpolate-by-three filter.

```
hs = dsp.FIRInterpolator
```

```
hs =

  dsp.FIRInterpolator with properties:

        NumeratorSource: 'Property'
              Numerator: [1×16 double]
    InterpolationFactor: 3

  Use get to show all properties
```

In this syntax, the matrix `p` contains all of the subfilters for `hm`, one filter per matrix row.

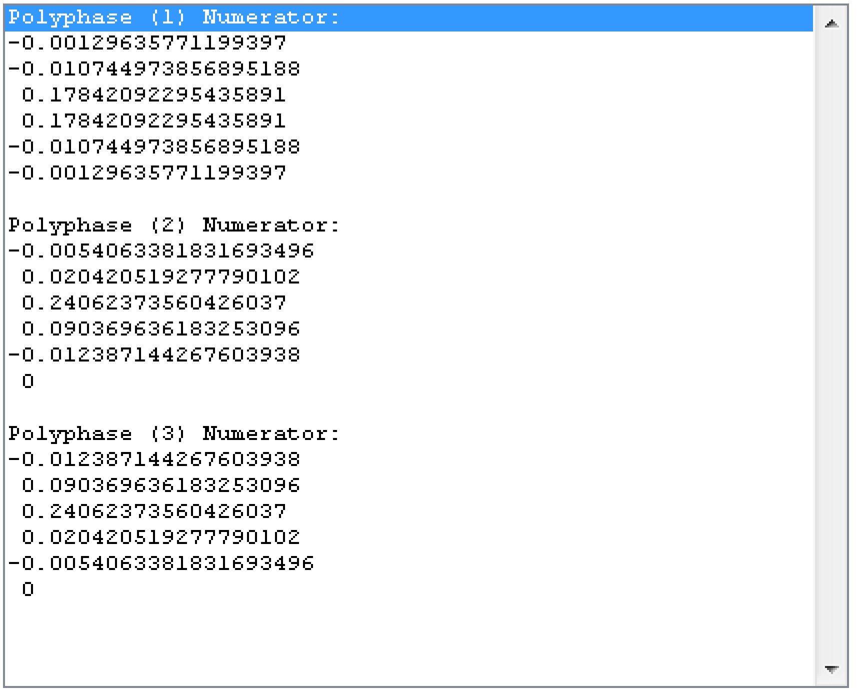
```
p = polyphase(hs)
```

```
p =

   -0.0013   -0.0107    0.1784    0.1784   -0.0107   -0.0013
   -0.0054    0.0204    0.2406    0.0904   -0.0124         0
   -0.0124    0.0904    0.2406    0.0204   -0.0054         0
```

Finally, using `polyphase` without an output argument opens the Filter Visualization Tool, ready for you to use the analysis capabilities of the tool to investigate the interpolator `hm`.

```
polyphase(hs)
```



The fvtool shows the coefficients of the subfilters. To see the magnitude response of the subfilters, click on the `Magnitude Response` button on the fvtool toolstrip.

dsp.FIRInterpolator

Introduced in R2011a

qreport

Most recent fixed-point filtering operation report

Syntax

```
rlog = qreport(h)
```

Description

`rlog = qreport(h)` returns the logging report stored in the filter object `h` in the object `rlog`. The ability to log features of the filtering operation is integrated in the fixed-point filter object and the `filter` method.

Each time you filter a signal with `h`, new log data overwrites the results in the filter from the previous filtering operation. To save the log from a filtering simulation, change the name of the output argument for the operation before subsequent filtering runs.

Note `qreport` requires Fixed-Point Designer software and that filter `h` is a fixed-point filter. Data logging for `fi` operations is a preference you set for each MATLAB session. To learn more about logging, `LoggingMode`, and `fi` object preferences, refer to `fipref` in the Fixed-Point Designer documentation.

Also, you cannot use `qreport` to log the filtering operations from a fixed-point Farrow filter.

Enable logging during filtering by setting `LoggingMode` to `on` for `fi` objects for your MATLAB session. Trigger logging by setting the `Arithmetic` property for `h` to `fixed`, making `h` a fixed-point filter and filtering an input signal.

Using Fixed-Point Filtering Logging

Filter operation logging with `qreport` requires some preparation in MATLAB. Complete these steps before you use `qreport`.

1. Set the fixed-point object preference for `LoggingMode` to `on` for your MATLAB session. This setting enables data logging.

   ```
   fipref('LoggingMode','on')
   ```
2. Create your fixed-point filter.
3. Filter a signal with the filter.
4. Use `qreport` to return the filtering information stored in the filter object.

`qreport` provides a way to instrument your fixed-point filters and the resulting data log offers insight into how the filter responds to a particular input data signal.

Report object `rlog` contains a filter-structure-specific list of internal signals for the filter. Each signal contains

- Minimum and maximum values that were recorded during the last simulation. Minimum and maximum values correspond to values before quantization.
- Representable numerical range of the word length and fraction length format
- Number of overflows during filtering for that signal.

Examples

View the Logging Report

This example shows how to use `qreport` to log the results of filtering a sinusoidal signal with a fixed-point direct-form FIR filter, firFilt. To use the `qreport`, set the `LoggingMode` of fixed-point objects to 'on'.

```
fipref('loggingmode','on');
hd = design(fdesign.lowpass,'equiripple');
hd.arithmetic = 'fixed';
hd.InputWordLength = 32;
fs = 1000;          % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
y = filter(hd,x);
rlog = qreport(hd)
```

```
rlog =
```

```
                              Fixed-Point Report
            ---------------------------------------------------------------------
                 Min               Max        |          Range             |
            ---------------------------------------------------------------------
       Input:             -1                 1 |        -65536        65536 |
      Output:       -1.02325           1.02325 |       -131072       131072 |
     Product:    -0.48538208        0.48538208 |        -32768        32768 |
 Accumulator:     -1.0852075         1.0852075 |       -131072       131072 |

Functions
`dfilt`

Introduced in R2011a

realizemdl

Simulink subsystem block for filter

Syntax

```
realizemdl(hq)
realizemdl(hq,Name,Value)
```

Description

`realizemdl(hq)` generates a model of filter `hq` in a Simulink subsystem block using sum, gain, and delay blocks from Simulink. The properties and values of `hq` define the resulting subsystem block parameters.

`realizemdl` requires Simulink. To accurately realize models of quantized filters, use Fixed-Point Designer.

`realizemdl(hq,Name,Value)` generates the model for `hq` with additional options specified by one or more `Name,Value` pair arguments. Using name-value pair arguments lets you control more fully the way the block subsystem model gets built. You can specify such details as where the block goes, what the name is, or how to optimize the block structure.

Input Arguments

hq — Filter System object
filter System object

List of filter system objects that the function supports:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter

Filter System objects
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRFilter
dsp.FIRInterpolator
dsp.FIRDecimator
dsp.FIRRateConverter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter

Name-Value Pair Arguments

`'Destination'` — Destination choices:
`'current'` (default) | `'new'` | `subsystemname`

Specify whether to add the block to your current Simulink model or create a new model to contain the block. If you provide the name of a current subsystem in *`subsystemname`*, `realizemdl` adds the new block to the specified subsystem.

`'Blockname'` — The name of the block (not the default) :
`'filter'` (default)

Provide the name for the new subsystem block. By default the block is named Filter.

'MapCoeffstoPorts' — Value options:
'off' (default) | 'on'

Specify whether to map the coefficients of the filter to the ports of the block.

'MapStates' — Value options:
'off' (default) | 'on'

Specify whether to apply the current filter states to the realized model. Such specification allows you to save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the model. Setting the property to 'on' preserves the current filter states in the realized model.

'OverwriteBlock' — Value options:
'off' (default) | 'on'

Specify whether to overwrite an existing block with the same name or create a new block.

'OptimizeZeros' — Value options:
'off' (default) | 'on'

Specify whether to remove zero-gain blocks.

'OptimizeOnes' — Value options:
'off' (default) | 'on'

Specify whether to replace unity-gain blocks with direct connections.

'OptimizeNegOnes' — Value options:
'off' (default) | 'on'

Specify whether to replace negative unity-gain blocks with a sign change at the nearest sum block.

'OptimizeDelayChains' — Value options:
'off' (default) | 'on'

Specify whether to replace delay chains made up of n unit delays with a single delay by n.

'CoeffNames' — Names of coefficients:
{'Num'} (default FIR) | {'Num','Den'} (default direct form IIR) | {'Num','Den','g'} (default IIR SOS) | {'Num_1,'Num_2,'Num_3'...} (default multistage) | {'K'} (default form lattice)

Specify the coefficient variable name as a cell array of character vectors. `MapCoeffsToPorts` must be set to `'on'` for this property to apply.

`'InputProcessing'` — Possible input processing options:
`'columns as channels'` (default) | `'elements as channels'`

Specify sample-based (`'elements as channels'`) or frame-based (`'columns as channels'`) processing.

`'RateOption'` — Rate options:
`'enforce single rate'` (default) | `'allow multirate'`

Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when `InputProcessing` is `'columns as channels'`.

`'Arithmetic'` — Value types:
`'double'` | `'single'`

The arithmetic for System object inputs must be `'double'` or `'single'`.

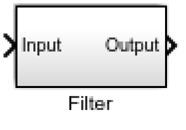
Examples

Realize Simulink Model of a Lowpass Butterworth Filter

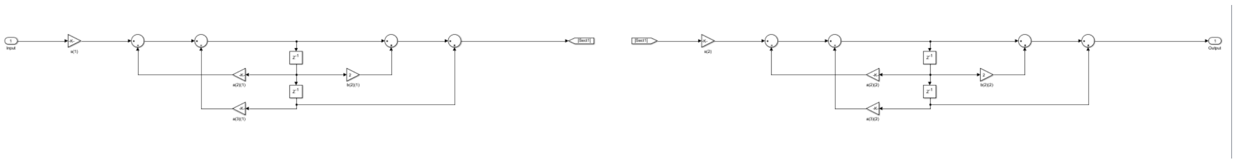
```
d = fdesign.lowpass('N,F3dB',4,0.25);
filterobject = design(d,'butter','systemobject',true);
```

Create a new model, `LPFilter.slx`, and realize the subsystem block in this model.

```
new_system('LPFilter');
realizemdl(filterobject);
```

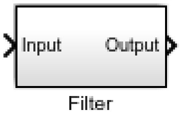


View the block diagram by clicking on the subsystem block.

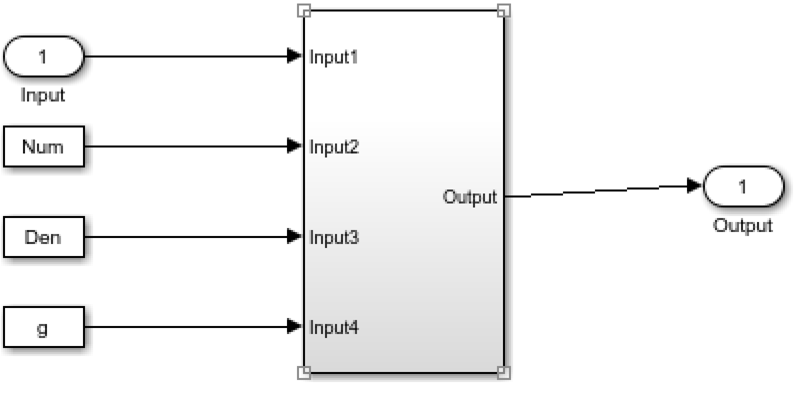


Create a new model, `LPFilterMapping.slx`, and realize the subsystem block, with coefficients mapped to ports, in this model.

```
new_system('LPFilterMapping');
realizemdl(filterobject,'MapCoeffsToPorts','on');
```



View the block diagram by clicking on the subsystem block.



In this case, the filter is an IIR filter with a direct form II second-order sections structure. Setting MapCoeffstoPorts to 'on' exports the numerator coefficients, the denominator coefficients, and the gains to the MATLAB® workspace using the default variable names Num, Den, and g. Each column of Num and Den represents one second-order section. You can modify the filter coefficients directly in the MATLAB workspace providing tunability to the realized Simulink model.

`design` | `fdesign`

Introduced in R2011a

rebuffer_delay

Number of samples of delay introduced by buffering and unbuffering operations

Syntax

```
d = rebuffer_delay(f,n,v)
d = rebuffer_delay(f,n,v,'mode')
```

Description

`d = rebuffer_delay(f,n,v)` returns the delay, in samples, introduced by the `Buffer` or `Unbuffer` block in multitasking operations.

`d = rebuffer_delay(f,n,v,'mode')` returns the delay, in samples, introduced by the Buffer or Unbuffer block in the specified tasking mode.

Input Arguments

f

Frame size of the input to the Buffer or Unbuffer block.

n

Size of the output buffer. Specify one of the following:

- The value of the **Output buffer size** parameter, if you are computing the delay introduced by a Buffer block.
- `1`, if you are computing the delay introduced by an Unbuffer block.

v

Amount of buffer overlap. Specify one of the following:

- The value of the **Buffer overlap** parameter, if you are computing the delay introduced by a Buffer block.

- `0`, if you are computing the delay introduced by an Unbuffer block.

`'mode'`

The tasking mode of the model. Specify one of the following options:

- `'singletasking'`
- `'multitasking'`

Default: `'multitasking'`

Examples

Compute the delay introduced by a Buffer block in a multitasking model:

1. Open a model containing a Buffer block. For this example, open the `ex_buffer_tut4` model by typing ex_buffer_tut4 at the MATLAB command line.
2. Double-click the Buffer block to open the block mask. Verify that you have the following settings:

   - **Output buffer size** = 3
   - **Buffer overlap** = 1
   - **Initial conditions** = 0

   Based on these settings, two of the required inputs to the `rebuffer_delay` function are as follows:

   - `n = 3`
   - `v = 1`
3. To determine the frame size of the input signal to the Buffer block, open the Signal From Workspace block mask. Verify that you have the following settings:

   - **Signal** = `sp_examples_src`
   - **Sample time** = `1`
   - **Samples per frame** = `4`

   Because **Samples per frame** = `4`, you know the `f` input to the `rebuffer_delay` function is `4`.

4 After you verify the values of all the inputs to the `rebuffer_delay` function, determine the delay that the Buffer block introduces in this multitasking model. To do so, type the following at the MATLAB command line:

```
d = rebuffer_delay(4,3,1)

d =
     8
```

Compute the delay introduced by an Unbuffer block in a multitasking model:

1 Open a model containing an Unbuffer block. For this example, open the `ex_unbuffer_ref1` model by typing ex_unbuffer_ref1 at the MATLAB command line.
2 To determine the frame size of the input to the Buffer block, open the Signal From Workspace block mask by double-clicking the block in your model. Verify that you have the following settings:

   - **Signal** = `sp_examples_src`
   - **Sample time** = `1`
   - **Samples per frame** = `3`

   Because **Samples per frame** = `3`, you know the `f` input to the `rebuffer_delay` function is `3`.
3 Use the `rebuffer_delay` function to determine the amount of delay that the Unbuffer block introduces in this multitasking model. To compute the delay introduced by the Unbuffer block, use `f = 3`, `n = 1` and `v = 0`.

```
d = rebuffer_delay(3,1,0)

d =
     3
```

Definitions

Multitasking

When you run a model in `MultiTasking` mode, Simulink processes groups of blocks with the same execution priority through each stage of simulation based on task priority.

Multitasking mode helps to create valid models of real-world multitasking systems, where sections of your model represent concurrent tasks. The **Treat each discrete rate as a separate task** parameter on the Solver (Simulink) pane of the Configuration Parameters dialog box controls this setting.

Singletasking

When you run a model in `SingleTasking` mode, Simulink processes all blocks through each stage of simulation together. The **Treat each discrete rate as a separate task** parameter on the Solver (Simulink) pane of the Configuration Parameters dialog box controls this setting.

Topics

"Buffer Delay and Initial Conditions"

Introduced before R2006a

reffilter

Reference filter for fixed-point or single-precision filter

Syntax

```
href = reffilter(hd)
```

Description

`href = reffilter(hd)` returns a new filter `href` that has the same structure as `hd`, but uses the reference coefficients and has its arithmetic property set to `double`. Note that `hd` can be either a fixed-point filter (arithmetic property set to '`fixed`', or a single-precision floating-point filter whose arithmetic property is '`single`').

`reffilter(hd)` differs from `double(hd)` in that

- the filter `href` returned by `reffilter` has the reference coefficients of `hd`.
- `double(hd)` returns the quantized coefficients of `hd` represented in double-precision.

To check the performance of your fixed-point filter, use `href` = `reffilter(hd)` to quickly have the floating-point, double-precision version of `hd` available for comparison.

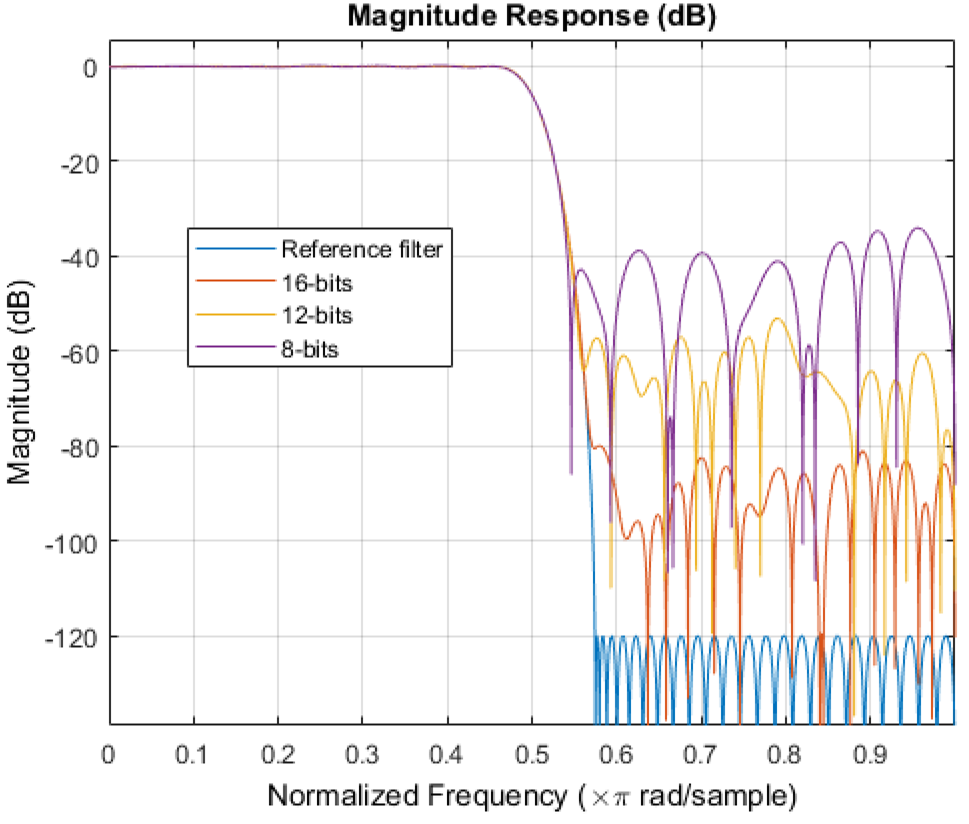
Examples

Compare Fixed-point Quantizations of a Filter

Compare several fixed-point quantizations of a filter with the same double-precision floating-point version of the filter.

```
h = dfilt.dffir(firceqrip(87,.5,[1e-3,1e-6])); % Lowpass filter.
h1 = copy(h); h2 = copy(h); % Create copies of h.
h.arithmetic = 'fixed';    % Set h to filter using fixed-point...
                           % arithmetic.
h1.arithmetic = 'fixed';   % Same for h1.
```

```
h2.arithmetic = 'fixed';  % Same for h2.
h.CoeffWordLength  = 16;  % Use 16 bits to represent the...
                          % coefficients.
h1.CoeffWordLength = 12;  % Use 12 bits to represent the...
                          % coefficients.
h2.CoeffWordLength =  8;  % Use 8 bits to represent the...
                          % coefficients.
href = reffilter(h);
hfvt = fvtool(href,h,h1,h2);
set(hfvt,'ShowReference','off'); % Reference displayed once
                                 % already.
legend(hfvt,'Reference filter','16-bits','12-bits','8-bits');
```



The fvtool shows `href`, the reference filter, and the effects of using three different word lengths to represent the coefficients.

`double`

Introduced in R2011a

reorder

Rearrange sections in SOS filter

Syntax

```
reorder(hs,order)
reorder(hs,numorder,denorder)
reorder(hs,numorder,denorder,svorder)
reorder(hs,filter_type)
reorder(hs,dir_flag)
reorder(hs,dir_flag,sv)
reorder(hs,...)
reorder(hs,...,Name,Value)
```

Description

`reorder(hs,order)` rearranges the sections of filter `hd` using the vector of indices provided in `order`.

`reorder(hs,numorder,denorder)` reorders the numerator and denominator separately using the vectors of indices in `numorder` and `denorder`.

`reorder(hs,numorder,denorder,svorder)` specifies that the scale values can be independently reordered.

`reorder(hs,filter_type)` reorders `hd` in a way suitable for the specified filter type. This reordering mode can be especially helpful for fixed-point implementations where the order of the filter sections can significantly affect your filter performance.

`reorder(hs,dir_flag)` specifies rearranges the sections according to proximity to the origin of the poles of the sections.

`reorder(hs,dir_flag,sv)` reorders scale values in addition to rearranging sections according to pole-origin proximity.

`reorder(hs,...)` rearranges the sections of the filter System object `hs` according to any of the preceding input arguments.

`reorder(hs,...,Name,Value)` rearranges the sections of the filter System object `hs` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`hs`

`dsp.BiquadFilter` filter System object with one of the following filter structures:

Structure	Description
`df1sos`	Direct-form I filter object with second-order sections.
`df1tsos`	Direct-Form I transposed filter with second-order sections.
`df2sos`	Direct-form II filter object with second-order sections.
`df2tsos`	Direct-Form II transposed filter with second-order sections.

`order`

Vector of indices used to reorder the filter sections. `order` does not need to contain all of the indices of the filter. Omitting one or more filter section indices removes the omitted sections from the filter. You can use a logical array to remove sections from the filter, but not to reorder it.

`numorder`

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

`denorder`

Vector of indices used to reorder the numerator. `numorder` and `denorder` must be the same length.

svorder

Independent reordering of scale values. When `svorder` is not specified, the scale values are reordered with the numerator. The output scale value always remains on the end when you use the argument `numorder` to reorder the scale values.

filter_type — Different types of filters:
'auto' | 'bandpass' | 'bandstop' | 'highpass' | 'lowpass'

Filter type. The `'auto'` option and automatic ordering only apply to filters that you used `fdesign` to create. With the `'auto'` option as an input argument, `reorder` automatically rearranges the filter sections depending on the specification response type of the design.

dir_flag — Direction options:
'down' | 'up'

Pole direction flag. When `dir_flag` is `'up'`, the first filter section contains the poles closest to the origin, and the last section contains the poles closest to the unit circle. When `ir_flag` is `'down'`, the sections are ordered in the opposite direction. `reorder` always pairs zeros with the poles closest to them.

sv — Scale value options:
'poles' | 'zeros'

Reorder scale values according to poles or zeros. By default the scale values are not reordered when you use the `dir_flag` input argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Arithmetic' — Value types:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Examples

Reorder a Biquad Filter

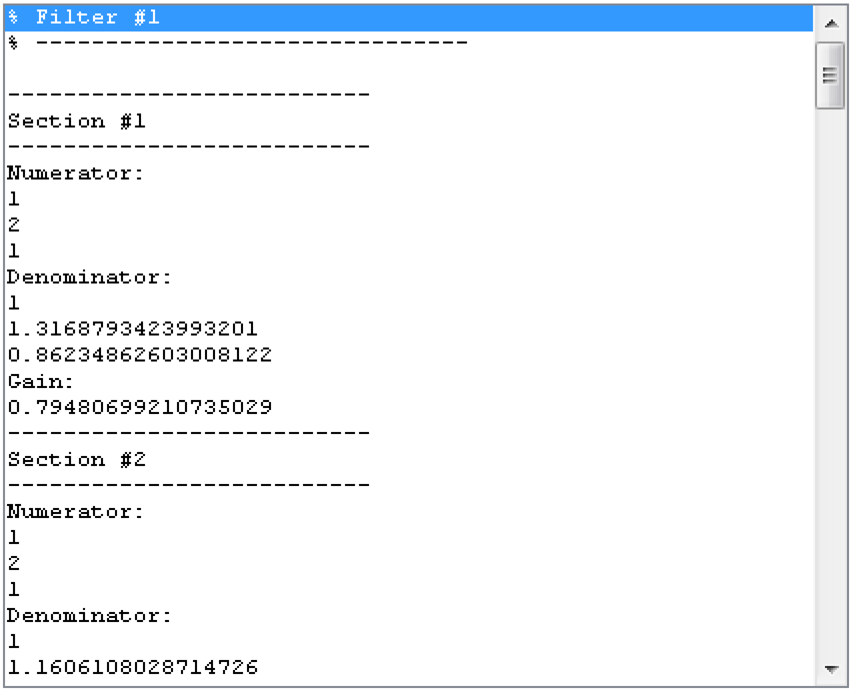
Being able to rearrange the order of the sections in a filter can be a powerful tool for controlling the filter process. This example uses reorder to change the sections of a df2sos filter. Let reorder do the reordering automatically in the first example. In the second, use reorder to specify the new order for the sections.

First use the automatic reordering option on a lowpass filter.

```
d = fdesign.lowpass('n,f3db',15,0.75);
biquad = design(d,'butter','SystemObject',true);
biquadreorder = reorder(biquad,'auto');
```

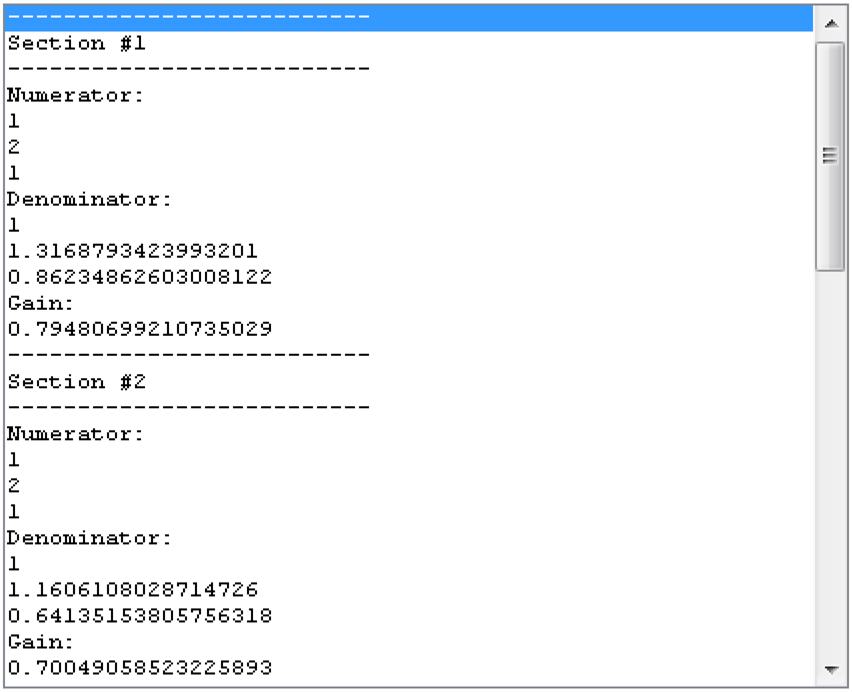
For another example of using reorder, create an SOS filter in the direct form II implementation.

```
biquad2sos = design(d,'butter', 'FilterStructure', 'df2sos',...
    'SystemObject',true);
biquad2sosreorder = reorder(biquad2sos,[1 3:7 2 8]);
fvt = fvtool(biquad2sos,biquad2sosreorder,'analysis','coefficients');
```



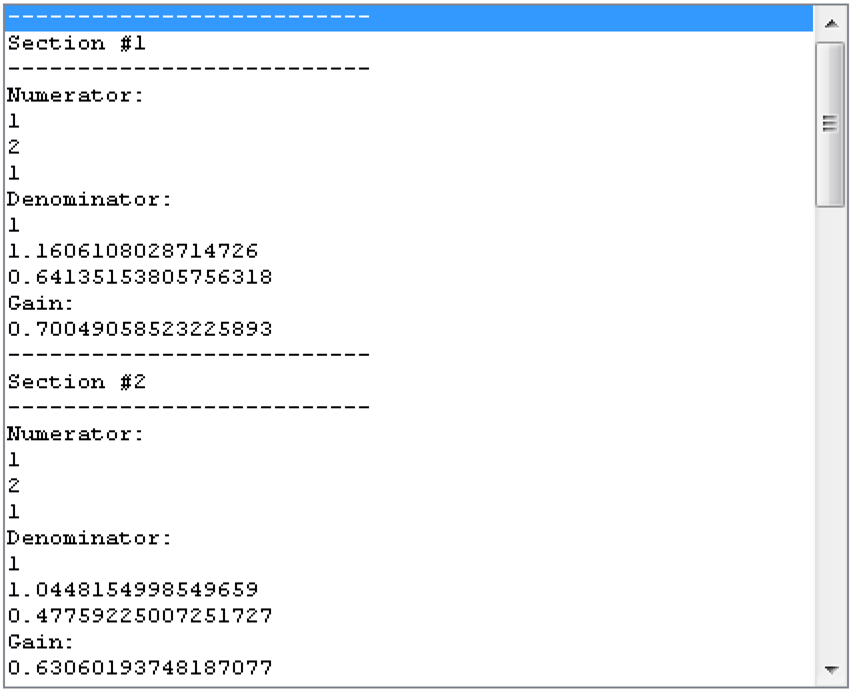
Remove the third, fourth, and seventh sections.

```
biquad2sosclone1 = clone(biquad2sos);
reorder(biquad2sosclone1, logical([1 1 0 0 1 1 0 1]));
setfilter(fvt, biquad2sosclone1);
```



Move the first filter to the end, and remove the eighth section.

```
biquad2sosclone2 = clone(biquad2sos);
reorder(biquad2sosclone2, [2:7 1]);
setfilter(fvt, biquad2sosclone2);
```



Move the numerator and denominator independently.

```
biquad2sosclone3 = clone(biquad2sos);
reorder(biquad2sosclone3, [1 3:8 2], [1:8]);
setfilter(fvt, biquad2sosclone3);
```

`cumsec` | `scale` | `scaleopts`

Introduced in R2011a

reset

Reset the internal states of a System object

Syntax

```
reset(sysobj)
```

Description

`reset(sysobj)` resets the internal states of System object, `sysobj` to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the filter to nonzero input data, the states might be nonzero. Invoking the `step` method again without first invoking the `reset` method might produce different outputs for an identical input. System objects with no states are unaffected by `reset`.

Examples

Reset a Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);

y1 = step(LPF,x);
y2 = step(LPF,x);

no = all(y2==y1)
```

```
no =

  1×2 logical array
```

```
   0    0
```

The output is different because the internal states of LPF have changed. Use reset to reset the lowpass filter and apply step again. Verify that the output is unchanged.

```
reset(LPF)

y3 = step(LPF,x);

yes = all(y3==y1)
```

```
yes =

  1×2 logical array

   1    1
```

set

Introduced in R2011a

scale

Scale second-order sections of `dsp.BiquadFilter` System object

Syntax

```
scale(biquad)
biquadnew = scale(biquad)
scale(biquad,pnorm)
scale(biquad,pnorm,Name,Value)
scale(biquad,pnorm,opts)
scale(biquad,'Arithmetic',ARITH)
```

Description

`scale(biquad)` scales the `dsp.BiquadFilter` System object, `biquad`, using peak magnitude response scaling (L-infinity, `'Linf'`). This scaling reduces the possibility of overflows when your filter `biquad` operates in fixed-point arithmetic mode.

`biquadnew = scale(biquad)` generates a new filter System object, `biquadnew`, with scaled second-order sections. The original filter System object, `biquad`, is not changed.

`scale(biquad,pnorm)` specifies the norm used to scale the filter. Pnorm can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are `'l1'`, `'l2'`, and `'linf'`. Valid frequency-domain norms are `'L1'`, `'L2'`, and `'Linf'`. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: `'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'`.

Using the most stringent scaling, `'l1'`, the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

`scale(biquad,pnorm,Name,Value)` specifies optional scaling parameters via by one or more `Name,Value` pair arguments.

scale(biquad,pnorm,opts) uses an options object to specify the optional scaling parameters in lieu of specifying parameter-value pairs. The opts object can be created using the scaleopts method: opts = scaleopts(biquad).

scale(biquad,'Arithmetic',ARITH) assumes that the filter arithmetic is equal to ARITH. ARITH can be set to one of 'double', 'single', or 'fixed'. The scale method assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. If 'Arithmetic' is 'double' or 'single', the default values are used for all scaling options that are not specified as an input to the scale method. If 'Arithmetic' is 'fixed', the values used for the scaling options are set according to the settings in the filter System object, biquad. However, if a scaling option is specified that differs from the settings in biquad, this option is used for scaling purposes but does not change the setting in biquad. For example, if you do not specify the 'OverflowMode' scaling option, the scale method assumes that the 'OverflowMode' is equal to the value in the OverflowAction property of the System object, biquad. If you do specify an 'OverflowMode' scaling option, then the scale method uses this overflow mode value regardless of the value in the OverflowAction property of the System object.

Input Arguments

biquad

dsp.BiquadFilter filter System object.

pnorm

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for pnorm are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf' . The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

Filter norms can be ordered in terms of how stringent they are, as follows from most stringent to least: 'l1', 'Linf', 'l2' ('L2'), 'linf'. Using 'l1', the most stringent scaling, produces a filter that is least likely to overflow, but has the worst signal-to-noise ratio performance. The default scaling 'Linf' (default) is the most commonly used scaling norm.

opts

Scale options object. You can create the `opts` object using the `scaleopts` function.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Arithmetic'

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.

System Object State	Coefficient Data Type	Rule
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

'MaxNumerator'

Maximum allowed value for numerator coefficients.

Default: 2

'MaxScaleValue'

Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit (the default setting). Setting MaxScaleValue to any numerical value automatically changes the ScaleValueConstraint setting to none.

Default: 'Not Used'

'NumeratorConstraint'

Specifies whether and how to constrain numerator coefficient values. Possible options:

- 'none' (default)
- 'normalized'
- 'po2'
- 'unit'

'OverflowMode'

Sets the way the filter handles arithmetic overflow situations during scaling. If your device does not have guard bits available, and you are using saturation arithmetic for filtering, use 'satall' instead of 'saturate'. The default is 'wrap'.

'ScaleValueConstraint'

Specify whether to constrain the filter scale values, and how to constrain them. Choosing `'unit'` for the constraint disables the `MaxScaleValue` property setting. `'po2'` constrains the scale values to be powers of 2, while `'none'` removes any constraint on the scale values. `'unit'` is the default value.

'sosReorder'

Reorder filter sections prior to applying scaling. Possible options:

- `'auto'` (default)
- `'none'`
- `'up'`
- `'down'`
- `'lowpass'`
- `'highpass'`
- `'bandpass'`
- `'bandstop'`

Examples

Linf-norm Scaling of a Biquad Filter

Demonstrate the Linf-norm scaling of a biquad filter using the `scale` function.

```
Fs = 8000; Fcutoff = 2000;
[z,p,k] = butter(10,Fcutoff/(Fs/2)); [s,g] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter('Structure', 'Direct form I', ...
    'SOSMatrix', s,'ScaleValues', g);
scale(biquad,'linf','scalevalueconstraint','none','maxscalevalue',2)
```

Functions

`cumsec` | `norm` | `reorder` | `scalecheck` | `scaleopts`

Introduced in R2011a

scalecheck

Check scaling of SOS filter

Syntax

```
s = scalecheck(biquad,pnorm)
s = scalecheck(biquad,pnorm,Name,Value)
```

Description

`s = scalecheck(biquad,pnorm)` checks the scaling of the filter System object `biquad`.

`s = scalecheck(biquad,pnorm,Name,Value)` checks the scaling of the filter System object `biquad` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`biquad`

`dsp.BiquadFilter` filter System object with one of the following filter structures:

Structure	Description
`df1sos`	Direct-form I filter object with second-order sections.
`df1tsos`	Direct-Form I transposed filter with second-order sections.
`df2sos`	Direct-form II filter object with second-order sections.
`df2tsos`	Direct-Form II transposed filter with second-order sections.

pnorm — Different types of norm:
'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf'

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for pnorm are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf'. The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

'Arithmetic' — Value type:
‘double’ | 'single' | 'fixed'

For filter System object inputs only, specify the arithmetic used during analysis. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed' , the arithmetic changes depending on the setting of the CoefficientDataType property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	'Same as input'	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

System Object State	Coefficient Data Type	Rule
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

s

Filter scaling for a given p-norm. An optimally scaled filter has partial norms equal to one. In such cases, `s` contains all ones.

For direct-form I (`df1sos`) and direct-form II transposed (`df2tsos`) filters, the function returns the p-norm of the filter computed from the filter input to the output of each second-order section. Therefore, the number of elements in `s` is one less than the number of sections in the filter. This p-norm computation does not include the trailing scale value of the filter, which you can find by entering `hd.scalevalue(end)` at the MATLAB prompt.

For direct-form II (`df2sos`) and direct-form I transposed (`df1tsos`) filters, the function returns a row vector whose elements contain the p-norm from the filter input to the input of the recursive part of each second-order section. This computation of the p-norm corresponds to the input to the multipliers in these filter structures. These inputs correspond to the locations in the signal flow where overflow should be avoided.

When hd has nontrivial scale values, that is, if any scale values are not equal to one, s is a two-row matrix, rather than a vector. The first row elements of s report the p-norm of the filter computed from the filter input to the output of each second-order section. The elements of the second row of s contain the p-norm computed from the input of the filter to the input of each scale value between the sections. For df2sos and df1tsos filter structures, the last numerator and the trailing scale value for the filter are not included when scalecheck checks the scaling.

Examples

Linf-norm scaling of a filter

This example shows how to check the Linf-norm scaling of a filter.

Design an elliptic sos filter in the direct form II structure with default specifications.

```
EllipII = design(fdesign.lowpass, 'ellip', 'FilterStructure', 'df2sos',...
    'SystemObject',true);
```

Check the scaling.

```
scalecheck(EllipII,'Linf')

ans =

    3.1678   15.0757    1.4974
    4.7360   52.6026    1.0000
```

Design an elliptic sos filter in the direct form I structure with default specifications.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20), 'ellip',...
    'FilterStructure', 'df1sos','SystemObject',true);
```

Check the scaling.

```
scalecheck(EllipI,'Linf')

ans =

    1.7078    2.0807    2.6084    7.1467    1.0000
```

See Also

`norm` | `reorder` | `scale` | `scaleopts`

Introduced in R2011a

scaleopts

Create an options object for second-order section scaling

Syntax

```
opts = scaleopts(biquad)
opts = scaleopts(biquad,Name,Value)
```

Description

`opts = scaleopts(biquad)` uses the current settings in the `dsp.BiquadFilter` System object, `biquad`, to create an options object `opts` that contains specified scaling options for second-order section scaling. You can pass `opts` as an input to `scale` to apply scaling settings to a second-order filter.

`opts = scaleopts(biquad,Name,Value)` creates an options object with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`biquad`

`dsp.BiquadFilter` filter System object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type.

Output Arguments

opts

Scaling object. The following table lists the properties of `opts`.

Parameter	Default	Description and Valid Value
`sosReorder`	`'auto'`	Reorder section prior to scaling. Valid options are `'auto'` (default), `'none'`, `'up'`, `'down'`, `'lowpass'`, `'highpass'`, `'bandpass'`, and `'bandstop'`.
`MaxNumerator`	`2`	Maximum allowed value for numerator coefficients.
`NumeratorConstraint`	`'none'`	Specifies whether and how to constrain numerator coefficient values. Options are `'none'` (default), `'unit'`, `'normalize'`, and `'po2'`.
`OverflowMode`	`'wrap'`	Sets the way the filter handles arithmetic overflow situations during scaling. Valid options are `'wrap'` (default), `'saturate'`, and `'satall'`.
`ScaleValueConstraint`	`'unit'`	Specify whether to constrain the filter scale values, and how to constrain them. Valid options are `'unit'` (default), `'none'`, and `'po2'`.
`MaxScaleValue`	`'Not used'`	Maximum allowed scale values. The filter applies the `MaxScaleValue` limit only when you set `ScaleValueConstraint` to a value other than `unit`. Setting `MaxScaleValue` to a numerical value

Parameter	Default	Description and Valid Value
		automatically changes the ScaleValueConstraint setting to none.

Examples

Options for scaling SOS filter

Create an options scaling object that contains the scaling options settings you require.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20), 'ellip', 'FilterStructure
opts = scaleopts(EllipI)
```

```
EllipI =

  dsp.BiquadFilter with properties:

                     Structure: 'Direct form I'
               SOSMatrixSource: 'Property'
                     SOSMatrix: [5×6 double]
                   ScaleValues: [6×1 double]
    NumeratorInitialConditions: 0
  DenominatorInitialConditions: 0
      OptimizeUnityScaleValues: true

  Use get to show all properties

opts =

             sosReorder: 'auto'
           MaxNumerator: 2
    NumeratorConstraint: 'none'
           OverflowMode: 'wrap'
   ScaleValueConstraint: 'unit'
          MaxScaleValue: 'Not used'
```

set2int

Configure filter for integer filtering

Syntax

```
set2int(h)
set2int(h,coeffwl)
set2int(...,inwl)
g = set2int(...)
```

Description

This section applies to discrete-time (`dfilt`) filters.

`set2int(h)` scales the filter coefficients to integer values and sets the filter coefficient and input fraction lengths to zero.

`set2int(h,coeffwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients.

`set2int(...,inwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients and the number of bits specified by `inwl` as the word length to represent the input data.

`g = set2int(...)` returns the gain `g` introduced into the filter by scaling the filter coefficients to integers. `g` is always calculated to be a power of 2.

Note `set2int` does not work with CIC decimators or interpolators because they do not have coefficients.

Examples

Configure an FIR Filter for Integer Filtering

Two parts comprise this example. Part 1 compares the step response of an FIR filter in both the fractional and integer filter modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients represented in fractional form (nonzero fraction length).

The second part of the example depends on the following - after you filter a set of data, the input data and output data cover the same range of values, unless the filter process introduces gain in the output. Converting your filter object to integer form, and then filtering a set of data, does introduce gain into the system. When the examples refer to resetting the output to the same range as the input, the examples are accounting for this added gain feature.

```
b = rcosdesign(.25,4,25,'sqrt');
hd = dfilt.dffir(b);
hd.Arithmetic = 'fixed';
hd.InputFracLength = 0; % Integer inputs.
x = ones(100,1);
yfrac = filter(hd,x); % Fractional mode output.
g = set2int(hd);      % Convert to integer coefficients.
yint = filter(hd,x);  % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. Later in this example, use the `fi` object properties `WordLength` and `FractionLength` to work with the output data. Now use the gain `g` to rescale the output from the integer mode filter operation. Verify that the scaled integer output is equal to the fractional output.

```
yints = double(yint)/g;
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))

ans =

     0
```

In part two, the example reinterprets the output binary data, putting the input and the output on the same scale by weighting the most significant bits in the input and output data equally.

```
WL = yint.WordLength;
FL = yint.FractionLength + log2(g);
yints2 = fi(zeros(size(yint)),true,WL,FL);
```

```
yints2.bin = yint.bin;
max(abs(double(yints2)-double(yfrac)))

ans =

     0
```

Introduced in R2011a

setspecs

Specifications for filter specification object

Syntax

```
setspecs(D,specvalue1,specvalue2,...)
setspecs(D,Specification,specvalue1,specvalue2,...)
setspecs(...Fs)
setspecs(...,MAGUNITS)
```

Description

`setspecs(D,specvalue1,specvalue2,...)` sets the specifications in filter specification object, `D`, in the same order they appear in the `Specification` property.

`setspecs(D,Specification,specvalue1,specvalue2,...)` changes the specifications for an existing filter specification object and sets values for the new `Specification` property.

`setspecs(...Fs)` specifies the sampling frequency, `Fs`, in Hz. The sampling frequency must be a scalar trailing all other specifications. Entering a sampling frequency causes all other frequency specifications to be in Hz.

`setspecs(...,MAGUNITS)` specifies the units for any magnitude specifications. `MAGUNITS` can be one of the following: `'linear'`, `'dB'`, or `'squared'`. The default is `'dB'`. The magnitude specifications are always converted and stored in dB regardless of how the units are specified.

Use `SET(D,'SPECIFICATION')` to get the list of all available specification types for the filter specification object, `D`.

Examples

Set the Filter Order and Cutoff Frequency Using `setspecs`

Construct a lowpass filter with specifications for the filter order and cutoff frequency (-6 dB). Use setspecs after construction to set the values of the filter order and cutoff frequency. Display the values in the MATLAB® command window.

```
D = fdesign.lowpass('N,Fc');
setspecs(D,10,0.2);
```

```
D.FilterOrder
```

```
ans =

    10
```

```
D.Fcutoff
```

```
ans =

    0.2000
```

Set the Specifications of a Highpass Filter Using `setspecs`

Construct a highpass filter with specifications for the numerator order, denominator order, and 3-dB frequency. Assume the sampling frequency is 1 kHz. Use setspecs to set the numerator and denominator orders to 6. Set the 3-dB frequency to 250 Hz. In order to use frequency specifications in Hz, specify the sampling frequency as a trailing scalar.

```
D = fdesign.highpass('Nb,Na,F3dB');
setspecs(D,6,6,250,1000);
```

Introduced in R2011b

sos

Convert quantized filter to second–order sections (SOS) form

Syntax

```
Hq2 = sos(Hq)
Hq2 = sos(Hq, order)
Hq2 = sos(Hq, order, scale)
```

Description

`Hq2 = sos(Hq)` returns a quantized filter `Hq2` that has second-order sections and the `dft2` structure. Use the same optional arguments used in `tf2sos`.

`Hq2 = sos(Hq, order)` specifies the order of the sections in `Hq2`, where `order` is one of the following options:

- `'down'` — to order the sections so the first section of `Hq2` contains the poles closest to the unit circle (L_∞ norm scaling)
- `'up'` — to order the sections so the first section of `Hq2` contains the poles farthest from the unit circle (L_2 norm scaling and the default)

`Hq2 = sos(Hq, order, scale)` also specifies the desired scaling of the gain and numerator coefficients of all second-order sections, where `scale` is one of the following options:

- `'none'` — to apply no scaling (default)
- `'inf'` — to apply infinity-norm scaling
- `'two'` — to apply 2-norm scaling

`Hq2` is a dsp.BiquadFilter filter System object.

Use infinity-norm scaling in conjunction with up-ordering to minimize the probability of overflow in the filter realization. Consider using 2-norm scaling in conjunction with down-ordering to minimize the peak round-off noise.

When Hq is a fixed-point filter, the filter coefficients are normalized so that the magnitude of the maximum coefficient in each section is 1. The gain of the filter is applied to the first scale value of Hq2.

sos uses the direct form II transposed (dft2) structure to implement second- order section filters.

Examples

```
[b,a]=butter(8,.5);
Hq = dfilt.df2t(b,a);
Hq.arithmetic = 'fixed';
Hq1 = sos(Hq)

Hq1 =

         FilterStructure: 'Direct-Form II Transposed, Second-Order Sections'
              Arithmetic: 'double'
               sosMatrix: [4x6 double]
             ScaleValues: [0.00927734375;1;1;1;1]
     OptimizeScaleValues: true
        PersistentMemory: false
```

Introduced in R2011a

specifyall

Fully specify fixed-point filter System object settings

Syntax

```
specifyall(sysobj)
specifyall(sysobj,false)
specifyall(sysobj,true)
```

Description

`specifyall(sysobj)` sets all the data type fixed-point properties of the filter System object `sysobj` to `'Custom'` so that you can easily specify all the fixed-point settings. If the object has a `FullPrecisionOverride` property, its value is set to `false`. `specifyall` is intended as a shortcut to changing all the fixed-point properties one by one.

`specifyall(sysobj,false)` sets all fixed-point properties of the filter System object `sysobj` to their default values and sets the filter to full-precision mode, if one is available.

`specifyall(sysobj,true)` is equivalent to `specifyall(sysobj)`.

Examples

Specify all Fixed-point Settings of an FIRFilter

This example demonstrates using `specifyall` to provide access to all of the fixed-point settings of an FIR filter implemented with the direct-form structure. Using `specifyall` disables all of the automatic filter scaling and reset the mode values.

```
b = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],{'w' 'c'});
firFilter = dsp.FIRFilter('Numerator',b);
get(firFilter)
```

```
ans = 

  struct with fields:

                              Numerator: [1×13 double]
                  ReflectionCoefficients: [0.5000 0.5000]
                       InitialConditions: 0
                         NumeratorSource: 'Property'
            ReflectionCoefficientsSource: 'Property'
                               Structure: 'Direct form'

Introduced in R2011a

stepz

Step response of discrete-time filter System object

Syntax

```
[stepResp,t] = stepz(sysobj)
[stepResp,t] = stepz(sysobj,n)
[stepResp,t] = stepz(sysobj,n,fs)
[stepResp,t] = stepz(sysobj,[],fs)
[stepResp,t] = stepz(sysobj,Name,Value)
stepz(sysobj)
```

Description

`[stepResp,t] = stepz(sysobj)` computes the step response of the filter System object, `sysobj`, and returns the response in column vector `stepResp`, and a vector of times (or sample intervals) in `t`, where `t = [0 1 2 ...k-1]'`. `k` is the number of filter coefficients.

`[stepResp,t] = stepz(sysobj,n)` computes the step response at `floor(n)` 1-second intervals. The time vector `t` equals `(0:floor(n)-1)'`.

`[stepResp,t] = stepz(sysobj,n,fs)` computes the step response at `floor(n)` 1/`fs`-second intervals. The time vector `t` equals `(0:floor(n)-1)'/fs`.

`[stepResp,t] = stepz(sysobj,[],fs)` computes the step response at `k` 1/`fs`-second intervals. `k` is the number of filter coefficients. The time vector `t` equals `(0:k-1)'/fs`.

`[stepResp,t] = stepz(sysobj,Name,Value)` returns a step response with additional options specified by one or more `Name,Value` pair arguments.

`stepz(sysobj)` uses `fvtool` to plot the step response of the filter System object `sysobj`.

For more input options, refer to `stepz` in Signal Processing Toolbox documentation.

Note `stepz` works for both real and complex filters. When you omit the output arguments, `stepz` plots only the real part of the step response.

Input Arguments

`sysobj`

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator

Filter System objects
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

n

Length of the step response vector.

Default: Number of filter coefficients

fs

Sampling frequency.

Default: 1

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'Arithmetic' — Value types:
'double' | 'single' | 'fixed'

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data

System Object State	Coefficient Data Type	Rule
		type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.
Locked	'Same as input'	When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	'Custom'	The function performs fixed-point analysis based on the setting of the CustomCoefficientsDataType property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

stepResp

n-element step response vector. If n is not specified, the length of the step response vector equals the number of coefficients in the filter.

t

Time vector of length `n`, in seconds. `t` consists of `n` equally spaced points in the range `(0:floor(n)-1)'/fs`. If `n` is not specified, the function uses the number of coefficients of the filter.

`freqz` | `impz`

Introduced in R2011a

sysobj

Create filter System object from discrete-time filter

Syntax

```
hs = sysobj(hfilt)
```

Description

`hs = sysobj(hfilt)` creates a new filter System object `hs` from the `dfilt` object, `hfilt`.

The function supports a subset of `dfilt` objects. The following table lists supported filter structures for `hfilt` and the filter System object that the function creates.

Single-rate	Filter System object
Lattice AR(`dfilt.latticear`)	`dsp.AllpoleFilter`
Coupled-allpass, power-complementary lattice filter (`dfilt.calatticepc`)	dsp.CoupledAllpassFilter
Coupled-allpass, lattice filter (`dfilt.calattice`)	dsp.CoupledAllpassFilter
Cascade of discrete time filters (`dfilt.cascade`)	dsp.CoupledAllpassFilter
Direct Form I (`dfilt.df1`)	`dsp.IIRFilter`
Direct Form I transposed (`dfilt.df1t`)	`dsp.IIRFilter`
Direct Form II (`dfilt.df2`)	`dsp.IIRFilter`
Direct Form II transposed (`dfilt.df2t`)	`dsp.IIRFilter`
Direct-form FIR (`dfilt.dffir`)	dsp.FIRFilter
Direct-form FIR transposed (`dfilt.dffirt`)	dsp.FIRFilter
Direct-form symmetric FIR (`dfilt.dfsymfir`)	dsp.FIRFilter

Single-rate	Filter System object
Direct-form antisymmetric FIR (`dfilt.dfasymfir`)	dsp.FIRFilter
Discrete-time, lattice, moving-average (`dfilt.latticemamin`)	dsp.FIRFilter
Discrete-time, second-order section, direct-form I (`dfilt.df1sos`)	dsp.BiquadFilter
Discrete-time, second-order section, direct-form I transposed (`dfilt.df1tsos`)	dsp.BiquadFilter
Discrete-time, second-order section, direct-form II (`dfilt.df2sos`)	dsp.BiquadFilter
Discrete-time, second-order section, direct-form II transposed (`dfilt.df2tsos`)	dsp.BiquadFilter

Input Arguments

`hfilt`

Discrete-time filter (`dfilt`) object. The preceding table lists supported filter structures.

If `hfilt` is a discrete-time filter with the `PersistentMemory` property set to `true`, then the filter states are copied into the initial conditions properties of `hs`. Otherwise, initial conditions are ignored.

The function does not support some properties for SOS filter structures:

- If the `CastBeforeSum` property is set to `false`, the function issues a warning. `dsp.BiquadFilter` System objects always have a cast before a sum.
- If the `Signed` property is `false`, the function issues an error. `dsp.BiquadFilter` System objects do not support unsigned arithmetic.

Output Arguments

`hs`

Filter System object. The function maps almost all properties of `hfilt` into the filter System object. However, some properties are not mapped exactly:

- Filter System objects do not have a `CoeffAutoScale` property. The function specifies a word length and a fraction length regardless of whether the `CoeffAutoScale` property of `hfilt` is `true` or `false`.
- `dsp.BiquadFilter` System objects do not have a `FullPrecisionOverride` property. Full-precision values in `hfilt` are mapped to word and fraction lengths in `hs`. These settings correspond to the full-precision setting of the input data type.

Examples

Convert a discrete-time filter object to a System object

```
hfilt = dfilt.df1sos; %Direct-form I SOS
hs = sysobj(hfilt)   %Biquadratic IIR filter
```

```
hs =

  dsp.BiquadFilter with properties:

                     Structure: 'Direct form I'
               SOSMatrixSource: 'Property'
                     SOSMatrix: [1 0 0 1 0 0]
                   ScaleValues: [2×1 double]
    NumeratorInitialConditions: 0
  DenominatorInitialConditions: 0
      OptimizeUnityScaleValues: true

  Use get to show all properties
```

`block`

Introduced in R2012a

tf2ca

Transfer function to coupled allpass

Syntax

```
[d1,d2] = tf2ca(b,a)
[d1,d2] = tf2ca(b,a)
[d1,d2,beta] = tf2ca(b,a)
```

Description

`[d1,d2] = tf2ca(b,a)` where `b` is a real, symmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors `d1` and `d2` containing the denominator coefficients of the allpass filters *H1(z)* and *H2(z)* such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

representing a coupled allpass decomposition.

`[d1,d2] = tf2ca(b,a)` where `b` is a real, antisymmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors `d1` and `d2` containing the denominator coefficients of the allpass filters *H1(z)* and *H2(z)* such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

In some cases, the decomposition is not possible with real *H1(z)* and *H2(z)*. In those cases a generalized coupled allpass decomposition may be possible, as described in the following syntax.

`[d1,d2,beta] = tf2ca(b,a)` returns complex vectors `d1` and `d2` containing the denominator coefficients of the allpass filters *H1(z)* and *H2(z)*, and a complex scalar `beta`, satisfying `|beta|` = 1, such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)\left[\bar{\beta} \cdot H1(z) + \beta \cdot H2(z)\right]$$

representing the generalized allpass decomposition.

In the above equations, *H1(z)* and *H2(z)* are real or complex allpass IIR filters given by

$$H1(z) = \frac{fliplr(\overline{(D1(z))})}{D1(z)}, H2(1)(z) = \frac{fliplr(\overline{(D2(1)(z))})}{D2(1)(z)}$$

where *D1(z)* and *D2(z)* are polynomials whose coefficients are given by `d1` and `d2`.

Note A coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

Examples

```
[b,a]=cheby1(9,.5,.4);
[d1,d2]=tf2ca(b,a);  % TF2CA returns denominators of the allpass.
num = 0.5*conv(fliplr(d1),d2)+0.5*conv(fliplr(d2),d1);
den = conv(d1,d2);  % Reconstruct numerator and denonimator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
       % numerator and denominators.
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

tf2cl

Transfer function to coupled allpass lattice

Syntax

```
[k1,k2] = tf2cl(b,a)
[k1,k2] = tf2cl(b,a)
[k1,k2,beta] = tf2cl(b,a)
```

Description

`[k1,k2] = tf2cl(b,a)` where `b` is a real, symmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, will perform the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

of a stable IIR filter *H(z)* and convert the allpass transfer functions *H1(z)* and *H2(z)* to a coupled lattice allpass structure with coefficients given in vectors `k1` and `k2`.

`[k1,k2] = tf2cl(b,a)` where `b` is a real, antisymmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, performs the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

of a stable IIR filter *H(z)* and converts the allpass transfer functions *H1(z)* and *H2(z)* to a coupled lattice allpass structure with coefficients given in vectors `k1` and `k2`.

In some cases, the decomposition is not possible with real *H1(z)* and *H2(z)*. In those cases, a generalized coupled allpass decomposition may be possible, using the syntax described below.

`[k1,k2,beta] = tf2cl(b,a)` performs the generalized allpass decomposition of a stable IIR filter *H(z)* and converts the complex allpass transfer functions *H1(z)* and *H2(z)* to corresponding lattice allpass filters

$$H(z)=\frac{B(z)}{A(z)}=\left(\frac{1}{2}\right)\left[\bar{\beta}\cdot H1(z)+\beta\cdot H2(z)\right]$$

where `beta` is a complex scalar of magnitude equal to 1.

Note Coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

Examples

```
[b,a]=cheby1(9,.5,.4);
[k1,k2]=tf2cl(b,a); % Get the reflection coeffs. for the lattices.
[num1,den1]=latc2tf(k1,'allpass'); % Convert each allpass lattice
[num2,den2]=latc2tf(k2,'allpass'); % back to transfer function.
num = 0.5*conv(num1,den2)+0.5*conv(num2,den1);
den = conv(den1,den2); % Reconstruct numerator and denonimator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
       % numerator and denominators.
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

validstructures

Structures for specification object with design method

Syntax

```
filtstruct = validstructures(D,'Systemobject',true)
filtstruct = validstructures(D,METHOD,'Systemobject',true)
```

Description

`filtstruct = validstructures(D,'Systemobject',true)` returns a structure of cell arrays, `filtstruct`, which contains a set of valid filter structures for the filter specification object, `D`. When you set `'Systemobject'` to `true`, `validstructures` returns a list of structures that support filter System objects. Each field in `filtstruct` lists a set of filter structures for the design method specified.

`filtstruct = validstructures(D,METHOD,'Systemobject',true)` returns the valid structures for the filter specification object, `D`, and the design method, `METHOD`, in a cell array of character vectors.

Examples

Valid Filter Structures

Design a default lowpass filter specification object. Return all valid design methods and structures in a structure array. Display the fieldnames to see all valid design methods. Display the valid filter structures for the `equiripple` field.

```
D = fdesign.lowpass;
filtstruct = validstructures(D,'SystemObject',true);

fn = fieldnames(filtstruct)
strs = eval(['filtstruct.' fn{5}])
```

```
fn =

  8×1 cell array
```

```
    'butter'
    'cheby1'
    'cheby2'
    'ellip'
    'equiripple'
    'ifir'
    'multistage'
    'kaiserwin'

strs =

  1×3 cell array

    'dffir'    'dffirt'    'dfsymfir'
```

Create a highpass filter of order 50 with a 3-dB frequency of 0.2. Obtain the available structures for a Butterworth design.

```
D = fdesign.highpass('N,F3dB',50,0.2);
C = validstructures(D,'butter','SystemObject',true)
```

```
C =

  1×6 cell array

  Columns 1 through 5

    'df1sos'    'df2sos'    'df1tsos'    'df2tsos'    'cascadeallpass'

  Column 6

    'cascadewdfallpass'
```

Introduced in R2009a

wdf2allpass

Wave Digital Filter to allpass coefficient transformation

Syntax

```
a = wdf2allpass(w)
A = wdf2allpass(W)
```

Description

`a = wdf2allpass(w)` accepts a vector of transformed real allpass coefficients, `w`, and returns the conventional allpass polynomial version `a`. `w` is used by allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with `Structure` set to `'Wave Digital Filter'`.

`A = wdf2allpass(W)` accepts the cell array of transformed allpass coefficient vectors `W`. Each cell of `W` contains the transformed real coefficients of a section of a cascade allpass filter. The output `A` is also a cell array, and each cell of `A` contains the conventional polynomial version of the corresponding cell of `W`. `W` is used by allpass filter objects such as dsp.AllpassFilter and dsp.CoupledAllpassFilter, with `Structure` set to `'Wave Digital Filter'`. Every cell of `W` must contain a real vector of length 1,2, or 4. When the length is 4, the second and fourth components must both be zero. `W` can be a row or column vector of cells while `A` is always returned as column.

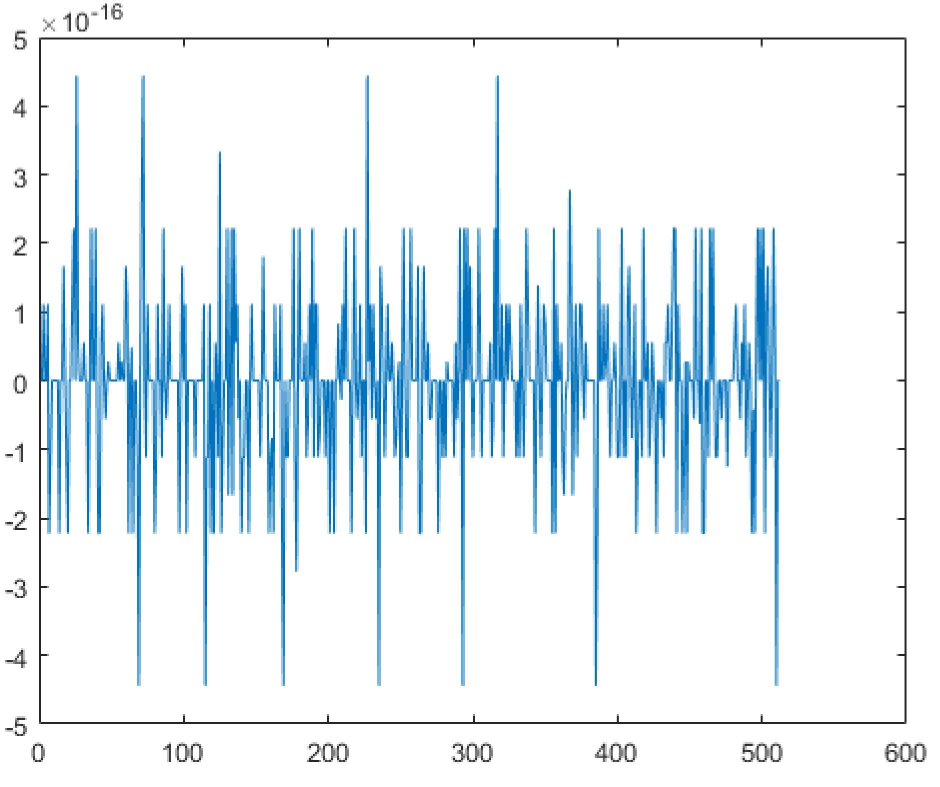
Examples

Convert Wave Digital Filter Coefficients to Allpass Polynomial Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a second order allpass filter with wave digital filter coefficients w = [0.5 0]. Convert these coefficients into polynomial form using `wdf2allpass`. Assign the polynomial coefficients to an allpass filter using the 'Minimum multiplier' structure. Pass a random input to both these filters and compare the outputs.

```
w = [0.5 0];
allpasswdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...
    'WDFCoefficients', w);
a = wdf2allpass(w);
allpass = dsp.AllpassFilter('AllpassCoefficients', a);
in = randn(512, 1);
outputallpasswdf = allpasswdf(in);
outputallpass = allpass(in);
plot(outputallpasswdf-outputallpass);
```



The difference between the two outputs is very small.

Input Arguments

w — Transformed Wave Digital Filter allpass coefficients

(default) | vector of real numbers

Numeric vector of transformed Wave Digital Filter allpass coefficients, specified as a real number. w can have only length equal to 1,2, and 4. When the length is 4, the second and fourth components must both be zero. w can be a row or a column vector.

Example: `[0.3,-0.2]`

Data Types: `double` | `single`

W — Transformed Wave Digital Filter allpass coefficients

(default) | vector of cells

Cascade of allpass filter coefficients in transformed Wave Digital Filter form, specified as a cell vector. Every cell of W must contain a real vector of length 1, 2, or 4. When the length is 4, the second and fourth components must both be zero. W can be a row or a column vector of cells.

Example: `{[0.3,-0.2];0.5}`

Data Types: `double` | `single`

Output Arguments

a — allpass filter coefficients

(default) | vector of real numbers

Numeric vector of polynomial allpass coefficients, determined as a numeric row vector.

Example: `3.1`

Data Types: `double` | `single`

A — allpass filter coefficients

(default) | vector cell array

Cascade of allpass filter coefficient, determined as a column of cells, each containing a vector of length 1, 2, or 4.

Example: `{0.3 5.0 0.2}`

Data Types: `double` | `single`

Algorithms

`wdf2allpass` provides the inverse operation of `allpass2wdf`, by transforming the transformed cascade of allpass coefficients `W` into their conventional polynomial representation `A`. Please refer to the reference page for `allpass2wdf` for more details about the two representations.

`W` defines a multisection allpass filter, and `wdf2allpass` applies separately to each section, with the same transformation used in the single-section case. In this case, the numeric coefficients vector `W` can have order 1, 2, or 4.

The relations between the vector of section coefficients a and w respectively depend on the order, as follows:

$$
\begin{aligned}
&\textit{for order } 1: \\
&a_1 = w_1 \\
&\textit{for order } 2: \\
&a_1 = w_2(1 + w_1) \\
&a_2 = w_1 \\
&\textit{for order } 4: \\
&a_2 = w_3(1 + w_1) \\
&a_4 = w_1 \\
&a_1 = a_3 = 0
\end{aligned}
$$

window

FIR filter using windowed impulse response

Syntax

```
h = window(d,fcnhndl,fcnarg,'SystemObject',true)
h = window(d,win,'SystemObject',true)
```

Description

`h = window(d,fcnhndl,fcnarg,'SystemObject',true)` designs a single-rate digital filter System object using the specifications in filter specification object `d`.

`fcnhndl` is a handle to a filter design function that returns a window vector, such as the `hamming` or `blackman` functions. `fcnarg` is an optional argument that returns a window. You pass the function to `window`.

`h = window(d,win,'SystemObject',true)` designs a filter using the vector you supply in `win`. The length of vector `win` must be the same as the impulse response of the filter, which is equal to the filter order plus one.

Examples

Design a Nyquist Filter Using Kaiser Window

This example designs a filter using the two design techniques of specifying a function handle and passing a window vector as an input argument.

Use a window vector provided by the kaiser window function to design a Nyquist filter. The window length must be the filter order plus one.

```
d = fdesign.nyquist(5,'n',150);
% Kaiser window with beta parameter 2.5
nyqFilter = window(d,'window',kaiser(151,2.5),'SystemObject',true);
fvtool(nyqFilter)
```

zerophase

Zero-phase response of discrete-time filter System object

Syntax

```
[zphase,w] = zerophase(sysobj)
[zphase,w] = zerophase(sysobj,n)
[zphase,w] = zerophase(sysobj,Name,Value)
zerophase(sysobj)
```

Description

`[zphase,w] = zerophase(sysobj)` returns the instantaneous zero-phase response `zphase` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the function evaluates the zero-phase response.

The zero-phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[zphase,w] = zerophase(sysobj,n)` returns the instantaneous zero-phase response of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[zphase,w] = zerophase(sysobj,Name,Value)` returns the zero-phase response with additional options specified by one or more `Name,Value` pair arguments.

`zerophase(sysobj)` displays the zero-phase response of the filter System object `sysobj` in the `fvtool`.

For information on more input options, refer to `zerophase` in Signal Processing Toolbox documentation.

Input Arguments

sysobj

Filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter

Filter System objects
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

n

Number of samples. For an FIR filter where `n` is a power of two, the computation is done faster using FFTs.

Default: 8192

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value type:
`‘double’ | 'single' | 'fixed'`

Specify the arithmetic used during analysis. When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based

System Object State	Coefficient Data Type	Rule
		on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

`zphase`

Zero phase response vector of length `n`. If `n` is not specified, the function uses a default value of `8192`.

`w`

Frequency vector of length `n`, in radians/sample. `w` consists of `n` points equally spaced around the upper half of the unit circle (from 0 to π radians/sample). If `n` is not specified, the function uses a default value of `8192`.

Introduced in R2011a

zpkbpc2bpc

Zero-pole-gain complex bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations, W_{t1}, and W_{t2} respectively. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
```

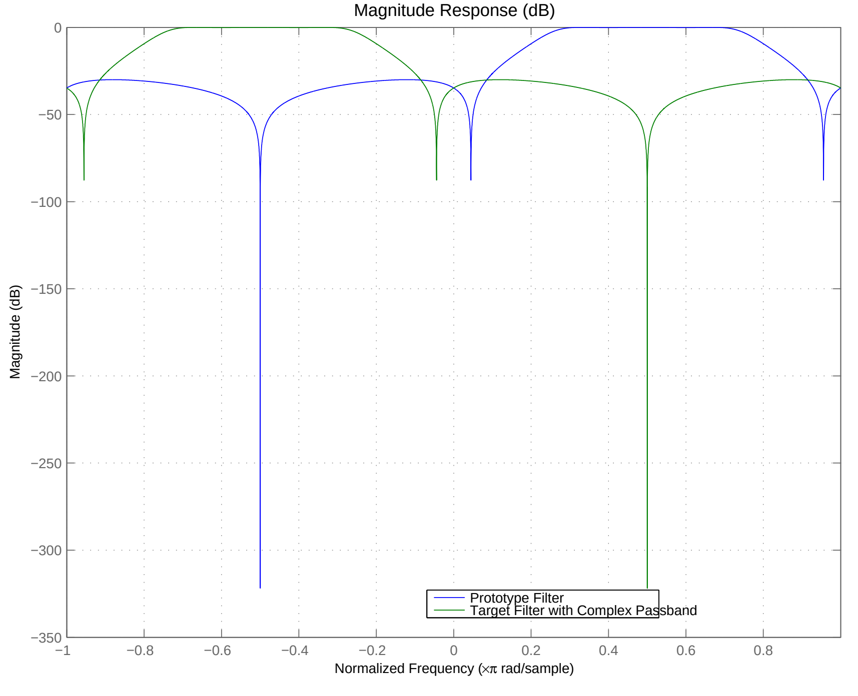
Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc(b,a,0.5,[0.25,0.75]);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpkbpc2bpc(z,p,k,[0.25, 0.75],[-0.75, -0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Comparing the filters in FVTool shows the example results. Use the features in FVTool to check the filter coefficients, or other filter analyses.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

See Also

`zpkftransf` | `allpassbpc2bpc` | `iirbpc2bpc`

Introduced in R2011a

zpkftransf

Zero-pole-gain frequency transformation

Syntax

```
[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)
```

Description

`[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the transformed lowpass digital filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`. If `AllpassDen` is not specified it will default to 1. If neither `AllpassNum` nor `AllpassDen` is specified, then the function returns the input filter.

Examples

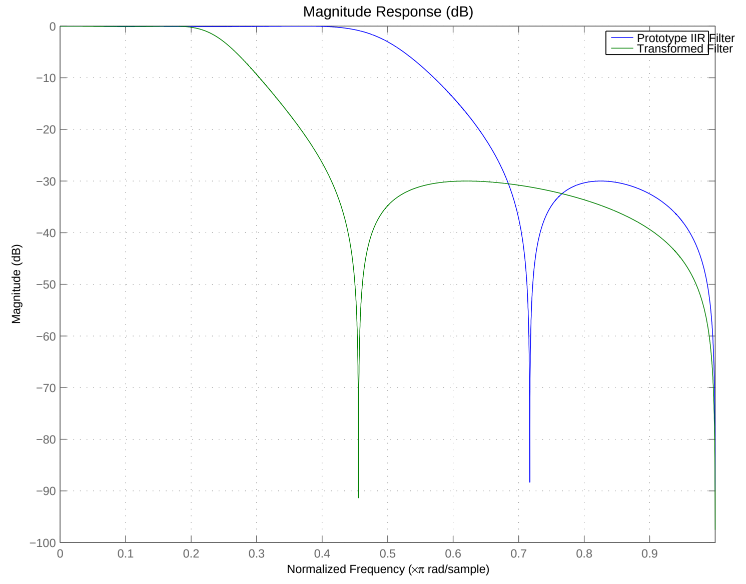
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[z2, p2, k2] = zpkftransf(roots(b),roots(a),b(1),AlpNum,AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

After transforming the filter, you get the response shown in the figure, where the passband has been shifted towards zero.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
FTFNum	Numerator of the mapping filter
FTFDen	Denominator of the mapping filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter

zpklp2bp

Zero-pole-gain lowpass to bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

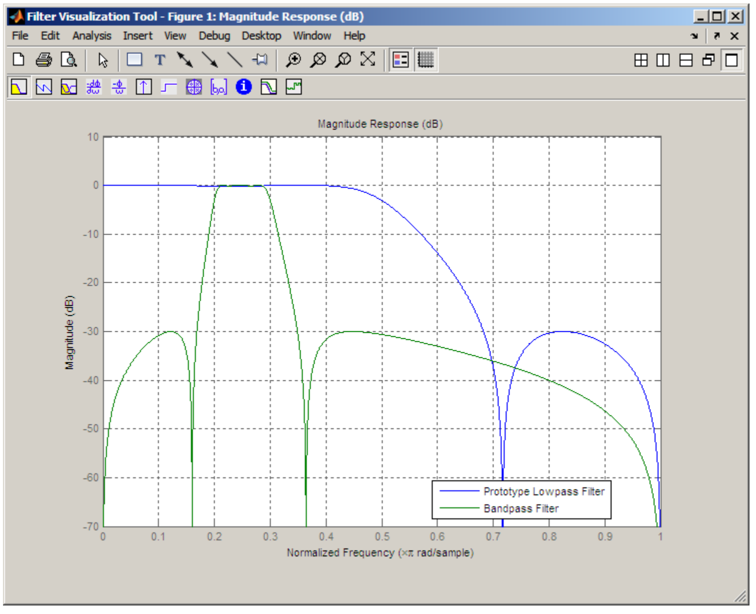
Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be easily doubled and positioned at two distinct, desired frequencies.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[B,A] = ellip(3,0.1,30,0.409);
Z = roots(B);
P = roots(A);
K = B(1);
[Z2,P2,K2] = zpklp2bp(Z,P,K, 0.5, [0.2 0.3]);
hfvt = fvtool(B,A,K2*poly(Z2),poly(P2));
legend(hfvt,'Prototype Lowpass Filter', 'Bandpass Filter');
axis([0 1 -70 10]);
```



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter

Variable	Description
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2bpc

Zero-pole-gain lowpass to complex bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bpc(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description

zpklp2bs

Zero-pole-gain lowpass to bandstop frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_ts.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bs(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`zpkftransf` | `iirlp2bs` | `allpasslp2bs`

Introduced in R2011a

zpklp2bsc

Zero-pole-gain lowpass to complex bandstop frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/ resonators.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bsc(z, p, k, 0.5, [0.2, 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

zpklp2hp

Zero-pole-gain lowpass to highpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real highpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency location, W_t, at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and the gain factor, `K`.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, or the deep minimum in the stopband, or other ones.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2hp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

zpklp2lp

Zero-pole-gain lowpass to lowpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real lowpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency location, W_t.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

Examples

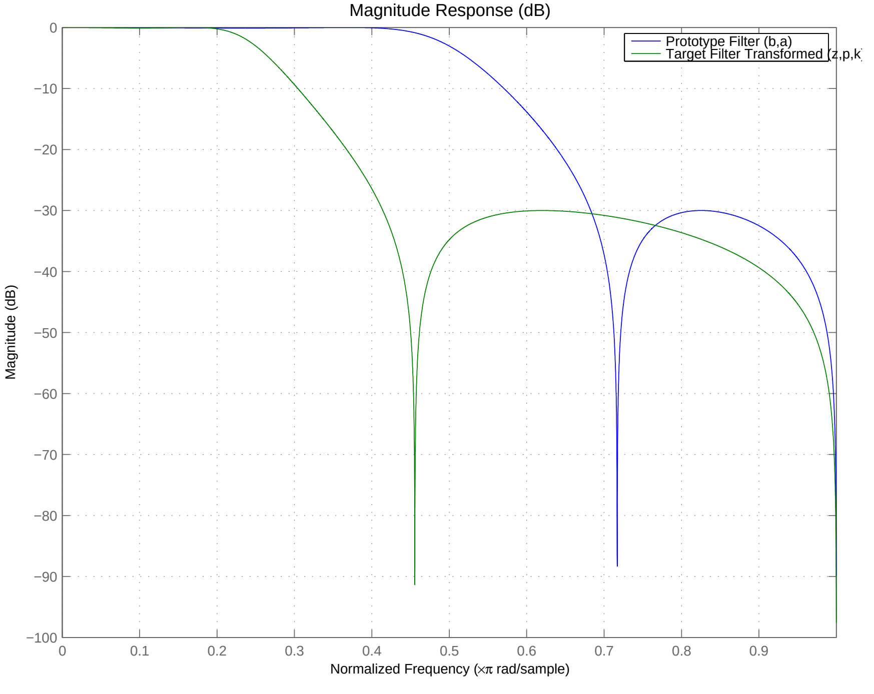
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2lp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Using `zpklp2lp` creates the desired half band IIR filter with the transformed features that you specify in the transformation function. This figure shows the results.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter

Variable	Description
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`zpkftransf` | `iirlp2lp` | `allpasslp2lp`

Introduced in R2011a

zpklp2mb

Zero-pole-gain lowpass to M-band frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to real multibandpass frequency mapping. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

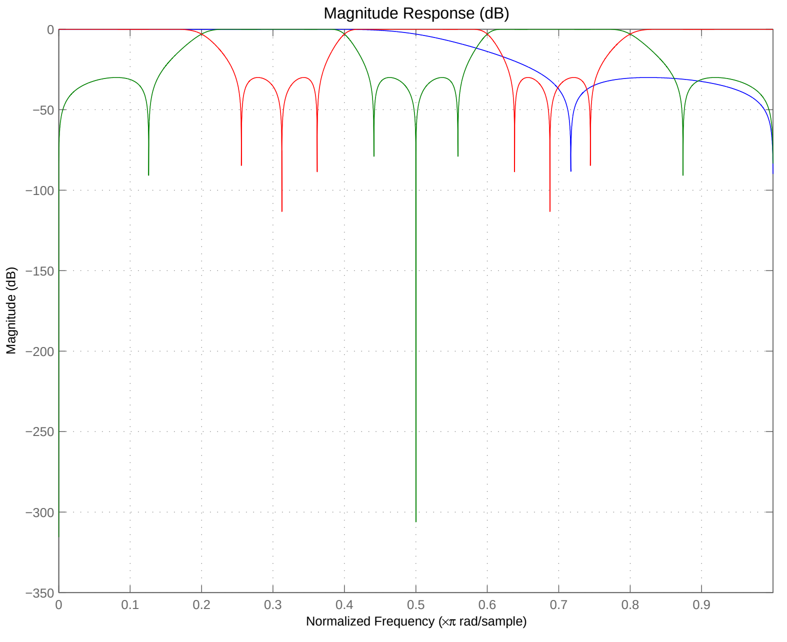
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'pass');
[z2,p2,k2] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

The resulting multiband filter that replicates features from the prototype appears in the figure shown. Note the accuracy of the replication process.



Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter
`Wt`	Desired frequency location in the transformed target filter
`Pass`	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`zpkftransf` | `iirlp2mb` | `allpasslp2mb`

Introduced in R2011a

zpklp2mbc

Zero-pole-gain lowpass to complex M-band frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, W_{t1},...,W_{tM}.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature, for example, the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., to replicate notch filters and resonators at any required location.

Examples

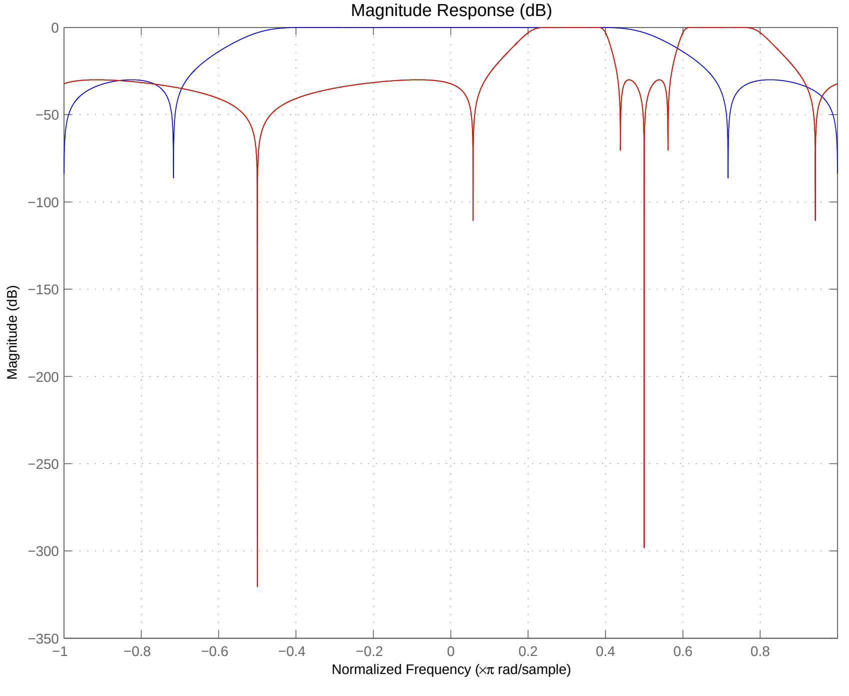
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
[z2,p2,k2] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

You could review the coefficients to compare the filters, but the graphical comparison shown here is quicker and easier.



However, looking at the coefficients in FVTool shows the complex nature desired.

Arguments

Variable	Description
`Z`	Zeros of the prototype lowpass filter
`P`	Poles of the prototype lowpass filter
`K`	Gain factor of the prototype lowpass filter
`Wo`	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
`Wt`	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
`Z2`	Zeros of the target filter
`P2`	Poles of the target filter
`K2`	Gain factor of the target filter
`AllpassNum`	Numerator of the mapping filter
`AllpassDen`	Denominator of the mapping filter

See Also

`zpkftransf` | `iirlp2mbc` | `allpasslp2mbc`

Introduced in R2011a

zpklp2xc

Zero-pole-gain lowpass to complex N-point frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies W_{o1},...,W_{oN}, at the required target frequency locations, W_{t1},...,W_{tM}.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

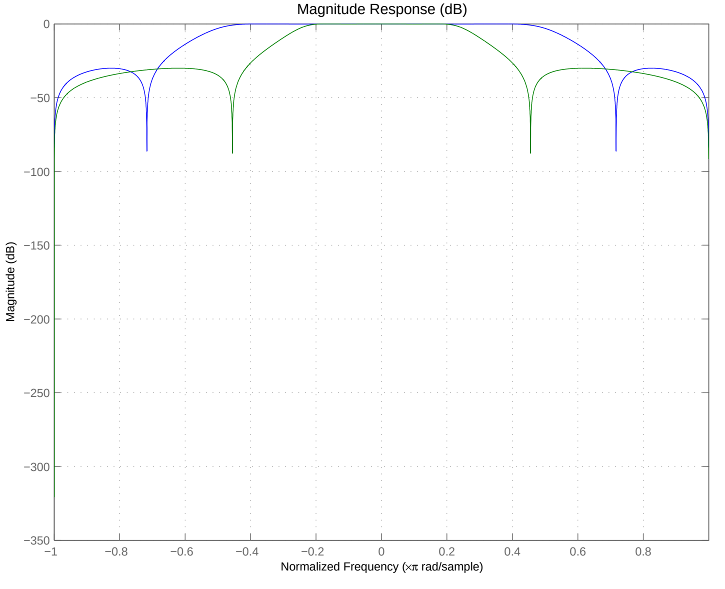
Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xc(z, p, k, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Plotting the filters on the same axes lets you compare the results graphically, shown here.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

See Also

`zpkftransf` | `iirlp2xc` | `allpasslp2xc`

Introduced in R2011a

zpklp2xn

Zero-pole-gain lowpass to N-point frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying an `N`th-order real lowpass to real multipoint frequency transformation, where `N` is the number of features being mapped. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xn(z, p, k, [-0.5 0.5], [0 0.25], 'pass');
hfvt = fvtool(b, a, k2*poly(z2), poly(p2));
legend(hfvt,'Original Filter','Half-band Filter');
```

As demonstrated by the figure, the target filter has the desired response shape and values replicated from the prototype.

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
Z2	Zeros of the target filter

Variable	Description
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassDen	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

zpkrateup

Zero-pole-gain complex bandpass frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter being transformed from any prototype by applying an `N`th-order rateup frequency transformation, where `N` is the upsample ratio. Transformation creates `N` equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros, `Z`, poles, `P`, and gain factor, `K`.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
% Upsample the prototype filter 4 times
[z2,p2,k2] = zpkrateup(z, p, k, 4);
% Compare prototype filter with target filter
fvtool(b, a, k2*poly(z2), poly(p2));
```

Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
N	Integer upsampling ratio
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

zpkshift

Zero-pole-gain real shift frequency transformation

Syntax

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)`

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)` returns the zeros,`Z2` , poles, `P2`, and gain factor, `K2`, of the target filter transformed from the zeros, poles, and gain factor of real lowpass prototype by applying a second-order real shift frequency mapping. It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen` of the allpass mapping filter.

This transformation places one selected feature of an original filter, located at frequency W_o, at the required target frequency location, W_t. This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without the need to design them again.

Examples

Rotate frequency response by π/2 radians/sample:

```
[B,A] = ellip(10,0.1,40,0.25);
% Elliptic lowpass filter with passband frequency 0.25*pi rad/sample
Z = roots(B); % get roots of numerator polynomial- filter zeros
P = roots(A); % get roots of denominator polynomial- filter poles
K = B(1);
[Z2,P2,K2] = zpkshift(Z,P,K,0.25,0.75); % shift by 0.25*pi rad/sample
Num = poly(Z2);
Den = poly(P2);
hfvt = fvtool(B,A,K2*Num,Den);
legend(hfvt,'Original Filter','Rotate by \pi/2 radians/sample');
axis([0 1 -90 10]);
```

zpkshiftc

Zero-pole-gain complex shift frequency transformation

Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,-0.5)
```

Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,Wo,Wt)` returns zeros, Z_2, poles, P_2, and gain factor, K_2, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at W_o, placed at W_t in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros, `Z`, poles, `P`, and the gain factor, `K`.

`[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,0.5)` performs the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = zpkshiftc(Z,P,K,0,-0.5)` performs the inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
```

Rotation by $\pi/4$ Radians/Sample

Rotation by -0.25:

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, 0.25);
hfvt = fvtool(b,a,k2*poly(z2),poly(p2));
```

Rotation by $\pi/2$ Radians/Sample

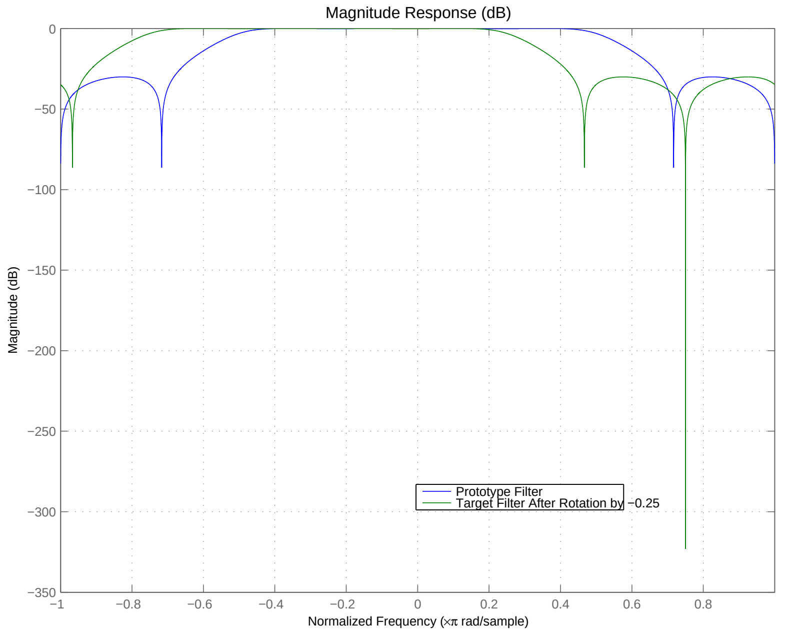
```
[z3,p3,k3] = zpkshiftc(z, p, k, 0, 0.5);
addfilter(hfvt,k3*poly(z3),poly(p3));
legend(hfvt,'Original Filter','Rotation by -\pi/4 radians/sample',...
    'Rotation by \pi/2 radians/sample');
```

Rotation by $-\pi/2$ Radians/Sample

```
[z2,p2,k2] = zpkshiftc(z, p, k, 0.5, -0.5);
fvtool(b, a, k2*poly(z2), poly(p2));
```

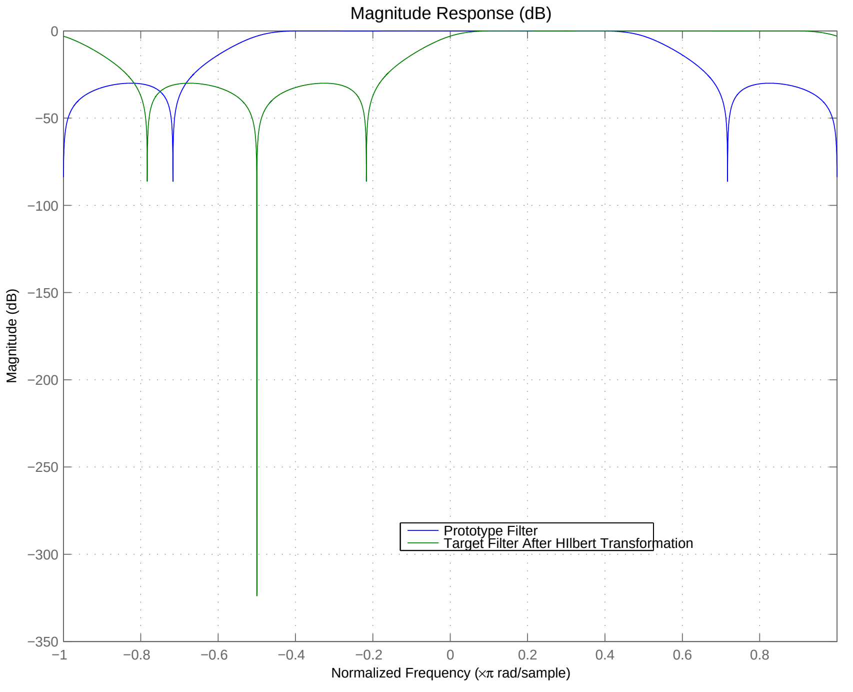
Result of Example 1

After performing the rotation, the resulting filter shows the features desired.



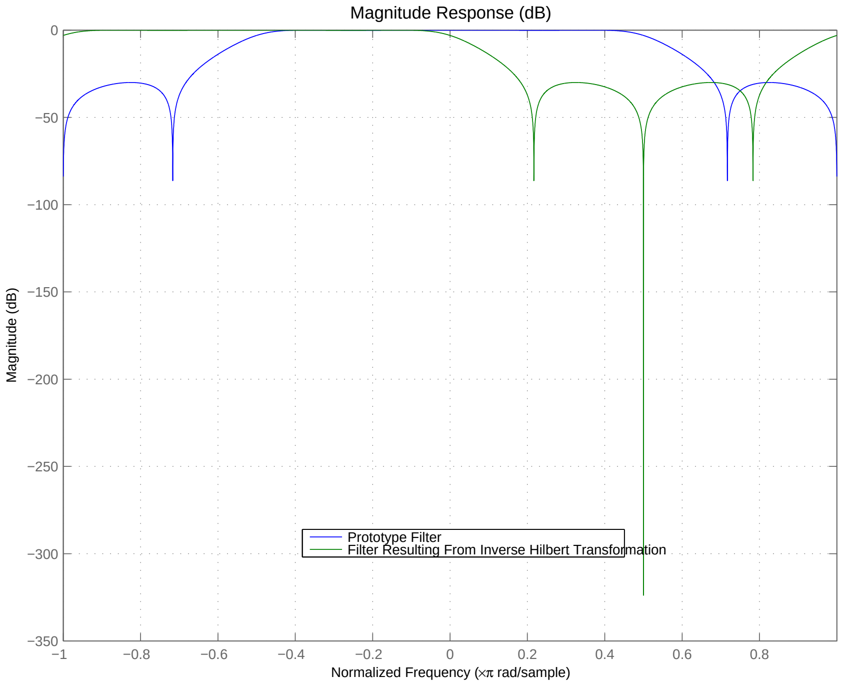
Result of Example 2

Similar to the first example, performing the Hilbert transformation generates the desired target filter, shown here.



Result of Example 3

Finally, using the inverse Hilbert transformation creates yet a third filter, as the figure shows.



Arguments

Variable	Description
Z	Zeros of the prototype lowpass filter
P	Poles of the prototype lowpass filter
K	Gain factor of the prototype lowpass filter
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
Z2	Zeros of the target filter
P2	Poles of the target filter
K2	Gain factor of the target filter
AllpassDen	Numerator of the mapping filter

Variable	Description
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Introduced in R2011a

zplane

Z-plane zero-pole plot for discrete-time filter System object

Syntax

```
zplane(filt)
zplane(filt,Name,Value)
[zLoc,pLoc,tLoc] = zplane(filt)
```

Description

`zplane(filt)` plots the zeros and poles of the filter System object, `filt`, with the unit circle for reference in the filter visualization tool (fvtool). Each zero is represented with a `'o'` and each pole with a `'x'` on the plot. Multiple zeros and poles are indicated by the multiplicity number shown to the upper right of the zero or pole.

When you call the `step` method on the filter System object with a fixed-point input, the filter becomes a quantized fixed-point filter, `filtQuant`. When `filtQuant` is a quantized filter, `zplane(filtQuant)` plots the poles and zeros of the quantized and unquantized filters. The symbols □ and + represent the zeros and poles of the quantized filter `filtQuant`. The plot includes the unit circle for reference.

`zplane(filt,Name,Value)` returns the pole zero plot with additional options specified by one or more `Name,Value` pair arguments.

`[zLoc,pLoc,tLoc] = zplane(filt)` returns the vector of locations for zeros, poles, and text objects. `zLoc` is the vector of locations of zeros, `pLoc` is the vector of locations of poles, and `tLoc` is the vector of locations of the axes/unit circle line and text objects which are present when there are multiple zeros or poles. In case there are no zeros or poles, `zLoc` or `pLoc` is set to the empty matrix `[]`.

Input Arguments

`filt`

A filter System object.

The following Filter System objects are supported by this analysis function:

Filter System objects
dsp.AllpassFilter
dsp.AllpoleFilter
dsp.BiquadFilter
dsp.CICCompensationDecimator
dsp.CICCompensationInterpolator
dsp.CICDecimator
dsp.CICInterpolator
dsp.CoupledAllpassFilter
dsp.FarrowRateConverter
dsp.FilterCascade
dsp.FIRDecimator
dsp.FIRFilter
dsp.FIRHalfbandDecimator
dsp.FIRHalfbandInterpolator
dsp.FIRInterpolator
dsp.FIRRateConverter
dsp.HighpassFilter
dsp.IIRFilter
dsp.IIRHalfbandDecimator
dsp.IIRHalfbandInterpolator
dsp.LowpassFilter
dsp.NotchPeakFilter
dsp.VariableBandwidthFIRFilter
dsp.VariableBandwidthIIRFilter

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Arithmetic'` — Value types:
`‘double’ | 'single' | 'fixed'`

When you specify `'double'` or `'single'`, the function performs double- or single-precision analysis. When you specify `'fixed'` , the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

Details for Fixed-Point Arithmetic

System Object State	Coefficient Data Type	Rule
Unlocked	`'Same as input'`	The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Unlocked	`'Custom'`	The function performs fixed-point analysis based on the setting of the `CustomCoefficientsDataType` property.
Locked	`'Same as input'`	When the input data type is `'double'` or `'fixed'`, the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption.
Locked	`'Custom'`	The function performs fixed-point analysis based

System Object State	Coefficient Data Type	Rule
		on the setting of the `CustomCoefficientsDataType` property.

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

Output Arguments

`zLoc`

Vector of locations of zeros.

`pLoc`

Vector of locations of poles.

`tLoc`

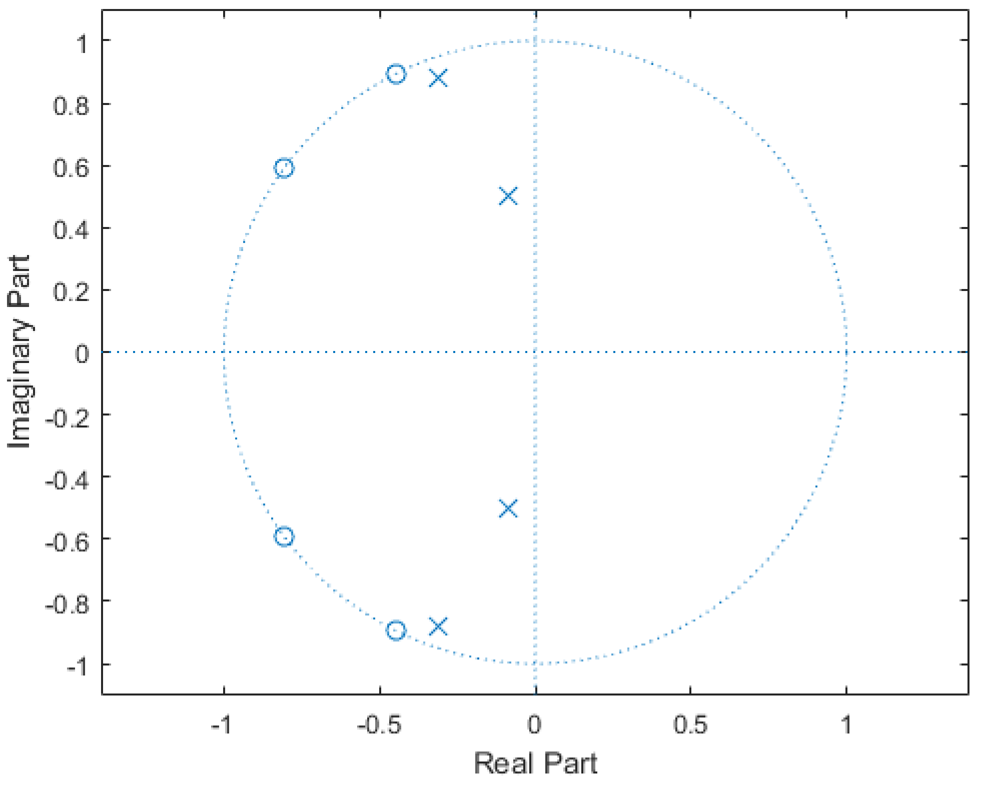
Vector of locations of axes/unit circle line and text objects.

Examples

Plot the Poles and Zeros of a Fourth-Order Filter

Create a Fourth-order IIR digital filter with a cutoff frequency of 0.6. Plot the poles and zeros of this filter.

```
[b,a] = ellip(4,.5,20,.6);
zplane(b,a);
```



Quantize the filter by passing a fixed-point input through the filter algorithm. Plot the quantized and unquantized poles and zeros associated with this filter.

```
iirFilt = dsp.IIRFilter('Numerator',b,'Denominator',a);
in = fi(randn(15,6),1,15,3);
out = iirFilt(in);
zplane(iirFilt);
```

"Property Details for Fixed-Point Filters" on page 6-17

Overview of Fixed-Point Filters

There is a distinction between fixed-point filters and quantized filters — quantized filters represent a superset that includes fixed-point filters.

When `dfilt` objects have their `Arithmetic` property set to `single` or `fixed`, they are quantized filters. However, after you set the `Arithmetic` property to `fixed`, the resulting filter is both quantized and fixed-point. Fixed-point filters perform arithmetic operations without allowing the binary point to move in response to the calculation — hence the name fixed-point. You can find out more about fixed-point arithmetic in your Fixed-Point Designer documentation or from the Help system.

With the `Arithmetic` property set to `single`, meaning the filter uses single-precision floating-point arithmetic, the filter allows the binary point to move during mathematical operations, such as sums or products. Therefore these filters cannot be considered fixed-point filters. But they are quantized filters.

The following sections present the properties for fixed-point filters, which includes all the properties for double-precision and single-precision floating-point filters as well.

Fixed-Point Objects and Filters

Fixed-point filters depend in part on fixed-point objects from Fixed-Point Designer software. You can see this when you display a fixed-point filter at the command prompt.

```
hd=dfilt.df2t

hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'double'
```

```
              Numerator: 1
            Denominator: 1
       PersistentMemory: false
                 States: [0x1 double]

set(hd,'arithmetic','fixed')
hd

hd =

        FilterStructure: 'Direct-Form II Transposed'
             Arithmetic: 'fixed'
              Numerator: 1
            Denominator: 1
       PersistentMemory: false
                 States: [1x1 embedded.fi]

        CoeffWordLength: 16
         CoeffAutoScale: true
                 Signed: true

        InputWordLength: 16
        InputFracLength: 15

       OutputWordLength: 16
       OutputFracLength: 15

        StateWordLength: 16
         StateAutoScale: true

            ProductMode: 'FullPrecision'

        AccumWordLength: 40
          CastBeforeSum: true

              RoundMode: 'convergent'
           OverflowMode: 'wrap'
```

Look at the States property, shown here

```
States: [1x1 embedded.fi]
```

The notation `embedded.fi` indicates that the states are being represented by fixed-point objects, usually called `fi` objects. If you take a closer look at the property `States`, you see how the properties of the `fi` object represent the values for the filter states.

```
hd.states

ans =

[]

              DataType: Fixed
               Scaling: BinaryPoint
                Signed: true
            WordLength: 16
        FractionLength: 15

             RoundMode: round
          OverflowMode: saturate
           ProductMode: FullPrecision
  MaxProductWordLength: 128
               SumMode: FullPrecision
      MaxSumWordLength: 128
         CastBeforeSum: true
```

To learn more about `fi` objects (fixed-point objects) in general, refer to your Fixed-Point Designer documentation.

As inputs (data to be filtered), fixed-point filters accept both regular double-precision values and `fi` objects. Which you use depends on your needs. How your filter responds to the input data is determined by the settings of the filter properties, discussed in the next few sections.

Summary — Fixed-Point Filter Properties

Discrete-time filters in this toolbox use objects that perform the filtering and configuration of the filter. As objects, they include properties and methods that are often referred to as functions — not strictly the same as MATLAB functions but mostly so) to provide filtering capability. In discrete-time filters, or `dfilt` objects, many of the properties are dynamic, meaning they become available depending on the settings of other properties in the `dfilt` object or filter.

Dynamic Properties

When you use a `dfilt.`*`structure`* function to create a filter, MATLAB displays the filter properties in the command window in return (unless you end the command with a semicolon which suppresses the output display). Generally you see six or seven properties, ranging from the property `FilterStructure` to `PersistentMemory`. These first properties are always present in the filter. One of the most important properties is `Arithmetic`. The `Arithmetic` property controls all of the dynamic properties for a filter.

Dynamic properties become available when you change another property in the filter. For example, when you change the `Arithmetic` property value to `fixed`, the display now shows many more properties for the filter, all of them considered dynamic. Here is an example that uses a direct form II filter. First create the default filter:

```
hd=dfilt.df2

hd =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]
```

With the filter `hd` in the workspace, convert the arithmetic to fixed-point. Do this by setting the property `Arithmetic` to `fixed`. Notice the display. Instead of a few properties, the filter now has many more, each one related to a particular part of the filter and its operation. Each of the now-visible properties is dynamic.

```
hd.arithmetic='fixed'

hd =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'fixed'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
```

```
     OutputMode: 'AvoidOverflow'

StateWordLength: 16
StateFracLength: 15

    ProductMode: 'FullPrecision'

AccumWordLength: 40
  CastBeforeSum: true

      RoundMode: 'convergent'
   OverflowMode: 'wrap'
```

Even this list of properties is not yet complete. Changing the value of other properties such as the `ProductMode` or `CoeffAutoScale` properties may reveal even more properties that control how the filter works. Remember this feature about `dfilt` objects and dynamic properties as you review the rest of this section about properties of fixed-point filters.

An important distinction is you cannot change the value of a property unless you see the property listed in the default display for the filter. Entering the filter name at the MATLAB prompt generates the default property display for the named filter. Using `get(filtername)` does not generate the default display — it lists all of the filter properties, both those that you can change and those that are not available yet.

The following table summarizes the properties, static and dynamic, of fixed-point filters and provides a brief description of each. Full descriptions of each property, in alphabetical order, follow the table.

Property Name	Valid Values [Default Value]	Brief Description
`AccumFracLength`	Any positive or negative integer number of bits [29]	Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — `DenAccumFracLength` and `NumAccumFracLength` — that let you set the precision for numerator and denominator operations separately.
`AccumWordLength`	Any positive integer number of bits [40]	Sets the word length used to store data in the accumulator/buffer.

Property Name	Valid Values [Default Value]	Brief Description
`Arithmetic`	[Double], single, fixed	Defines the arithmetic the filter uses. Gives you the options `double`, `single`, and `fixed`. In short, this property defines the operating mode for your filter.
`CastBeforeSum`	[True] or false	Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.
`CoeffAutoScale`	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to `false` enables you to change the `NumFracLength` and `DenFracLength` properties to specify the precision used.
`CoeffFracLength`	Any positive or negative integer number of bits [14]	Set the fraction length the filter uses to interpret coefficients. `CoeffFracLength` is not available until you set `CoeffAutoScale` to `false`. Scalar filters include this property.
`CoeffWordLength`	Any positive integer number of bits [16]	Specifies the word length to apply to filter coefficients.
`DenAccumFracLength`	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving denominator coefficients.
`DenFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length the filter uses to interpret denominator coefficients. `DenFracLength` is always available, but it is read-only until you set `CoeffAutoScale` to `false`.
`Denominator`	Any filter coefficient value [1]	Holds the denominator coefficients for IIR filters.

Property Name	Valid Values [Default Value]	Brief Description
DenProdFracLength	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value after you set ProductMode to SpecifyPrecision.
DenStateFracLength	Any positive or negative integer number of bits [15]	Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.
FracDelay	Any decimal value between 0 and 1 samples	Specifies the fractional delay provided by the filter, in decimal fractions of a sample.
FDAutoScale	[True] or false	Specifies whether the filter automatically chooses the proper scaling to represent the fractional delay value without overflowing. Turning this off by setting the value to false enables you to change the FDWordLength and FDFracLength properties to specify the data format applied.
FDFracLength	Any positive or negative integer number of bits [5]	Specifies the fraction length to represent the fractional delay.
FDProdFracLength	Any positive or negative integer number of bits [34]	Specifies the fraction length to represent the result of multiplying the coefficients with the fractional delay.
FDProdWordLength	Any positive or negative integer number of bits [39]	Specifies the word length to represent result of multiplying the coefficients with the fractional delay.
FDWordLength	Any positive or negative integer number of bits [6]	Specifies the word length to represent the fractional delay.
DenStateWordLength	Any positive integer number of bits [16]	Specifies the word length used to represent the states associated with denominator coefficients in the filter.

Property Name	Valid Values [Default Value]	Brief Description
`FilterInternals`	`[FullPrecision]`, `SpecifyPrecision`	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
`FilterStructure`	Not applicable.	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.
`InputFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length the filter uses to interpret data to be processed by the filter.
`InputWordLength`	Any positive integer number of bits [16]	Specifies the word length applied to represent input data.
`Ladder`	Any ladder coefficients in double-precision data type [1]	`latticearma` filters include this property to store the ladder coefficients.
`LadderAccumFrac Length`	Any positive or negative integer number of bits [29]	`latticearma` filters use this to define the fraction length applied to values output by the accumulator that stores the results of ladder computations.
`LadderFracLength`	Any positive or negative integer number of bits [14]	`latticearma` filters use ladder coefficients in the signal flow. This property determines the fraction length used to interpret the coefficients.
`Lattice`	Any lattice structure coefficients. No default value.	Stores the lattice coefficients for lattice-based filters.

Property Name	Valid Values [Default Value]	Brief Description
`LatticeAccumFracLength`	Any positive or negative integer number of bits [29]	Specifies how the accumulator outputs the results of operations on the lattice coefficients.
`LatticeFracLength`	Any positive or negative integer number of bits [15]	Specifies the fraction length applied to the lattice coefficients.
`MultiplicandFracLength`	Any positive or negative integer number of bits [15]	Sets the fraction length for values used in product operations in the filter. Direct-form I transposed (df1t) filter structures include this property.
`MultiplicandWordLength`	Any positive integer number of bits [16]	Sets the word length applied to the values input to a multiply operation (the multiplicands). The filter structure df1t includes this property.
`NumAccumFracLength`	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients.
`Numerator`	Any double-precision filter coefficients [1]	Holds the numerator coefficient values for the filter.
`NumFracLength`	Any positive or negative integer number of bits [14]	Sets the fraction length used to interpret the numerator coefficients.
`NumProdFracLength`	Any positive or negative integer number of bits [29]	Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. You can change the property value after you set `ProductMode` to `SpecifyPrecision`.
`NumStateFracLength`	Any positive or negative integer number of bits [15]	For IIR filters, this defines the fraction length applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficients in the filter.

Property Name	Valid Values [Default Value]	Brief Description
`NumStateWordLength`	Any positive integer number of bits [16]	For IIR filters, this defines the word length applied to the numerator states of the filter. Specifies the word length used to interpret the states associated with numerator coefficients in the filter.
`OutputFracLength`	Any positive or negative integer number of bits — [15] or [12] bits depending on the filter structure	Determines how the filter interprets the filtered data. You can change the value of `OutputFracLength` after you set `OutputMode` to `SpecifyPrecision`.
`OutputMode`	[AvoidOverflow], BestPrecision, SpecifyPrecision	Sets the mode the filter uses to scale the filtered input data. You have the following choices: • `AvoidOverflow` — directs the filter to set the output data fraction length to avoid causing the data to overflow. • `BestPrecision` — directs the filter to set the output data fraction length to maximize the precision in the output data. • `SpecifyPrecision` — lets you set the fraction length used by the filtered data.
`OutputWordLength`	Any positive integer number of bits [16]	Determines the word length used for the filtered data.

Property Name	Valid Values [Default Value]	Brief Description
OverflowMode	Saturate or [wrap]	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — hey maintain full precision.
ProductFracLength	Any positive or negative integer number of bits [29]	For the output from a product operation, this sets the fraction length used to interpret the numeric data. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.
ProductMode	[FullPrecision], KeepLSB, KeepMSB, SpecifyPrecision	Determines how the filter handles the output of product operations. Choose from full precision (FullPrecision), or whether to keep the most significant bit (KeepMSB) or least significant bit (KeepLSB) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.
ProductWordLength	Any positive number of bits. Default is 16 or 32 depending on the filter structure	Specifies the word length to use for the results of multiplication operations. This property becomes writable (you can change the value) after you set ProductMode to SpecifyPrecision.

Property Name	Valid Values [Default Value]	Brief Description
`PersistentMemory`	`True` or `[false]`	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. `True` is the default setting.
`RoundMode`	[Convergent], ceil, fix, floor, nearest, round	Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). • `ceil` - Round toward positive infinity. • `convergent` - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software. • `fix` - Round toward zero. • `floor` - Round toward negative infinity. • `nearest` - Round toward nearest. Ties round toward positive infinity. • `round` - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

Property Name	Valid Values [Default Value]	Brief Description
`ScaleValueFracLength`	Any positive or negative integer number of bits [29]	Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Available only when you disable `CoeffAutoScale` by setting it to `false`.
`ScaleValues`	[2 x 1 double] array with values of 1	Stores the scaling values for sections in SOS filters.
`Signed`	[True] or false	Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.
`sosMatrix`	`[1 0 0 1 0 0]`	Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A `[15x6 double]` SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type `double` to represent the coefficients.
`SectionInputAuto Scale`	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data entering a section of an SOS filter. Setting this property to `false` enables you to change the Section`InputFracLength` property to specify the precision used. Available only for SOS filters.

Property Name	Valid Values [Default Value]	Brief Description
SectionInputFrac Length	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data entering a section. Compare to SectionOutputFracLength. Available only when you disable SectionInputAutoScale by setting it to false.
SectionInputWord Length	Any positive or negative integer number of bits [29]	Sets the word length used to represent the data moving into a section of an SOS filter.
SectionOutputAuto Scale	[True] or false	Specifies whether the filter automatically chooses the proper fraction length to prevent overflow by data leaving a section of an SOS filter. Setting this property to false enables you to change the SectionOutputFracLength property to specify the precision used.
SectionOutputFrac Length	Any positive or negative integer number of bits [29]	Section values work with SOS filters. Setting this property controls how your filter interprets the section values between sections of the filter by setting the fraction length. This applies to data leaving a section. Compare to SectionInputFracLength. Available after you disable SectionOutputAutoScale by setting it to false.
SectionOutputWord Length	Any positive or negative integer number of bits [32]	Sets the word length used to represent the data moving out of one section of an SOS filter.
StateFracLength	Any positive or negative integer number of bits [15]	Lets you set the fraction length applied to interpret the filter states.

Property Name	Valid Values [Default Value]	Brief Description
`States`	[1x1 embedded `fi`]	Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Notice that the states use `fi` objects, with the associated properties from those objects. For details, refer to `filtstates` in your Signal Processing Toolbox documentation or in the Help system.
`StateWordLength`	Any positive integer number of bits [16]	Sets the word length used to represent the filter states.
`TapSumFracLength`	Any positive or negative integer number of bits [15]	Sets the fraction length used to represent the filter tap values in addition operations. This is available after you set `TapSumMode` to `false`. Symmetric and antisymmetric FIR filters include this property.
`TapSumMode`	FullPrecision, KeepLSB, [KeepMSB], SpecifyPrecision	Determines how the accumulator outputs stored that involve filter tap weights. Choose from full precision (`FullPrecision`) to prevent overflows, or whether to keep the most significant bits (`KeepMSB`) or least significant bits (`KeepLSB`) when outputting results from the accumulator. To let you set the precision (the fraction length) used by the output from the accumulator, set `FilterInternals` to `SpecifyPrecision`. Symmetric and antisymmetric FIR filters include this property.
`TapSumWordLength`	Any positive number of bits [17]	Sets the word length used to represent the filter tap weights during addition. Symmetric and antisymmetric FIR filters include this property.

Property Details for Fixed-Point Filters

When you create a fixed-point filter, you are creating a filter object (a `dfilt` object). In this manual, the terms filter, `dfilt` object, and filter object are used interchangeably. To filter data, you apply the filter object to your data set. The output of the operation is the data filtered by the filter and the filter property values.

Filter objects have properties to which you assign property values. You use these property values to assign various characteristics to the filters you create, including

- The type of arithmetic to use in filtering operations
- The structure of the filter used to implement the filter (not a property you can set or change — you select it by the `dfilt.`*`structure`* function you choose)
- The locations of quantizations and cast operations in the filter
- The data formats used in quantizing, casting, and filtering operations

Details of the properties associated with fixed-point filters are described in alphabetical order on the following pages.

AccumFracLength

Except for state-space filters, all `dfilt` objects that use fixed arithmetic have this property that defines the fraction length applied to data in the accumulator. Combined with `AccumWordLength`, `AccumFracLength` helps fully specify how the accumulator outputs data after processing addition operations. As with all fraction length properties, `AccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

AccumWordLength

You use `AccumWordLength` to define the data word length used in the accumulator. Set this property to a value that matches your intended hardware. For example, many digital signal processors use 40-bit accumulators, so set `AccumWordLength` to 40 in your fixed-point filter:

```
set(hq,'arithmetic','fixed');
set(hq,'AccumWordLength',40);
```

Note that `AccumWordLength` only applies to filters whose `Arithmetic` property value is `fixed`.

Arithmetic

Perhaps the most important property when you are working with `dfilt` objects, `Arithmetic` determines the type of arithmetic the filter uses, and the properties or quantizers that compose the fixed-point or quantized filter. You use strings to set the `Arithmetic` property value.

The next table shows the valid strings for the Arithmetic property. Following the table, each property string appears with more detailed information about what happens when you select the string as the value for `Arithmetic` in your `dfilt`.

Arithmetic Property String	Brief Description of Effect on the Filter
`double`	All filtering operations and coefficients use double-precision floating-point representations and math. When you use `dfilt.`*`structure`* to create a filter object, `double` is the default value for the `Arithmetic` property.
`single`	All filtering operations and coefficients use single-precision floating-point representations and math.
`fixed`	This string applies selected default values for the properties in the fixed-point filter object, including such properties as coefficient word lengths, fraction lengths, and various operating modes. Generally, the default values match those you use on many digital signal processors. Allows signed fixed data types only. Fixed-point arithmetic filters are available only when you install Fixed-Point Designer software with this toolbox.

double

When you use one of the `dfilt.`*`structure`* methods to create a filter, the `Arithmetic` property value is `double` by default. Your filter is identical to the same filter without the `Arithmetic` property, as you would create if you used Signal Processing Toolbox software.

`Double` means that the filter uses double-precision floating-point arithmetic in all operations while filtering:

- All input to the filter must be double data type. Any other data type returns an error.
- The states and output are doubles as well.

- All internal calculations are done in double math.

When you use `double` data type filter coefficients, the reference and quantized (fixed-point) filter coefficients are identical. The filter stores the reference coefficients as double data type.

single

When your filter should use single-precision floating-point arithmetic, set the `Arithmetic` property to `single` so all arithmetic in the filter processing gets restricted to single-precision data type.

- Input data must be single data type. Other data types return errors.
- The filter states and filter output use single data type.

When you choose `single`, you can provide the filter coefficients in either of two ways:

- Double data type coefficients. With `Arithmetic` set to `single`, the filter casts the double data type coefficients to single data type representation.
- Single data type. These remain unchanged by the filter.

Depending on whether you specified single or double data type coefficients, the reference coefficients for the filter are stored in the data type you provided. If you provide coefficients in double data type, the reference coefficients are double as well. Providing single data type coefficients generates single data type reference coefficients. Note that the arithmetic used by the reference filter is always double.

When you use `reffilter` to create a reference filter from the reference coefficients, the resulting filter uses double-precision versions of the reference filter coefficients.

To set the `Arithmetic` property value, create your filter, then use `set` to change the `Arithmetic` setting, as shown in this example using a direct form FIR filter.

```
b=fir1(7,0.45);

hd=dfilt.dffir(b)

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
               Numerator: [1x8 double]
        PersistentMemory: false
```

```
                 States: [7x1 double]

set(hd,'arithmetic','single')
hd

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'single'
               Numerator: [1x8 double]
        PersistentMemory: false
                  States: [7x1 single]
```

fixed

Converting your `dfilt` object to use fixed arithmetic results in a filter structure that uses properties and property values to match how the filter would behave on digital signal processing hardware.

Note The `fixed` option for the property `Arithmetic` is available only when you install Fixed-Point Designer software as well as DSP System Toolbox software.

After you set `Arithmetic` to `fixed`, you are free to change any property value from the default value to a value that more closely matches your needs. You cannot, however, mix floating-point and fixed-point arithmetic in your filter when you select `fixed` as the `Arithmetic` property value. Choosing `fixed` restricts you to using either fixed-point or floating point throughout the filter (the data type must be homogenous). Also, all data types must be signed. `fixed` does not support unsigned data types except for unsigned coefficients when you set the property `Signed` to `false`. Mixing word and fraction lengths within the fixed object is acceptable. In short, using fixed arithmetic assumes

- fixed word length.
- fixed size and dedicated accumulator and product registers.
- the ability to do either saturation or wrap arithmetic.
- that multiple rounding modes are available.

Making these assumptions simplifies your job of creating fixed-point filters by reducing repetition in the filter construction process, such as only requiring you to enter the accumulator word size once, rather than for each step that uses the accumulator.

Default property values are a starting point in tailoring your filter to common hardware, such as choosing 40-bit word length for the accumulator, or 16-bit words for data and coefficients.

In this `dfilt` object example, `get` returns the default values for `dfilt.df1t` structures.

```
[b,a]=butter(6,0.45);
hd=dfilt.df1(b,a)

hd =

         FilterStructure: 'Direct-Form I'
              Arithmetic: 'double'
               Numerator: [1x7 double]
             Denominator: [1x7 double]
        PersistentMemory: false
                  States: Numerator:  [6x1 double]
                          Denominator:[6x1 double]

set(hd,'arithmetic','fixed')
get(hd)
        PersistentMemory: false
         FilterStructure: 'Direct-Form I'
                  States: [1x1 filtstates.dfiir]
               Numerator: [1x7 double]

            OverflowMode: 'wrap'
         InputWordLength: 16
         InputFracLength: 15
             ProductMode: 'FullPrecision'
        OutputWordLength: 16
        OutputFracLength: 15
           NumFracLength: 16
           DenFracLength: 14
       ProductWordLength: 32
       NumProdFracLength: 31
       DenProdFracLength: 29
         AccumWordLength: 40
```

```
      NumAccumFracLength: 31
      DenAccumFracLength: 29
           CastBeforeSum: 1
```

Here is the default display for `hd`.

```
hd

hd =

         FilterStructure: 'Direct-Form I'
              Arithmetic: 'fixed'
               Numerator: [1x7 double]
             Denominator: [1x7 double]
        PersistentMemory: false
                  States: Numerator:  [6x1 fi]
                          Denominator:[6x1 fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
        OutputFracLength: 15

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

This second example shows the default property values for `dfilt.latticemamax` filter objects, using the coefficients from an `fir1` filter.

```
b=fir1(7,0.45)

hdlat=dfilt.latticemamax(b)
```

```
hdlat =

          FilterStructure: [1x45 char]
               Arithmetic: 'double'
                  Lattice: [1x8 double]
         PersistentMemory: false
                   States: [8x1 double]

hdlat.arithmetic='fixed'

hdlat =

          FilterStructure: [1x45 char]
               Arithmetic: 'fixed'
                  Lattice: [1x8 double]
         PersistentMemory: false
                   States: [1x1 embedded.fi]

          CoeffWordLength: 16
           CoeffAutoScale: true
                   Signed: true

          InputWordLength: 16
          InputFracLength: 15

         OutputWordLength: 16
               OutputMode: 'AvoidOverflow'

          StateWordLength: 16
          StateFracLength: 15

              ProductMode: 'FullPrecision'

          AccumWordLength: 40
            CastBeforeSum: true

                RoundMode: 'convergent'
             OverflowMode: 'wrap'
```

Unlike the `single` or `double` options for `Arithmetic`, `fixed` uses properties to define the word and fraction lengths for each portion of your filter. By changing the property value of any of the properties, you control your filter performance. Every word length and fraction length property is independent — set the one you need and the others remain unchanged, such as setting the input word length with InputWordLength, while leaving the fraction length the same.

```
d=fdesign.lowpass('n,fc',6,0.45)

d =

               Response: 'Lowpass with cutoff'

```

Notice that the properties for the lattice filter `hdlat` and direct-form II filter `hd` are different, as befits their differing filter structures. Also, some properties are common to both objects, such as `RoundMode` and `PersistentMemory` and behave the same way in both objects.

Notes About Fraction Length, Word Length, and Precision

Word length and fraction length combine to make the format for a fixed-point number, where word length is the number of bits used to represent the value and fraction length specifies, in bits, the location of the binary point in the fixed-point representation. Therein lies a problem — fraction length, which you specify in bits, can be larger than the word length, or a negative number of bits. This section explains how that idea works and how you might use it.

Unfortunately fraction length is somewhat misnamed (although it continues to be used in this User's Guide and elsewhere for historical reasons).

Fraction length defined as the number of fractional bits (bits to the right of the binary point) is true only when the fraction length is positive and less than or equal to the word length. In MATLAB format notation you can use [word length fraction length]. For example, for the format [16 16], the second 16 (the fraction length) is the number of fractional bits or bits to the right of the binary point. In this example, all 16 bits are to the right of the binary point.

But it is also possible to have fixed-point formats of [16 18] or [16 -45]. In these cases the fraction length can no longer be the number of bits to the right of the binary point since the format says the word length is 16 — there cannot be 18 fraction length bits on the right. And how can there be a negative number of bits for the fraction length, such as [16 -45]?

A better way to think about fixed-point format [word length fraction length] and what it means is that the representation of a fixed-point number is a weighted sum of powers of two driven by the fraction length, or the two's complement representation of the fixed-point number.

Consider the format [B L], where the fraction length L can be positive, negative, 0, greater than B (the word length) or less than B. (B and L are always integers and B is always positive.)

Given a binary string b(1) b(2) b(3) ... b(B), to determine the two's-complement value of the string in the format described by [B L], use the value of the individual bits in the binary string in the following formula, where b(1) is the first binary bit (and most significant bit, MSB), b(2) is the second, and on up to b(B).

The decimal numeric value that those bits represent is given by

```
value =-b(1)*2^(B-L-1)+b(2)*2^(B-L-2)+b(3)*2^(B-L-3)+...+ b(B)*2^(-L)
```

L, the fraction length, represents the negative of the weight of the last, or least significant bit (LSB). L is also the step size or the precision provided by a given fraction length.

Precision

Here is how precision works.

When all of the bits of a binary string are zero except for the LSB (which is therefore equal to one), the value represented by the bit string is given by $2^{(-L)}$. If L is negative, for example L=-16, the value is 2^{16}. The smallest step between numbers that can be represented in a format where L=-16 is given by 1 x 2^{16} (the rightmost term in the formula above), which is 65536. Note the precision does not depend on the word length.

Take a look at another example. When the word length set to 8 bits, the decimal value 12 is represented in binary by 00001100. That 12 is the decimal equivalent of 00001100 tells you that you are using [8 0] data format representation — the word length is 8 bits and fraction length 0 bits, and the step size or precision (the smallest difference between two adjacent values in the format [8,0], is 2^0=1.

Suppose you plan to keep only the upper 5 bits and discard the other three. The resulting precision after removing the right-most three bits comes from the weight of the lowest remaining bit, the fifth bit from the left, which is 2^3=8, so the format would be [5,-3].

Note that in this format the step size is 8, I cannot represent numbers that are between multiples of 8.

In MATLAB, with Fixed-Point Designer software installed:

```
x=8;
q=quantizer([8,0]); % Word length = 8, fraction length = 0
xq=quantize(q,x);
binxq=num2bin(q,xq);
q1=quantizer([5 -3]); % Word length = 5, fraction length = -3
xq1 = quantize(q1,xq);
binxq1=num2bin(q1,xq1);
binxq

binxq =

00001000

binxq1

binxq1 =

00001
```

But notice that in [5,-3] format, 00001 is the two's complement representation for 8, not for 1; `q = quantizer([8 0])` and `q1 = quantizer([5 -3])` are not the same. They cover the about the same range — `range(q)>range(q1)` — but their quantization step is different — `eps(q)`= 8, and `eps(q1)=1`.

Look at one more example. When you construct a quantizer `q`

```
q = quantizer([a,b])
```

the first element in `[a,b]` is `a`, the word length used for quantization. The second element in the expression, `b`, is related to the quantization step — the numerical difference between the two closest values that the quantizer can represent. This is also related to the weight given to the LSB. Note that `2^(-b)` = `eps(q)`.

Now construct two quantizers, q1 and q2. Let q1 use the format [32,0] and let q2 use the format [16, -16].

```
q1 = quantizer([32,0])
q2 = quantizer([16,-16])
```

Quantizers q1 and q2 cover the same range, but q2 has less precision. It covers the range in steps of 2^{16}, while q covers the range in steps of 1.

This lost precision is due to (or can be used to model) throwing out 16 least-significant bits.

An important point to understand is that in dfilt objects and filtering you control which bits are carried from the sum and product operations in the filter to the filter output by setting the format for the output from the sum or product operation.

For instance, if you use [16 0] as the output format for a 32-bit result from a sum operation when the original format is [32 0], you take the lower 16 bits from the result. If you use [16 -16], you take the higher 16 bits of the original 32 bits. You could even take 16 bits somewhere in between the 32 bits by choosing something like [16 -8], but you probably do not want to do that.

Filter scaling is directly implicated in the format and precision for a filter. When you know the filter input and output formats, as well as the filter internal formats, you can scale the inputs or outputs to stay within the format ranges.

Notice that overflows or saturation might occur at the filter input, filter output, or within the filter itself, such as during add or multiply or accumulate operations. Improper scaling at any point in the filter can result in numerical errors that dramatically change the performance of your fixed-point filter implementation.

CastBeforeSum

Setting the CastBeforeSum property determines how the filter handles the input values to sum operations in the filter. After you set your filter Arithmetic property value to fixed, you have the option of using CastBeforeSum to control the data type of some inputs (addends) to summations in your filter. To determine which addends reflect the CastBeforeSum property setting, refer to the reference page for the signal flow diagram for the filter structure.

CastBeforeSum specifies whether to cast selected addends to summations in the filter to the output format from the addition operation before performing the addition. When you specify `true` for the property value, the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

Specifying `CastBeforeSum` to be `false` prevents the addends from being cast to the output format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use.

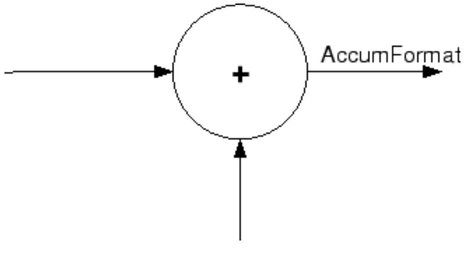
Notice that the output format for every sum operation reflects the value of the output property specified in the filter structure diagram. Which input property is referenced by `CastBeforeSum` depends on the structure.

Property Value	Description
`false`	Configures filter summation operations to retain the addends in the format carried from the previous operation.
`true`	Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually this generates results from the summation that more closely match those found from digital signal processors

Another point — with `CastBeforeSum` set to `false`, the filter realization process inserts an intermediate data type format to hold temporarily the full precision sum of the inputs. A separate Convert block performs the process of casting the addition result to the accumulator format. This intermediate data format occurs because the Sum block in Simulink always casts input (addends) to the output data type.

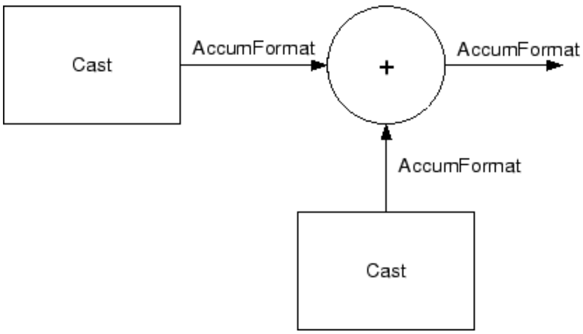
Diagrams of CastBeforeSum Settings

When `CastBeforeSum` is `false`, sum elements in filter signal flow diagrams look like this:



showing that the input data to the sum operations (the addends) retain their format word length and fraction length from previous operations. The addition process uses the existing input formats and then casts the output to the format defined by `AccumFormat`. Thus the output data has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

When `CastBeforeSum` is `true`, sum elements in filter signal flow diagrams look like this:



showing that the input data gets recast to the accumulator format word length and fraction length (AccumFormat) before the sum operation occurs. The data output by the addition operation has the word length and fraction length defined by `AccumWordLength` and `AccumFracLength`.

CoeffAutoScale

How the filter represents the filter coefficients depends on the property value of `CoeffAutoScale`. When you create a `dfilt` object, you use coefficients in double-precision format. Converting the `dfilt` object to fixed-point arithmetic forces the coefficients into a fixed-point representation. The representation the filter uses depends on whether the value of `CoeffAutoScale` is `true` or `false`.

- `CoeffAutoScale` = `true` means the filter chooses the fraction length to maintain the value of the coefficients as close to the double-precision values as possible. When you change the word length applied to the coefficients, the filter object changes the fraction length to try to accommodate the change. `true` is the default setting.
- `CoeffAutoScale` = `false` removes the automatic scaling of the fraction length for the coefficients and exposes the property that controls the coefficient fraction length

so you can change it. For example, if the filter is a direct form FIR filter, setting `CoeffAutoScale` = `false` exposes the `NumFracLength` property that specifies the fraction length applied to numerator coefficients. If the filter is an IIR filter, setting `CoeffAutoScale` = `false` exposes both the `NumFracLength` and `DenFracLength` properties.

Here is an example of using `CoeffAutoScale` with a direct form filter.

```
hd2=dfilt.dffir([0.3 0.6 0.3])

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
               Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [2x1 double]

hd2.arithmetic='fixed'

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
```

```
             OverflowMode: 'wrap'
```

To this point, the filter coefficients retain the original values from when you created the filter as shown in the `Numerator` property. Now change the `CoeffAutoScale` property value from `true` to `false`.

```
hd2.coeffautoScale=false

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.3000 0.6000 0.3000]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: false
           NumFracLength: 15
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

With the `NumFracLength` property now available, change the word length to 5 bits.

Notice the coefficient values. Setting `CoeffAutoScale` to `false` removes the automatic fraction length adjustment and the filter coefficients cannot be represented by the current format of [5 15] — a word length of 5 bits, fraction length of 15 bits.

```
hd2.coeffwordlength=5

hd2 =
```

```
         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [4.5776e-004 4.5776e-004 4.5776e-004]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 5
          CoeffAutoScale: false
           NumFracLength: 15
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'

         AccumWordLength: 40
           CastBeforeSum: true

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

Restoring `CoeffAutoScale` to `true` goes some way to fixing the coefficient values. Automatically scaling the coefficient fraction length results in setting the fraction length to 4 bits. You can check this with `get(hd2)` as shown below.

```
hd2.coeffautoScale=true

hd2 =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.3125 0.6250 0.3125]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 5
          CoeffAutoScale: true
                  Signed: true
```

```
          InputWordLength: 16
          InputFracLength: 15

         OutputWordLength: 16
               OutputMode: 'AvoidOverflow'

              ProductMode: 'FullPrecision'

          AccumWordLength: 40
            CastBeforeSum: true

                RoundMode: 'convergent'
             OverflowMode: 'wrap'

get(hd2)
        PersistentMemory: false
FilterStructure: 'Direct-Form FIR'
                  States: [1x1 embedded.fi]
               Numerator: [0.3125 0.6250 0.3125]
              Arithmetic: 'fixed'
         CoeffWordLength: 5
          CoeffAutoScale: 1
                  Signed: 1
               RoundMode: 'convergent'
            OverflowMode: 'wrap'
         InputWordLength: 16
         InputFracLength: 15
        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'
             ProductMode: 'FullPrecision'
           NumFracLength: 4
        OutputFracLength: 12
       ProductWordLength: 21
       ProductFracLength: 19
         AccumWordLength: 40
         AccumFracLength: 19
           CastBeforeSum: 1
```

Clearly five bits is not enough to represent the coefficients accurately.

CoeffFracLength

Fixed-point scalar filters that you create using `dfilt.scalar` use this property to define the fraction length applied to the scalar filter coefficients. Like the coefficient-fractionlength-related properties for the FIR, lattice, and IIR filters, `CoeffFracLength` is not displayed for scalar filters until you set `CoeffAutoScale` to `false`. Once you change the automatic scaling you can set the fraction length for the coefficients to any value you require.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 14 bits, with the `CoeffWordlength` of 16 bits.

CoeffWordLength

One primary consideration in developing filters for hardware is the length of a data word. `CoeffWordLength` defines the word length for these data storage and arithmetic locations:

- Numerator and denominator filter coefficients
- Tap sum in `dfilt.dfsymfir` and `dfilt.dfasymfir` filter objects
- Section input, multiplicand, and state values in direct-form SOS filter objects such as `dfilt.df1t` and `dfilt.df2`
- Scale values in second-order filters
- Lattice and ladder coefficients in lattice filter objects, such as `dfilt.latticearma` and `dfilt.latticemamax`
- Gain in `dfilt.scalar`

Setting this property value controls the word length for the data listed. In most cases, the data words in this list have separate fraction length properties to define the associated fraction lengths.

Any positive, integer word length works here, limited by the machine you use to develop your filter and the hardware you use to deploy your filter.

DenAccumFracLength

Filter structures `df1`, `df1t`, `df2`, and `df2t` that use `fixed` arithmetic have this property that defines the fraction length applied to denominator coefficients in the accumulator. In combination with `AccumWordLength`, the properties fully specify how the accumulator outputs data stored there.

As with all fraction length properties, `DenAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

To be able to change the property value for this property, you set `FilterInternals` to `SpecifyPrecision`.

DenFracLength

Property `DenFracLength` contains the value that specifies the fraction length for the denominator coefficients for your filter. `DenFracLength` specifies the fraction length used to interpret the data stored in `C`. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the denominator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

Denominator

The denominator coefficients for your IIR filter, taken from the prototype you start with, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All IIR filter objects include `Denominator`, except the lattice-based filters which store their coefficients in the `Lattice` property, and second-order section filters, such as `dfilt.df1tsos`, which use the `SosMatrix` property to hold the coefficients for the sections.

DenProdFracLength

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `DenProdFracLength` specifies the fraction length applied to data output from product operations that the filter performs on denominator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `DenProdFracLength` setting manually. Otherwise, for multiplication operations that use the denominator coefficients, the filter sets the fraction length as defined by the `ProductMode` setting.

DenStateFracLength

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with denominator coefficient operations take the fraction length from this property. In combination with the `DenStateWordLength` property, these properties fully specify how the filter interprets the states.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `DenStateWordLength` of 16 bits.

DenStateWordLength

When you look at the flow diagram for the `dfilt.df1sos` filter object, the states associated with the denominator coefficient operations take the data format from this property and the `DenStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

By default, the value is 16 bits, with the `DenStateFracLength` of 15 bits.

FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them. Note that

FilterStructure

Every `dfilt` object has a `FilterStructure` property. This is a read-only property containing a string that declares the structure of the filter object you created.

When you construct filter objects, the `FilterStructure` property value is returned containing one of the strings shown in the following table. Property `FilterStructure` indicates the filter architecture and comes from the constructor you use to create the filter.

After you create a filter object, you cannot change the `FilterStructure` property value. To make filters that use different structures, you construct new filters using the appropriate methods, or use `convert` to switch to a new structure.

Default value

Since this depends on the constructor you use and the constructor includes the filter structure definition, there is no default value. When you try to create a filter without specifying a structure, MATLAB returns an error.

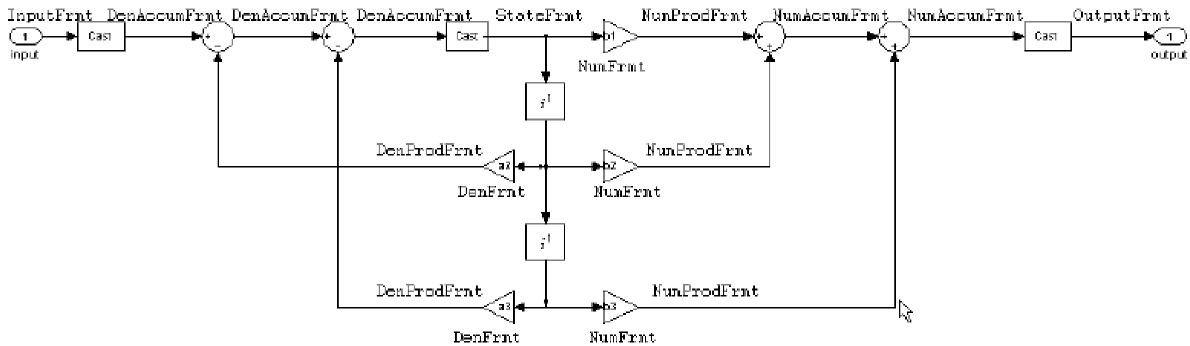
Filter Constructor Name	FilterStructure Property String and Filter Type
`'dfilt.df1'`	Direct form I
`'dfilt.df1sos'`	Direct form I filter implemented using second-order sections
`'dfilt.df1t'`	Direct form I transposed
`'dfilt.df2'`	Direct form II
`'dfilt.df2sos'`	Direct form II filter implemented using second order sections
`'dfilt.df2t'`	Direct form II transposed
`'dfilt.dfasymfir'`	Antisymmetric finite impulse response (FIR). Even and odd forms.
`'dfilt.dffir'`	Direct form FIR
`'dfilt.dffirt'`	Direct form FIR transposed
`'dfilt.latticeallpass'`	Lattice allpass
`'dfilt.latticear'`	Lattice autoregressive (AR)
`'dfilt.latticemamin'`	Lattice moving average (MA) minimum phase
`'dfilt.latticemamax'`	Lattice moving average (MA) maximum phase
`'dfilt.latticearma'`	Lattice ARMA
`'dfilt.dfsymfir'`	Symmetric FIR. Even and odd forms
`'dfilt.scalar'`	Scalar

Filter Structures with Quantizations Shown in Place

To help you understand how and where the quantizations occur in filter structures in this toolbox, the figure below shows the structure for a Direct Form II filter, including the quantizations (fixed-point formats) that compose part of the fixed-point filter. You see that one or more quantization processes, specified by the *format label, accompany each filter element, such as a delay, product, or summation element. The input to or output from each element reflects the result of applying the associated quantization as defined by the word length and fraction length format. Wherever a particular filter element appears in a filter structure, recall the quantization process that accompanies the element as it appears in this figure. Each filter reference page, such as the `dfilt.df2` reference page, includes the signal flow diagram showing the formatting elements that define the quantizations that occur throughout the filter flow.

For example, a product quantization, either numerator or denominator, follows every product (gain) element and a sum quantization, also either numerator or denominator, follows each sum element. The figure shows the `Arithmetic` property value set to `fixed`.

df2 IIR Filter Structure Including the Formatting Objects, with Arithmetic Property Value fixed



When your `df2` filter uses the `Arithmetic` property set to `fixed`, the filter structure contains the formatting features shown in the diagram. The formats included in the structure are fixed-point objects that include properties to set various word and fraction length formats. For example, the `NumFormat` or `DenFormat` in the fixed-point arithmetic filter set the properties for quantizing numerator or denominator coefficients according to word and fraction length settings.

When the leading denominator coefficient a(1) in your filter is not 1, choose it to be a power of two so that a shift replaces the multiply that would otherwise be used.

Fixed-Point Arithmetic Filter Structures

You choose among several filter structures when you create fixed-point filters. You can also specify filters with single or multiple cascaded sections of the same type. Because quantization is a nonlinear process, different fixed-point filter structures produce different results.

To specify the filter structure, you select the appropriate `dfilt.`*`structure`* method to construct your filter. Refer to the function reference information for `dfilt` and `set` for details on setting property values for quantized filters.

The figures in the following subsections of this section serve as aids to help you determine how to enter your filter coefficients for each filter structure. Each subsection contains an example for constructing a filter of the given structure.

Scale factors for the input and output for the filters do not appear in the block diagrams. The default filter structures do not include, nor assume, the scale factors. For filter scaling information, refer to `scale` in the Help system.

About the Filter Structure Diagrams

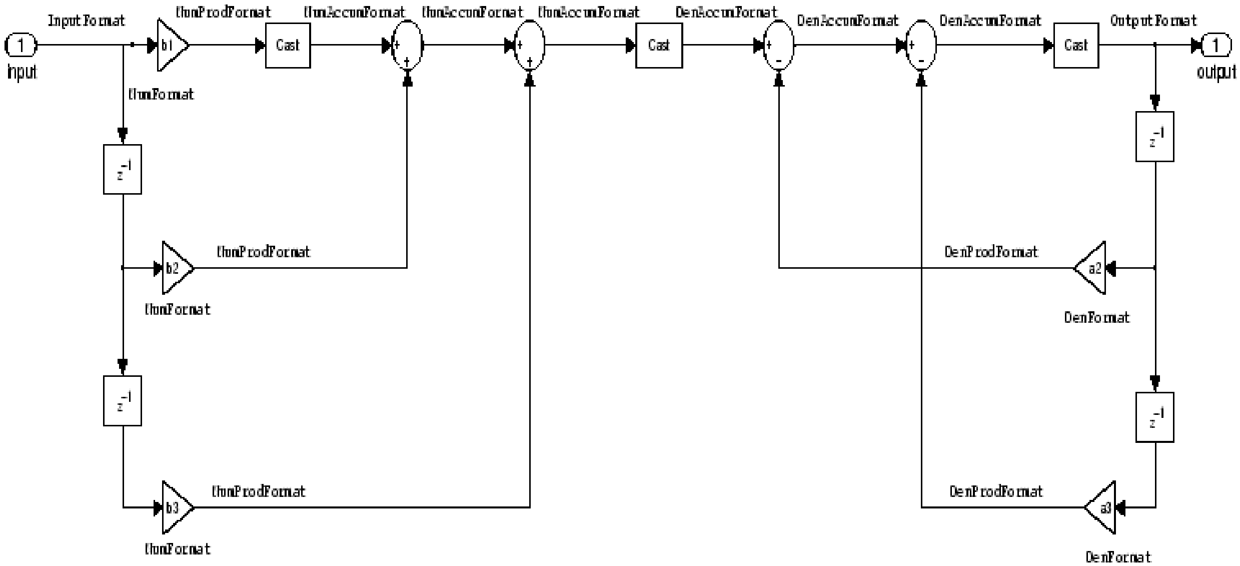
In the diagrams that accompany the following filter structure descriptions, you see the active operators that define the filter, such as sums and gains, and the formatting features that control the processing in the filter. Notice also that the coefficients are labeled in the figure. This tells you the order in which the filter processes the coefficients.

While the meaning of the block elements is straightforward, the labels for the formats that form part of the filter are less clear. Each figure includes text in the form *`labelFormat`* that represents the existence of a formatting feature at that point in the structure. The *`Format`* stands for formatting object and the *`label`* specifies the data that the formatting object affects.

For example, in the `dfilt.df2` filter shown above, the entries `InputFormat` and `OutputFormat` are the formats applied, that is the word length and fraction length, to the filter input and output data. For example, filter properties like `OutputWordLength` and `InputWordLength` specify values that control filter operations at the input and output points in the structure and are represented by the formatting objects `InputFormat` and `OutputFormat` shown in the filter structure diagrams.

Direct Form I Filter Structure

The following figure depicts the *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are numbered $b(i)$, i =1, 2, 3; the denominator coefficients are numbered $a(i)$, i = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, the `Arithmetic` property is set to `fixed`.



Example — Specifying a Direct Form I Filter

You can specify a second-order direct form I structure for a quantized filter `hq` with the following code.

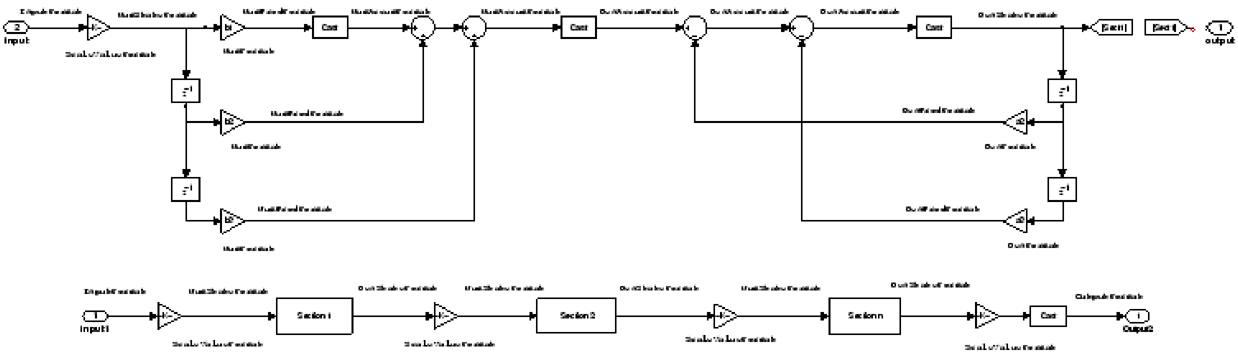
```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1(b,a);
```

To create the fixed-point filter, set the `Arithmetic` property to `fixed` as shown here.

```
set(hq,'arithmetic','fixed');
```

Direct Form I Filter Structure With Second-Order Sections

The following figure depicts a *direct form I* filter structure that directly realizes a transfer function with a second-order numerator and denominator and second-order sections. The numerator coefficients are numbered $b(i)$, i =1, 2, 3; the denominator coefficients are numbered $a(i)$, i = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, the `Arithmetic` property is set to `fixed` to place the filter in fixed-point mode.



Example — Specifying a Direct Form I Filter with Second-Order Sections

You can specify an eighth-order direct form I structure for a quantized filter `hq` with the following code.

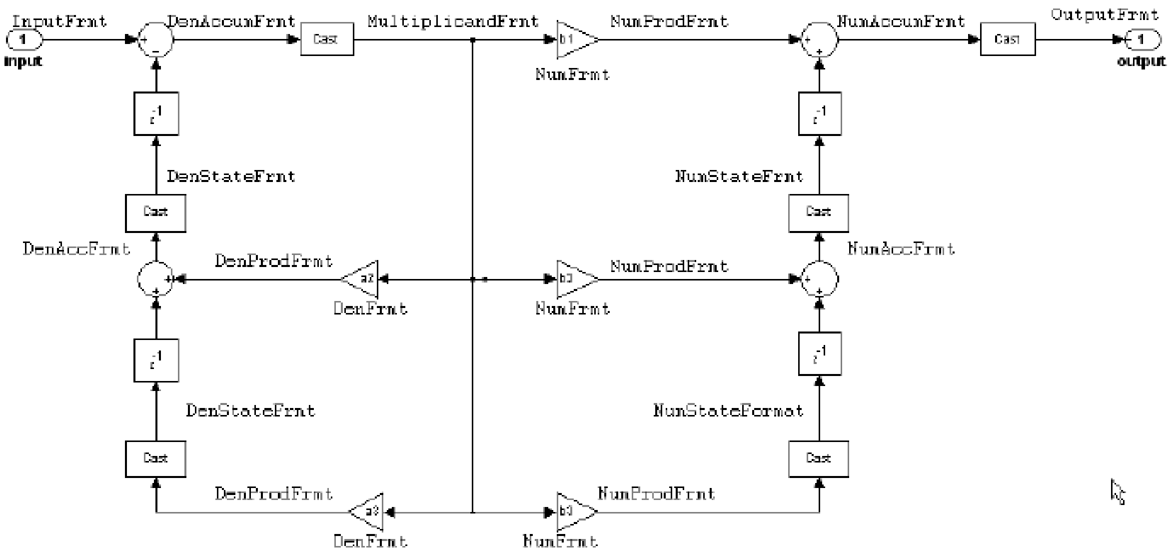
```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1sos(b,a);
```

To create the fixed-point filter, set the `Arithmetic` property to `fixed`, as shown here.

```
set(hq,'arithmetic','fixed');
```

Direct Form I Transposed Filter Structure

The next signal flow diagram depicts a *direct form I transposed* filter structure that directly realizes a transfer function with a second-order numerator and denominator. The numerator coefficients are $b(i)$, i = 1, 2, 3; the denominator coefficients are $a(i)$, i = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$. With the `Arithmetic` property value set to `fixed`, the figure shows the filter with the properties indicated.



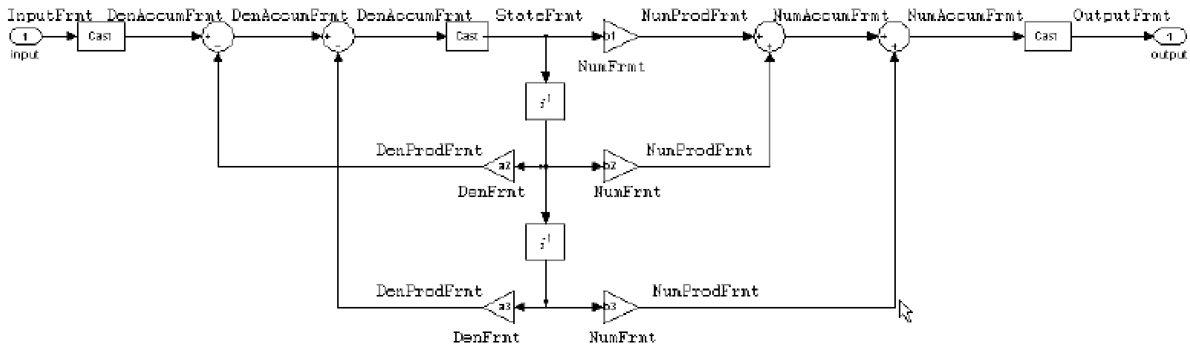
Example — Specifying a Direct Form I Transposed Filter

You can specify a second-order direct form I transposed filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df1t(b,a);
set(hq,'arithmetic','fixed');
```

Direct Form II Filter Structure

The following graphic depicts a *direct form II* filter structure that directly realizes a transfer function with a second-order numerator and denominator. In the figure, the `Arithmetic` property value is `fixed`. Numerator coefficients are named $b(i)$; denominator coefficients are named $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are named $z(i)$.



Use the method `dfilt.df2` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

Example — Specifying a Direct Form II Filter

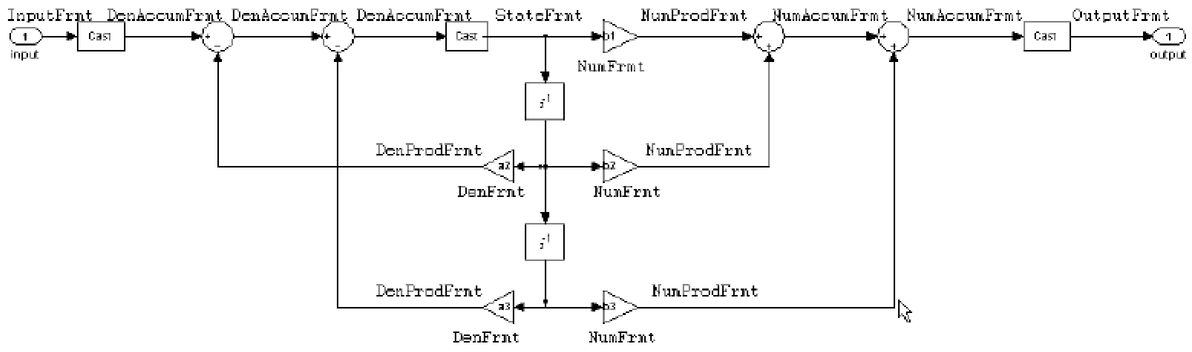
You can specify a second-order direct form II filter structure for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2(b,a);
hq.arithmetic = 'fixed'
```

To convert your initial double-precision filter `hq` to a quantized or fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

Direct Form II Filter Structure With Second-Order Sections

The following figure depicts *direct form II* filter structure using second-order sections that directly realizes a transfer function with a second-order numerator and denominator sections. In the figure, the `Arithmetic` property value is `fixed`. Numerator coefficients are labeled $b(i)$; denominator coefficients are labeled $a(i)$, $i = 1, 2, 3$; and the states (used for initial and final state values in filtering) are labeled $z(i)$.



Use the method `dfilt.df2sos` to construct a quantized filter whose `FilterStructure` property is `Direct-Form II`.

Example — Specifying a Direct Form II Filter with Second-Order Sections

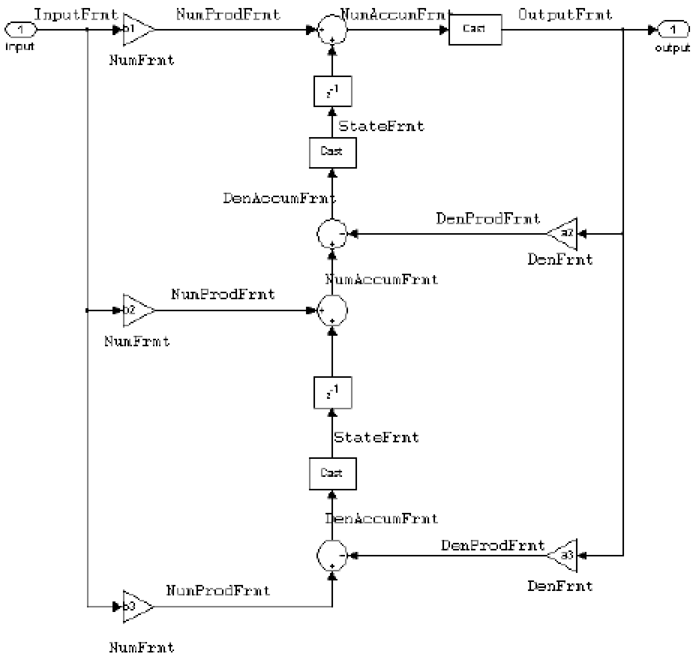
You can specify a tenth-order direct form II filter structure that uses second-order sections for a quantized filter `hq` with the following code.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hq = dfilt.df2sos(b,a);
hq.arithmetic = 'fixed'
```

To convert your prototype double-precision filter `hq` to a fixed-point filter, set the `Arithmetic` property to `fixed`, as shown.

Direct Form II Transposed Filter Structure

The following figure depicts the *direct form II transposed* filter structure that directly realizes transfer functions with a second-order numerator and denominator. The numerator coefficients are labeled $b(i)$, the denominator coefficients are labeled $a(i)$, $i = 1$, 2, 3, and the states (used for initial and final state values in filtering) are labeled $z(i)$. In the first figure, the `Arithmetic` property value is `fixed`.



Use the constructor `dfilt.df2t` to specify the value of the `FilterStructure` property for a filter with this structure that you can convert to fixed-point filtering.

Example — Specifying a Direct Form II Transposed Filter

Specifying or constructing a second-order direct form II transposed filter for a fixed-point filter `hq` starts with the following code to define the coefficients and construct the filter.

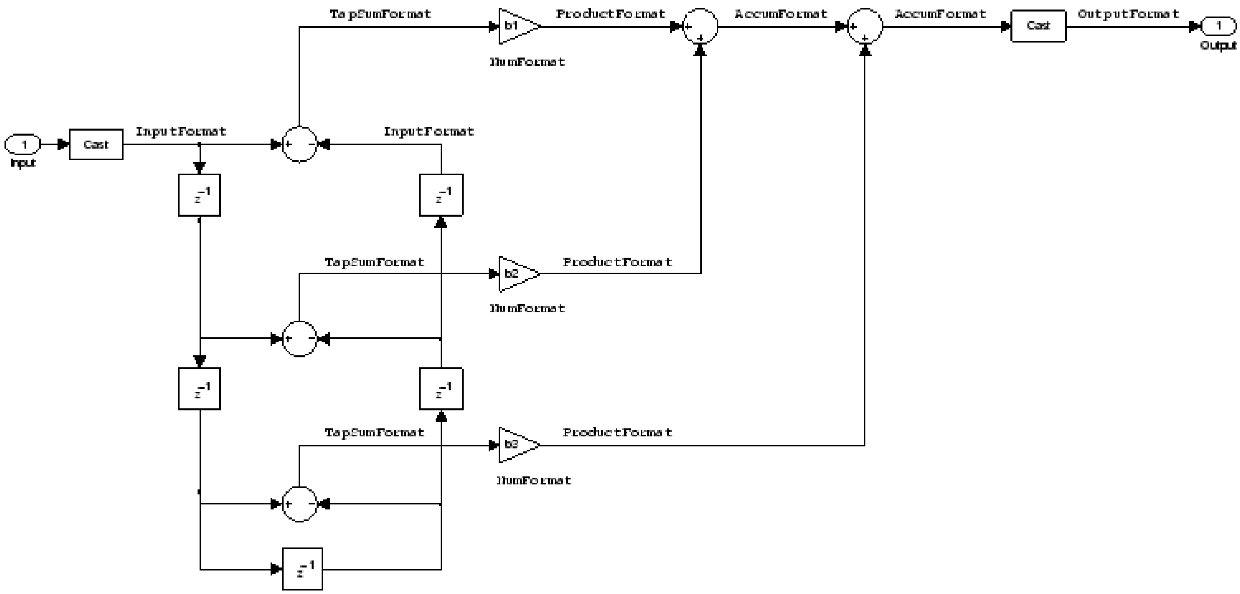
```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df2t(b,a);
```

Now create the fixed-point filtering version of the filter from `hd`, which is floating point.

```
hq = set(hd,'arithmetic','fixed');
```

Direct Form Antisymmetric FIR Filter Structure (Any Order)

The following figure depicts a *direct form antisymmetric FIR* filter structure that directly realizes a second-order antisymmetric FIR filter. The filter coefficients are labeled *b(i)*, and the initial and final state values in filtering are labeled *z*(*i*). This structure reflects the `Arithmetic` property set to `fixed`.



Use the method `dfilt.dfasymfir` to construct the filter, and then set the `Arithmetic` property to `fixed` to convert to a fixed-point filter with this structure.

Example — Specifying an Odd-Order Direct Form Antisymmetric FIR Filter

Specify a fifth-order direct form antisymmetric FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hq = dfilt.dfasymfir(b);
set(hq,'arithmetic','fixed')

hq

hq =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: [-0.0080 0.0600 -0.4400 0.4400 -0.0600 0.0080]
        PersistentMemory: false
                  States: [1x1 fi object]

Example — Specifying an Even-Order Direct Form Antisymmetric FIR Filter

You can specify a fourth-order direct form antisymmetric FIR filter structure for a fixed-point filter hq with the following code.

```
b = [-0.01 0.1 0.0 -0.1 0.01];
hq = dfilt.dfasymfir(b);
hq.arithmetic='fixed'

hq =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: [-0.0100 0.1000 0 -0.1000 0.0100]
        PersistentMemory: false
                  States: [1x1 fi object]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'KeepMSB'
        TapSumWordLength: 17
```

```
       ProductMode: 'FullPrecision'

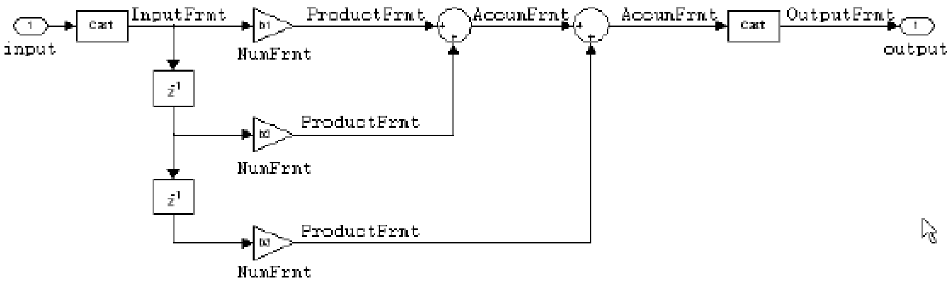
    AccumWordLength: 40

      CastBeforeSum: true
          RoundMode: 'convergent'
       OverflowMode: 'wrap'

    InheritSettings: false
```

Direct Form Finite Impulse Response (FIR) Filter Structure

In the next figure, you see the signal flow graph for a *direct form finite impulse response (FIR)* filter structure that directly realizes a second-order FIR filter. The filter coefficients are $b(i)$, $i = 1, 2, 3$, and the states (used for initial and final state values in filtering) are $z(i)$. To generate the figure, set the `Arithmetic` property to `fixed` after you create your prototype filter in double-precision arithmetic.



Use the `dfilt.dffir` method to generate a filter that uses this structure.

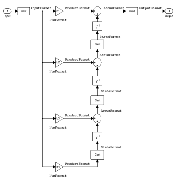
Example — Specifying a Direct Form FIR Filter

You can specify a second-order direct form FIR filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
hq = set(hd,'arithmetic','fixed');
```

Direct Form FIR Transposed Filter Structure

This figure uses the filter coefficients labeled *b*(*i*), *i* = 1, 2, 3, and states (used for initial and final state values in filtering) are labeled *z*(*i*). These depict a *direct form finite impulse response (FIR) transposed* filter structure that directly realizes a second-order FIR filter.



With the `Arithmetic` property set to `fixed`, your filter matches the figure. Using the method `dfilt.dffirt` returns a double-precision filter that you convert to a fixed-point filter.

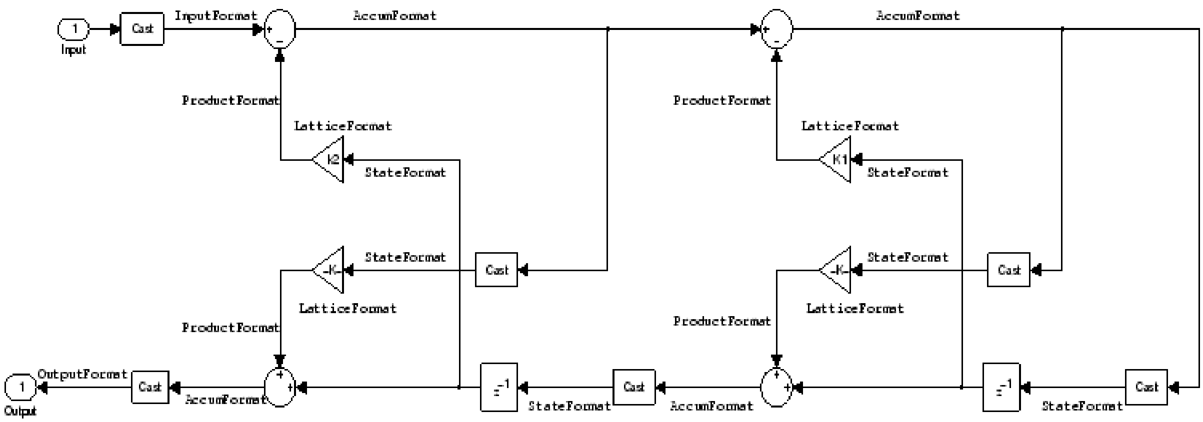
Example — Specifying a Direct Form FIR Transposed Filter

You can specify a second-order direct form FIR transposed filter structure for a fixed-point filter `hq` with the following code.

```
b = [0.05 0.9 0.05];
hd=dfilt.dffirt(b);
hq = copy(hd);
hq.arithmetic = 'fixed';
```

Lattice Allpass Filter Structure

The following figure depicts the *lattice allpass* filter structure. The pictured structure directly realizes third-order lattice allpass filters using fixed-point arithmetic. The filter reflection coefficients are labeled *k1*(*i*), *i* = 1, 2, 3. The states (used for initial and final state values in filtering) are labeled *z*(*i*).



To create a quantized filter that uses the lattice allpass structure shown in the figure, use the `dfilt.latticeallpass` method and set the `Arithmetic` property to `fixed`.

Example — Specifying a Lattice Allpass Filter

You can create a third-order lattice allpass filter structure for a quantized filter `hq` with the following code.

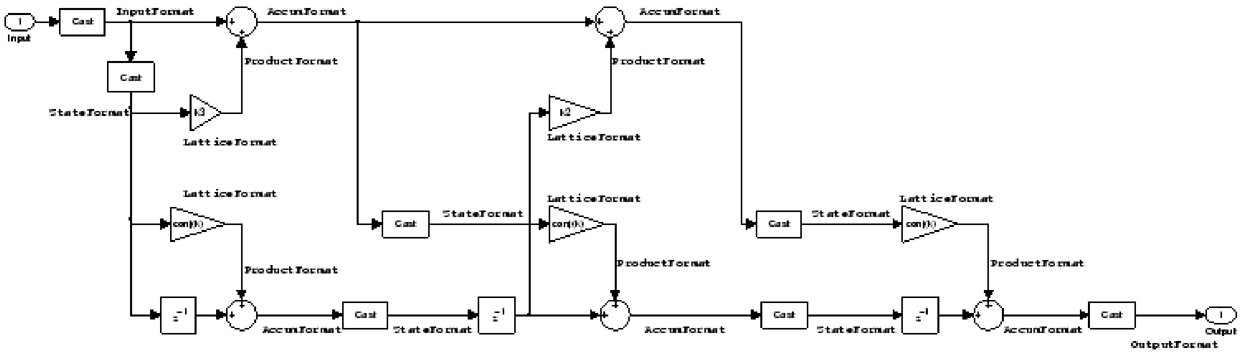
```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
set(hq,'arithmetic','fixed');
```

Lattice Moving Average Maximum Phase Filter Structure

In the next figure you see a *lattice moving average maximum phase* filter structure. This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a maximum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average maximum phase structure will not be maximum phase.
- When you start with a maximum phase filter, the resulting lattice filter is maximum phase also.

The filter reflection coefficients are labeled $k(i)$, $i = 1, 2, 3$. The states (used for initial and final state values in filtering) are labeled $z(i)$. In the figure, we set the `Arithmetic` property to `fixed` to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.



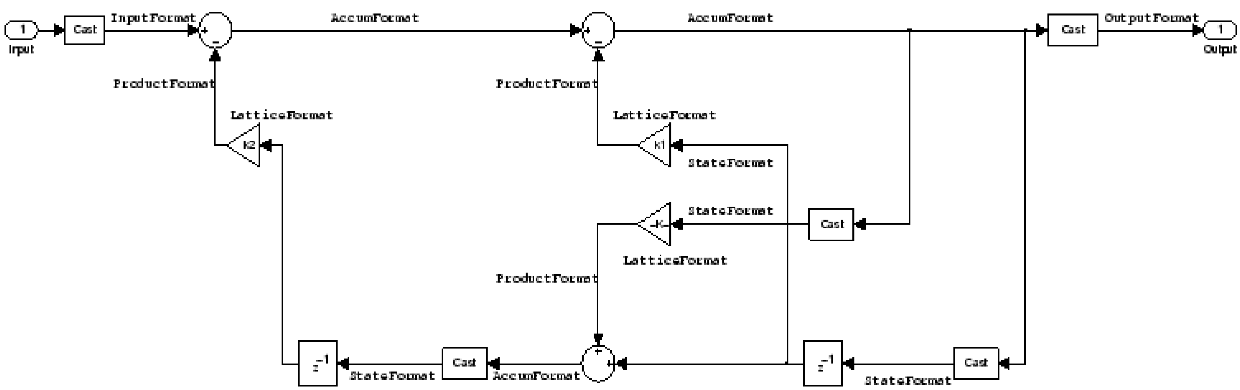
Example — Constructing a Lattice Moving Average Maximum Phase Filter

Constructing a fourth-order lattice MA maximum phase filter structure for a quantized filter `hq` begins with the following code.

```
k = [.66 .7 .44 .33];
hd=dfilt.latticemamax(k);
```

Lattice Autoregressive (AR) Filter Structure

The method `dfilt.latticear` directly realizes lattice autoregressive filters in the toolbox. The following figure depicts the third-order *lattice autoregressive (AR)* filter structure — with the `Arithmetic` property equal to `fixed`. The filter reflection coefficients are labeled $k(i)$, $i = 1, 2, 3$, and the states (used for initial and final state values in filtering) are labeled $z(i)$.



Example — Specifying a Lattice AR Filter

You can specify a third-order lattice AR filter structure for a quantized filter hq with the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticear(k);
hq.arithmetic = 'custom';
```

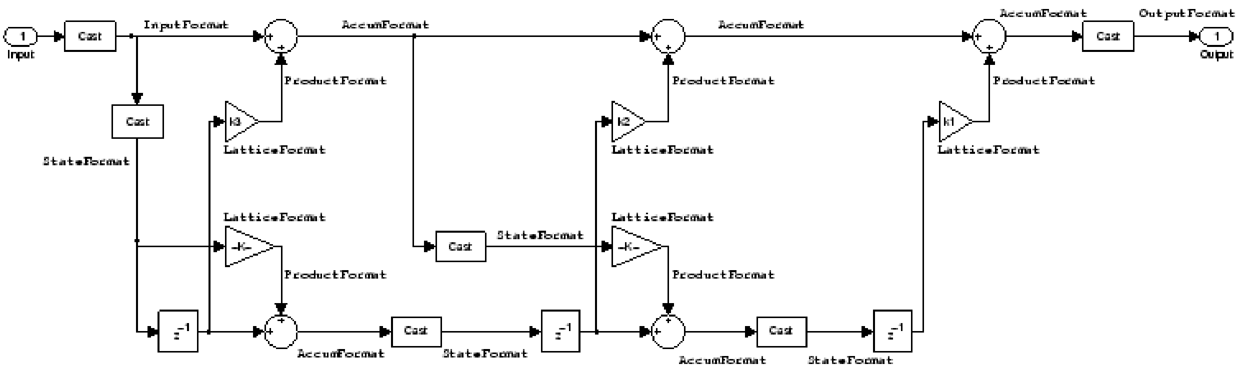
Lattice Moving Average (MA) Filter Structure for Minimum Phase

The following figures depict *lattice moving average (MA)* filter structures that directly realize third-order lattice MA filters for minimum phase. The filter reflection coefficients are labeled $k(i)$, (i). = 1, 2, 3, and the states (used for initial and final state values in filtering) are labeled $z(i)$. Setting the `Arithmetic` property of the filter to `fixed` results in a fixed-point filter that matches the figure.

This signal flow diagram directly realizes a third-order lattice moving average (MA) filter with the following phase form depending on the initial transfer function:

- When you start with a minimum phase transfer function, the upper branch of the resulting lattice structure returns a minimum phase filter. The lower branch returns a minimum phase filter.
- When your transfer function is neither minimum phase nor maximum phase, the lattice moving average minimum phase structure will not be minimum phase.
- When you start with a minimum phase filter, the resulting lattice filter is minimum phase also.

The filter reflection coefficients are labeled $k((i).)$, i = 1, 2, 3. The states (used for initial and final state values in filtering) are labeled $z((i).)$. This figure shows the filter structure when the`Arithmetic` property is set to `fixed` to reveal the fixed-point arithmetic format features that control such options as word length and fraction length.



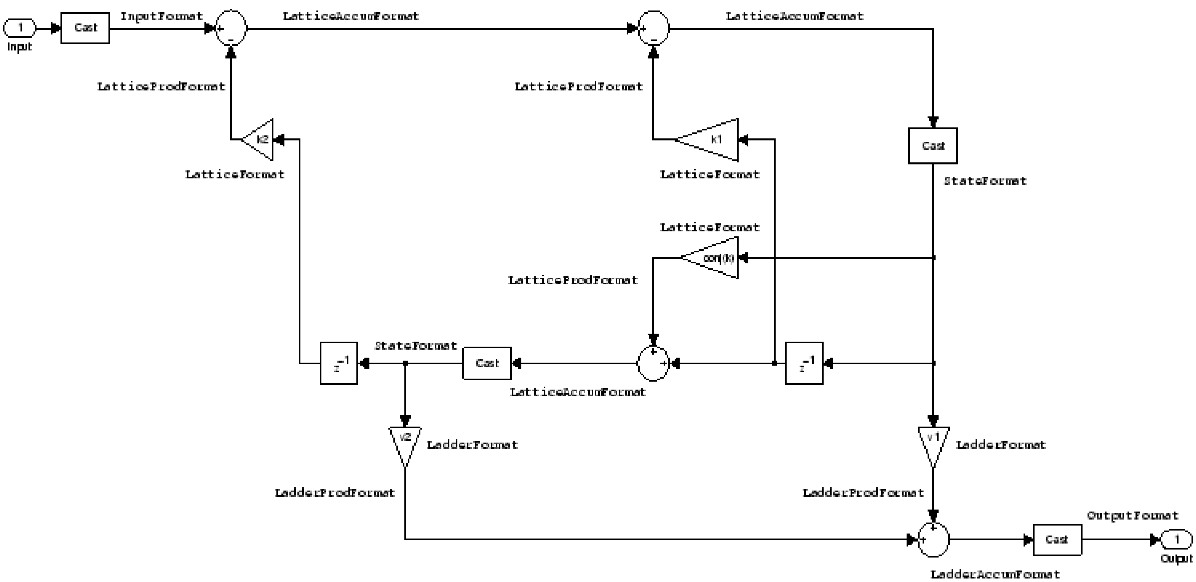
Example — Specifying a Minimum Phase Lattice MA Filter

You can specify a third-order lattice MA filter structure for minimum phase applications using variations of the following code.

```
k = [.66 .7 .44];
hd=dfilt.latticemamin(k);
set(hq,'arithmetic','fixed');
```

Lattice Autoregressive Moving Average (ARMA) Filter Structure

The figure below depicts a *lattice autoregressive moving average (ARMA)* filter structure that directly realizes a fourth-order lattice ARMA filter. The filter reflection coefficients are labeled $k(i)$, (i). = 1, ..., 4; the ladder coefficients are labeled $v(i)$, (i). = 1, 2, 3; and the states (used for initial and final state values in filtering) are labeled $z(i)$.



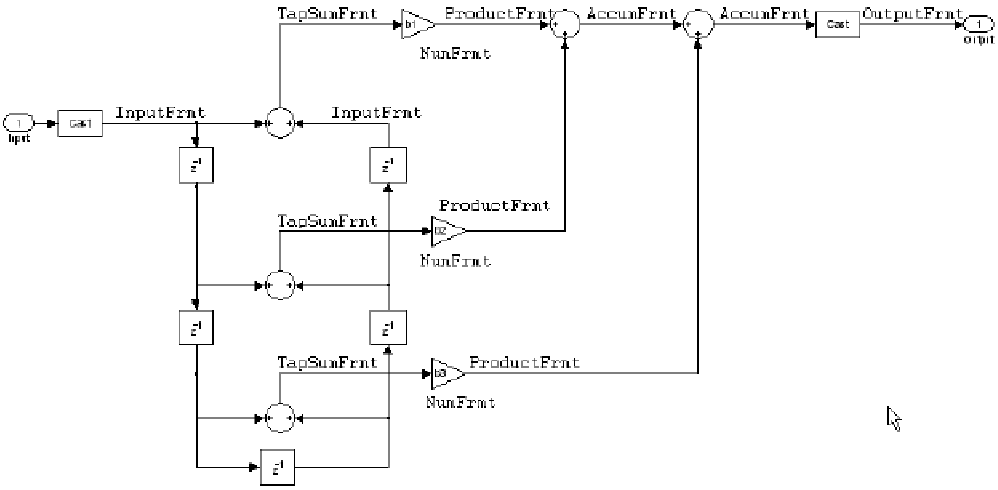
Example — Specifying an Lattice ARMA Filter

The following code specifies a fourth-order lattice ARMA filter structure for a quantized filter `hq`, starting from `hd`, a floating-point version of the filter.

```
k = [.66 .7 .44 .66];
v = [1 0 0];
hd=dfilt.latticearma(k,v);
hq.arithmetic = 'fixed';
```

Direct Form Symmetric FIR Filter Structure (Any Order)

Shown in the next figure, you see signal flow that depicts a *direct form symmetric FIR* filter structure that directly realizes a fifth-order direct form symmetric FIR filter. Filter coefficients are labeled $b(i)$, $i = 1, ..., n$, and states (used for initial and final state values in filtering) are labeled $z(i)$. Showing the filter structure used when you select `fixed` for the `Arithmetic` property value, the first figure details the properties in the filter object.



Example — Specifying an Odd-Order Direct Form Symmetric FIR Filter

By using the following code in MATLAB, you can specify a fifth-order direct form symmetric FIR filter for a fixed-point filter `hq`:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd=dfilt.dfsymfir(b);
set(hq,'arithmetic','fixed');
```

Assigning Filter Coefficients

The syntax you use to assign filter coefficients for your floating-point or fixed-point filter depends on the structure you select for your filter.

Converting Filters Between Representations

Filter conversion functions in this toolbox and in Signal Processing Toolbox software let you convert filter transfer functions to other filter forms, and from other filter forms to transfer function form. Relevant conversion functions include the following functions.

Conversion Function	Description
`ca2tf`	Converts from a coupled allpass filter to a transfer function.
`cl2tf`	Converts from a lattice coupled allpass filter to a transfer function.

Conversion Function	Description
convert	Convert a discrete-time filter from one filter structure to another.
sos	Converts quantized filters to create second-order sections. We recommend this method for converting quantized filters to second-order sections.
tf2ca	Converts from a transfer function to a coupled allpass filter.
tf2cl	Converts from a transfer function to a lattice coupled allpass filter.
tf2latc	Converts from a transfer function to a lattice filter.
tf2sos	Converts from a transfer function to a second-order section form.
tf2ss	Converts from a transfer function to state-space form.
tf2zp	Converts from a rational transfer function to its factored (single section) form (zero-pole-gain form).
zp2sos	Converts a zero-pole-gain form to a second-order section form.
zp2ss	Conversion of zero-pole-gain form to a state-space form.
zp2tf	Conversion of zero-pole-gain form to transfer functions of multiple order sections.

Note that these conversion routines do not apply to `dfilt` objects.

The function `convert` is a special case — when you use convert to change the filter structure of a fixed-point filter, you lose all of the filter states and settings. Your new filter has default values for all properties, and it in not fixed-point.

To demonstrate the changes that occur, convert a fixed-point direct form I transposed filter to direct form II structure.

```
hd=dfilt.df1t

hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
```

```
        PersistentMemory: false
                  States: Numerator:  [0x0 double]
                          Denominator:[0x0 double]

hd.arithmetic='fixed'
hd =

         FilterStructure: 'Direct-Form I Transposed'
              Arithmetic: 'fixed'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: Numerator:  [0x0 fi]
                          Denominator:[0x0 fi]

convert(hd,'df2')

Warning: Using reference filter for structure conversion.
Fixed-point attributes will not be converted.

ans =

         FilterStructure: 'Direct-Form II'
              Arithmetic: 'double'
               Numerator: 1
             Denominator: 1
        PersistentMemory: false
                  States: [0x1 double]
```

You can specify a filter with L sections of arbitrary order by

1. Factoring your entire transfer function with `tf2zp`. This converts your transfer function to zero-pole-gain form.
2. Using `zp2tf` to compose the transfer function for each section from the selected first-order factors obtained in step 1.

Note You are not required to normalize the leading coefficients of each section's denominator polynomial when you specify second-order sections, though `tf2sos` does.

Gain

dfilt.scalar filters have a gain value stored in the gain property. By default the gain value is one — the filter acts as a wire.

InputFracLength

InputFracLength defines the fraction length assigned to the input data for your filter. Used in tandem with InputWordLength, the pair defines the data format for input data you provide for filtering.

As with all fraction length properties in dfilt objects, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, in this case InputWordLength, as well.

InputWordLength

Specifies the number of bits your filter uses to represent your input data. Your word length option is limited by the arithmetic you choose — up to 32 bits for double, float, and fixed. Setting Arithmetic to single (single-precision floating-point) limits word length to 16 bits. The default value is 16 bits.

Ladder

Included as a property in dfilt.latticearma filter objects, Ladder contains the denominator coefficients that form an IIR lattice filter object. For instance, the following code creates a high pass filter object that uses the lattice ARMA structure.

```
[b,a]=cheby1(5,.5,.5,'high')

b =

    0.0282   -0.1409    0.2817   -0.2817    0.1409   -0.0282

a =

    1.0000    0.9437    1.4400    0.9629    0.5301    0.1620

hd=dfilt.latticearma(b,a)

hd =

         FilterStructure: [1x44 char]
```

```
            Arithmetic: 'double'
               Lattice: [1x6 double]
                Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
      PersistentMemory: false
                States: [6x1 double]

hd.arithmetic='fixed'

hd =

       FilterStructure: [1x44 char]
            Arithmetic: 'fixed'
               Lattice: [1x6 double]
                Ladder: [1 0.9437 1.4400 0.9629 0.5301 0.1620]
      PersistentMemory: false
                States: [1x1 embedded.fi]

       CoeffWordLength: 16
        CoeffAutoScale: true
                Signed: true

       InputWordLength: 16
       InputFracLength: 15

      OutputWordLength: 16
            OutputMode: 'AvoidOverflow'

       StateWordLength: 16
       StateFracLength: 15

           ProductMode: 'FullPrecision'

       AccumWordLength: 40
         CastBeforeSum: true

             RoundMode: 'convergent'
          OverflowMode: 'wrap'
```

LadderAccumFracLength

Autoregressive, moving average lattice filter objects (`lattticearma`) use ladder coefficients to define the filter. In combination with `LadderFracLength` and `CoeffWordLength`, these three properties specify or reflect how the accumulator outputs data stored there. As with all fraction length properties, `LadderAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. The default value is 29 bits.

LadderFracLength

To let you control the way your `latticearma` filter interprets the denominator coefficients, `LadderFracLength` sets the fraction length applied to the ladder coefficients for your filter. The default value is 14 bits.

As with all fraction length properties, `LadderFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers.

Lattice

When you create a lattice-based IIR filter, your numerator coefficients (from your IIR prototype filter or the default `dfilt` lattice filter function) get stored in the `Lattice` property of the `dfilt` object. The properties `CoeffWordLength` and `LatticeFracLength` define the data format the object uses to represent the lattice coefficients. By default, lattice coefficients are in double-precision format.

LatticeAccumFracLength

Lattice filter objects (`latticeallpass`, `latticearma`, `latticemamax`, and `latticemamin`) use lattice coefficients to define the filter. In combination with `LatticeFracLength` and `CoeffWordLength`, these three properties specify how the accumulator outputs lattice coefficient-related data stored there. As with all fraction length properties, `LatticeAccumFracLength` can be any integer, including integers larger than `AccumWordLength`, and positive or negative integers. By default, the property is set to 31 bits.

LatticeFracLength

To let you control the way your filter interprets the denominator coefficients, `LatticeFracLength` sets the fraction length applied to the lattice coefficients for your lattice filter. When you create the default lattice filter, `LatticeFracLength` is 16 bits.

As with all fraction length properties, `LatticeFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers.

MultiplicandFracLength

Each input data element for a multiply operation has both word length and fraction length to define its representation. `MultiplicandFracLength` sets the fraction length to use when the filter object performs any multiply operation during filtering. For default filters, this is set to 15 bits.

As with all word and fraction length properties, MultiplicandFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers.

MultiplicandWordLength

Each input data element for a multiply operation has both word length and fraction length to define its representation. MultiplicandWordLength sets the word length to use when the filter performs any multiply operation during filtering. For default filters, this is set to 16 bits. Only the df1t and df1tsos filter objects include the MultiplicandFracLength property.

Only the df1t and df1tsos filter objects include the MultiplicandWordLength property.

NumAccumFracLength

Filter structures df1, df1t, df2, and df2t that use fixed arithmetic have this property that defines the fraction length applied to numerator coefficients in output from the accumulator. In combination with AccumWordLength, the NumAccumFracLength property fully specifies how the accumulator outputs numerator-related data stored there.

As with all fraction length properties, NumAccumFracLength can be any integer, including integers larger than AccumWordLength, and positive or negative integers. 30 bits is the default value when you create the filter object. To be able to change the value for this property, set FilterInternals for the filter to SpecifyPrecision.

Numerator

The numerator coefficients for your filter, taken from the prototype you start with or from the default filter, are stored in this property. Generally this is a 1-by-N array of data in double format, where N is the length of the filter.

All of the filter objects include Numerator, except the lattice-based and second-order section filters, such as dfilt.latticema and dfilt.df1tsos.

NumFracLength

Property NumFracLength contains the value that specifies the fraction length for the numerator coefficients for your filter. NumFracLength specifies the fraction length used to interpret the numerator coefficients. Used in combination with `CoeffWordLength`, these two properties define the interpretation of the coefficients stored in the vector that contains the numerator coefficients.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 15 bits, with the `CoeffWordLength` of 16 bits.

NumProdFracLength

A property of all of the direct form IIR `dfilt` objects, except the ones that implement second-order sections, `NumProdFracLength` specifies the fraction length applied to data output from product operations the filter performs on numerator coefficients.

Looking at the signal flow diagram for the `dfilt.df1t` filter, for example, you see that denominators and numerators are handled separately. When you set `ProductMode` to `SpecifyPrecision`, you can change the `NumProdFracLength` setting manually. Otherwise, for multiplication operations that use the numerator coefficients, the filter sets the word length as defined by the `ProductMode` setting.

NumStateFracLength

All the variants of the direct form I structure include the property `NumStateFracLength` to store the fraction length applied to the numerator states for your filter object. By default, this property has the value 15 bits, with the `CoeffWordLength` of 16 bits, which you can change after you create the filter object.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well.

NumStateWordLength

When you look at the flow diagram for the `df1sos` filter object, the states associated with the numerator coefficient operations take the data format from this property and the `NumStateFracLength` property. In combination, these properties fully specify how the filter interprets the state it uses.

As with all fraction length properties, the value you enter here can be any negative or positive integer, or zero. Fraction length can be larger than the associated word length, as well. By default, the value is 16 bits, with the `NumStateFracLength` of 11 bits.

OutputFracLength

To define the output from your filter object, you need both the word and fraction lengths. `OutputFracLength` determines the fraction length applied to interpret the output data. Combining this with `OutputWordLength` fully specifies the format of the output.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

OutputMode

Sets the mode the filter uses to scale the filtered (output) data. You have the following choices:

- `AvoidOverflow` — directs the filter to set the property that controls the output data fraction length to avoid causing the data to overflow. In a `df2` filter, this would be the `OutputFracLength` property.
- `BestPrecision` — directs the filter to set the property that controls the output data fraction length to maximize the precision in the output data. For `df1t` filters, this is the `OutputFracLength` property. When you change the word length (`OutputWordLength`), the filter adjusts the fraction length to maintain the best precision for the new word size.
- `SpecifyPrecision` — lets you set the fraction length used by the filtered data. When you select this choice, you can set the output fraction length using the `OutputFracLength` property to define the output precision.

All filters include this property except the direct form I filter which takes the output format from the filter states.

Here is an example that changes the mode setting to `bestprecision`, and then adjusts the word length for the output.

```
hd=dfilt.df2

hd =

         FilterStructure: 'Direct-Form II'

      NumAccumFracLength: 29
      DenAccumFracLength: 29
           CastBeforeSum: 1
```

Changing the `OutputWordLength` to `8` bits caused the filter to change the `OutputFracLength` to `5` bits to keep the best precision for the output data.

OutputWordLength

Use the property `OutputWordLength` to set the word length used by the output from your filter. Set this property to a value that matches your intended hardware. For example, some digital signal processors use 32-bit output so you would set `OutputWordLength` to `32`.

```
[b,a] = butter(6,.5);
hd=dfilt.df1t(b,a);

set(hd,'arithmetic','fixed')

hd

               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

When you create a filter object, this property starts with the value 16.

OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest. `saturate` is the default value for `OverflowMode`.
- `'wrap'` — wrap all overflows to the range of representable values.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

Note Numbers in floating-point filters that extend beyond the dynamic range overflow to ±`inf`.

ProductFracLength

After you set `ProductMode` for a fixed-point filter to `SpecifyPrecision`, this property becomes available for you to change. `ProductFracLength` sets the fraction length the filter uses for the results of multiplication operations. Only the FIR filters such as asymmetric FIRs or lattice autoregressive filters include this dynamic property.

Your fraction length can be any negative or positive integer, or zero. In addition, the fraction length you specify can be larger than the associated word length. Generally, the default value is 11 bits.

ProductMode

This property, available when your filter is in fixed-point arithmetic mode, specifies how the filter outputs the results of multiplication operations. All `dfilt` objects include this property when they use fixed-point arithmetic.

When available, you select from one of the following values for `ProductMode`:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length it uses to represent the results of multiplication operations. The setting allow the product to retain the precision provided by the inputs (multiplicands) to the operation.
- `KeepMSB` — means you specify the word length for representing product operation results. The filter sets the fraction length to discard the LSBs, keep the higher order bits in the data, and maintain the precision.
- `KeepLSB` — means you specify the word length for representing the product operation results. The filter sets the fraction length to discard the MSBs, keep the lower order bits, and maintain the precision. Compare to the `KeepMSB` option.
- `SpecifyPrecision` — means you specify the word length and the fraction length to apply to data output from product operations.

When you switch to fixed-point filtering from floating-point, you are most likely going to throw away some data bits after product operations in your filter, perhaps because you have limited resources. When you have to discard some bits, you might choose to discard the least significant bits (LSB) from a result since the resulting quantization error would be small as the LSBs carry less weight. Or you might choose to keep the LSBs because the results have MSBs that are mostly zero, such as when your values are small relative to the range of the format in which they are represented. So the options for `ProductMode` let you choose how to maintain the information you need from the accumulator.

For more information about data formats, word length, and fraction length in fixed-point arithmetic, refer to “Notes About Fraction Length, Word Length, and Precision” on page 6-26.

ProductWordLength

You use `ProductWordLength` to define the data word length used by the output from multiplication operations. Set this property to a value that matches your intended application. For example, the default value is 32 bits, but you can set any word length.

```
set(hq,'arithmetic','fixed');
set(hq,'ProductWordLength',64);
```

Note that `ProductWordLength` applies only to filters whose `Arithmetic` property value is `fixed`.

PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false` — the filter does not retain memory about filtering operations from one to the next. Maintaining memory (setting `PersistentMemory` to `true`) lets you filter large data sets as collections of smaller subsets and get the same result.

In this example, filter `hd` first filters data `xtot` in one pass. Then you can use `hd` to filter `x` as two separate data sets. The results `ytot` and `ysec` are the same in both cases.

```
xtot=[x,x];
ytot=filter(hd,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hd,x) filter(hd,x)]

ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

RoundMode

The `RoundMode` property value specifies the rounding method used for quantizing numerical values. Specify the `RoundMode` property values as one of the following five strings.

RoundMode String	Description of Rounding Algorithm
`Ceiling`	Round toward positive infinity.
`Floor`	Round toward negative infinity.

RoundMode String	Description of Rounding Algorithm
Nearest	Round toward nearest. Ties round toward positive infinity.
Nearest(Convergent)	Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
Round	Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.
Zero	Round toward zero.

The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.

ScaleValueFracLength

Filter structures `df1sos`, `df1tsos`, `df2sos`, and `df2tsos` that use `fixed` arithmetic have this property that defines the fraction length applied to the scale values the filter uses between sections. In combination with `CoeffWordLength`, these two properties fully specify how the filter interprets and uses the scale values stored in the property `ScaleValues`. As with fraction length properties, `ScaleValueFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter.

ScaleValues

The `ScaleValues` property values are specified as a scalar (or vector) that introduces scaling for inputs (and the outputs from cascaded sections in the vector case) during filtering:

- When you only have a single section in your filter:
  - Specify the `ScaleValues` property value as a scalar if you only want to scale the input to your filter.
  - Specify the `ScaleValues` property as a vector of length 2 if you want to specify scaling to the input (scaled with the first entry in the vector) and the output (scaled with the last entry in the vector).

- When you have L cascaded sections in your filter:
  - Specify the ScaleValues property value as a scalar if you only want to scale the input to your filter.
  - Specify the value for the ScaleValues property as a vector of length L+1 if you want to scale the inputs to every section in your filter, along with the output:

    The first entry of your vector specifies the input scaling

    Each successive entry specifies the scaling at the output of the next section

    The final entry specifies the scaling for the filter output.

The default value for ScaleValues is 0.

The interpretation of this property is described as follows with diagrams in "Interpreting the ScaleValues Property" on page 6-75.

Note: The value of the ScaleValues property is not quantized. Data affected by the presence of a scaling factor in the filter is quantized according to the appropriate data format.

When you apply normalize to a fixed-point filter, the value for the ScaleValues property is changed accordingly.

It is good practice to choose values for this property that are either positive or negative powers of two.

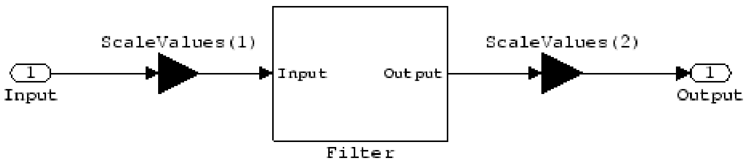
Interpreting the ScaleValues Property

When you specify the values of the ScaleValues property of a quantized filter, the values are entered as a vector, the length of which is determined by the number of cascaded sections in your filter:

- When you have only one section, the value of the Scalevalues property can be a scalar or a two-element vector.
- When you have L cascaded sections in your filter, the value of the ScaleValues property can be a scalar or an L+1-element vector.

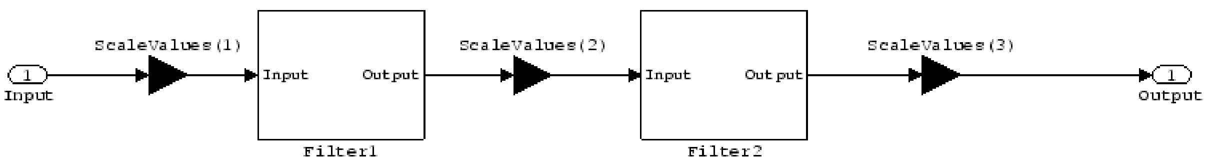
The following diagram shows how the ScaleValues property values are applied to a quantized filter with only one section.

Application of ScaleValues to a Single Section



The following diagram shows how the `ScaleValues` property values are applied to a quantized filter with two sections.

Application of ScaleValues to Multiple Sections



Signed

When you create a `dfilt` object for fixed-point filtering (you set the property `Arithmetic` to `fixed`, the property `Signed` specifies whether the filter interprets coefficients as signed or unsigned. This setting applies only to the coefficients. While the default setting is `true`, meaning that all coefficients are assumed to be signed, you can change the setting to `false` after you create the fixed-point filter.

For example, create a fixed-point direct-form II transposed filter with both negative and positive coefficients, and then change the property value for `Signed` from `true` to `false` to see what happens to the negative coefficient values.

```
hd=dfilt.df2t(-5:5)

hd =

         FilterStructure: 'Direct-Form II Transposed'
              Arithmetic: 'double'
               Numerator: [-5 -4 -3 -2 -1 0 1 2 3 4 5]
```

```
            Denominator: 1
       PersistentMemory: false
                 States: [10x1 double]

set(hd,'arithmetic','fixed')
hd.numerator

ans =

    -5    -4    -3    -2    -1     0
     1     2     3     4     5

set(hd,'signed',false)
hd.numerator

ans =

     0     0     0     0     0     0
     1     2     3     4     5
```

Using unsigned coefficients limits you to using only positive coefficients in your filter. `Signed` is a dynamic property — you cannot set or change it until you switch the setting for the `Arithmetic` property to `fixed`.

SosMatrix

When you convert a `dfilt` object to second-order section form, or create a second-order section filter, `sosMatrix` holds the filter coefficients as property values. Using the `double` data type by default, the matrix is in [sections coefficients per section] form, displayed as `[15-x-6]` for filters with 6 coefficients per section and 15 sections, [15 6].

To demonstrate, the following code creates an order 30 filter using second-order sections in the direct-form II transposed configuration. Notice the `sosMatrix` property contains the coefficients for all the sections.

```
d = fdesign.lowpass('n,fc',30,0.5);
hd = butter(d);

hd =

  FilterStructure: 'Direct-Form II, Second-Order Sections'
       Arithmetic: 'double'
        sosMatrix: [15x6 double]
      ScaleValues: [16x1 double]
```

```
PersistentMemory: false
          States: [2x15 double]

hd.arithmetic='fixed'

hd =

    1.0000    2.0000    1.0000    1.0000         0    0.0062
    1.0000    2.0000    1.0000    1.0000         0    0.0007
```

The SOS matrix is an M-by-6 matrix, where M is the number of sections in the second-order section filter. Filter `hd` has M equal to 15 as shown above (15 rows). Each row of the SOS matrix contains the numerator and denominator coefficients (b's and a's) and the scale factors of the corresponding section in the filter.

SectionInputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of `SectionInputAutoScale`. The representation the filter uses between the filter sections depends on whether the value of `SectionInputAutoScale` is `true` or `false`.

- `SectionInputAutoScale` = `true` means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. `true` is the default setting.
- `SectionInputAutoScale` = `false` removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (`SectionInputFracLength`) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting `SectionInputAutoScale` to `false` exposes the `SectionInputFracLength` property that specifies the fraction length applied to data between the sections.

SectionInputFracLength

Second-order section filters use quantizers at the input to each section of the filter. The quantizers apply to the input data entering each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the input values, use the property value in `SectionInputFracLength`.

In combination with `CoeffWordLength`, `SectionInputFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`. As with all word and fraction length properties, `SectionInputFracLength` can be any integer, including integers larger than `CoeffWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

SectionInputWordLength

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. `SectionInputWordLength` specifies the word length applied to data as it enters one filter section from the previous section. Only second-order implementations of direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier `=1`, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.

SectionOutputAutoScale

Second-order section filters include this property that determines who the filter handles data in the transitions from one section to the next in the filter.

How the filter represents the data passing from one section to the next depends on the property value of SectionOutputAutoScale. The representation the filter uses between the filter sections depends on whether the value of SectionOutputAutoScale is true or false.

- SectionOutputAutoScale = true means the filter chooses the fraction length to maintain the value of the data between sections as close to the output values from the previous section as possible. true is the default setting.
- SectionOutputAutoScale = false removes the automatic scaling of the fraction length for the intersection data and exposes the property that controls the coefficient fraction length (SectionOutputFracLength) so you can change it. For example, if the filter is a second-order, direct form FIR filter, setting SectionOutputAutoScale = false exposes the SectionOutputFracLength property that specifies the fraction length applied to data between the sections.

SectionOutputFracLength

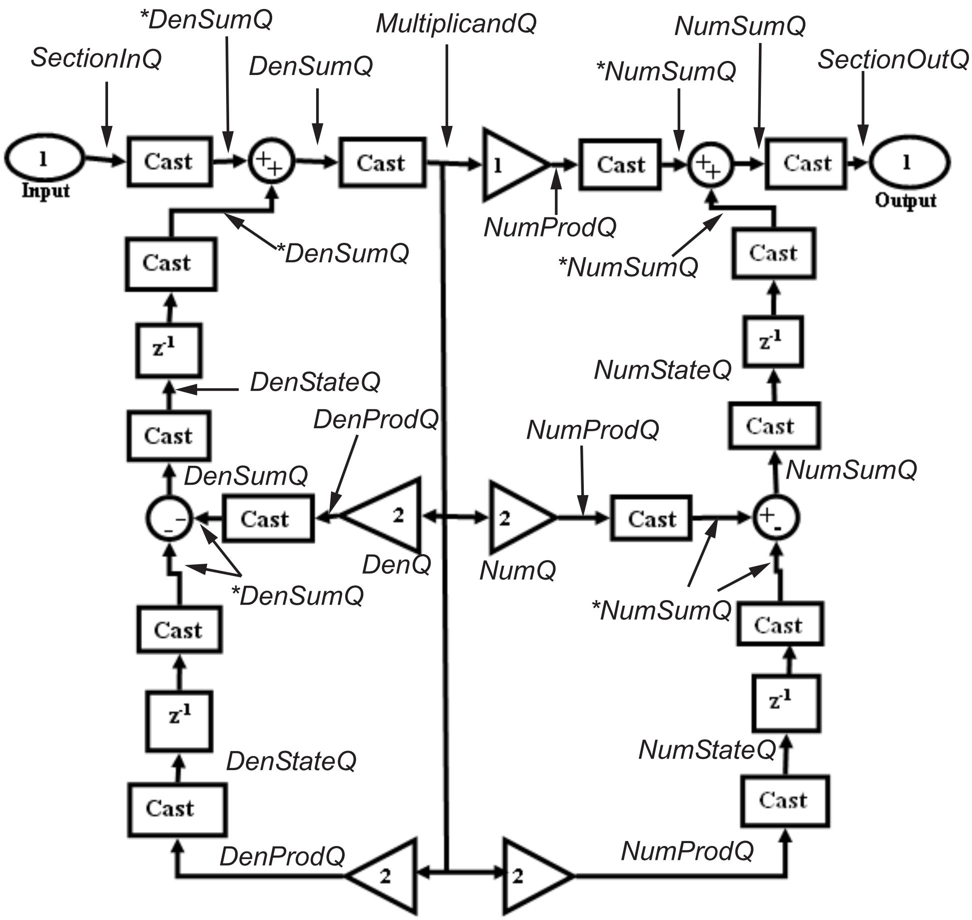
Second-order section filters use quantizers at the output from each section of the filter. The quantizers apply to the output data leaving each filter section. Note that the quantizers for each section are the same. To set the fraction length for interpreting the output values, use the property value in SectionOutputFracLength.

In combination with CoeffWordLength, SectionOutputFracLength determines how the filter interprets and uses the state values stored in the property States. As with all fraction length properties, SectionOutputFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers. 15 bits is the default value when you create the filter object.

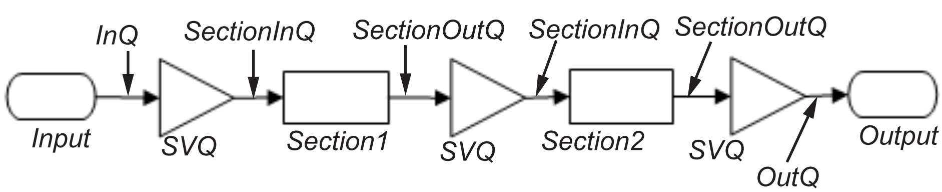
SectionOutputWordLength

SOS filters are composed of sections, each one a second-order filter. Filtering data input to the filter involves passing the data through each filter section. SectionOutputWordLength specifies the word length applied to data as it leaves one filter section to go to the next. Only second-order implementations direct-form I transposed and direct-form II transposed filters include this property.

The following diagram shows an SOS filter composed of sections (the bottom part of the diagram) and a possible internal structure of each Section (the top portion of the diagram), in this case — a direct form I transposed second order sections filter structure. Note that the output of each section is fed through a multiplier. If the gain of the multiplier =1, then the last Cast block of the Section is ignored, and the format of the output is NumSumQ.



* : only if CastBeforeSum is True



SectionOutputWordLength defaults to 16 bits.

StateAutoScale

Although all filters use states, some do not allow you to choose whether the filter automatically scales the state values to prevent overruns or bad arithmetic errors. You select either of the following settings:

- StateAutoScale = true means the filter chooses the fraction length to maintain the value of the states as close to the double-precision values as possible. When you change the word length applied to the states (where allowed by the filter structure), the filter object changes the fraction length to try to accommodate the change. true is the default setting.
- StateAutoScale = false removes the automatic scaling of the fraction length for the states and exposes the property that controls the coefficient fraction length so you can change it. For example, in a direct form I transposed SOS FIR filter, setting StateAutoScale = false exposes the NumStateFracLength and DenStateFracLength properties that specify the fraction length applied to states.

Each of the following filter structures provides the StateAutoScale property:

- df1t
- df1tsos
- df2t
- df2tsos
- dffirt

Other filter structures do not include this property.

StateFracLength

Filter states stored in the property States have both word length and fraction length. To set the fraction length for interpreting the stored filter object state values, use the property value in StateFracLength.

In combination with CoeffWordLength, StateFracLength fully determines how the filter interprets and uses the state values stored in the property States.

As with all fraction length properties, StateFracLength can be any integer, including integers larger than CoeffWordLength, and positive or negative integers. 15 bits is the default value when you create the filter object.

States

Digital filters are dynamic systems. The behavior of dynamic systems (their response) depends on the input (stimulus) to the system and the current or previous *state* of the system. You can say the system has memory or inertia. All fixed- or floating-point digital filters (as well as analog filters) have states.

Filters use the states to compute the filter output for each input sample, as well using them while filtering in loops to maintain the filter state between loop iterations. This toolbox assumes zero-valued initial conditions (the dynamic system is at rest) by default when you filter the first input sample. Assuming the states are zero initially does not mean the states are not used; they are, but arithmetically they do not have any effect.

Filter objects store the state values in the property `States`. The number of stored states depends on the filter implementation, since the states represent the delays in the filter implementation.

When you review the display for a filter object with fixed arithmetic, notice that the states return an embedded `fi` object, as you see here.

```
b = ellip(6,3,50,300/500);
hd=dfilt.dffir(b)

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'double'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
        PersistentMemory: false
                  States: [6x1 double]

hd.arithmetic='fixed'

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858 0.2938 0.0773]
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: 'on'
                  Signed: 'on'

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

             ProductMode: 'FullPrecision'
```

```
AccumWordLength: 40
  CastBeforeSum: 'on'

      RoundMode: 'convergent'
   OverflowMode: 'wrap'

InheritSettings: 'off'
```

fi objects provide fixed-point support for the filters. To learn more about the details about fi objects, refer to your Fixed-Point Designer documentation.

The property States lets you use a fi object to define how the filter interprets the filter states. For example, you can create a fi object in MATLAB, then assign the object to States, as follows:

```
statefi=fi([],16,12)

statefi =

[]
   DataTypeMode = Fixed-point: binary point scaling
         Signed = true
     Wordlength = 16
 Fractionlength = 12
```

This fi object does not have a value associated (notice the [] input argument to fi for the value), and it has word length of 16 bits and fraction length of 12 bit. Now you can apply statefi to the States property of the filter hd.

```
set(hd,'States',statefi);
Warning: The 'States' property will be reset to the value
specified at construction before filtering.
Set the 'PersistentMemory' flag to 'True'
to avoid changing this property value.
hd

hd =

         FilterStructure: 'Direct-Form FIR'
              Arithmetic: 'fixed'
               Numerator: [0.0773 0.2938 0.5858 0.7239 0.5858
                           0.2938 0.0773]
        PersistentMemory: false

```

```
             Signed: 'on'

    InputWordLength: 16
    InputFracLength: 15

   OutputWordLength: 16
         OutputMode: 'AvoidOverflow'

        ProductMode: 'FullPrecision'
    AccumWordLength: 40
      CastBeforeSum: 'on'

          RoundMode: 'convergent'
       OverflowMode: 'wrap'
```

StateWordLength

While all filters use states, some do not allow you to directly change the state representation — the word length and fraction lengths — independently. For the others, `StateWordLength` specifies the word length, in bits, the filter uses to represent the states. Filters that do not provide direct state word length control include:

- `df1`
- `dfasymfir`
- `dffir`
- `dfsymfir`

For these structures, the filter derives the state format from the input format you choose for the filter — except for the `df1` IIR filter. In this case, the numerator state format comes from the input format and the denominator state format comes from the output format. All other filter structures provide control of the state format directly.

TapSumFracLength

Direct-form FIR filter objects, both symmetric and antisymmetric, use this property. To set the fraction length for output from the sum operations that involve the filter tap weights, use the property value in `TapSumFracLength`. To enable this property, set the `TapSumMode` to `SpecifyPrecision` in your filter.

As you can see in this code example that creates a fixed-point asymmetric FIR filter, the `TapSumFracLength` property becomes available after you change the `TapSumMode` property value.

```
hd=dfilt.dfasymfir

hd =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'double'
               Numerator: 1
        PersistentMemory: false
                  States: [0x1 double]

set(hd,'arithmetic','fixed');
hd

hd =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'KeepMSB'
        TapSumWordLength: 17

             ProductMode: 'FullPrecision'

         AccumWordLength: 40

           CastBeforeSum: true
               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

With the filter now in fixed-point mode, you can change the `TapSumMode` property value to `SpecifyPrecision`, which gives you access to the `TapSumFracLength` property.

```
set(hd,'TapSumMode','SpecifyPrecision');
hd

hd =

         FilterStructure: 'Direct-Form Antisymmetric FIR'
              Arithmetic: 'fixed'
               Numerator: 1
        PersistentMemory: false
                  States: [1x1 embedded.fi]

         CoeffWordLength: 16
          CoeffAutoScale: true
                  Signed: true

         InputWordLength: 16
         InputFracLength: 15

        OutputWordLength: 16
              OutputMode: 'AvoidOverflow'

              TapSumMode: 'SpecifyPrecision'
        TapSumWordLength: 17
        TapSumFracLength: 15

             ProductMode: 'FullPrecision'

         AccumWordLength: 40

           CastBeforeSum: true
               RoundMode: 'convergent'
            OverflowMode: 'wrap'
```

In combination with `TapSumWordLength`, `TapSumFracLength` fully determines how the filter interprets and uses the state values stored in the property `States`.

As with all fraction length properties, `TapSumFracLength` can be any integer, including integers larger than `TapSumWordLength`, and positive or negative integers. 15 bits is the default value when you create the filter object.

TapSumMode

This property, available only after your filter is in fixed-point mode, specifies how the filter outputs the results of summation operations that involve the filter tap weights.

Only symmetric (`dfilt.dfsymfir`) and antisymmetric (`dfilt.dfasymfir`) FIR filters use this property.

When available, you select from one of the following values:

- `FullPrecision` — means the filter automatically chooses the word length and fraction length to represent the results of the sum operation so they retain all of the precision provided by the inputs (addends).
- `KeepMSB` — means you specify the word length for representing tap sum summation results to keep the higher order bits in the data. The filter sets the fraction length to discard the LSBs from the sum operation. This is the default property value.
- `KeepLSB` — means you specify the word length for representing tap sum summation results to keep the lower order bits in the data. The filter sets the fraction length to discard the MSBs from the sum operation. Compare to the `KeepMSB` option.
- `SpecifyPrecision` — means you specify the word and fraction lengths to apply to data output from the tap sum operations.

TapSumWordLength

Specifies the word length the filter uses to represent the output from tap sum operations. The default value is 17 bits. Only `dfasymfir` and `dfsymfir` filters include this property.

Adaptive Filter Properties

In this section...
"Compatibility" on page 6-92
"Property Summaries" on page 6-92
"Property Details for Adaptive Filter Properties" on page 6-96
"References for Adaptive Filters" on page 6-103

Compatibility

`adaptfilt` objects will be removed in a future release. Refer to the reference page for a specific `adaptfilt` object to see its recommended replacement.

Property Summaries

The following table summarizes the adaptive filter properties and provides a brief description of each. Full descriptions of each property, in alphabetical order, are given in the subsequent section.

Property	Description
`Algorithm`	Reports the algorithm the object uses for adaptation. When you construct your adaptive filter object, this property is set automatically by the constructor, such as `adaptfilt.nlms` creating an adaptive filter that uses the normalized LMS algorithm. You cannot change the value — it is read only.
`AvgFactor`	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `AvgFactor` should lie between zero and one. For default filter objects, `AvgFactor` equals (1 - `step`). `lambda` is the input argument that represents `AvgFactor`
`BkwdPredErrorPower`	Returns the minimum mean-squared prediction error. Refer to [3] in the bibliography for details about linear prediction.

Property	Description
BkwdPrediction	Returns the predicted samples generated during adaptation. Refer to [3] in the bibliography for details about linear prediction.
Blocklength	Block length for the coefficient updates. This must be a positive integer such that (l/blocklength) is also an integer. For faster execution, blocklength should be a power of two. blocklength defaults to two.
Coefficients	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input.
ConversionFactor	Conversion factor defaults to the matrix [1 -1] that specifies soft-constrained initialization. This is the gamma input argument for some of the fast transversal algorithms.
Delay	Update delay given in time samples. This scalar should be a positive integer—negative delays do not work. delay defaults to 1 for most algorithms.
DesiredSignalStates	Desired signal states of the adaptive filter. dstates defaults to a zero vector with length equal to (blocklen - 1) or (swblocklen - 1) depending on the algorithm.
EpsilonStates	Vector of the epsilon values of the adaptive filter. EpsilonStates defaults to a vector of zeros with (projectord - 1) elements.
ErrorStates	Vector of the adaptive filter error states. ErrorStates defaults to a zero vector with length equal to (projectord - 1).
FFTCoefficients	Stores the discrete Fourier transform of the filter coefficients in coeffs.
FFTStates	Stores the states of the FFT of the filter coefficients during adaptation.
FilteredInputStates	Vector of filtered input states with length equal to l - 1.

Property	Description
`FilterLength`	Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.
`ForgettingFactor`	Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.
`FwdPredErrorPower`	Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.
`FwdPrediction`	Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. Called `delta` as an input argument, this defaults to one.
`InvCov`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are `l`-by-`l`, where `l` is the filter length.
`KalmanGain`	Empty when you construct the object, this gets populated after you run the filter.
`KalmanGainStates`	Contains the states of the Kalman gain updates during adaptation.
`Leakage`	Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.
`OffsetCov`	Contains the offset covariance matrix.

Property	Description
Offset	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.
Power	A vector of 2*l elements, each initialized with the value delta from the input arguments. As you filter data, Power gets updated by the filter process.
ProjectionOrder	Projection order of the affine projection algorithm. projectord defines the size of the input signal covariance matrix and defaults to two.
ReflectionCoeffs	Coefficients determined for the reflection portion of the filter during adaptation.
ReflectionCoeffsStep	Size of the steps used to determine the reflection coefficients.
PersistentMemory	Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states and coefficients from previous filtering runs.
SecondaryPathCoeffs	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
SecondaryPathEstimate	An estimate of the secondary path filter model.
SecondaryPathStates	The states of the secondary path filter, the unknown system.
SqrtCov	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
SqrtInvCov	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

Property	Description
States	Vector of the adaptive filter states. states defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length l and another input argument to the filter object, such as projectord.
StepSize	Reports the size of the step taken between iterations of the adaptive filter process. Each adaptfilt object has a default value that best meets the needs of the algorithm.
SwBlockLength	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Like dfilt objects, adaptfilt objects have properties that govern their behavior and store some of the results of filtering operations. The following pages list, in alphabetical order, the name of every property associated with adaptfilt objects. Note that not all adaptfilt objects have all of these properties. To view the properties of a particular adaptive filter, such as an adaptfilt.bap filter, use get with the object handle, like this:

```
ha = adaptfilt.bap(32,0.5,4,1.0);
get(ha)
        PersistentMemory: false
               Algorithm: 'Block Affine Projection FIR Adaptive Filter'
            FilterLength: 32
            Coefficients: [1x32 double]
                  States: [35x1 double]
                StepSize: 0.5000
         ProjectionOrder: 4
               OffsetCov: [4x4 double]
```

get shows you the properties for ha and the values for the properties. Entering the object handle returns the same values and properties without the formatting of the list and the more familiar property names.

Property Details for Adaptive Filter Properties

Algorithm

Reports the algorithm the object uses for adaptation. When you construct you adaptive filter object, this property is set automatically. You cannot change the value—it is read only.

AvgFactor

Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `AvgFactor` should lie between zero and one. For default filter objects, `AvgFactor` equals (1 - `step`). `lambda` is the input argument that represent `AvgFactor`

BkwdPredErrorPower

Returns the minimum mean-squared prediction error in the backward direction. Refer to [3] in the bibliography for details about linear prediction.

BkwdPrediction

When you use an adaptive filter that does backward prediction, such as `adaptfilt.ftf`, one property of the filter contains the backward prediction coefficients for the adapted filter. With these coefficient, the forward coefficients, and the system under test, you have the full set of knowledge of how the adaptation occurred. Two values stored in properties compose the `BkwdPrediction` property:

- Coefficients, which contains the coefficients of the system under test, as determined using backward predictions process.
- Error, which is the difference between the filter coefficients determined by backward prediction and the actual coefficients of the sample filter. In this example, `adaptfilt.ftf` identifies the coefficients of an unknown FIR system.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
N  = 31;               % Adaptive filter order
lam = 0.99;            % RLS forgetting factor
del = 0.1;             % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);

```

Blocklength

Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.

Coefficients

Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

ConversionFactor

Conversion factor defaults to the matrix [1 -1] that specifies soft-constrained initialization. This is the `gamma` input argument for some of the fast transversal algorithms.

Delay

Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1 for most algorithms.

DesiredSignalStates

Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`blocklen` - 1) or (`swblocklen` - 1) depending on the algorithm.

EpsilonStates

Vector of the epsilon values of the adaptive filter. `EpsilonStates` defaults to a vector of zeros with (`projectord` - 1) elements.

ErrorStates

Vector of the adaptive filter error states. `ErrorStates` defaults to a zero vector with length equal to (`projectord` - 1).

FFTCoefficients

Stores the discrete Fourier transform of the filter coefficients in `coeffs`.

FFTStates

Stores the states of the FFT of the filter coefficients during adaptation.

FilteredInputStates

Vector of filtered input states with length equal to `l` - 1.

FilterLength

Contains the length of the filter. Note that this is not the filter order. Filter length is 1 greater than filter order. Thus a filter with length equal to 10 has filter order equal to 9.

ForgettingFactor

Determines how the RLS adaptive filter uses past data in each iteration. You use the forgetting factor to specify whether old data carries the same weight in the algorithm as more recent data.

This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor = 1` denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.

FwdPredErrorPower

Returns the minimum mean-squared prediction error in the forward direction. Refer to [3] in the bibliography for details about linear prediction.

FwdPrediction

Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.

InitFactor

Returns the soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.

InvCov

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix. Dimensions are `l`-by-`l`, where `l` is the filter length.

KalmanGain

Empty when you construct the object, this gets populated after you run the filter.

KalmanGainStates

Contains the states of the Kalman gain updates during adaptation.

Leakage

Contains the setting for leakage in the adaptive filter algorithm. Using a leakage factor that is not 1 forces the weights to adapt even when they have found the minimum error solution. Forcing the adaptation can improve the numerical performance of the LMS algorithm.

OffsetCov

Contains the offset covariance matrix.

Offset

Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors.

Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small, or dividing by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to one.

Power

A vector of 2*`l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.

ProjectionOrder

Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.

ReflectionCoeffs

For adaptive filters that use reflection coefficients, this property stores them.

ReflectionCoeffsStep

As the adaptive filter changes coefficient values during adaptation, the step size used between runs is stored here.

PersistentMemory

Determines whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter.

PersistentMemory returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to false.

SecondaryPathCoeffs

A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.

SecondaryPathEstimate

An estimate of the secondary path filter model.

SecondaryPathStates

The states of the secondary path filter, the unknown system.

SqrtCov

Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.

SqrtInvCov

Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.

States

Vector of the adaptive filter states. states defaults to a vector of zeros whose length depends on the chosen algorithm. Usually the length is a function of the filter length l and another input argument to the filter object, such as projectord.

StepSize

Reports the size of the step taken between iterations of the adaptive filter process. Each adaptfilt object has a default value that best meets the needs of the algorithm.

SwBlockLength

Block length of the sliding window. This integer must be at least as large as the filter length. swblocklength defaults to 16.

"Property Summaries" on page 6-104
"Property Details for Multirate Filter Properties" on page 6-108
"References for Multirate Filters" on page 6-118

Compatibility

`mfilt` objects will be removed in a future release. Refer to the reference page for a specific `mfilt` object to see its recommended replacement.

Property Summaries

The following table summarizes the multirate filter properties and provides a brief description of each. Full descriptions of each property are given in the subsequent section.

Name	Values	Default	Description
`BlockLength`	Positive integers	100	Length of each block of data input to the FFT used in the filtering. `fftfirinterp` multirate filters include this property.
`DecimationFactor`	Any positive integer	2	Amount to reduce the input sampling rate.
`DifferentialDelay`	Any integer	1	Sets the differential delay for the filter. Usually a value of one or two is appropriate.
`FilterInternals`	`FullPrecision`, `MinWordlengths`, `SpecifyWordLengths` `SpecifyPrecision`	`FullPrecision`	Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain

Name	Values	Default	Description
			the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.
`FilterStructure`	`mfilt` structure string	None	Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. You cannot set this property — it is always read only and results from your choice of `mfilt` object.
`InputOffset`	Integers	0	Contains the number of input data samples processed without generating an output sample. `InputOffset = mod(length(nx),m)` where `nx` is the number of input samples that have been processed so far and m is the decimation factor.
`InterpolationFactor`	Positive integers	2	Interpolation factor for the filter. `l` specifies the amount to increase the input sampling rate.

Name	Values	Default	Description
`NumberOfSections`	Any positive integer	2	Number of sections used in the decimator, or in the comb and integrator portions of CIC filters.
`Numerator`	Array of double values	No default values	Vector containing the coefficients of the FIR lowpass filter used for interpolation.
`OverflowMode`	saturate, [wrap]	wrap	Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either `saturate` (limit the output to the largest positive or negative representable value) or `wrap` (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.

Name	Values	Default	Description
PolyphaseAccum	Values depend on filter type. Either double, single, or fixed-point object	0	Stores the value remaining in the accumulator after the filter processes the last input sample. The stored value for PolyphaseAccum affects the next output when PersistentMemory is true and InputOffset is not equal to 0. Always provides full precision values. Compare the AccumWordLength and AccumFracLength.
PersistentMemory	false or true	false	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.
RateChangeFactors	[l,m]	[2,3] or [3,2]	Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal. The default changes depending on whether the filter decimates or interpolates.

Name	Values	Default	Description
States	Any m+1-by-n matrix of double values	2-by-2 matrix, int32	Stored conditions for the filter, including values for the integrator and comb sections. n is the number of filter sections and m is the differential delay. Stored in a filtstates object.
SpecifyWordLengths	Vector of integers	[16 16 16 16] bits	
WordLengthPerSection	Any integer or a vector of length 2*n	16	Defines the word length used in each section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WordLengthPerSection as a scalar or vector of length 2*n, where n is the number of sections. When WordLengthPerSection is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

The following sections provide details about the properties that govern the way multirate filter work. Creating any multirate filter object puts in place a number of these properties. The following pages list the mfilt object properties in alphabetical order.

Property Details for Multirate Filter Properties

BitsPerSection

Any integer or a vector of length 2*n.

Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using `wrap` arithmetic). Enter `bps` as a scalar or vector of length 2*`n`, where `n` is the number of sections. When `bps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

BlockLength

Length of each block of input data used in the filtering.

`mfilt.fftfirinterp` objects process data in blocks whose length is determined by the value you set for the `BlockLength` property. By default the property value is 100. When you set the `BlockLength` value, try choosing a value so that [`BlockLength` + `length`(filter order)] is a power of two.

Larger block lengths generally reduce the computation time.

DecimationFactor

Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. You can enter any integer value. The default value is 2.

DifferentialDelay

Sets the differential delay for the filter. Usually a value of one or two is appropriate. While you can set any value, the default is one and the maximum is usually two.

FilterInternals

Similar to the FilterInternals pane in FDATool, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.

About FilterInternals Mode

There are four usage modes for this that you set using the `FilterInternals` property in multirate filters.

- `FullPrecision` — All word and fraction lengths set to B_{max} + 1, called B_{accum} by Fred Harris in [2]. Full precision is the default setting.
- `MinWordLengths` — Minimum Word Lengths
- `SpecifyWordLengths` — Specify Word Lengths
- `SpecifyPrecision` — Specify Precision

Full Precision

In full precision mode, the word lengths of all sections and the output are set to B_{accum} as defined by

$$B_{accum} = ceil(N_{\mathrm{secs}}(Log_2(D \times M)) + InputWordLength)$$

where N_{secs} is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display looks for this mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'FullPrecision'
```

Minimum Word Lengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than B_{accum}, roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [3] in the following References section) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than B_{accum} as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from B_{accum} to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output word length for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'MinWordLengths'

OutputWordLength: 16
```

Specify Word Lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length 2*(`NumberOfSections`), where each vector element represents the word length for a section. If you specify a scalar, such as B_{accum}, the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display looks like for the `SpecifyWordLengths` mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]

OutputWordLength: 16
```

Specify Precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the word length for each section. When you enter a scalar such as B_{accum}, the CIC algorithm expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length 2*(`NumberOfSections`) with elements that represent the fraction length for each section as well. When you enter a scalar such as B_{accum}, the design applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
```

```
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]

OutputWordLength: 16
OutputFracLength: 11
```

FilterStructure

Reports the type of filter object, such as a decimator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` object. Because of the length of the names of multirate filters, `FilterStructure` often returns a vector specification for the string. For example, when you use `mfilt.firfracinterp` to design a filter, `FilterStructure` returns as [1x49 char].

```
hm=mfilt.firfracinterp

hm =

         FilterStructure: [1x49 char]
               Numerator: [1x72 double]
       RateChangeFactors: [3 2]
        PersistentMemory: false
                  States: [24x1 double]
```

InputOffset

When you decimate signals whose length is not a multiple of the decimation factor M, the last samples — (nM +1) to [(n+1)(M) -1], where *n* is an integer — are processed and used to track where the filter stopped processing input data and when to expect the next output sample. If you think of the filtering process as generating an output for a block of input data, `InputOffset` contains a count of the number of samples in the last incomplete block of input data.

Note `InputOffset` applies only when you set `PersistentMemory` to `true`. Otherwise, `InputOffset` is not available for you to use.

Two different cases can arise when you decimate a signal:

1. The input signal is a multiple of the filter decimation factor. In this case, the filter processes the input samples and generates output samples for all inputs as determined by the decimation factor. For example, processing 99 input samples with a filter that decimates by three returns 33 output samples.
2. The input signal is not a multiple of the decimation factor. When this occurs, the filter processes all of the input samples, generates output samples as determined by the decimation factor, and has one or more input samples that were processed but did not generate an output sample.

   For example, when you filter 100 input samples with a filter which has decimation factor of 3, you get 33 output samples, and 1 sample that did not generate an output. In this case, `InputOffset` stores the value 1 after the filter run.

   `InputOffset` equal to 1 indicates that, if you divide your input signal into blocks of data with length equal to your filter decimation factor, the filter processed one sample from a new (incomplete) block of data. Subsequent inputs to the filter are concatenated with this single sample to form the next block of length m.

One way to define the value stored in `InputOffset` is

```
InputOffset = mod(length(nx),m)
```

where `nx` is the number of input samples in the data set and `m` is the decimation factor.

Storing `InputOffset` in the filter allows you to stop filtering a signal at any point and start over from there, provided that the `PersistentMemory` property is set to `true`. Being able to resume filtering after stopping a signal lets you break large data sets in to smaller pieces for filtering. With `PersistentMemory` set to `true` and the `InputOffset` property in the filter, breaking a signal into sections of arbitrary length and filtering the sections is equivalent to filtering the entire signal at once.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
```

```
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

InterpolationFactor

Amount to increase the sampling rate. Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer. Two is the default value. You may use any positive value.

NumberOfSections

Number of sections used in the multirate filter. By default multirate filters use two sections, but any positive integer works.

OverflowMode

The `OverflowMode` property is specified as one of the following two strings indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest.
- `'wrap'` — wrap all overflows to the range of representable values.

  When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.

- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

Default value

: 'saturate'

Note Numbers in floating-point filters that extend beyond the dynamic range overflow to ±inf.

PolyphaseAccum

The idea behind PolyphaseAccum and AccumWordLength/AccumFracLength is to distinguish between the adders that always work in full precision (PolyphaseAccum) from the others [the adders that are controlled by the user (through AccumWordLength and AccumFracLength) and that may introduce quantization effects when you set property FilterInternals to SpecifyPrecision.

Given a product format determined by the input word and fraction lengths, and the coefficients word and fraction lengths, doing full precision accumulation means allowing enough guard bits to avoid overflows and underflows.

Property PolyphaseAccum stores the value that was in the accumulator the last time your filter ran out of input samples to process. The default value for PolyphaseAccum affects the next output only if PersistentMemory is true and InputOffset is not equal to 0.

PolyphaseAccum stores data in the format for the filter arithmetic. Double-precision filters store doubles in PolyphaseAccum. Single-precision filter store singles in PolyphaseAccum. Fixed-point filters store fi objects in PolyphaseAccum.

PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true` — the filter retains memory about filtering operations from one to the next. Maintaining memory lets you filter large data sets as collections of smaller subsets and get the same result.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1);  % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

         0   -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

RateChangeFactors

Reports the decimation (`m`) and interpolation (`l`) factors for the filter object when you create fractional integrators and decimators, although `m` and `l` are used as arguments to both decimators and integrators, applying the same meaning. Combining these factors as input arguments to the fractional decimator or integrator results in the final rate change for the signal.

For decimating filters, the default is [2,3]. For integrators, [3,2].

States

Stored conditions for the filter, including values for the integrator and comb sections. `m` is the differential delay and `n` is the number of sections in the filter.

About the States of Multirate Filters

In the `states` property you find the states for both the integrator and comb portions of the filter, stored in a `filtstates` object. `states` is a matrix of dimensions `m`+1-by-`n`, with the states in CIC filters apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.

- States for the comb portion fill the remaining rows in the state matrix.

In the state matrix, state values are specified and stored in `double` format.

States stores conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter, including values for the interpolator and comb states.

The number of states is (`lh`-1)*`m`+(l-1)*(`lo`+`mo`) where `lh` is the length of each subfilter, and `l` and `m` are the interpolation and decimation factors. `lo` and `mo`, the input and output delays between each interpolation phase, are integers from Euclid's theorem such that `lo`*l-`mo`*`m` = -1 (refer to the reference for more details). Use `euclidfactors` to get `lo` and `mo` for an `mfilt.firfracdecim` object.

`States` defaults to a vector of zeros that has length equal to `nstates`(`hm`)

Glossary

This glossary defines terms related to fixed-point data types and numbers. These terms may appear in some or all of the documents that describe MathWorks® products that have fixed-point support.

arithmetic shift
Shift of the bits of a binary word for which the sign bit is recycled for each bit shift to the right. A zero is incorporated into the least significant bit of the word for each bit shift to the left. In the absence of overflows, each arithmetic shift to the right is equivalent to a division by 2, and each arithmetic shift to the left is equivalent to a multiplication by 2.

See also binary point, binary word, bit, logical shift, most significant bit

bias
Part of the numerical representation used to interpret a fixed-point number. Along with the slope, the bias forms the scaling of the number. Fixed-point numbers can be represented as

$$\textit{real-world value} = (\textit{slope} \times \textit{stored integer}) + \textit{bias}$$

where the slope can be expressed as

$$\textit{slope} = \textit{fractional slope} \times 2^{\textit{exponent}}$$

See also fixed-point representation, fractional slope, integer, scaling, slope, [Slope Bias]

binary number
Value represented in a system of numbers that has two as its base and that uses 1's and 0's (bits) for its notation.

See also bit

binary point
Symbol in the shape of a period that separates the integer and fractional parts of a binary number. Bits to the left of the binary point are integer bits and/or sign bits, and bits to the right of the binary point are fractional bits.

See also binary number, bit, fraction, integer, radix point

binary point-only scaling

Scaling of a binary number that results from shifting the binary point of the number right or left, and which therefore can only occur by powers of two.

See also binary number, binary point, scaling

binary word

Fixed-length sequence of bits (1's and 0's). In digital hardware, numbers are stored in binary words. The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

See also bit, data type, word

bit

Smallest unit of information in computer software or hardware. A bit can have the value 0 or 1.

ceiling (round toward)

Rounding mode that rounds to the closest representable number in the direction of positive infinity. This is equivalent to the `ceil` mode in Fixed-Point Designer software.

See also convergent rounding, floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

contiguous binary point

Binary point that occurs within the word length of a data type. For example, if a data type has four bits, its contiguous binary point must be understood to occur at one of the following five positions:

.0000
0.000
00.00
000.0
0000.

See also data type, noncontiguous binary point, word length

convergent rounding

Rounding mode that rounds to the nearest allowable quantized value. Numbers that are exactly halfway between the two nearest allowable quantized values are rounded up only if the least significant bit (after rounding) would be set to 0.

See also ceiling (round toward), floor (round toward), nearest (round toward), rounding, truncation, zero (round toward)

data type

Set of characteristics that define a group of values. A fixed-point data type is defined by its word length, its fraction length, and whether it is signed or unsigned. A floating-point data type is defined by its word length and whether it is signed or unsigned.

See also fixed-point representation, floating-point representation, fraction length, signedness, word length

data type override

Parameter in the Fixed-Point Tool that allows you to set the output data type and scaling of fixed-point blocks on a system or subsystem level.

See also data type, scaling

exponent

Part of the numerical representation used to express a floating-point or fixed-point number.

1. Floating-point numbers are typically represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

2. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

The exponent of a fixed-point number is equal to the negative of the fraction length:

$$exponent = -1 \times fraction\ length$$

See also bias, fixed-point representation, floating-point representation, fraction length, fractional slope, integer, mantissa, slope

fixed-point representation

Method for representing numerical values and data types that have a set range and precision.

1. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

The slope and the bias together represent the scaling of the fixed-point number.

2. Fixed-point data types can be defined by their word length, their fraction length, and whether they are signed or unsigned.

See also bias, data type, exponent, fraction length, fractional slope, integer, precision, range, scaling, slope, word length

floating-point representation

Method for representing numerical values and data types that can have changing range and precision.

1. Floating-point numbers can be represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

2. Floating-point data types are defined by their word length.

See also data type, exponent, mantissa, precision, range, word length

floor (round toward)

Rounding mode that rounds to the closest representable number in the direction of negative infinity.

See also ceiling (round toward), convergent rounding, nearest (round toward), rounding, truncation, zero (round toward)

fraction

Part of a fixed-point number represented by the bits to the right of the binary point. The fraction represents numbers that are less than one.

See also binary point, bit, fixed-point representation

fraction length

Number of bits to the right of the binary point in a fixed-point representation of a number.

See also binary point, bit, fixed-point representation, fraction

fractional slope

Part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

The term *slope adjustment* is sometimes used as a synonym for fractional slope.

See also bias, exponent, fixed-point representation, integer, slope

full range

The broadest range available for a data type. From $-\infty$ to ∞ for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from `-128` to `127` for a signed 8–bit integer. Also known as representable range.

guard bits

Extra bits in either a hardware register or software simulation that are added to the high end of a binary word to ensure that no information is lost in case of overflow.

See also binary word, bit, overflow

incorrect range

A range that is too restrictive and does not include values that can actually occur in the model element. A range that is too broad is not considered incorrect because it will not lead to overflow.

See also range analysis

integer

1. Part of a fixed-point number represented by the bits to the left of the binary point. The integer represents numbers that are greater than or equal to one.

2. Also called the "stored integer." The raw binary number, in which the binary point is assumed to be at the far right of the word. The integer is part of the numerical representation used to express a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also bias, fixed-point representation, fractional slope, integer, real-world value, slope

integer length

Number of bits to the left of the binary point in a fixed-point representation of a number.

See also binary point, bit, fixed-point representation, fraction length, integer

least significant bit (LSB)

Bit in a binary word that can represent the smallest value. The LSB is the rightmost bit in a big-endian-ordered binary word. The weight of the LSB is related to the fraction length according to

$$weight\ of\ LSB = 2^{-fraction\ length}$$

See also big-endian, binary word, bit, most significant bit

logical shift

Shift of the bits of a binary word, for which a zero is incorporated into the most significant bit for each bit shift to the right and into the least significant bit for each bit shift to the left.

See also arithmetic shift, binary point, binary word, bit, most significant bit

mantissa

Part of the numerical representation used to express a floating-point number. Floating-point numbers are typically represented as

$$real\text{-}world\ value = mantissa \times 2^{exponent}$$

See also exponent, floating-point representation

model element

Entities in a model that range analysis software tracks, for example, blocks, signals, parameters, block internal data (such as accumulators, products).

See also range analysis

most significant bit (MSB)

Bit in a binary word that can represent the largest value. The MSB is the leftmost bit in a big-endian-ordered binary word.

See also binary word, bit, least significant bit

nearest (round toward)

Rounding mode that rounds to the closest representable number, with the exact midpoint rounded to the closest representable number in the direction of positive infinity. This is equivalent to the `nearest` mode in Fixed-Point Designer software.

See also ceiling (round toward), convergent rounding, floor (round toward), rounding, truncation, zero (round toward)

noncontiguous binary point

Binary point that is understood to fall outside the word length of a data type. For example, the binary point for the following 4-bit word is understood to occur two bits to the right of the word length,

0000__.

thereby giving the bits of the word the following potential values:

$2^5 2^4 2^3 2^2$ __.

See also binary point, data type, word length

one's complement representation

Representation of signed fixed-point numbers. Negating a binary number in one's complement requires a bitwise complement. That is, all 0's are flipped to 1's and all 1's are flipped to 0's. In one's complement notation there are two ways to represent zero. A binary word of all 0's represents "positive" zero, while a binary word of all 1's represents "negative" zero.

See also binary number, binary word, sign/magnitude representation, signed fixed-point, two's complement representation

overflow

Situation that occurs when the magnitude of a calculation result is too large for the range of the data type being used. In many cases you can choose to either saturate or wrap overflows.

See also saturation, wrapping

padding

Extending the least significant bit of a binary word with one or more zeros.

See also least significant bit

precision

1. Measure of the smallest numerical interval that a fixed-point data type and scaling can represent, determined by the value of the number's least significant bit. The precision is given by the slope, or the number of fractional bits. The term *resolution* is sometimes used as a synonym for this definition.

2. Measure of the difference between a real-world numerical value and the value of its quantized representation. This is sometimes called quantization error or quantization noise.

See also data type, fraction, least significant bit, quantization, quantization error, range, slope

Q format

Representation used by Texas Instruments™ to encode signed two's complement fixed-point data types. This fixed-point notation takes the form

$Qm.n$

where

- Q indicates that the number is in Q format.
- m is the number of bits used to designate the two's complement integer part of the number.
- n is the number of bits used to designate the two's complement fractional part of the number, or the number of bits to the right of the binary point.

In Q format notation, the most significant bit is assumed to be the sign bit.

See also binary point, bit, data type, fixed-point representation, fraction, integer, two's complement

quantization

Representation of a value by a data type that has too few bits to represent it exactly.

See also bit, data type, quantization error

quantization error

Error introduced when a value is represented by a data type that has too few bits to represent it exactly, or when a value is converted from one data type to a shorter data type. Quantization error is also called quantization noise.

See also bit, data type, quantization

radix point

Symbol in the shape of a period that separates the integer and fractional parts of a number in any base system. Bits to the left of the radix point are integer and/or sign bits, and bits to the right of the radix point are fraction bits.

See also binary point, bit, fraction, integer, sign bit

range

Span of numbers that a certain data type can represent.

See also data type, full range, precision, representable range

range analysis

Static analysis of model to derive minimum and maximum range values for elements in the model. The software statically analyzes the ranges of the individual computations in the model based on specified design ranges, inputs, and the semantics of the calculation.

real-world value

Stored integer value with fixed-point scaling applied. Fixed-point numbers can be represented as

$$real\text{-}world\ value = 2^{-fraction\ length} \times stored\ integer$$

or

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also integer

representable range

The broadest range available for a data type. From –∞ to ∞ for floating-point types. For integer types, the representable range is the range from the smallest to largest integer value (finite) the type can represent. For example, from -128 to 127 for a signed 8–bit integer. Also known as full range.

resolution

See **precision**

rounding

Limiting the number of bits required to express a number. One or more least significant bits are dropped, resulting in a loss of precision. Rounding is necessary when a value cannot be expressed exactly by the number of bits designated to represent it.

See also bit, ceiling (round toward), convergent rounding, floor (round toward), least significant bit, nearest (round toward), precision, truncation, zero (round toward)

saturation

Method of handling numeric overflow that represents positive overflows as the largest positive number in the range of the data type being used, and negative overflows as the largest negative number in the range.

See also overflow, wrapping

scaled double

A double data type that retains fixed-point scaling information. For example, in Simulink and Fixed-Point Designer software you can use data type override to convert your fixed-point data types to scaled doubles. You can then simulate to determine the ideal floating-point behavior of your system. After you gather that information you can turn data type override off to return to fixed-point data types, and your quantities still have their original scaling information because it was held in the scaled double data types.

scaling

1. Format used for a fixed-point number of a given word length and signedness. The slope and bias together form the scaling of a fixed-point number.

2. Changing the slope and/or bias of a fixed-point number without changing the stored integer.

See also bias, fixed-point representation, integer, slope

shift

Movement of the bits of a binary word either toward the most significant bit ("to the left") or toward the least significant bit ("to the right"). Shifts to the right can be either logical, where the spaces emptied at the front of the word with each shift are filled in with zeros, or arithmetic, where the word is sign extended as it is shifted to the right.

See also arithmetic shift, logical shift, sign extension

sign bit

Bit (or bits) in a signed binary number that indicates whether the number is positive or negative.

See also binary number, bit

sign extension

Addition of bits that have the value of the most significant bit to the high end of a two's complement number. Sign extension does not change the value of the binary number.

See also binary number, guard bits, most significant bit, two's complement representation, word

sign/magnitude representation

Representation of signed fixed-point or floating-point numbers. In sign/magnitude representation, one bit of a binary word is always the dedicated sign bit, while the remaining bits of the word encode the magnitude of the number. Negation using sign/magnitude representation consists of flipping the sign bit from 0 (positive) to 1 (negative), or from 1 to 0.

See also binary word, bit, fixed-point representation, floating-point representation, one's complement representation, sign bit, signed fixed-point, signedness, two's complement representation

signed fixed-point

Fixed-point number or data type that can represent both positive and negative numbers.

See also data type, fixed-point representation, signedness, unsigned fixed-point

signedness

The signedness of a number or data type can be signed or unsigned. Signed numbers and data types can represent both positive and negative values, whereas unsigned numbers and data types can only represent values that are greater than or equal to zero.

See also data type, sign bit, sign/magnitude representation, signed fixed-point, unsigned fixed-point

slope

Part of the numerical representation used to express a fixed-point number. Along with the bias, the slope forms the scaling of a fixed-point number. Fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

where the slope can be expressed as

$$slope = fractional\ slope \times 2^{exponent}$$

See also bias, fixed-point representation, fractional slope, integer, scaling, [Slope Bias]

slope adjustment

See **fractional slope**

[Slope Bias]

Representation used to define the scaling of a fixed-point number.

See also bias, scaling, slope

stored integer

See **integer**

trivial scaling

Scaling that results in the real-world value of a number being simply equal to its stored integer value:

$$real\text{-}world\ value = stored\ integer$$

In [Slope Bias] representation, fixed-point numbers can be represented as

$$real\text{-}world\ value = (slope \times stored\ integer) + bias$$

In the trivial case, slope = 1 and bias = 0.

In terms of binary point-only scaling, the binary point is to the right of the least significant bit for trivial scaling, meaning that the fraction length is zero:

$$real\text{-}world\ value = stored\ integer \times 2^{-fraction\ length} = stored\ integer \times 2^{0}$$

Scaling is always trivial for pure integers, such as `int8`, and also for the true floating-point types `single` and `double`.

See also bias, binary point, binary point-only scaling, fixed-point representation, fraction length, integer, least significant bit, scaling, slope, [Slope Bias]

truncation

Rounding mode that drops one or more least significant bits from a number.

See also ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, zero (round toward)

two's complement representation
Common representation of signed fixed-point numbers. Negation using signed two's complement representation consists of a translation into one's complement followed by the binary addition of a one.

See also binary word, one's complement representation, sign/magnitude representation, signed fixed-point

unsigned fixed-point
Fixed-point number or data type that can only represent numbers greater than or equal to zero.

See also data type, fixed-point representation, signed fixed-point, signedness

word
Fixed-length sequence of binary digits (1's and 0's). In digital hardware, numbers are stored in words. The way hardware components or software functions interpret this sequence of 1's and 0's is described by a data type.

See also binary word, data type

word length
Number of bits in a binary word or data type.

See also binary word, bit, data type

wrapping
Method of handling overflow. Wrapping uses modulo arithmetic to cast a number that falls outside of the representable range the data type being used back into the representable range.

See also data type, overflow, range, saturation

zero (round toward)
Rounding mode that rounds to the closest representable number in the direction of zero. This is equivalent to the `fix` mode in Fixed-Point Designer software.

See also ceiling (round toward), convergent rounding, floor (round toward), nearest (round toward), rounding, truncation
