Revision History

April 2011	Online only	New for Version 6.0 (Release 2011a)
September 2011	Online only	Revised for Version 6.1 (Release 2011b)
March 2012	Online only	Revised for Version 6.2 (Release 2012a)
September 2012	Online only	Revised for Version 6.3 (Release 2012b)
March 2013	Online only	Revised for Version 6.4 (Release 2013a)
September 2013	Online only	Revised for Version 6.5 (Release 2013b)
March 2014	Online only	Revised for Version 6.6 (Release 2014a)
October 2014	Online only	Revised for Version 6.7 (Release 2014b)
March 2015	Online only	Revised for Version 6.8 (Release 2015a)
September 2015	Online only	Revised for Version 6.9 (Release 2015b)
October 2015	Online only	Rereleased for Version 6.8.1 (Release 2015aSP1)
March 2016	Online only	Revised for Version 6.10 (Release 2016a)
September 2016	Online only	Revised for Version 6.11 (Release 2016b)
March 2017	Online only	Revised for Version 6.12 (Release 2017a)

Check Bug Reports for Issues and Fixes

Software is inherently complex and is not free of errors. The output of a code generator might contain bugs, some of which are not detected by a compiler. MathWorks reports critical known bugs brought to its attention on its Bug Report system at www.mathworks.com/support/bugreports/. Use the Saved Searches and Watched Bugs tool with the search phrase "Incorrect Code Generation" to obtain a report of known bugs that produce code that might compile and execute, but still produce wrong answers.

The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release, as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

In addition to reviewing bug reports, you should implement a verification and validation strategy to identify potential bugs in your design, code, and tools.

Modeling Environment for Embedded Coder

Design Models for Generated Embedded Code Deployment

When using Embedded Coder® to generate code for an embedded system architecture, it is important to design your Simulink models with code generation in mind from the very beginning of the design process. Think about relevant design factors and issues such as:

In this section...

Application Algorithms and Run-Time Environments

Use Simulink to design models that represent application algorithms and run-time environments from which you intend to generate deployable code. Depending on your application, you might deploy code to an execution environment that consists of a combination of:

Execution Environment Components	Choices
Hardware	• Development computer • Rapid-prototyping board • Microprocessor • Microcontroller • FPGA • ASIC
Cores	• Single • Multiple
Operating system	• General-purpose • Real-time • None (bare metal)
Scheduling	• Single-tasking

Execution Environment Components	Choices
	• Multitasking • Interrupt driven • Concurrency • Provided by operating system • Generated from model
Application algorithm code	• Generated from model • External code

As you design models to generate C or C++ code for rapid prototyping or production deployment, keep in mind the execution environment. Generate code that meets implementation requirements and avoids potential design rework. As the preceding table reflects, the execution environment for code that you generate can range from relatively simple to complex. For example, a simple case is code that you generate from a single, single-tasking model that runs on a single-core microprocessor. A complex case is code that generate from a model partitioned to run as a distributed system on a multicore microprocessor and an FPGA.

Software Execution Framework for Generated Code

Part of an application execution environment is the software execution framework that is responsible for scheduling and running the generated code. That software can preexist, as in the case of an operating system and its scheduler, or you can code the software manually. The level of complexity varies depending on which of the following modeling and code generation scenarios applies:

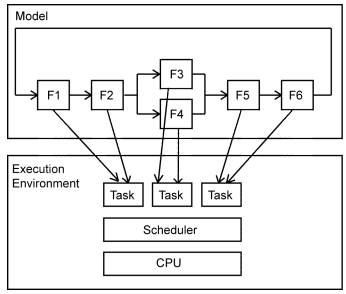
- Generate code from a single top model, which represents the algorithms intended to run in the execution environment.
- Generate code from a model, which represents part of an overall algorithm. You can mix the generated code with code written manually and code generated from other sources or releases of MathWorks® products.

Single Top Model

For a single top model, the software execution framework is responsible for running generated code the same way that Simulink simulates the model. Functions in the generated code are highly coordinated and optimized because Simulink is aware of

dependencies. The framework interfaces with code generated for the top model only. Code generated for a top model handles interfacing with code for referenced Model blocks.

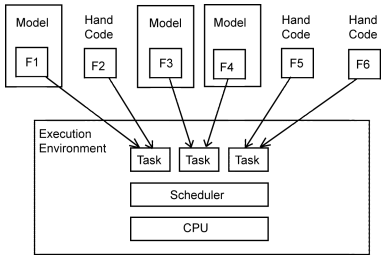
Consider the following example, where a single top model is mapped to tasks that run on a single-core CPU.



For this system, you map model clock rates to tasks that run on the hardware. You can choose for Simulink to map the rates implicitly or you can map them explicitly in your model. You can model latency effects resulting from how you map rates in a model to single-tasking or multitasking execution environments. Simulink schedules the tasks properly based on rates in the model and data dependencies between tasks. The code generator implements the same dependencies in the code that it generates. The software execution framework invokes generated entry-point functions at rates based on system timers and interrupts. The generated code executes in the same manner that Simulink simulates the model, and contains code dedicated to communicating data between functions running at different rates.

Multiple Top-Level Models

When you generate code from multiple top models separately and mix that code with code acquired in other ways, the execution environment of the application takes on more software execution framework responsibility. For this modeling scenario, you generate code for standalone, atomic reusable components.



With this scenario, Simulink is not aware of model dependencies. Functions in code generated from the different models are minimally coordinated and optimized. For example, the models might share generated utility functions. Potential optimizations that cross model boundaries are not possible. You must design the software execution framework taking into account dependencies between units of code, including execution order. For an application that requires concurrent execution across multiple cores, you must consider data latency effects across the cores.

The code generator helps you address software execution framework challenges, such as sharing global data and avoiding identifier conflicts. The code generated for a each model handles the interfacing for referenced Model blocks.

Map Embedded System Architecture to Simulink Modeling Environment

When mapping an embedded system architecture to the Simulink modeling environment, think about the model design.

"Modeling Algorithms" on page 1-6	Given initial state and input, a set of tasks or instructions that efficiently produce the results that you want.
"Modeling Interfaces" on page 1-6	Mechanisms that enable algorithm components to communicate and exchange information across component boundaries.
"Modeling Systems" on page 1-8	Collection of algorithm components that achieve a higher-level, domain-specific goal or result. Components often share resources.
"Modeling Run-Time Environments" on page 1-11	Framework that handles scheduling of system algorithm resources and execution.

Consider the following questions regarding an embedded system architecture with corresponding modeling capabilities and links to related information. Use the information as a guide for mapping your architecture details to the Simulink modeling environment. Designing a model architecture with your specific embedded system architecture in mind can help you avoid rework and future conversion and maintenance costs.

Model Templates for Code Generation

The code generator provides a set of built-in templates to use as a starting point to create models for common application designs. Use the templates to create models that are preconfigured to generate code for rapid-prototyping or embedded system applications.

Template	Description
Code Generation System	Basic model consisting of an Inport block and Output block.
Exported functions	Model for generating code from function-call subsystems. You can export each function-call subsystem separately by right-clicking a

Template	Description
	subsystem, selecting **C/C++ Code** > **Export Functions**, and clicking **Build**.
Fixed-step, multirate	Fixed-step model that uses multiple rates and consists of Inport blocks, an Outport block, and a Sum block. The model is configured to use a fixed-step discrete solver and to use two rates with **Periodic sample time constraint** set to `Unconstrained` and the **Treat each discrete rate as a separate task** option selected. Simulink inserts a Rate Transition block to handle the two sample rates.
Fixed-step, single rate	Fixed-step model that uses a single rate and consists of Inport blocks, an Outport block, and a Sum block. The model is configured to use a fixed-step discrete solver.

To create a model from a template:

1. On the MATLAB® home tab, click **Simulink**.
2. In the Simulink start page, expand **Embedded Coder**.
3. Select a template.
4. Click **Create**. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see "Create a Template from a Model" (Simulink).

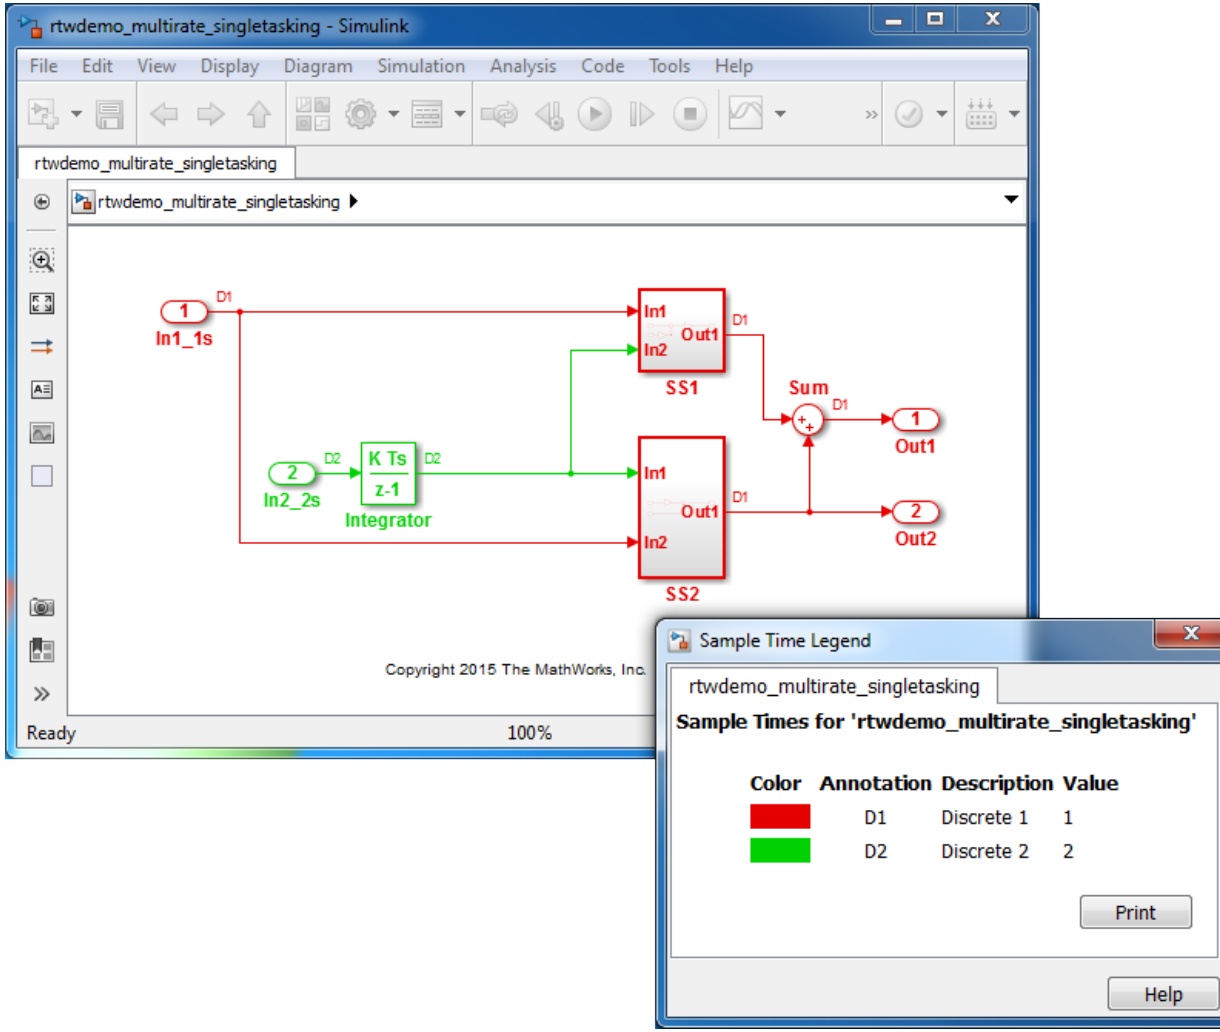
Model Single-Core, Single-Tasking Platform Execution

This example shows a model designed and configured for embedded system code generation intended to execute on a single-core, single-tasking platform. The application algorithm is captured in a single model hierarchy, making it possible to use Simulink® time-based, single-task scheduling to simulate the model and execute the generated code.

Periodic Multirate Model Set Up for Single-Tasking Execution

Open the example model `rtwdemo_multirate_singletasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



- Sample times for Inport blocks `In1_1s` and `In2_2s` are set to 1 and 2 seconds, respectively.
- To provide clean partitioning of rates, sample times for subsystems `SS1` and `SS2` are set to 1.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between tasks running at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on single-tasking execution semantics.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_multirate_singletasking_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_singletasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_singletasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_singletasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_singletasking_step(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1

- `rtY.Out2` of data type `real_T` with dimension of 1

More About

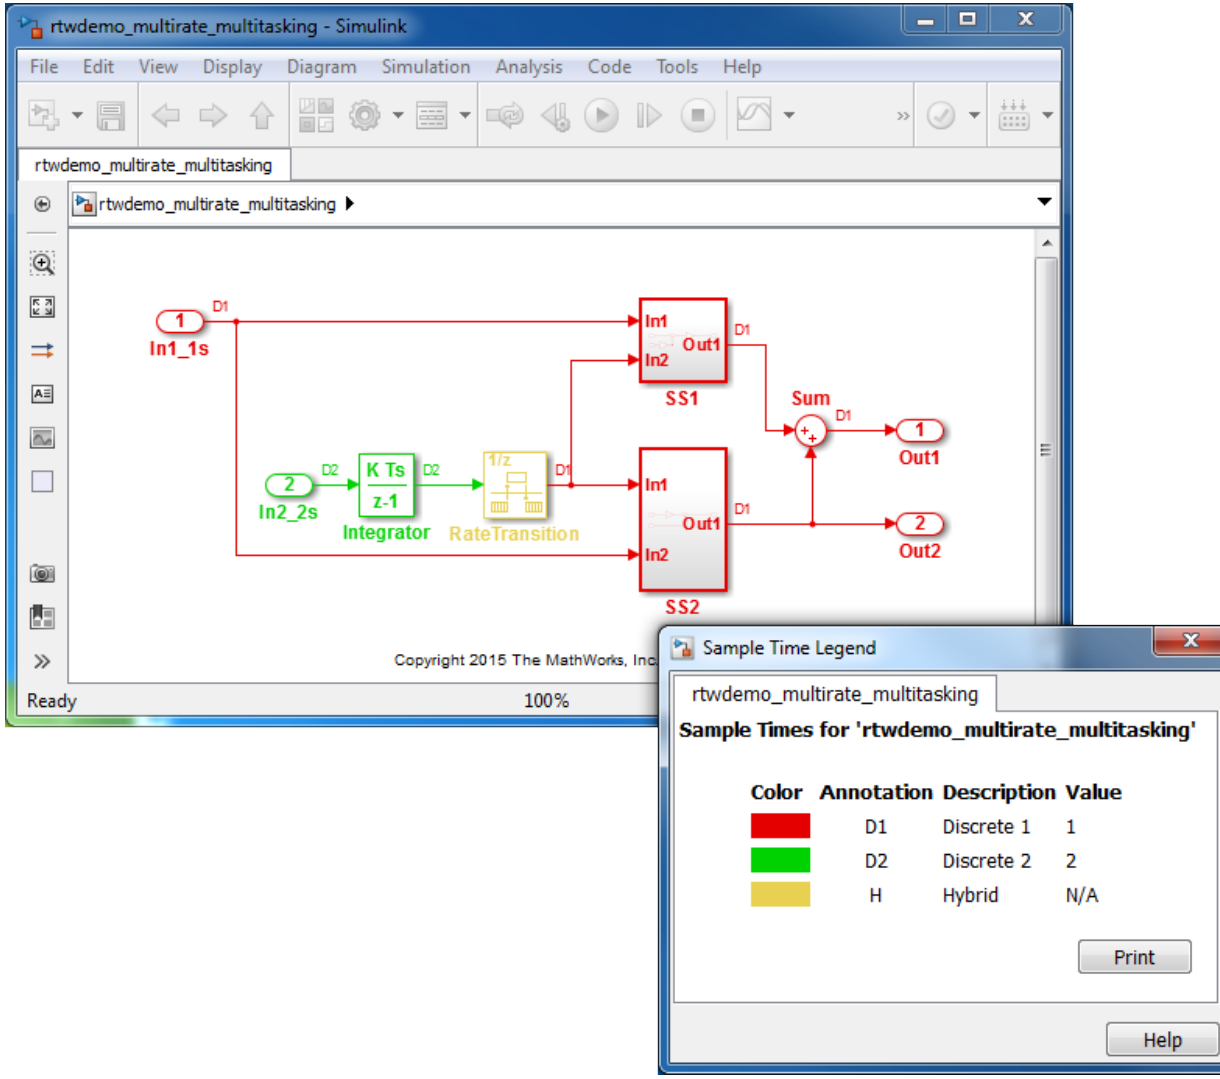
- "Modeling for Single-Tasking Execution" (Simulink Coder)
- "Deploy Generated Standalone Executable Programs To Target Hardware"
- "Customize Code Organization and Format"

Model Single-Core, Multitasking Platform Execution

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a single-core, multitasking platform. The model simulates and the generated code executes based on the model configuration and a rate monotonic scheduling algorithm.

Periodic Multirate Model Set Up for Multitasking Execution

Open the example model `rtwdemo_multirate_multitasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



- Sample times for Inport blocks `In1_1s` and `In2_2s` are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for subsystems `SS1` and `SS2` are set to 1.

- The Rate Transition block models an explicit rate transition. Alternatively, instruct Simulink to insert Rate Transition blocks for you by selecting model configuration parameter **Solver > Automatically handle rate transition for data transfer**.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

Simulink® simulates the model based on the model configuration. Code that this model generates implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on multitasking execution semantics.

Simulink enforces data transfer constraints to achieve rate monotonic scheduling:

- Data transfers occur between a single read task and a single write task.
- When data transfers between two tasks, only one task can preempt the other task.

- For periodic tasks, a task with a faster rate has a higher priority than a task with a slower rate. In addition, a task with the faster rate, preempts a task with a slower rate.
- Tasks run on a single processor.
- Time slicing, use of a defined time period during which a task can run in a preemptive multitasking system, is not allowed.
- Processes do not crash or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework communicates with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point functions `rtwdemo_multirate_multitasking_step0` and `rtwdemo_multirate_multitasking_step1`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_multitasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_multitasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.

2 Write input data to the generated code for model Inport blocks.

3 Call the generated entry-point functions.

4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_multitasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_multitasking_step0(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, `void rtwdemo_multirate_multitasking_step1(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

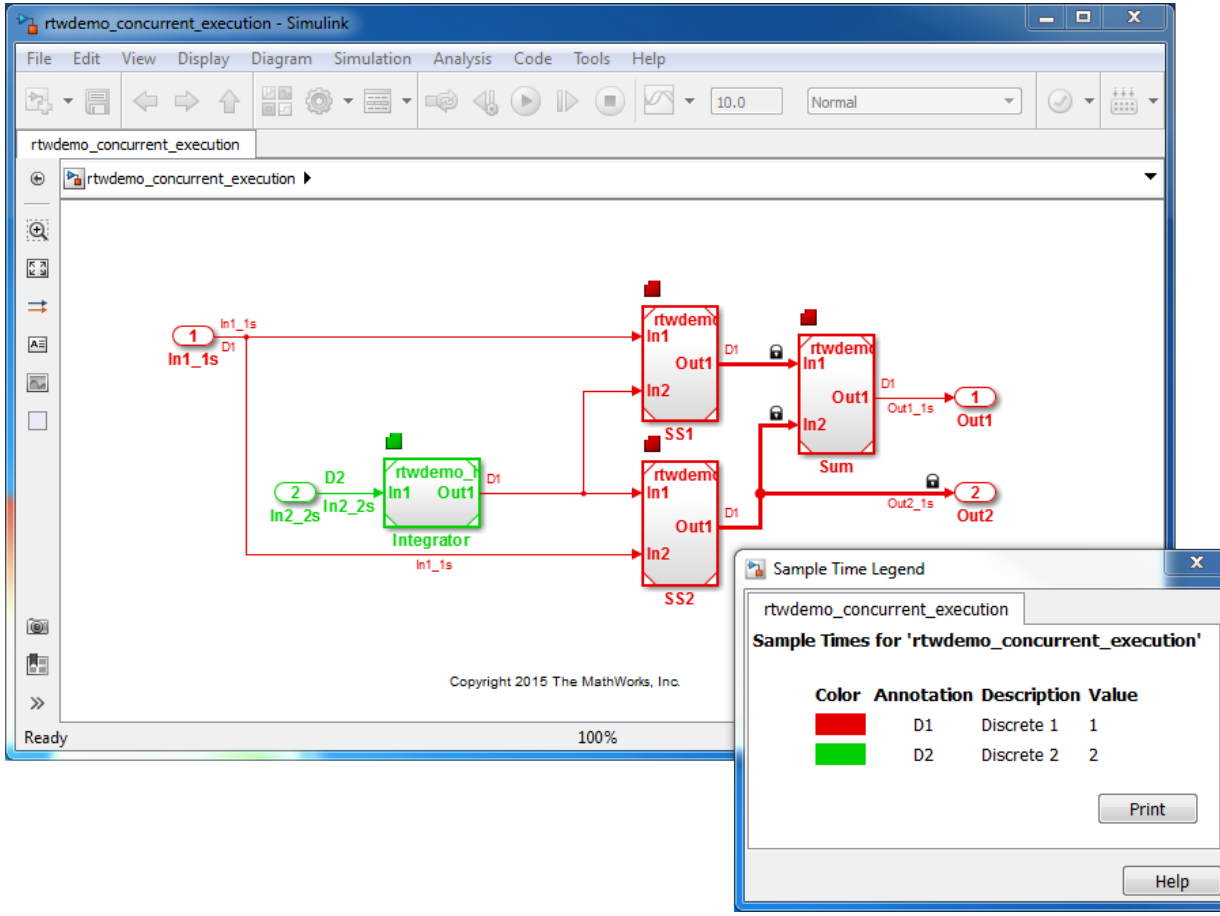
Model Concurrent Execution for Symmetric Multicore CPU Platforms

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a symmetric multicore, multitasking platform.

Periodic Multirate Model Set Up for Multitasking Concurrent Execution

Open the example model `rtwdemo_concurrent_execution`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



Simulink supports simulating concurrent task execution by assigning partitions of a model to tasks that you designate to run concurrently on multicore hardware. Use an implicit or explicit approach to designating partitions.

Simulink implicit partitioning:

- Partitions the model based on sample times specified in the model.
- Assigns a task to each sample rate and designates that the tasks run concurrently.
- Controls the granularity of partitions. For example, you cannot split a sample rate into multiple tasks.

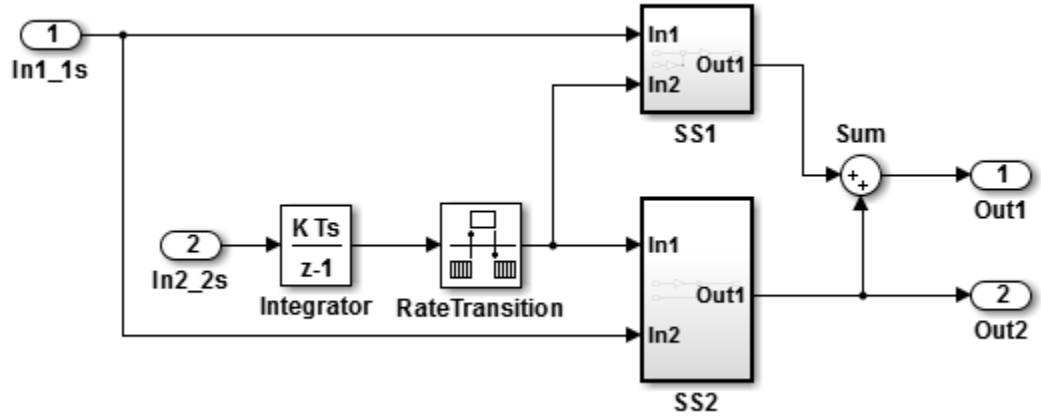
- Does not impose modeling constraints.
- Provides ready-to-use hardware solutions, such as solutions that the Simulink® Real-Time™ product produces.
- Is not relevant to standalone production code generation due to the lack of control over partition granularity.

Explicit partitioning:

- Use Model and Subsystem blocks to partition the model.
- Create an arbitrary number of tasks.
- Simulink assigns each partition to a task.
- Simulink imposes modeling constraints.
- Control the granularity of partitions.
- Split a sample rate into multiple tasks.
- Assign partitions to different processor cores.
- Is for standalone production code generation due to the level of control you have over granularity of partitions.

This example shows explicit partitioning.

Consider the following periodic multirate model that is set up for multitasking execution.



- Sample times for Inport blocks `In1_1s` and `In2_2s` are set to 1 and 2 seconds, respectively.

- To provide a clear partitioning of rates, sample times for models SS1 and SS2 are set to 1.
- The Rate Transition block explicitly models a rate transition.

To support concurrent execution of tasks in a multicore run-time environment, the preceding model was modified:

- The Integrator block is in a Model block configured with a fixed-step discrete solver and a step size of two seconds.
- Subsystems SS1 and SS2 were converted to Model blocks configured with a fixed-step discrete solver and a step size of one second.
- The Sum block is in a Model block configured with a fixed-step discrete solver and a step size of one second. Another option for the Sum block is to place it in SS1 or SS2 and compute its value coincident with the Model block. For concurrent execution of tasks, only connection blocks, Model blocks, and Subsystem blocks can be at the root level of a model.
- The Rate Transition block was removed.

Relevant Model Configuration Parameter Settings

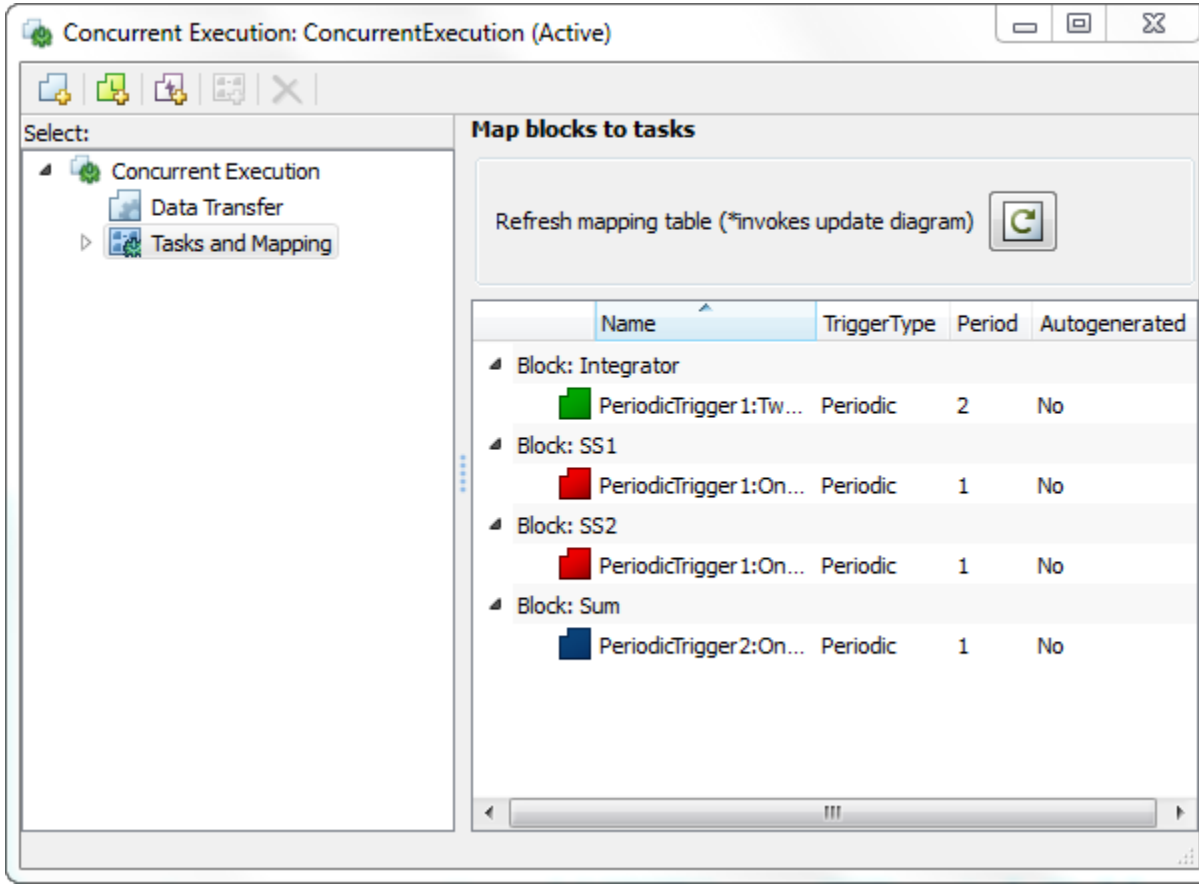
- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** selected.
- **Solver > Automatically handle rate transition for data transfer** selected. Necessary because Rate Transition block was removed.
- **Solver > Allow tasks to execute concurrently on target** selected.

Concurrent Execution Parameter Settings

Open the Concurrent Execution dialog box by clicking **Configure Tasks** on the Configuration Parameters **Solver** pane. Selecting **Allow tasks to execute concurrently on target** enables the **Configure Tasks** button.

When selected, the **Enable explicit model partitioning for concurrent behavior** parameter enables concurrent execution options for the top-level model.

Click **Tasks and Mapping** to review the tasks and mapping.



Simulink creates a default mapping for each partition (Model block) by assigning each partition to a separate task. Simulink designates that each partition executes concurrently and simulates latency effects that data communication between processor cores imposes. This dialog box displays a mapping consisting of partitions spread across two independent periodic triggers: `SS1`, `SS2`, and `Sum` mapped to periodic trigger 1 and `Integrator` mapped to periodic trigger 2.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the

Inport block sample times to order block execution based on a multicore, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between the rates.

Benefits of implicit Simulink rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within it.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates, based on multitasking execution semantics.

Simulink enforces data transfer constraints:

- Data transfers occur between a single read task and a single write task.
- Tasks run on a single processor.
- Processes do not stop or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by indirectly

calling entry-point functions `PeriodicTrigger1_OneSecond_step`, `PeriodicTrigger1_TwoSecond_step`, and `PeriodicTrigger2_OneSecond_step` with the function `rtwdemo_concurrent_execution_step`. Use this file as a starting point for coding your execution framework.

- `rtwdemo_concurrent_execution.c` contains entry points for the code that implements the model algorithm. This file includes the rate and task scheduling code.
- `rtwdemo_concurrent_execution.h` declares model data structures and a public interface to the model entry points and data structures.
- `model_reference_types.h` contains type definitions for timing bridges. These type definitions are generated for a model reference target or a model containing Model blocks.
- `rtw_windows.h` declares mutex and semaphore function protoypes that the generated code uses for concurrent execution on Microsoft® Windows® platforms.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_concurrent_execution.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `In1_1s` of data type `real_T` with dimension of 1
- `In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_concurrent_execution_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void PeriodicTrigger1_OneSecond_step(void)`. Call this function periodically for

one of two tasks that require scheduling at the fastest rate in the model. For this model, call the function every second.

- Output and update entry-point function, `void PeriodicTrigger1_TwoSecond_step(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds.
- Output and update entry-point function, `void PeriodicTrigger2_OneSecond_step(void)`. Call this function periodically for the second task that requires scheduling at the fastest rate in the model. For this model, call the function every second.

To achieve real-time execution, define a task or thread for each entry-point step function. Trigger execution of each function based on a timer that has the same rate as the given function. The operating system schedules the tasks across cores dynamically or based on your mapping of tasks to cores.

Output ports:

- `Out1_1s` of data type `real_T` with dimension 1
- `Out2_1s` of data type `real_T` with dimension 1

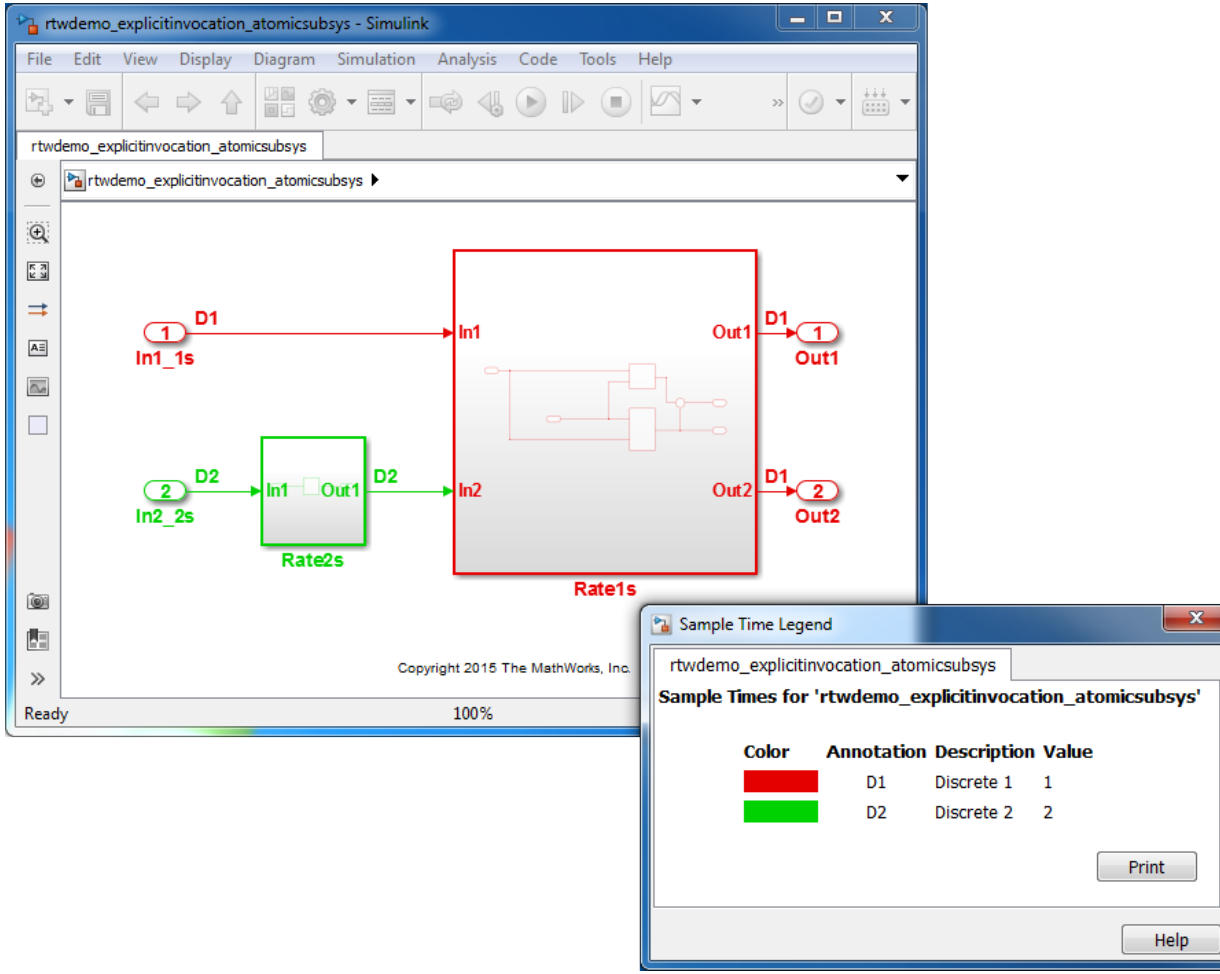
- "Customize Code Organization and Format"

Model Explicit Function Invocation with Atomic Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into multiple atomic subsystems that you build separately.

Atomic Subsystem Model

Open the example model `rtwdemo_explicitinvocation_atomicsubsys`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



This model partitions an algorithm into two atomic subsystems: `Rate1s` and `Rate2s`. Subsystem `Rate1s` is configured with a sample time of 1 second. Subsystem `Rate2s` is configured with a sample time of 2 seconds.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this example, the sample time legend shows implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

Based on ratemonotonic scheduling, your application code (execution framework) must transfer data between subsystems `Rate2s` and `Rate1s` at a frequency of 2 seconds with the priority of 1 second. That is, the generated function transfers data in the 1 second task every other time prior to executing code for subsystem `Rate1s`.

Your execution framework must schedule the generated function code and handle the data transfers between them. This is an advantage for multirate models because the generated code assumes no scheduling or data transfer semantics. However, the execution framework must handle data transfers explicitly.

Generate Code and Report

Generate a single callable function for each subsystem without connections between them. Multiple ways are available to generate code for a subsystem, including from the subsystem context menu. For example, right-click a subsystem block and click **C/C++ Code > Build This Subsystem**. In the Build code for Subsystem dialog box, click **Build**.

The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the subsystem. This code controls model code execution by calling entry-point function `Rate1s_step` or `Rate2s_step`. Use this file as a starting point for coding your execution framework.
- `Rate1s.c` and `Rate2s.c` contain entry points for the code that implements subsystem `Rate1s` and `Rate2s`, respectively. This file includes the rate and task scheduling code.
- `Rate1s.h` and `Rate2s.h` declare model data structures and a public interface to subsystem entry points and data structures.

- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_explicitinvocation_atomicsusys.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports, `Rate1s`:

- `rtU.In1` of type `real_T` with dimension of 1
- `rtU.In2` of type `real_T` with dimension of 1

Entry-point functions, `Rate1s`:

- Initialize entry-point function, `void Rate1s_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void Rate1s_step(void)`. Call this function periodically, every second.
- Termination function, `void Rate1s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate1s`:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

Input ports, `Rate2s`:

- `rtU.In1` of type `real_T` with dimension of 1

Entry-point functions, `Rate2s`:

- Initialize entry-point function, `void Rate2s_initialize(void)`. Call this function once at startup.

- Output and update entry-point (step), `void Rate2s_step(void)`. Call this function periodically, every 2 seconds.
- Termination function, `void Rate2s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate2s`:

- `rtY.Out1` of type `real_T` with dimension of 1

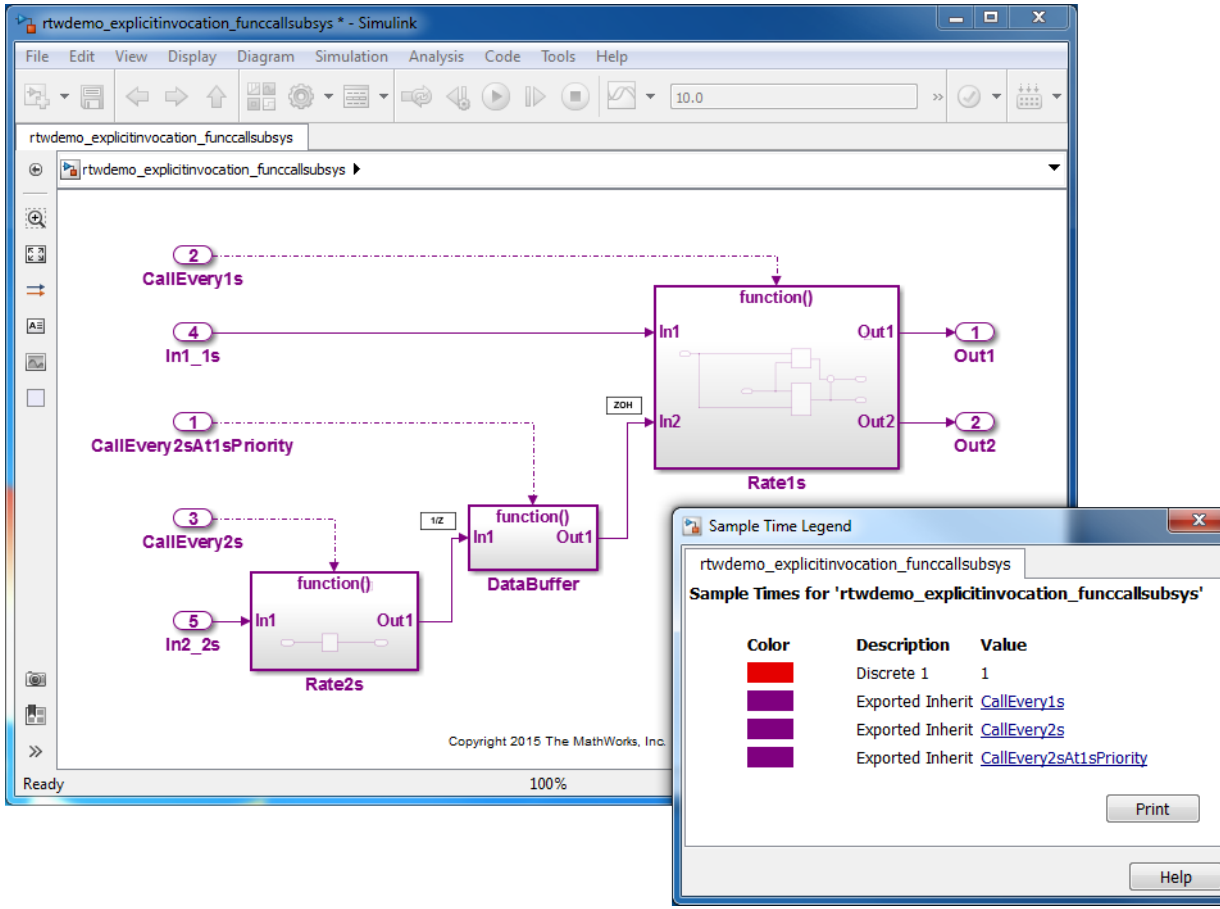
Model Explicit Function Invocation with Function-Call Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into function-call subsystems that you build separately.

Function-Call Subsystem Model

Open the example model `rtwdemo_explicitinvocation_funccallsubsys`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



This model partitions an algorithm into three function-call subsystems: `Rate1s`, `Rate2s`, and `DataBuffer`. Use function-call subsystems to model multirate systems explicitly.

Subsystems `Rate1s` and `DataBuffer` use a sample time of 1 second. Subsystem `Rate2s` usea a sample time of 2 seconds.

This model design is referred to as export function modeling. Simulink constrains the model to function-call subsystems at the root level. The driving Inport block specifies the function name.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** selected. Simulink applies multitasking execution because the model uses multiple sample rates.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

In the sample time legend, red identifies the fastest discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and transfer data between functions.

Your execution framework needs to schedule the generated function code and handle data transfers between functions. The generated code is simple and you control the order of execution.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize, execute, and terminate the generated code.
- `rtwdemo_explicitinvocation_funccallsubsys.c` calls the initialization function and exported functions for subsystems `Rate1s`, `Rate2s`, and `DataBuffer`.
- `rtwdemo_explicitinvocation_funccallsubsys.h` declares model data structures and a public interface to the exported entry point functions and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header files by adding directives `#include Rate1s.h`, `#include DataBuffer.h`, and `#include Rate2s.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of type `real_T` with dimension of 1
- `rtU.In2_2s` of type `real_T` with dimension of 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_explicitinvocation_funccallsubsys_initialize(void)`. At startup, call this function once.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery2sAt1sPriority(void)`. Call this function as needed.

Output ports:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

Model for AUTOSAR Platform

Different ways are available for using Simulink® to model AUTOSAR atomic software components.

Prerequisites

The Embedded Coder Support Package for AUTOSAR Standard is required for generating C and ARXML code for AUTOSAR atomic software components.

Install the AUTOSAR Standard Support Package

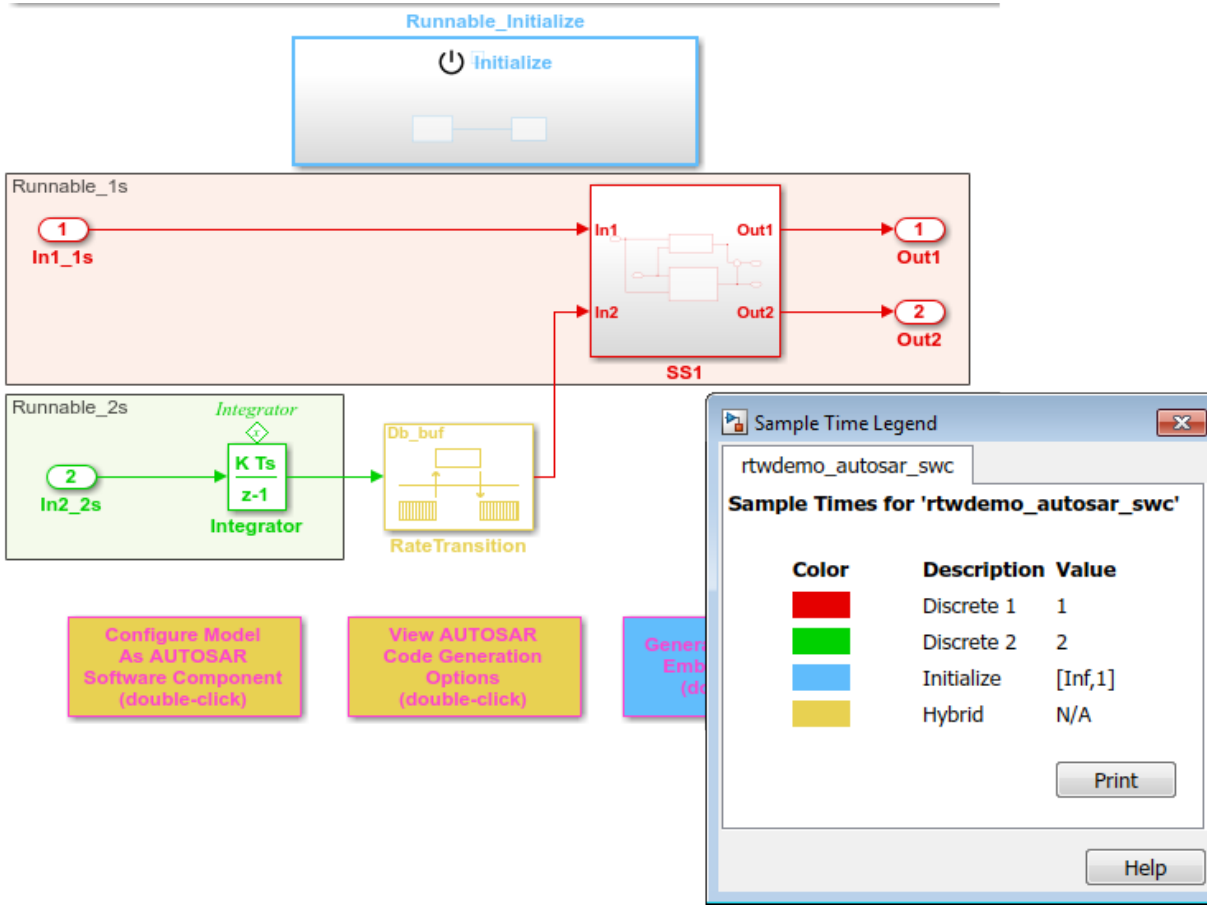
"Support Package Installation" (MATLAB)

Multiple Periodic Runnables Configured for Multitasking

Open the example model `rtwdemo_autosar_swc`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). Two periodic runnables, `Runnable_1s` and `Runnable_2s`, are modeled with multiple sample rates: 1 second (`In1_1s`) and 2 seconds (`In2_2s`). To maximize execution efficiency, the model is configured for multitasking.

The model includes an Initialize Function block, which initializes the integrator in `Runnable_2s` to a value of 1.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.



Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Fixed-step size (fundamental sample time)** set to `auto`.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

In the model window, enable sample time color-coding by selecting **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red

represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

Because the model has multiple rates and the **Solver** parameter **Treat each discrete rate as a separate task** is selected, the model simulates in multitasking mode. The model handles the rate transition for `In2_2s` explicitly with the Rate Transition block.

The Rate Transition block parameter **Ensure deterministic data transfer** is cleared to facilitate integration into an AUTOSAR RTE.

The generated code for the model schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR run-time environment (RTE).

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_swc.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_autosar_swc.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwdemo_autosar_swc_private.h` contains local `define` constants and local data required by the model and subsystems.
- `rtwdemo_autosar_swc_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_swc_component.arxml`, `rtwdemo_autosar_swc_datatype.arxml`, `rtwdemo_autosar_swc_implementation.arxml`, and `rtwdemo_autosar_swc_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and

packages. You import these files into the Simulink environment by using the AUTOSAR `arxml` importer tool.

- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

Code Interface

Open and review the Code Interface Report. This information is captured in the ARXML files. The RTE generator uses the ARXML to interface the code into an AUTOSAR RTE.

Input ports:

- Require port, interface: sender-receiver of type `real-T` of 1 dimension
- Require port, interface: sender-receiver of type `real-T` of 1 dimension

Entry-point functions:

- Initialization entry-point function, `void Runnable_Initialize(void)`. At startup, call this function once.
- Output and update entry-point function, `void Runnable_1s(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, `void Runnable_2s(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every 2 seconds. To achieve real-time execution, attach this function to a timer.

Output ports:

- Provide port, interface: sender-receiver of type `real-T` of 1 dimension
- Provide port, interface: sender-receiver of type `real-T` of 1 dimension

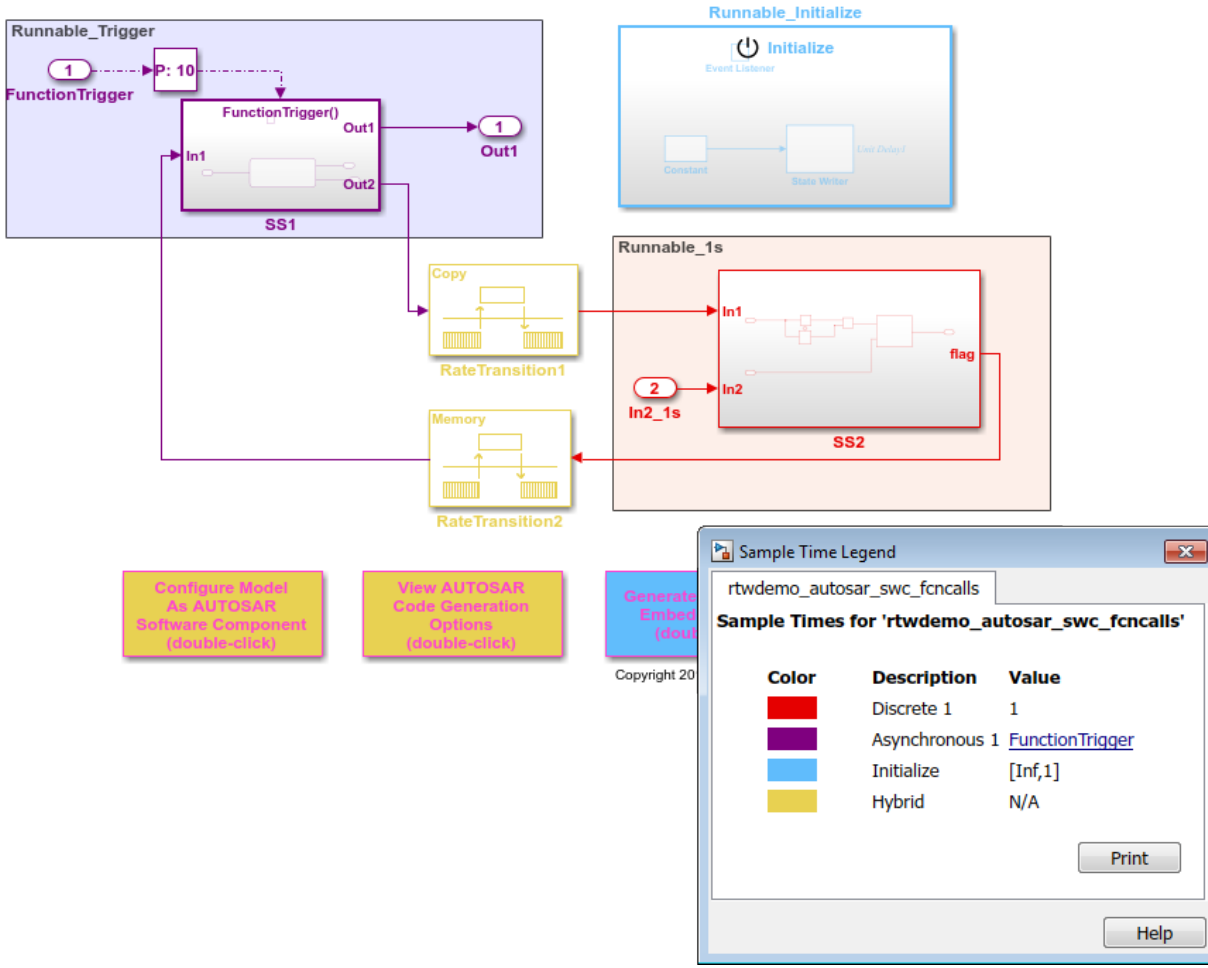
Multiple Runnables Configured as Periodic-Rate Runnable and Asynchronous Function-Call Runnable

Open the example model `rtwdemo_autosar_swc_fcncalls`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). The model uses an asynchronous function-call runnable, `Runnable_Trigger`, which is triggerd by an external event. The model also includes a periodic rate-based runnable, `Runnable_1s`. The Rate Transition blocks represent interrunnable variables.

Use this approach to model the JMAAB complex control model type beta architecture. In JMAAB type beta modeling, at the top level of a control model, you place function layers above scheduling layers.

The model includes an Initialize Function block, which initializes the unit delay in `Runnable_1s` to a value of 0.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.



Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Fixed-step size (fundamental sample time)** set to 1.
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

In the model window, enable sample time color-coding by selecting **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red represents the discrete rate. Magenta represents the asynchronous function trigger. Yellow represents the mixture of two rates.

The asynchronous trigger runnable runs at asynchronous rates (the **Sample time type** parameter of the function-call subsystem Trigger block is set to |triggered]) while the periodic rate runnable runs at the specified discrete rate. The generated code manages the rates by using single-tasking assumptions. For models with one discrete rate, the code generator does not produce scheduling code because there is only a single rate to execute. Use this technique for a single-rate application when you have one periodic runnable.

The model handles transitions between the asynchronous and discrete rates of the interrunnables with the two Rate Transition blocks. The Rate Transition block parameter **Ensure deterministic data transfer** is cleared to facilitate integration into an AUTOSAR RTE.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR run-time environment (RTE).

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_swc_fcncalls.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.

- `rtwdemo_autosar_swc_fcncalls.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwdemo_autosar_swc_fcncalls_private.h` contains local `define` constants and local data required by the model and subsystems.
- `rtwdemo_autosar_swc_fcncalls_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_swc_fcncalls_component.arxml`, `rtwdemo_autosar_swc_fcncalls_datatype.arxml`, `rtwdemo_autosar_swc_fcncalls_implementation.arxml`, and `rtwdemo_autosar_swc_fcncalls_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You import these files into the Simulink environment by using the AUTOSAR `arxml` importer tool.
- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

Code Interface

Open and review the Code Interface Report. This information is captured in the ARXML files. The RTE generator uses the ARXML to interface the code into an AUTOSAR RTE.

Input port:

- Require port, interface: sender-receiver of type `real-T` of 1 dimension

Entry-point functions:

- Initialization entry-point function, `void Runnable_Initialize(void)`. At startup, call this function once.
- Simulink function, `void Runnable_1s(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Exported function, `void Runnable_Trigger(void)`. Call this function at any time from an external trigger.

Output port:

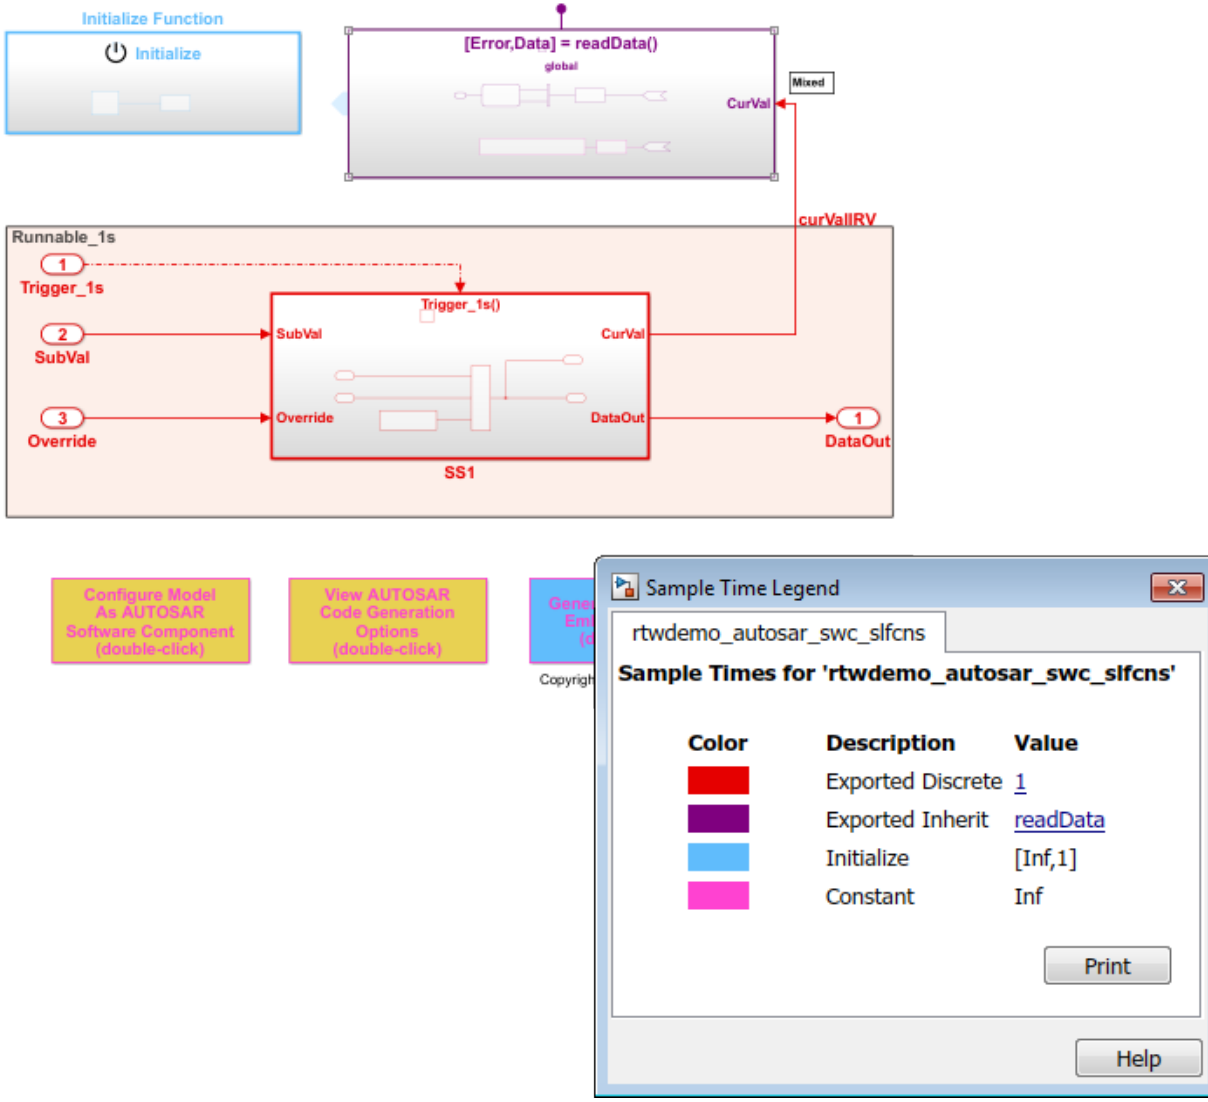
- Provide port, interface: sender-receiver of type `real-T` of 1 dimension

Multiple Runnables Configured As Function-Call Subsystem and Simulink Function

Open the example model `rtwdemo_autosar_swc_slfcns`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). The model includes one periodic rate runnable, `Runnable_1s`, that uses a function-call subsystem, `SS1`. The model also includes a Simulink function, `readData`, to provide a value (`CurVal`) to clients that request it.

The model includes an Initialize Function block, which initializes the unit delay in subsystem `RollingCounter` to a value of 0.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.



Use function-call subsystems:

- When it is difficult or not possible to specify system events in a Simulink model.

- To achieve complex multirate scheduling of runnables. Model each rate as a separate function-call subsystem.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Fixed-step size (fundamental sample time)** set to 1.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

In the model window, enable sample time color-coding by clicking **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red identifies the discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and handle data transfers between functions.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

The code generator:

- Produces an AUTOSAR runnable for the function-call subsystem at the root level of the model.
- Implements signal connections between runnables as AUTOSAR interrunable variables (IRVs).

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR run-time environment (RTE).

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_swc_slfcns.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_autosar_swc_slfcns.h` declares model data structures and a public interface to the model entry points and data structures.

- `rtwdemo_autosar_swc_slfcns_private.h` contains local `define` constants and local data required by the model and subsystems.
- `rtwdemo_autosar_swc_slfcns_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `readData.c` contains code for the Simulink function.
- `readData_private.h` contains local `define` constants and local data required by the function.
- `readData.h` declares data structures and a public interface for calling the function.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_swc_slfcns_component.arxml`, `rtwdemo_autosar_swc_slfcns_datatype.arxml`, `rtwdemo_autosar_swc_slfcns_implementation.arxml`, and `rtwdemo_autosar_swc_slfcns_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You import these files into the Simulink environment by using the AUTOSAR `arxml` importer tool.
- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

Code Interface

Open and review the Code Interface Report. This information is captured in the ARXML files. The RTE generator uses the ARXML to interface the code into an AUTOSAR RTE.

Input ports:

- Require port, interface: sender-receiver of type `uint16-T` of 1 dimension
- Require port, interface: sender-receiver of type `real-T` of 1 dimension Entry-point functions:

Entry-point functions:

- Initialization entry-point function, `void Runnable_Init(void)`. At startup, call this function once.
- Exported function, `void Runnable_1s(void)`. Call this function periodically, every second.

- Simulink function, `Std_ReturnType readData(real_T Data[2])`. Call this function at any time.

Output ports:

- Provide port, interface: sender-receiver of type `uint16-T` of 1 dimension

Modeling in Simulink Coder

Configure a Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

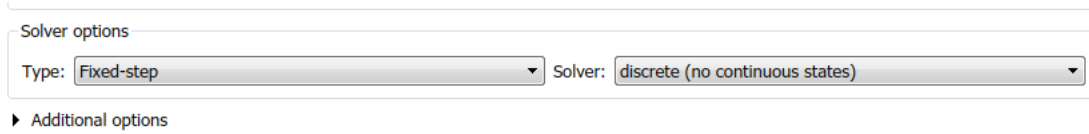
1 Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

Note: This model uses Stateflow® software.

---

2 Open the Configuration Parameters dialog box **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. For this example, set the parameters as noted in the following table.

Parameter	Setting	Effect on Generated Code
Type	`Fixed-step`	Maintains a constant (fixed) step size, which is required for code generation
Solver	`discrete (no continuous states)`	Applies a fixed-step integration technique for computing the state derivative of the model
Fixed-step size	`.001`	Sets the base rate; must be the lowest common multiple of all rates in the system



3 Open the **Code Generation** pane and make sure that **System target file** is set to `grt.tlc`.

Note: The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file (STF) defines a target, which is an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a target is code format. The grt configuration requires a fixed step solver and the rsim.tlc supports variable step code generation.

4 Open the **Code Generation** > **Custom Code** pane, and under **Include list of additional**, select **Include directories**. In the **Include directories** text field, enter:

```
"$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
```

This directory includes files that are required to build an executable for the model.

5 Apply your changes and close the dialog box.

Supported Products and Block Usage

In this section...

Related Products

The following table summarizes MathWorks products that extend and complement Simulink Coder software. For information about these and other MathWorks products, see `www.mathworks.com`.

Product	Extends Code Generation Capabilities for ...
Aerospace Blockset™	Aircraft, spacecraft, rocket, propulsion systems, and unmanned airborne vehicles
Audio System Toolbox™	Audio processing systems
Automated Driving System Toolbox™	Designing, simulating, and testing ADAS and autonomous driving systems
Communications System Toolbox™	Physical layer of communication systems
Computer Vision System Toolbox™	Video processing, image processing, and computer vision systems
Control System Toolbox™	Linear control systems
DSP System Toolbox™	Signal processing systems
Embedded Coder	Embedded systems, rapid prototyping boards, and microprocessors in mass production
Fixed-Point Designer™	Fixed-point systems
Fuzzy Logic Toolbox™	System designs based on fuzzy logic
HDL Verifier™	Direct programming interface (DPI) component and transaction-level model (TLM) generation from Simulink
IEC Certification Kit	ISO 26262 and IEC 61508 certification

Product	Extends Code Generation Capabilities for ...
Model-Based Calibration Toolbox™	Developing processes for systematically identifying optimal balance of engine performance, emissions, and fuel economy, and reusing statistical models for control design, hardware-in-the-loop (HIL) testing, or powertrain simulation
Model Predictive Control Toolbox™	Controllers that optimize performance of multi-input and multi-output systems that are subject to input and output constraints
Neural Network Toolbox™	Neural networks
Phased Array System Toolbox™	Sensor array systems in radar, sonar, wireless communications, and medical imaging applications
Polyspace® Bug Finder™	MISRA-C compliance and static analysis of generated code
Polyspace Code Prover™	Formal analysis of generated code
Powertrain Blockset™	Real-time testing of powertrain applications
Robotics System Toolbox™	Robot Operating System (ROS) node generation
Simscape™	Systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks
Simscape Driveline™	Driveline (drivetrain) systems
Simscape Electronics™	Electronic and electromechanical systems
Simscape Fluids™	Hydraulic power and control systems
Simscape Multibody™	Three-dimensional mechanical systems
Simscape Power Systems™	Systems that generate, transmit, distribute, and consume electrical power
Simulink 3D Animation™	Systems with 3D visualizations
Simulink Code Inspector™	Automated reviews of generated code
Simulink Design Optimization™	Systems requiring maximum overall system performance

Product	Extends Code Generation Capabilities for ...
Simulink Desktop Real-Time™	Rapid prototyping or hardware-in-the-loop (HIL) simulation of control system and signal processing algorithms
Simulink Real-Time™	Rapid control prototyping, hardware-in-the-loop (HIL) simulation, and other real-time testing applications
Simulink Report Generator™	Automatically generating project documentation in a standard format
Simulink Test™	Software-in-the-loop (SIL), processor-in-the-loop (PIL), and real-time hardware-in-the-loop (HIL) testing of generated code
Simulink Verification and Validation™	Applications requiring automated requirements tracing, model standards compliance checking, and test harness generation
Stateflow	State machines and flow charts
System Identification Toolbox™	Systems constructed from measured input-output data Support exceptions: • Nonlinear IDNLGREY Model, IDDATA Source, IDDATA Sink, and estimator blocks • Nonlinear ARX models that contain custom regressors • `neuralnet` nonlinearities • `customnet` nonlinearities
Vehicle Network Toolbox™	CAN blocks for Accelerator and Rapid Accelerator simulations and code deployment on Windows®

Simulink Built-In Blocks That Support Code Generation

The following tables summarize code generator support for Simulink blocks. There is a table for each block library. For more detail, including data types each block supports, in

the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages. For some blocks, the generated code might rely on `memcpy` or `memset` (`string.h`).

Additional Math and Discrete: Additional Discrete

Block	Support Notes
Fixed-Point State-Space	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Transfer Fcn Direct Form II	
Transfer Fcn Direct Form II Time Varying	

Additional Math and Discrete: Increment/Decrement

Block	Support Notes
Decrement Real World	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Decrement Stored Integer	
Decrement Time To Zero	Supports code generation.
Decrement To Zero	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Increment Real World	
Increment Stored Integer	

Continuous

Block	Support Notes
Derivative	Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, select **Analysis > Control Design > Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.
Integrator	
Integrator Limited (Simulink)	
PID Controller	
PID Controller (2DOF)	
Second-Order Integrator (Simulink)	
Second-Order Integrator Limited (Simulink)	
State-Space	
Transfer Fcn	
Transport Delay	
Variable Time Delay (Simulink)	

Block	Support Notes
Variable Transport Delay	
Zero-Pole	

Discontinuities

Block	Support Notes
Backlash	Supports code generation.
Coulomb and Viscous Friction (Simulink)	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Dead Zone	Supports code generation.
Dead Zone Dynamic	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Hit Crossing	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Quantizer	Supports code generation.
Rate Limiter	Cannot use inside a triggered subsystem hierarchy.
Rate Limiter Dynamic	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked

Block	Support Notes
	subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Relay	Support code generation.
Saturation	
Saturation Dynamic	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Wrap To Zero	

Discrete

Block	Support Notes
Delay	Supports code generation.
Difference	• The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option. • Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Discrete Derivative	• Depends on absolute time when used inside a triggered subsystem hierarchy. • Supports code generation.
Discrete Filter	Support code generation.
Discrete FIR Filter	

Block	Support Notes
PID Controller	• Depends on absolute time when used inside a triggered subsystem hierarchy. • Support code generation.
PID Controller (2DOF)	
Discrete State-Space	Support code generation.
Discrete Transfer Fcn	
Discrete Zero-Pole	
Discrete-Time Integrator	Depends on absolute time when used inside a triggered subsystem hierarchy.
Enabled Delay (Simulink)	Supports code generation.
First-Order Hold	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Memory	Support code generation.
Resettable Delay	
Tapped Delay	
Transfer Fcn First Order	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Transfer Fcn Lead or Lag	
Transfer Fcn Real Zero	
Unit Delay	Support code generation.
Variable Integer Delay	
Zero-Order Hold	

Logic and Bit Operations

Block	Support Notes
Bit Clear	Support code generation.
Bit Set	
Bitwise Operator	
Combinatorial Logic	
Compare to Constant	
Compare to Zero

Math Function (reciprocal)	
Math Function (rem)	
Math Function (square)	
Math Function (transpose)	
Matrix Concatenate (Simulink)	
MinMax	
MinMax Running Resettable	
Permute Dimensions	
Polynomial	
Product	
Product of Elements	
Real-Imag to Complex	
Reciprocal Sqrt (Simulink)	
Reshape	
Rounding Function	
Sign	

Block	Support Notes
Signed Sqrt (Simulink)	
Sine Wave Function	• Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation. • Depends on absolute time when used inside a triggered subsystem hierarchy.
Slider Gain	Support code generation.
Sqrt	
Squeeze	
Subtract	
Sum	
Sum of Elements	
Trigonometric Function	Functions `asinh`, `acosh`, and `atanh` are not supported by all compilers. If you use a compiler that does not support those functions, the software issues a warning for the block and the generated code fails to link.
Unary Minus	Support code generation.
Vector Concatenate (Simulink)	
Weighted Sample Time Math	

Model Verification

Block	Support Notes
Assertion	Supports code generation.
Check Discrete Gradient	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being

Block	Support Notes
	suitable for production code. Thus, blocks suitable for production code remain suitable.
Check Dynamic Gap	Support code generation.
Check Dynamic Lower Bound	
Check Dynamic Range	
Check Dynamic Upper Bound	
Check Input Resolution	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Check Static Gap	
Check Static Lower Bound	
Check Static Range	
Check Static Upper Bound	

Model-Wide Utilities

Block	Support Notes
Block Support Table	Ignored during code generation.
DocBlock	Uses the template symbol you specify for the **Embedded Coder Flag** block parameter to add comments to generated code. Requires an Embedded Coder license. For more information, see "Use a Simulink DocBlock to Add a Comment" on page 36-8.
Model Info	Ignored during code generation.
Timed-Based Linearization	
Trigger-Based Linearization	

Ports & Subsystems

Signal Attributes

Block	Support Notes
Bus to Vector (Simulink)	Support code generation.
Data Type Conversion	
Data Type Conversion Inherited	
Data Type Duplicate	
Data Type Propagation (Simulink)	
Data Type Scaling Strip	
IC	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Probe	Supports code generation.
Rate Transition	• Supports code generation. • Cannot use inside a triggered subsystem hierarchy.
Signal Conversion	Support code generation.
Signal Specification	
Unit Conversion	
Weighted Sample Time	
Width	

Signal Routing

Block	Support Notes
Bus Assignment	Support code generation.
Bus Creator	
Bus Selector	
Data Store Memory	
Data Store Read	
Data Store Write	
Demux	
Environment Controller	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
From	Support code generation.
Goto	
Goto Tag Visibility	
Index Vector	
Manual Switch	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Manual Variant Sink	Support code generation.
Manual Variant Source	

Block	Support Notes
Merge	When multiple signals connected to a Merge block have a non-`Auto` storage class, all non-`Auto` signals connected to that block must *be identically labeled* and *have the same storage class*. When Merge blocks connect directly to one another, these rules apply to all signals connected to Merge blocks in the group.
Multiport Switch	Support code generation.
Mux	
Selector	
State Reader	
State Writer	
Switch	
Variant Sink	
Variant Source	
Vector Concatenate	

Sinks

Block	Support Notes
Display	Ignored for code generation.
Floating Scope (Simulink)	
Outport (Out1)	Supports code generation.
Scope (Simulink)	Ignored for code generation.
Stop Simulation	• Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable. • Generated code stops executing when the stop condition is true.
Terminator	Supports code generation.

Block	Support Notes
To File	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
To Workspace	Ignored for code generation.
XY Graph	

Sources

Block	Support Notes
Band-Limited White Noise	Cannot use inside a triggered subsystem hierarchy.
Chirp Signal	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Clock	
Constant	Supports code generation.
Counter Free-Running	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Block	Support Notes
Counter Limited	• The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option. • Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Digital Clock	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Enumerated Constant	Supports code generation.
From File	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
From Spreadsheet	
From Workspace	Ignored for code generation.
Ground	Support code generation.

Block	Support Notes
Inport (In1)	
Pulse Generator	Cannot use inside a triggered subsystem hierarchy. Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.
Ramp	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Random Number	Supports code generation.
Repeating Sequence	• Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable. • Consider using the Repeating Sequence Stair or Repeating Sequence Interpolated block instead.
Repeating Sequence Interpolated	• The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option. • Cannot use inside a triggered subsystem hierarchy.
Repeating Sequence Stair	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In

Block	Support Notes
	certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Signal Builder	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Signal Generator	
Sine Wave	• Depends on absolute time when used inside a triggered subsystem hierarchy. • Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.
Step	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Uniform Random Number	Supports code generation.
Waveform Generator	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

User-Defined

Block	Support Notes
Fcn	Support code generation.
Function Caller	
Initialize Function	
Interpreted MATLAB Function	Consider using the MATLAB Function block instead.
Level-2 MATLAB S-Function	Ignored during code generation.
MATLAB Function	Support code generation.
MATLAB System	
S-Function	S-functions that call into MATLAB are not supported for code generation.
S-Function Builder	
Simulink Function	Support code generation.
Terminate Function	

Simulink Block Data Type Support Table

The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages.

Block Set Support for Code Generation

Several products that include blocks are available for you to consider for code generation. However, before using the blocks for one of these products, consult the documentation for that product to confirm which blocks support code generation.

Modeling Semantic Considerations

In this section...

Data Propagation

The first stage of code generation is compilation of the block diagram. This stage is analogous to that of a C or C++ program. The compiler carries out type checking and preprocessing. Similarly, the Simulink engine verifies that input/output data types of block ports are consistent, line widths between blocks are of expected thickness, and the sample times of connecting blocks are consistent.

The Simulink engine propagates data from one block to the next along signal lines. The data propagated consists of

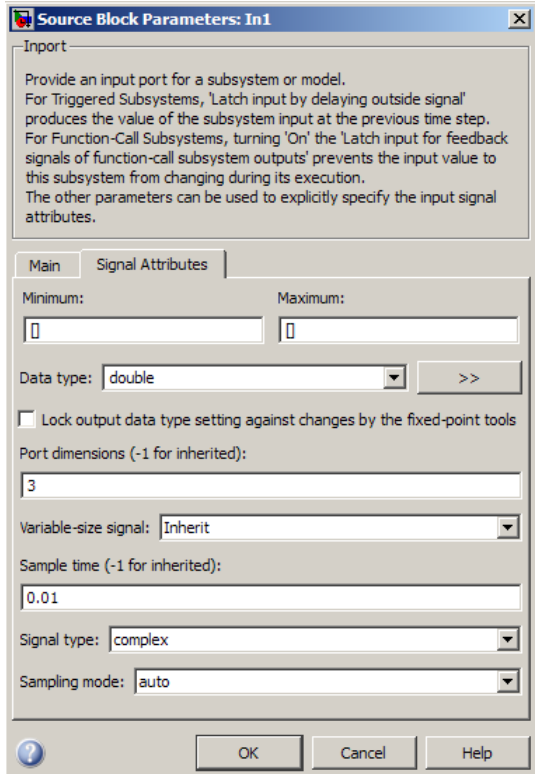
- Data type
- Line widths
- Sample times

You can verify what data types a Simulink block supports by typing

```
showblockdatatypetable
```

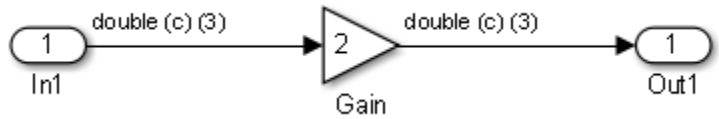
at the MATLAB prompt, or (from the Help browser) clicking the command above.

The Simulink engine typically derives signal attributes from a source block. For example, the Inport block's parameters dialog box specifies the signal attributes for the block.



In this example, the Inport block has a port width of 3, a sample time of .01 seconds, the data type is double, and the signal is complex.

This figure shows the propagation of the signal attributes associated with the Inport block through a simple block diagram.



In this example, the Gain and Outport blocks inherit the attributes specified for the Inport block.

Sample Time Propagation

Inherited sample times in source blocks (for example, a root inport) can sometimes lead to unexpected and unintended sample time assignments. Since a block may specify an inherited sample time, information available at the outset is often insufficient to compile a block diagram completely.

In such cases, the Simulink engine propagates the known or assigned sample times to those blocks that have inherited sample times but that have not yet been assigned a sample time. Thus, the engine continues to fill in the blanks (the unknown sample times) until sample times have been assigned to as many blocks as possible. Blocks that still do not have a sample time are assigned a default sample time.

For a completely deterministic model (one where no sample times are set using the above rules), you should explicitly specify the sample times of your source blocks. Source blocks include root inport blocks and blocks without input ports. You do not have to set subsystem input port sample times. You might want to do so, however, when creating modular systems.

An unconnected input implicitly connects to ground. For ground blocks and ground connections, the sample time is always constant (`inf`).

All blocks have an inherited sample time ($T_s = -1$). They are assigned a sample time of ($T_f - T_i$)/50.

Blocks Whose Outputs Have Constant Values

When you display sample time colors, by default, Constant blocks appear magenta in color to indicate that the block outputs have constant values during simulation. Downstream blocks whose output values are also constant during simulation, such as Gain blocks, similarly appear magenta if they use an inherited sample time. The code generated for these blocks depends in part on the tunability of the block parameters.

If you set **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to `Inlined`, the block parameters are not tunable in the generated code. Because the block outputs are constant, the code generator eliminates the block code due to constant folding. If the code generator cannot fold the code, or if you select settings to disable constant folding, the block code appears in the model initialization function. The generated code is more efficient because it does not compute the outputs of these blocks during execution.

However, if you configure a block or model so that the block parameters appear in the generated code as tunable variables, the code generator represents the blocks in a different way. Block parameters are tunable if, for example:

- You set **Default parameter behavior** to `Tunable`. By default, numeric block parameters appear as tunable fields of a global parameter structure.
- You use a tunable parameter, such as a `Simulink.Parameter` object that uses a storage class other than `Auto`, as the value of one or more numeric block parameters. These block parameters are tunable regardless of the setting that you choose for **Default parameter behavior**.

If a block parameter is tunable, the generated code must compute the block outputs during execution. Therefore, the block code appears in the model `step` function. If the model uses multiple discrete rates, the block code appears in the output function for the fastest downstream rate that uses the block outputs.

Latches for Subsystem Blocks

When an Inport block is the signal source for a triggered or function-call subsystem, you can use latch options to preserve input values while the subsystem executes. The Inport block latch options include:

For	Use
Triggered subsystems	**Latch input by delaying outside signal**
Function-call subsystems	**Latch input for feedback signals of function-call subsystem outputs**

When you use **Latch input for feedback signals of function-call subsystem outputs** for a function-call subsystem, the code generator

- Preserves latches in generated code regardless of optimizations that might be set
- Places the code for latches at the start of a subsystem's output/update function

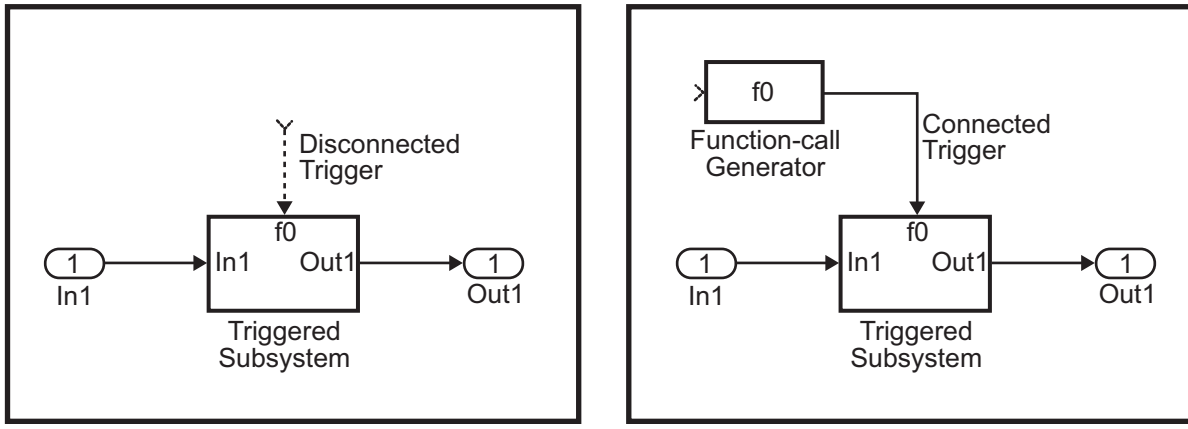
For more information on these options, see the block description of Inport.

Block Execution Order

Once the Simulink engine compiles the block diagram, it creates a *`model`*`.rtw` file (analogous to an object file generated from a C or C++ file). The *`model`*`.rtw` file contains

the connection information of the model, as well as the signal attributes. Thus, the timing engine in can determine when blocks with different rates should be executed.

You cannot override this execution order by directly calling a block (in handwritten code) in a model. For example, in the next figure the `disconnected_trigger` model on the left has its trigger port connected to ground, which can lead to the blocks inheriting a constant sample time. Calling the trigger function, `f()`, directly from user code does not work. Instead, you should use a function-call generator to specify the rate at which `f()` should be executed, as shown in the `connected_trigger` model on the right.



Instead of the function-call generator, you could use another block that can drive the trigger port. Then, you should call the model's main entry point to execute the trigger function.

For multirate models, a common use of the code generator is to generate code for individual models separately and then manually code the I/O between the generated code modules. This approach places the burden of data consistency between models on the developer of the models. Another approach is to let Simulink and the code generator maintain data consistency between rates and generate multirate code for use in a multitasking environment. The Rate Transition block is able to interface periodic and asynchronous signals. For a description of the Simulink Coder block libraries, see "Asynchronous Events" (Simulink Coder). For more information on multirate code generation, see "Modeling for Multitasking Execution" (Simulink Coder).

Algebraic Loops

Algebraic loops are circular dependencies between variables. This prevents the straightforward direct computation of their values. For example, in the case of a system of equations

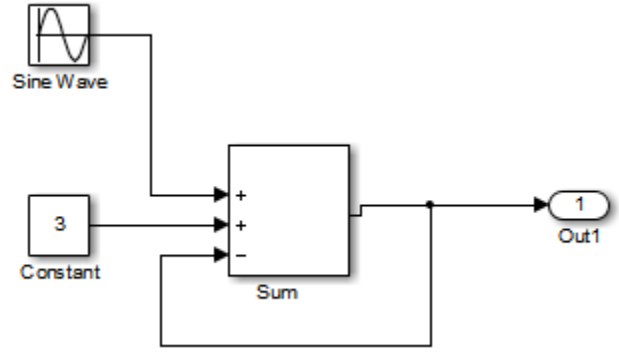
- `x = y + 2`
- `y = -x`

the values of `x` and `y` cannot be directly computed.

To solve this, either repeatedly try potential solutions for `x` and `y` (in an intelligent manner, for example, using gradient based search) or "solve" the system of equations. In the previous example, solving the system into an explicit form leads to

- `2x = 2`
- `y = -x`
- `x = 1`
- `y = -1`

An algebraic loop exists whenever the output of a block having direct feedthrough (such as Gain, Sum, Product, and Transfer Fcn) is fed back as an input to the same block. The Simulink engine is often able to solve models that contain algebraic loops, such as the next diagram.

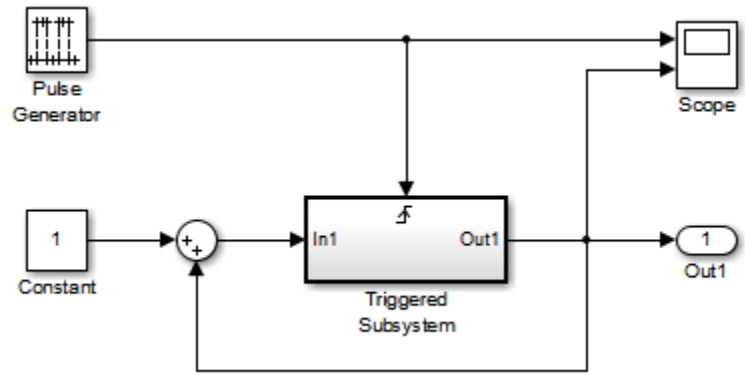


The code generator does not produce code that solves algebraic loops. This restriction includes models that use Algebraic Constraint blocks in feedback paths. However, the

Simulink engine can often eliminate algebraic loops that arise, by grouping equations in certain ways in models that contain them. It does this by separating the update and output functions to avoid circular dependencies. For details, see "Algebraic Loops" (Simulink).

Algebraic Loops in Triggered Subsystems

While the Simulink engine can minimize algebraic loops involving atomic and enabled subsystems, a special consideration applies to some triggered subsystems. An example for which code can be generated is shown in the following model and triggered subsystem.



The default Simulink behavior is to combine output and update methods for the subsystem, which creates an apparent algebraic loop, even though the Unit Delay block in the subsystem has no direct feedthrough.

You can allow the Simulink engine to solve the problem by splitting the output and update methods of triggered and enabled-triggered subsystems when feasible. If you want the code generator to take advantage of this feature, select the **Minimize algebraic loop occurrences** check box in the Subsystem Parameters dialog box. Select this option to avoid algebraic loop warnings in triggered subsystems involved in loops.

Note: If you check this box, the generated code for the subsystem might contain split output and update methods, even if the subsystem is not actually involved in a loop. Also, if a direct feedthrough block (such as a Gain block) is connected to the inport in the

above triggered subsystem, the Simulink engine cannot solve the problem, and the code generator is unable to generate code.

A similar **Minimize algebraic loop occurrences** option appears on the **Model Referencing** pane of the Configuration Parameters dialog box. Selecting it enables the Simulink Coder software to generate code for models containing Model blocks that are involved in algebraic loops.

Modeling Guidelines for Blocks

Code generation modeling guidelines include recommended model settings, block usage, and block parameters. When you develop models for code generation, use these guidelines.

For more information, see "Modeling Guidelines" (Simulink).

Subsystems in Simulink Coder

Code Generation of Subsystems

For you to control how code is generated for a nonvirtual subsystem, the code generator provides subsystem parameters that you can use. The categories of nonvirtual subsystems are:

- *Conditionally executed* subsystems. Execution depends upon a control signal or control block. These subsystems include:
  - Triggered
  - Enabled
  - Action
  - Iterator
  - Function-call

  For more information, see "Conditional Subsystems" (Simulink).
- *Atomic* subsystems: A virtual subsystem can be declared atomic (and therefore nonvirtual) by using the "Treat as atomic unit" (Simulink) parameter in the Subsystem Parameters dialog box.

For more information on nonvirtual subsystems and atomic subsystems, see "Systems and Subsystems" (Simulink) and open the Subsystem Semantics library.

You can design and configure your model to control the code generated from nonvirtual subsystems.

To...	See...

Generate code for only a subsystem.	"Generate Code and Executables for Individual Subsystem" on page 3-4
Generate separate functions with no arguments, and optionally place the subsystem code in a separate file.	"Generate Subsystem Code as Separate Function and Files" on page 3-10
Generate a single reentrant function for a subsystem that is included in multiple places within a model.	"Generate Reusable Function for Identical Subsystems Within a Model" on page 3-11

To...	See...
Generate a single reentrant function for a subsystem that is included in multiple places in a model reference hierarchy.	"Generate Reusable Code for Subsystems Shared Across Models" on page 3-28 and "Code Reuse For Subsystems Shared Across Models" on page 3-20

Note: If you generate code for a virtual subsystem, code generator treats the subsystem as atomic and generates the code accordingly. The resulting code can change the execution behavior of your model, for example, by applying algebraic loops, and therefore introduce inconsistencies with the simulation behavior. Declare virtual subsystems as atomic subsystems, which makes simulation and execution behavior consistent for your model consistent.

Subsystem Code Dependence

Code generated from nonvirtual subsystems may or may not be completely independent of the generating model. When generating code for a subsystem, the code may reference global data structures of the model, even if the subsystem code is in a separate file. Each subsystem code file contains `include` directives and comments describing the dependencies. The code generator checks for cyclic file dependencies and warns about them at build time. For descriptions of how generated code is packaged, see "Manage Build Process File Dependencies" (Simulink Coder).

To generate subsystem code that is independent of the generating model, place the subsystem in a library and configure it as a reusable subsystem. For more information, see "Code Reuse For Subsystems Shared Across Models" on page 3-20.

Generate Code and Executables for Individual Subsystem

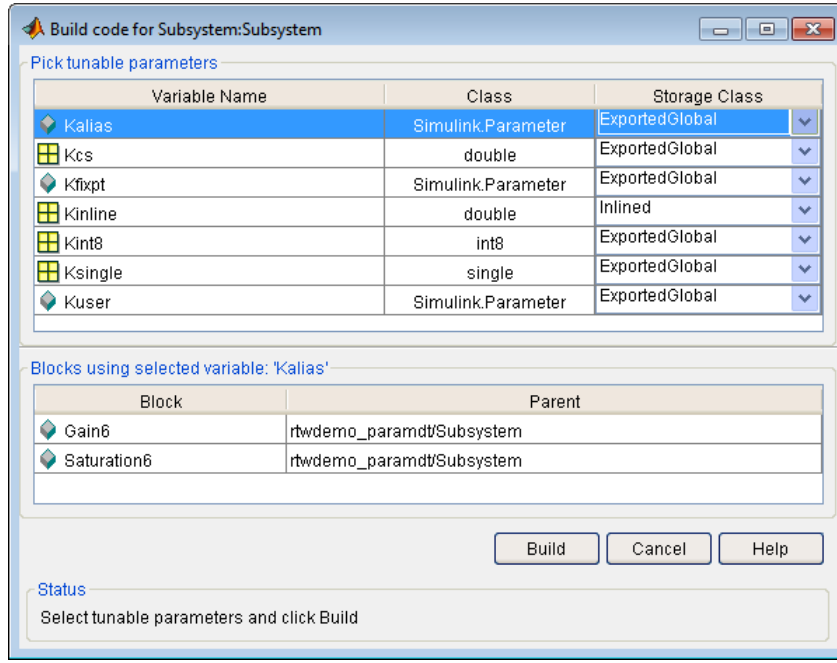
You can generate code and build an executable for a subsystem within a model. The code generation and build process uses the code generation and build parameters of the root model.

1. In the Configuration Parameters dialog box, set up the code generation and build parameters, similar to setting up the code generation for a model.
2. Right-click the Subsystem block. From the context menu, select **C/C++ Code > Build This Subsystem** from the context menu.

   Alternatively, in the current model, click a subsystem and then from the **Code** menu, select **C/C++ Code > Build Selected Subsystem**.

   Note When you select **Build This Subsystem**, if the model is operating in external mode, the build process automatically turns off external mode for the duration of the build. The code generator restores external mode upon completion of the build process.
3. The **Build code for Subsystem** window displays a list of the subsystem parameters. The upper pane displays the name, class, and storage class of each variable (or data object) that is referenced as a block parameter in the subsystem. When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter and the parent system of each block.

   The **Storage Class** column contains a menu for each row. The menu options set the storage class or inline the parameter. To declare a parameter to be tunable, set the **Storage Class** to a value other than **Inlined**.



For more information on tunable and inlined parameters and storage classes, see "Block Parameter Representation in the Generated Code" (Simulink Coder).

4 After selecting tunable parameters, **Build** to initiate the code generation and build process.

5 The build process displays status messages in the MATLAB Command Window. When the build is complete, the generated executable is in your working folder. The name of the generated executable is *`subsystem`*`.exe` (on PC platforms) or *`subsystem`* (on The Open Group UNIX® platforms). *`subsystem`* is the name of the source subsystem block.

The generated code is in a build subfolder, named *`subsystem_target`*`_rtw`. *`subsystem`* is the name of the source subsystem block and *`target`* is the name of the target configuration.

When you generate code for a subsystem, you can generate an S-function by selecting **Code > C/C++ Code> Generate S-Function**, or you right-click the subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu. For more

information on S-functions, see "Automate S-Function Generation with S-Function Builder" (Simulink Coder).

Subsystem Build Limitations

The following limitations apply to building subsystems:

- Subsystem build does not support a subsystem that has a function-call trigger input or a function-call output.
- When you right-click a subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu to build a subsystem that includes an Outport block for which the **Data type** parameter specifies a bus object, you must address errors that result from setting signal labels. To configure the software to display these errors, in the Configuration Parameters dialog box for the parent model, on the **Diagnostics > Connectivity** pane, set the **Signal label mismatch** parameter to `error`.
- When a subsystem is in a triggered or function-call subsystem, the right-click build process might fail if the subsystem code is not sample-time independent. To find out whether a subsystem is sample-time independent:

  1. Copy all blocks in the subsystem to an empty model.
  2. In the Configuration Parameters dialog box, on the **Solver** pane, set:
     a. **Type** to `Fixed-step`.
     b. **Periodic sample time constraint** to `Ensure sample time independent`.
     c. Click **Apply**.
  3. Update the model. If the model is sample-time dependent, Simulink generates an error in the process of updating the diagram.

Inline Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, setting the **Function packaging** parameter to `Auto` or `Inline` inlines the generated code of the subsystem.

The `Auto` option is the default. When there is only one instance of a subsystem in the model, the `Auto` option inlines the subsystem code. When multiple instances of a subsystem exist, the `Auto` option results in a single copy of the function (as a reusable function). For function-call subsystems with multiple callers, the subsystem code is generated as if you specified `Nonreusable function`.

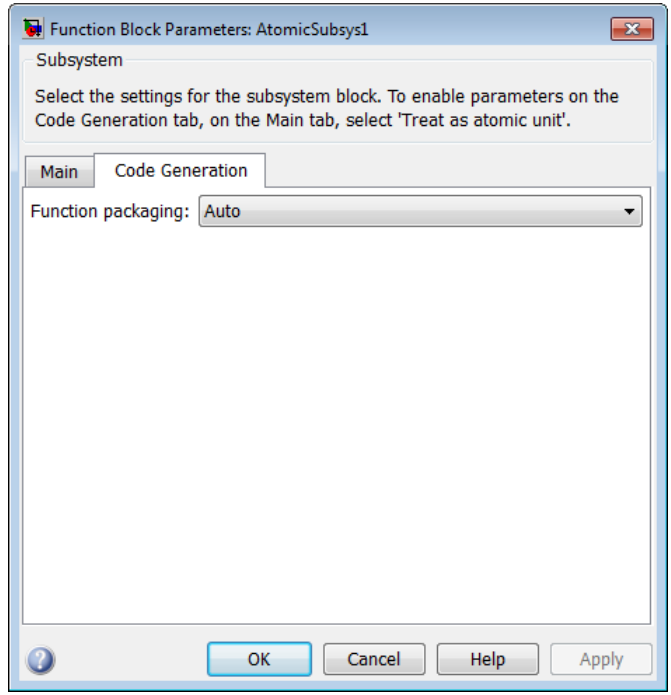
To inline subsystem code, select `Inline`. The `Inline` option explicitly directs the code generator to inline the subsystem unconditionally.

Configure Subsystem to Inline Code

To configure your subsystem for inlining:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.

   If the system is already nonvirtual, the **Function packaging** option is already selected.
3. Click the **Code Generation** tab and select `Auto` or `Inline` from the **Function packaging** parameter.



4 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within *model*`.c` or *model*`.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though the **Inline** option is selected.

- If the subsystem is a function-call subsystem that is called by a noninlined S-function, the **Inline** option is ignored. Noninlined S-functions make calls by using function

pointers. Therefore, the function-call subsystem must generate a function with all arguments present.

- In a feedback loop involving function-call subsystems, the code generator forces one of the subsystems to be generated as a function instead of inlining it. Based on the order in which the subsystems are sorted internally, the software selects the subsystem to be generated as a function.
- If a subsystem is called from an S-function block that sets the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` to `TRUE`, it is not inlined. When user-defined Async Interrupt blocks or Task Sync blocks are present, this result might occur. Such blocks must be generated as functions. These blocks are located in the `vxlib1` block library and use the `SS_OPTION_FORCE_NONINLINED_FCNCALL` option. This library demonstrates integration with an example RTOS (VxWorks®).[1]

Note: You can use the blocks in the `vxlib1` (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

1. VxWorks is a registered trademark of Wind River® Systems, Inc.

Generate Subsystem Code as Separate Function and Files

To generate both a separate subsystem function and a separate file for a subsystem in a model:

1. Right-click a Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. On the **Code Generation** tab, the **Function packaging** parameter is now available.
3. Click the **Code Generation** tab and select `Nonreusable function` from the **Function packaging** parameter. The `Nonreusable function` option enables two parameters:
   - The "Function name options" (Simulink) parameter controls the naming of the generated function.
   - The "File name options" (Simulink) parameter controls the naming of the generated file.
4. Set the **Function name options** parameter.
5. Set the **File name options** parameter to a value other than `Auto`. If you are generating a reusable function for your subsystem, see "Generate Reusable Function for Identical Subsystems Within a Model" on page 3-11 or "Generate Reusable Code for Subsystems Shared Across Models" on page 3-28.
6. Click **Apply** and close the dialog box.

Generate Reusable Function for Identical Subsystems Within a Model

In the Subsystem Parameters dialog box, the **Function packaging** parameter option `Nonreusable function` generates functions that use global data. The `Reusable function` option generates reusable functions that have data passed as arguments (enabling them to be reentrant). Selecting `Reusable function` generates a function with arguments that allows the subsystem code to be shared by other instances of it in the model. This action supports less code instead of replicating the code for each instance of a subsystem or each time it is called.

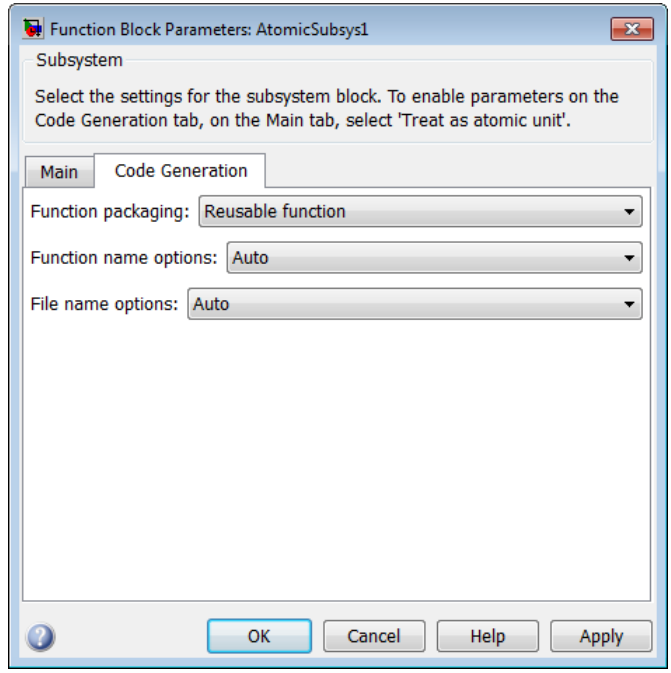
To determine reusability of the subsystem code, the code generator performs a checksum to determine if subsystems are identical. The generated function has arguments, for example, for block inputs and outputs (`rtB_*`), continuous states (`rtDW_*`), parameters (`rtP_*`).

Note: In the generated code, the call interface is subject to change from release to release. Therefore, do not directly call reusable functions from external code.

To generate one reusable function for identical subsystems within a model:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. On the **Code Generation** tab, the **Function packaging** menu is now available.

   If the subsystem is already nonvirtual, the **Function packaging** menu is already selected.
3. Click the **Code Generation** tab and select `Reusable function` for the **Function packaging** parameter.



For more information about this setting, see "Considerations for Function Packaging Options Auto and Reusable function" on page 3-13.

4 Set the function name using the "Function name options" (Simulink) parameter.

Note: If you do not choose `Auto`, for other Subsystem blocks that you want to share this code, specify the same function name for those Subsystem blocks.

---

5 Set the file name using the "File name options" (Simulink) parameter to a value other than `Auto`. If your generated code is under source control, a value other than `Auto` prevents the generated file name from changing due to unrelated model modifications.

Note: For other Subsystem blocks that you want to share this code, specify the same file name for those Subsystem blocks.

---

6 Click **Apply** and close the dialog box.

For a summary of code reuse limitations, see "Code Reuse Limitations for Subsystems" on page 3-17.

Considerations for Function Packaging Options `Auto` and `Reusable function`

When you want multiple instances of a subsystem to be represented as one reusable function, you can designate each one of them as `Auto` or as `Reusable function`. Use one or the other, because using both creates two reusable functions, one for each specification. The outcomes of these choices differ only when reuse is not possible. Selecting `Auto` does not allow control of the function or file name for the subsystem code.

The `Reusable function` and `Auto` options both try to determine if multiple instances of a subsystem exist and if the code can be reused. When reuse is not possible, there are differences in the options behavior:

- `Auto` yields inlined code. If circumstances prohibit inlining, then the generated code is separate functions for each subsystem instance.
- `Reusable function` yields a separate function with arguments for each subsystem instance in the model.

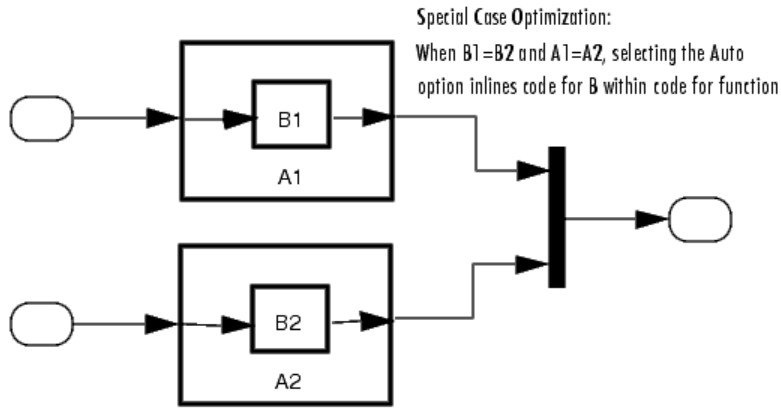
Code Reuse for Subsystems with Mask Parameters

The code generator can produce reusable (reentrant) code for a model containing identical atomic subsystems. Selecting the `Reusable function` option for **Function packaging** enables such code reuse, and causes a single function with arguments to be generated that is called when an identical atomic subsystem executes. See "Subsystems" (Simulink Coder) for details and restrictions on the use of this option.

Mask parameters become arguments to reusable functions. However, for reuse to occur, each instance of a reusable subsystem must declare the same set of mask parameters. If, for example subsystem A has mask parameters `b` and `K`, and subsystem B has mask parameters `c` and `K`, then code reuse is not possible, and the code generator produces separate functions for A and B.

Optimize Code for Identical Nested Subsystems

The **Function packaging** parameter `Auto` option can optimize code in situations in which identical subsystems contain other identical subsystems, by both reusing and inlining generated code. Suppose a model, such as the one shown in Reuse of Identical Nested Subsystems, contains identical subsystems `A1` and `A2`. `A1` contains subsystem `B1`, and `A2` contains subsystem `B2`, which are identical. In such cases, the `Auto` option causes one function to be generated which is called for both `A1` and `A2`. This function contains one piece of inlined code to execute `B1` and `B2`. This optimization generates less code which improves execution speed.



Reuse of Identical Nested Subsystems

Generate Reusable Code for Subsystems Containing S-Function Blocks

There are several requirements that need to be met in order for subsystems containing S-function blocks to be reused. For the list of requirements, see "S-Functions That Support Code Reuse" (Simulink Coder).

When you select the `Reusable function` option, two additional options are enabled, **Function name options** and **File name options**. If you use these fields to enter a function name and/or a file name, you must specify exactly the same function name and file name for each instance of identical subsystems for the code generator to reuse the subsystem code. For an example, follow the procedure in "Generate Reusable Function for Identical Subsystems Within a Model" on page 3-11.

Generate Reusable Code from Stateflow Charts

You can generate reusable code from a Stateflow chart, or from a subsystem containing a chart, *except* when the Stateflow chart contains exported graphical functions.

Code Reuse Limitations for Subsystems

The code generator uses a checksum to determine whether subsystems are identical and reusable. Subsystem code is not reused, if:

- In blocks and data objects, you use symbols to specify dimensions.
- A port used by multiple instances of a subsystem has different sample times, data types, complexity, frame status, or dimensions across the instances.
- The output of a subsystem is marked as a global signal.
- Subsystems contain identical blocks with different names or parameter settings.
- The output of a subsystem is connected to a Merge block, and the output of the Merge block is a custom storage class that is implemented in the C code as memory that is nonaddressable (for example, `BitField`).
- The input of a subsystem is nonscalar and has a custom storage class that is implemented in the C code as memory that is nonaddressable.
- A masked subsystem has a parameter that is nonscalar and has a custom storage class that is implemented in the C code as memory that is nonaddressable.
- A function-call subsystem uses mask parameters of any kind when you set the model configuration parameter "Default parameter behavior" (Simulink) to `Tunable`. To reuse the masked function-call subsystem, you can place the masked subsystem inside a new atomic subsystem without a mask, and move the Trigger block from the masked subsystem into the atomic subsystem.
- A block in the subsystems uses a *partially tunable expression*. Some partially tunable expressions can disable code reuse.

  Partially tunable expressions are expressions that contain one or more tunable variables in addition to an expression that is not tunable. For example, suppose that you create the tunable variable `K` with value `15.23` and the tunable variable `P` with value `[5;7;9]`. The expression `K+P'` is a partially tunable expression because the expression `P'` is not tunable. For more information about tunable expression limitations, see "Tunable Expression Limitations" (Simulink Coder).

If you select `Reusable function`, and the code generator determines that you cannot reuse the code for a subsystem, it generates a separate function that is not reused. The code generation report might show that the separate function is reusable, even if only one subsystem uses it. If you prefer that subsystem code be inlined in such circumstances rather than deployed as functions, choose `Auto` for the **Function packaging** option.

Blocks That Prevent Code Reuse

Use of the following blocks in a subsystem can also prevent the subsystem code from being reused:

- Scope blocks (with data logging enabled)
- S-Function blocks that fail to meet certain criteria (see "S-Functions That Support Code Reuse" (Simulink Coder))
- To File blocks (with data logging enabled)
- To Workspace blocks (with data logging enabled)

Code Reuse Limitations for Subsystems Shared Across Referenced Models

The code generator uses a checksum to determine whether reusable library subsystems are identical. The code generator places the reusable library subsystem code in the shared utilities folder, and the reusable code is independent of the generated code of the top model or the referenced model. For example, the reusable library subsystem code does not include *`model`*`.h` or *`model`*`_types.h`.

Reusable code that is generated to the shared utilities folder and is dependent on the model code does not compile. If the code generator determines that the reusable library subsystem code is dependent on the model code, the reusable subsystem code is not generated to the shared utilities folder. The following cases can generate code that is dependent on the model code, when the reusable library subsystem:

- Contains a block that uses time-related functionality, such as a Step block, or continuous time or multirate blocks.
- Contains one or more Model blocks.
- Contains subsystems that are not inlined or a reusable library subsystem.
- Contains a signal that is not an `Auto` storage class. Variables of non-`Auto` storage classes are generated to *`model`*`.h`.
- Contains a parameter that is not an `Auto` storage class.
- Contains a user-defined type where **Data Scope** is not set to `Exported`. The code generator might place the type definition in *`model`*`_types.h`.
- Is a variant subsystem that generates preprocessor conditionals. Preprocessor directives defining the variant objects are included in *`model`*`_types.h`.

Code Reuse For Subsystems Shared Across Models

To reuse common functionality, you can include multiple instances of a subsystem:

- Within a single model, which is a top model or part of model reference hierarchy
- Across multiple referenced models in a model reference hierarchy
- Across multiple top models that contain Model blocks
- Across multiple top models that do not include Model blocks

To generate a reusable function for a subsystem which is included in multiple models:

- If the subsystem is in a model reference hierarchy, set the configuration parameter, "Shared code placement" (Simulink Coder) to `Auto`. Otherwise, for each model that uses the subsystem, set **Shared code placement** to `Shared location`. The **Shared code placement** parameter is in the Configuration Parameters dialog box, on the **Code Generation > Interface** pane.
- The subsystem must be defined in a library and configured for reuse. This subsystem is referred to as a *reusable library subsystem*. For more information, see "Reusable Library Subsystem" on page 3-21.

For an example, see "Generate Reusable Code for Subsystems Shared Across Models" on page 3-28.

The code generator performs a checksum to determine reusability. There are cases when the code generator cannot reuse subsystem code. For more information, see "Code Reuse Limitations for Subsystems" on page 3-17.

Related Examples

- "Determine Why Subsystem Code Is Not Reused" on page 3-36

Reusable Library Subsystem

A reusable library subsystem is a subsystem included in a library that is configured for reuse. The Subsystem parameters must be set as follows:

- **Treat as an atomic unit** is selected.
- On the **Code Generation** tab:
  - **Function packaging** is set to `Reusable function`.
  - **Function name options**

    and **File name options** are set to `Auto` or `Use subsystem name`.

For more information on creating a library, see "Libraries" (Simulink). For an example of creating a reusable library subsystem, see "Generate Reusable Code for Subsystems Shared Across Models" on page 3-28.

Code Generation of a Reusable Library Subsystem

For incremental code generation, if the reusable library subsystem changes, a rebuild of itself and its parents occurs. During the build, if a matching function is not found, a new instance of the reusable function is generated into the shared utilities folder. If a different matching function is found from previous builds, that function is used, and a new reusable function is not emitted.

For subsequent builds, unused files are not replaced or deleted from your folder. During development of a model, when many obsolete shared functions exist in the shared utilities folder, you can delete the folder and regenerate the code. If all instances of a reusable library subsystem are removed from a model reference hierarchy and you regenerate the code, the obsolete shared functions remain in the shared utilities folder until you delete them.

If a model changes such that the change might cause different generated code for the subsystem, a new reusable function is generated. For example, model configuration parameters that modify code comments might cause different generated code for the subsystem even if the reusable library subsystem did not change.

Reusable Library Subsystem Code Placement and Naming

The code generator uses checksums to determine reusability. The generated code of a reusable library subsystem is independent of the generated code of the model. Code for the reusable library subsystem is generated to the shared utility folder, `slprj/target/_sharedutils`, instead of the model reference hierarchy folders. The generated code for the supporting types, which are generated to the `.h` file, are also in the shared utilities folder.

For unique naming, reusable function names have a checksum appended to the reusable library subsystem name. For example, the code and files for a subsystem, `SS1`, which links to a reusable library subsystem, `RLS`, might be:

- Function name: `RLS_mgdjlngd`
- File name: `RLS_mgdjlnd.c` and `RLS_mgdjlnd.h`

Reusable Library Subsystem in the Top Model

In a model reference hierarchy, if an instance of the reusable library subsystem is in the top model, then on the **Model Referencing** pane of the Configuration Parameters dialog box, you must select the **Pass fixed-size scalar root input by value for code generation** parameter. If you do not select the parameter, a separate shared function is generated for the reusable library subsystem instance in the top model, and a reusable function is generated for instances in the referenced models.

Reusable Library Subsystem Connected to Root Outport

If a reusable library subsystem is connected to the root outport, reuse does not happen with identical subsystems that are not connected to the root outport. However, you can set **Pass reusable system outputs as** to `Individual arguments` on the **Optimizations > Signals and Parameters** pane to make sure that reuse occurs between these subsystems. This parameter requires an Embedded Coder license.

Code Generation of Constant Parameters

The code generator attempts to generate constant parameters to the shared utilities folder first. If constant parameters are not generated to the shared utilities folder, they are defined in the top model in a global constant parameter structure. The declaration of the structure, `ConstParam_`*`model`*, is in *`model`*`.h`:

```
/* Constant parameters (auto storage) */
typedef struct {
   /* Expression: [1 2 3 4 5 6 7]
    * Referenced by: '<Root>/Constant'
    */
   real_T Constant_Value[7];

   /* Expression: [7 6 5 4 3 2 1]
    * Referenced by: '<Root>/Gain'
    */
   real_T Gain_Gain[7];
 } ConstParam_model;
```

The definition of the constant parameters, *`model`*`_constP`, is in:

```
/* Constant parameters (auto storage) */
const ConstParam_model model_ConstP = {
   /* Expression: [1 2 3 4 5 6 7]
    * Referenced by: '<Root>/Constant'
    */
   { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 },

   /* Expression: [7 6 5 4 3 2 1]
    * Referenced by: '<Root>/Gain'
    */
   { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 }
};
```

The *`model`*`_constP` is passed as an argument to referenced models. For more information on how shared constants are generated, see “Shared Constant Parameters for Code Reuse” on page 3-24.

Shared Constant Parameters for Code Reuse

You can share the generated code for constant parameters across models if:

- Constant parameters are shared in a model reference hierarchy, or
- On the **Code Generation > Interface** pane, the model configuration parameter "Shared code placement" (Simulink Coder) is set to `Shared location`.

If you do not want to generate shared constants, and **Shared code placement** is set to `Shared location`, set the parameter `GenerateSharedConstants` to `off`. For example, to turn off shared constants for the current model, in the Command Window, type the following.

```
set_param(gcs,'GenerateSharedConstants','off');
```

The shared constant parameters are generated individually to the `const_params.c` file, which is placed in the shared utilities folder `slprj/`*`target`*`/_sharedutils`.

For example, if a constant has multiple uses within a model reference hierarchy where the top model is named `topmod`, the code for the shared constant is as follows:

- In the shared utility folder, `slprj/grt/_sharedutils`, the constant parameters are defined in `const_params.c` and named `rtCP_pooled_` appended to a unique checksum:

  ```
  extern const real_T rtCP_pooled_lfcjjmohiecj[7];
  const real_T rtCP_pooled_lfcjjmohiecj[7] = { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 };

  extern const real_T rtCP_pooled_ppphohdbfcba[7];
  const real_T rtCP_pooled_ppphohdbfcba[7] = { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 };
  ```

- In *`top_model`*`_private.h` or in a referenced model, *`ref_model`*`_private.h`, for better readability, the constants are renamed as follows:

  ```
  extern const real_T rtCP_pooled_lfcjjmohiecj[7];
  extern const real_T rtCP_pooled_ppphohdbfcba[7];

  #define rtCP_Constant_Value   rtCP_pooled_lfcjjmohiecj  /* Expression: [1 2 3 4 5 6 7]
                                                           * Referenced by: '<Root>/Constant'*/
  #define rtCP_Gain_Gain        rtCP_pooled_ppphohdbfcba  /* Expression: [7 6 5 4 3 2 1]
                                                           * Referenced by: '<Root>/Gain' */
  ```

- In `topmod.c` or `refmod.c`, the call site might be:

  ```
  for (i = 0; i < 7; i++) {
     topmod_Y.Out1[i] = (topmod_U.In1 + rtCP_Constant_Value[i]) * rtCP_Gain_Gain[i];
  }
  ```

The code generator attempts to generate all constants as individual constants to the `const_params.c` file in the shared utilities folder. Otherwise, constants are generated as described in "Code Generation of Constant Parameters" on page 3-23.

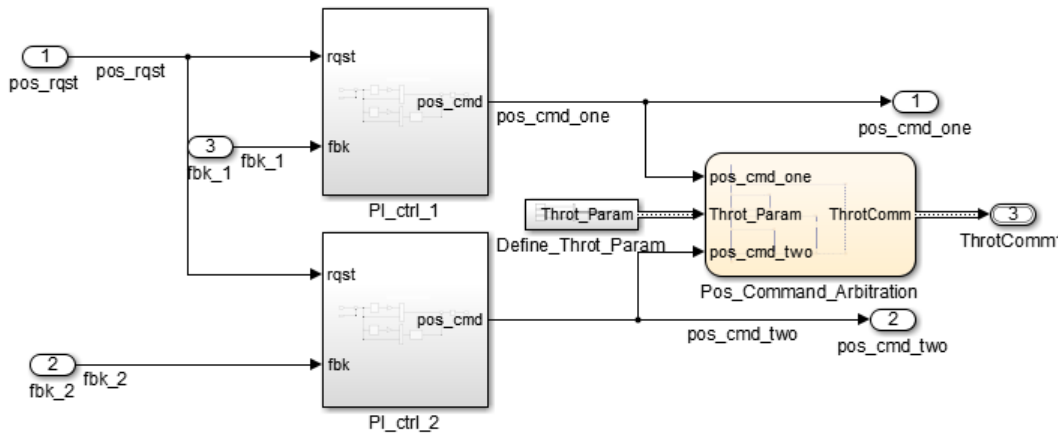
Suppress Shared Constants in the Generated Code

You can choose whether or not the code generator produces shared constants and shared functions. You may want to be able to keep the code and data separate between subsystems, or you may find that sharing constants results in a memory shortage during code generation.

You can change this parameter programmatically using the parameter `GenerateSharedConstants` with `set_param` and `get_param`.

In the following example, when `GenerateSharedConstants` is set to `on`, the code generator defines the constant values in the `_sharedutils` folder in the `const_params.c` file. When `GenerateSharedConstants` is set to `off`, the code generator defines the constant values in a nonshared area, in the `model_ert_rtw` file in the `model_data.c` file.

Open the model `rtwdemo_throttlecntrl`:



In the Configuration parameters dialog box, on the **Code Generation** > **Interface** pane, verify that "Shared code placement" (Simulink Coder) is set to `Shared location`. If

Shared code placement is set to `Auto`, the `GenerateSharedConstants` setting is ignored. If you try to set the parameter value, an error message appears. The default value of `GenerateSharedConstants` is `on`.

In the Command Window, set `GenerateSharedConstants` to `on`:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','on')
```

You see the shared constant definitions in the folder `slprj/grt/_sharedutils`, in the file `const_params.c`:

```
extern const real_T rtCP_pooled_H4eTKtECwveN[9];
const real_T rtCP_pooled_H4eTKtECwveN[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6,
  0.75, 1.0 } ;

extern const real_T rtCP_pooled_SghuHxKVKGHD[9];
const real_T rtCP_pooled_SghuHxKVKGHD[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05,
  0.25, 0.5, 1.0 } ;

extern const real_T rtCP_pooled_WqWb2t17NA2R[7];
const real_T rtCP_pooled_WqWb2t17NA2R[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25,
  1.0 } ;

extern const real_T rtCP_pooled_YgnalOwM3c14[7];
const real_T rtCP_pooled_YgnalOwM3c14[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0
} ;
```

In the Command Window, set `GenerateSharedConstants` to `off`:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','off')
```

You can see the unshared constants in the folder `rtwdemo_throttlecntrl_grt_rtw`, in the file `rtwdemo_throttlecntrl_data.c`:

```
/* Constant parameters (auto storage) */
const ConstP_rtwdemo_throttlecntrl_T rtwdemo_throttlecntrl_ConstP = {
  /* Pooled Parameter (Expression: P_OutMap)
   * Referenced by:
   *   '<S2>/Proportional  Gain Shape'
   *   '<S3>/Proportional  Gain Shape'
   */
  { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 },

  /* Pooled Parameter (Expression: P_InErrMap)
   * Referenced by:
   *   '<S2>/Proportional  Gain Shape'
   *   '<S3>/Proportional  Gain Shape'
   */
  { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 },

  /* Pooled Parameter (Expression: I_OutMap)
   * Referenced by:
```

```
   *   '<S2>/Integral  Gain Shape'
   *   '<S3>/Integral  Gain Shape'
   */
  { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 },

  /* Pooled Parameter (Expression: I_InErrMap)
   * Referenced by:
   *   '<S2>/Integral  Gain Shape'
   *   '<S3>/Integral  Gain Shape'
   */
  { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5, 1.0 }
};
```

Shared Constant Parameters Limitations

No shared constants or shared functions are generated for a model when:

- The model has a Code Replacement Library (CRL) that is specified for data alignment.
- The model is specified to replace data type names in the generated code.
- The **Memory Section** for constants is `MemVolatile` or `MemConstVolatile`.
- The parameter `GenerateSharedConstants` is set to `off`.

Individual constants are not shared, if:

- A constant is referenced by a non-inlined S-function.
- A constant has a user-defined type where **Data Scope** is not set to `Exported`.

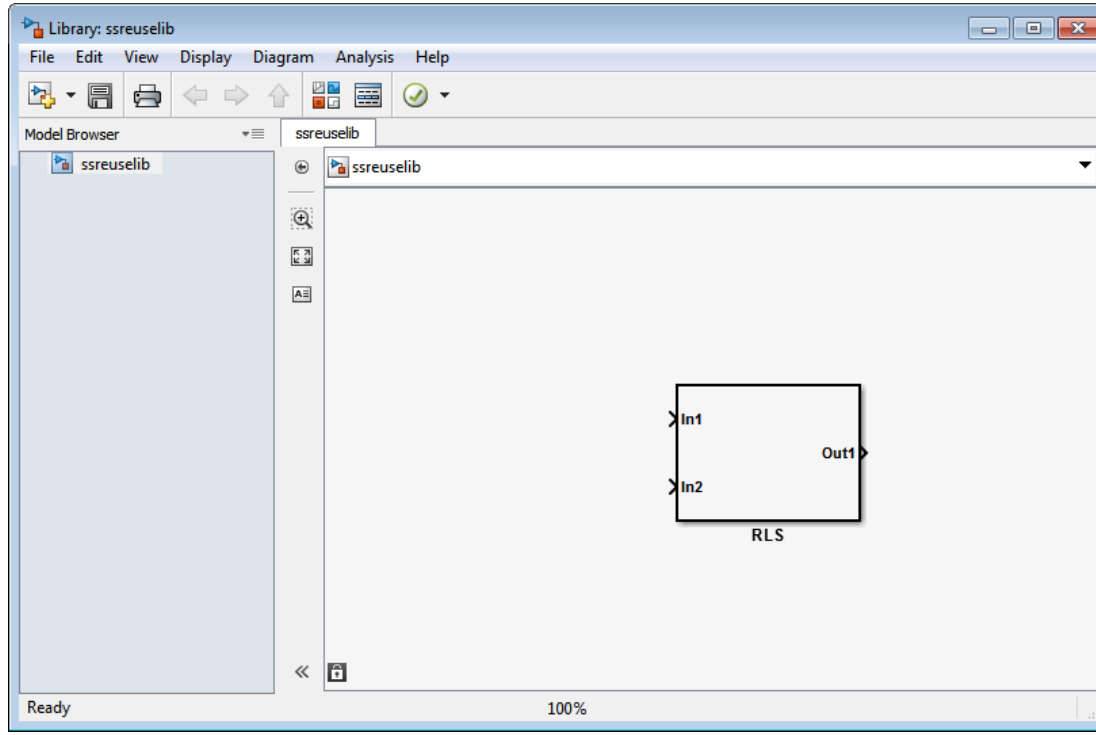
Generate Reusable Code for Subsystems Shared Across Models

This example shows how to configure a reusable library subsystem and generate a reusable function for a subsystem shared across referenced models. The result is reusable code for the subsystem, which is generated to the shared utility folder (`slprj/target/_sharedutils`).

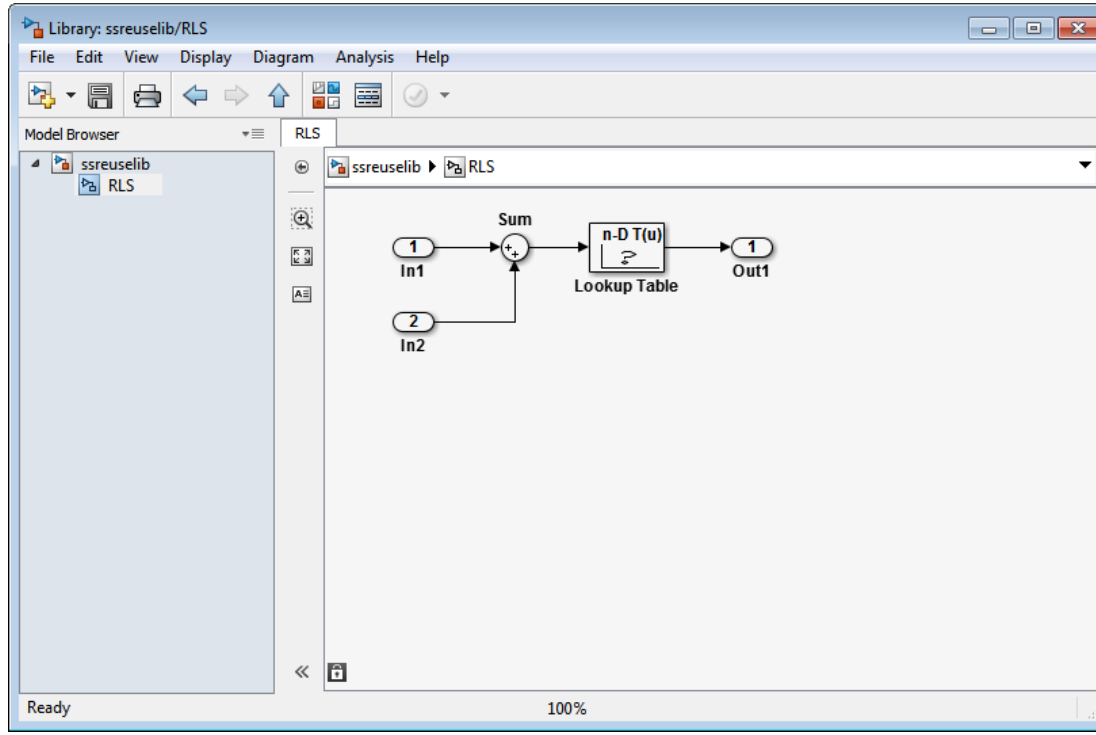
In this section...

Create a reusable library subsystem.

1 In the Simulink Editor, select **File > New > Library**. Open `rtwdemo_ssreuse` to copy and paste subsystem `SS1` into the Library Editor. This action loads the variables for `SS1` into the base workspace. Rename the subsystem block to `RLS`.



2 Click the Subsystem block and press **Ctrl+U** to view the contents of subsystem RLS.



3 To configure the subsystem, in the Library editor, right-click `RLS`. In the context menu, select **Block Parameters(Subsystem)**. In the Subsystem Parameters dialog box, choose the following options:

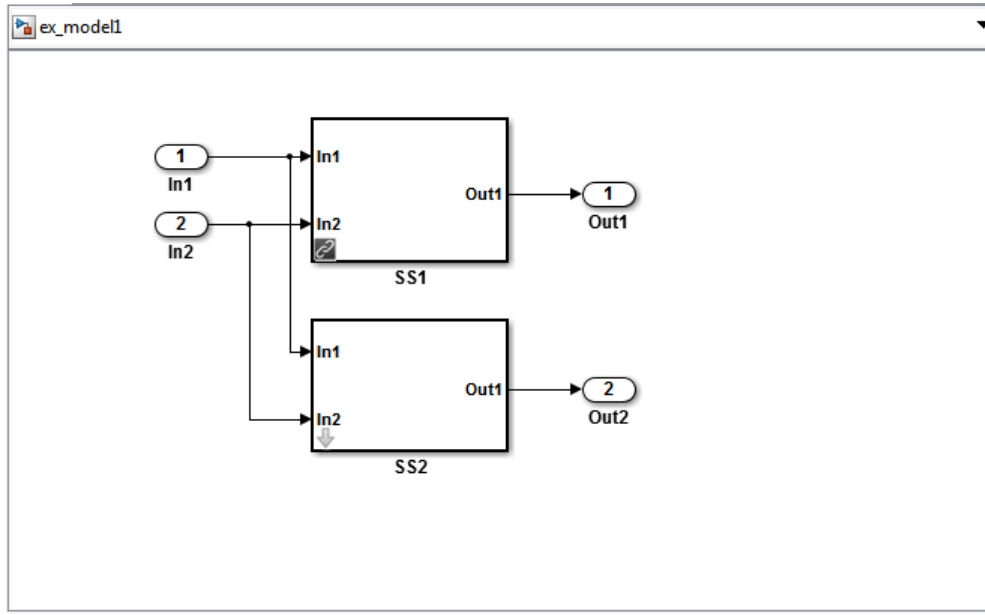
   - Select **Treat as an atomic unit**.
   - On the **Code Generation** tab:
     - Set **Function packaging** to `Reusable function`.
     - Set **Function name options** and **File name options** to `Auto`.

4 Click **Apply** and **OK**.

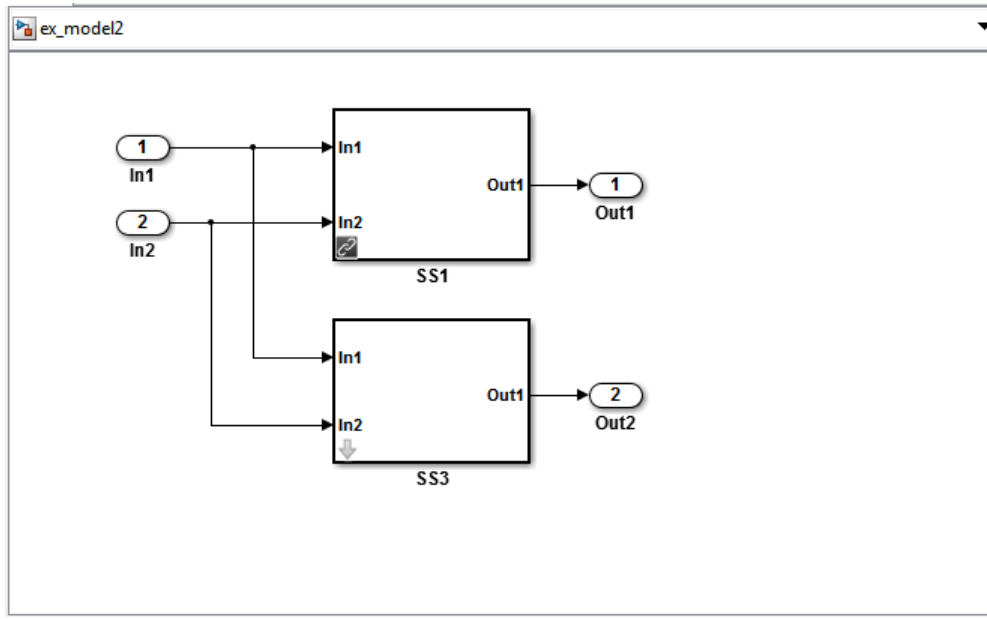
5 Save the reusable library subsystem as `ssreuselib`, which creates a file, `ssreuselib.slx`.

Create the example model.

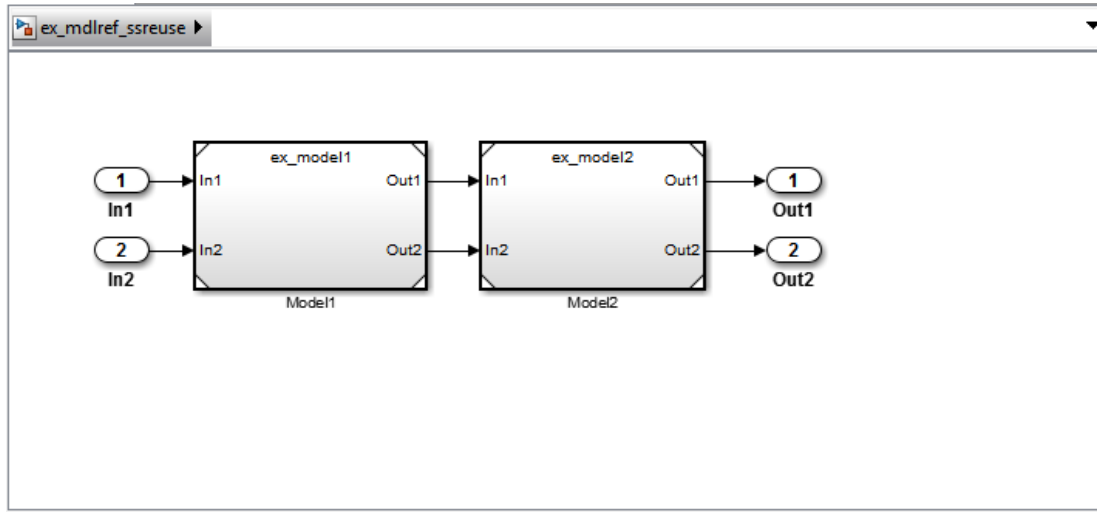
1 Create a model which includes one instance of `RLS` from `ssreuselib`. Name this subsystem `SS1`. Add another subsystem and name it `SS2`. Name the model `ex_model1`.



2 Create another model which includes one instance of `RLS` from `ssreuselib`. Name this subsystem `SS1`. Add another subsystem and name it `SS3`. Name the model `ex_model2`.



3 Create a top model with two model blocks that reference `ex_model1` and `ex_model2`. Save the top model as `ex_mdlref_ssreuse`.



Set configuration parameters of the top model.

1. With model `ex_mdlref_ssreuse` open in the Simulink Editor, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. On the **Solver** pane, specify the **Type** as `Fixed-step`.
3. On the **Model Referencing** pane, select **Pass fixed-size scalar root inputs by value for code generation**.
4. On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
5. On the **Code Generation > Interface** pane, set the "Shared code placement" (Simulink Coder) to `Shared location`.
6. On the **Code Generation > Symbols** pane, set the **Maximum identifier length** to `256`. This step is optional.
7. Click **Apply** and **OK**.

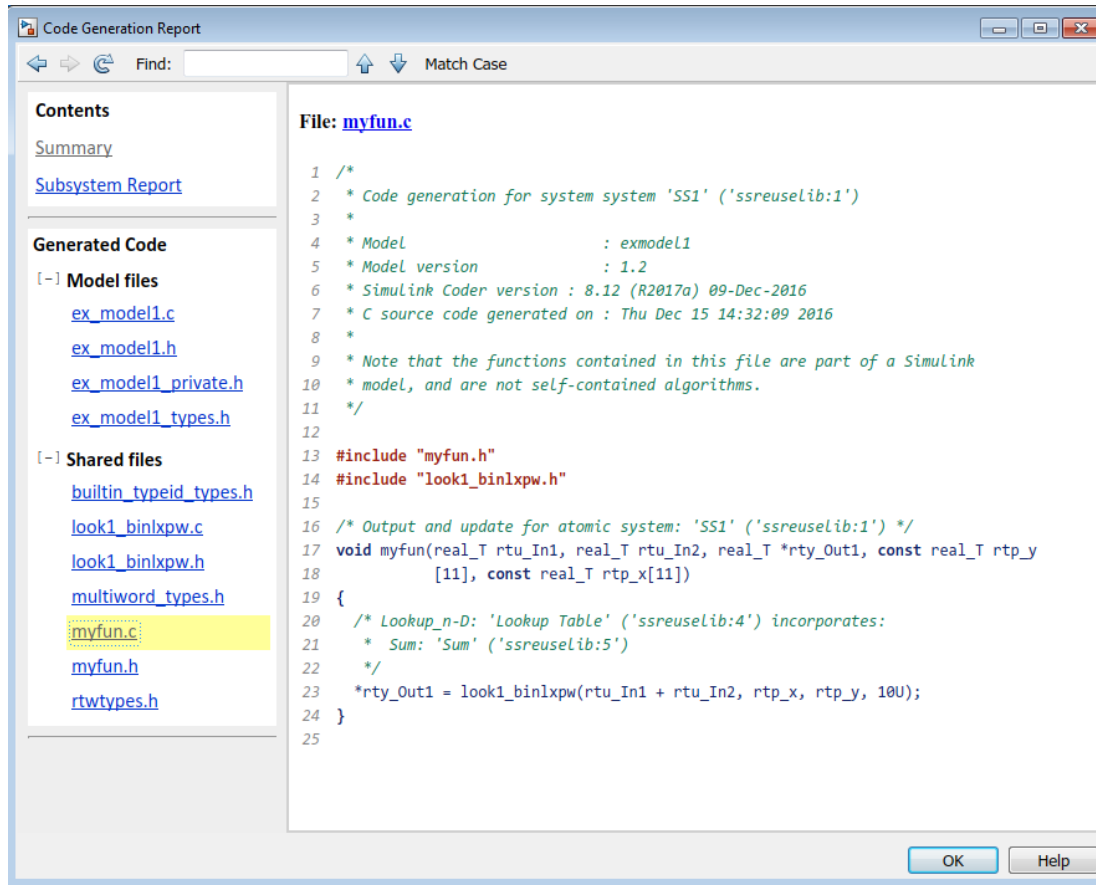
Create and propagate a configuration reference.

1. In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer. In the left navigation column of the Model Explorer, expand the `ex_mdlref_ssreuse` node.
2. Right-click **Configuration** and select `Convert to Configuration Reference`.
3. In the Convert Active Configuration to Reference dialog box, click **OK**. This action converts the model configuration set to a configuration reference, `Simulink.ConfigSetRef`, and creates the configuration reference object, `configSetObj`, in the base workspace.
4. In the left navigation column, right-click **Reference (Active)** and select `Propagate to Referenced Models`.
5. In the Configuration Reference Propagation to Referenced Models dialog box, select the referenced models in the list. Click **Propagate**.

Now, the top model and referenced models use the same configuration reference, `Reference (Active)`, which points to a model configuration reference object, `configSetObj`, in the base workspace. When you save your model, you also need to export the `configSetObj` to a MAT-file.

Generate and view the code.

1. To generate code, in the Simulink Editor, press **Ctrl-B**. After the code is generated, the code generation report opens.
2. To view the code generation report for a referenced model, in the left navigation pane, in the **Referenced Models** section, select `ex_model1`. The code generation report displays the generated files for `ex_model1`.
3. In the left navigation pane, expand the **Shared files**. The code generator uses the reusable library subsystem name. The code for subsystem `SS1` is in `myfun.c` and `myfun.h`.



4 Click **Back** and navigate to the `ex_model2` code generation report. `ex_model2` uses the same source code, `myfun.c` and `myfun.h`, as the code for `ex_model1`. Your subsystem function and file names will be different.

More About

- "Code Generation of Subsystems" on page 3-2
- "Code Reuse For Subsystems Shared Across Models" on page 3-20
- "Code Reuse Limitations for Subsystems" on page 3-17
- "Libraries" (Simulink)

Determine Why Subsystem Code Is Not Reused

Due to the limitations described in "Code Reuse Limitations for Subsystems" on page 3-17, the code generator might not reuse generated code as you expect. To determine why code generated for a subsystem is not reused, see "Review Subsystems Section of HTML Code Generation Report" on page 3-36. If you cannot determine why based on the report, see "Compare Subsystem Checksum Data" on page 3-36.

Review Subsystems Section of HTML Code Generation Report

If you determine that the code generator does not generate code for a subsystem as reusable code, and you specified the subsystem as reusable, examine the Subsystems section of the HTML code generation report (see "Generate a Code Generation Report" (Simulink Coder)). The Subsystems section contains:

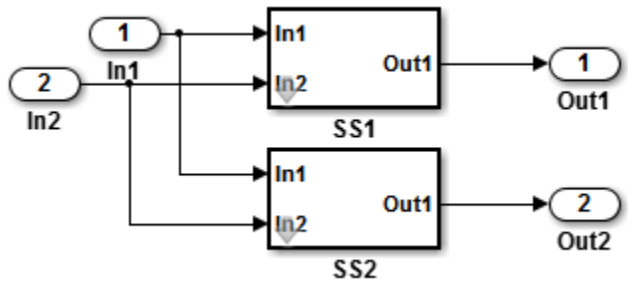
- A table that summarizes how nonvirtual subsystems were converted to generated code.
- Diagnostic information that describes why the contents of some subsystems were not generated as reusable code.

The Subsystems section also indicates the mapping of each noninlined subsystem in the model to functions or reused functions in the generated code. For an example, open and build the `rtwdemo_atomic` model.

Compare Subsystem Checksum Data

You can determine why subsystem code is not reused by accessing and comparing subsystem checksum data. The code generator determines whether subsystems are identical by comparing subsystem checksums, as noted in "Code Reuse Limitations for Subsystems" on page 3-17. For subsystem reuse across referenced models, this procedure might not catch every difference.

Consider the model, `rtwdemo_ssreuse`. `SS1` and `SS2` are instances of the same subsystem. In both instances the subsystem parameter **Function packaging** is set to `Reusable function`.



Use the method, `Simulink.SubSystem.getChecksum`, to get the checksum for a subsystem. Compare the results to determine why code is not reused.

1. Open the model `rtwdemo_ssreuse`. Save a copy of the model in a folder where you have write access.
2. In the model window, select subsystem `SS1`. In the command window, enter

   ```
   SS1 = gcb;
   ```
3. In the model window, select subsystem `SS2`. In the command window, enter

   ```
   SS2 = gcb;
   ```
4. Use the method, `Simulink.SubSystem.getChecksum`, to get the checksum for each subsystem. This method returns two output values: the checksum value and details on the input used to compute the checksum.

   ```
   [chksum1, chksum1_details] = ...
   Simulink.SubSystem.getChecksum(SS1);
   [chksum2, chksum2_details] = ...
   Simulink.SubSystem.getChecksum(SS2);
   ```
5. Compare the two checksum values. They should be equal based on the subsystem configurations.

   ```
   isequal(chksum1, chksum2)
   ans =
        1
   ```
6. To see how you can use `Simulink.SubSystem.getChecksum` to determine why the checksums of two subsystems differ, change the data type mode of the output port of SS1 so that it differs from that of SS2.

a Look under the mask of SS1. Right-click the subsystem. In the context menu, select **Mask > Look Under Mask**.

b In the block diagram of the subsystem, double-click the Lookup Table block to open the Subsystem Parameters dialog box.

c Click **Data Types**.

d Select **Saturate on integer overflow** and click **OK**.

7 Get the checksum for SS1. Compare the checksums for the two subsystems. This time, the checksums are not equal.

```
[chksum1, chksum1_details] = ...
Simulink.SubSystem.getChecksum(SS1);
isequal(chksum1, chksum2)
ans =
     0
```

8 After you determine that the checksums are different, find out why. The Simulink engine uses information, such as signal data types, some block parameter values, and block connectivity information, to compute the checksums. To determine why checksums are different, you compare the data used to compute the checksum values. You can get this information from the second value returned by `Simulink.SubSystem.getChecksum`, which is a structure array with four fields.

Look at the structure `chksum1_details`.

```
chksum1_details

chksum1_details =
          ContentsChecksum: [1x1 struct]
         InterfaceChecksum: [1x1 struct]
     ContentsChecksumItems: [287x1 struct]
    InterfaceChecksumItems: [53x1 struct]
```

`ContentsChecksum` and `InterfaceChecksum` are component checksums of the subsystem checksum. The remaining two fields, `ContentsChecksumItems` and `InterfaceChecksumItems`, contain the checksum details.

9 Determine whether a difference exists in the subsystem contents, interface, or both. For example:

```
isequal(chksum1_details.ContentsChecksum.Value,...
        chksum2_details.ContentsChecksum.Value)
ans =
```

```
     0
isequal(chksum1_details.InterfaceChecksum.Value,...
        chksum2_details.InterfaceChecksum.Value)
ans =
     1
```

In this case, differences exist in the contents.

10 Write a script like the following to find the differences.

```
idxForCDiffs=[];
for idx = 1:length(chksum1_details.ContentsChecksumItems)
    if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Identifier, ...
                chksum2_details.ContentsChecksumItems(idx).Identifier))
            disp(['Identifiers different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
    end
    if (ischar(chksum1_details.ContentsChecksumItems(idx).Value))
            if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Value, ...
                        chksum2_details.ContentsChecksumItems(idx).Value))
            disp(['Character vector values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
            end
    end
    if (isnumeric(chksum1_details.ContentsChecksumItems(idx).Value))
            if (chksum1_details.ContentsChecksumItems(idx).Value ~= ...
                        chksum2_details.ContentsChecksumItems(idx).Value)
            disp(['Numeric values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
            end
    end
end
```

11 Run the script. The following example assumes that you named the script `check_details`.

```
check_details
Character vector values different for contents item 202
```

The results indicate that differences exist for index item 202 in the subsystem contents.

12 Use the returned index values to get the handle, identifier, and value details for each difference found.

```
chksum1_details.ContentsChecksumItems(202)

ans =

        Handle: 'rtwdemo_ssreuse/SS1/Lookup Table'
    Identifier: 'SaturateOnIntegerOverflow'
         Value: 'on'
```

The details identify the Lookup Table block parameter **Saturate on integer overflow** as the focus for debugging a subsystem reuse issue.

4

Code Generation of Functions and Function Callers in Simulink Coder

Modeling Functions and Callers for Code Generation

In this section...

Functions and Callers

Use a Simulink Function block and a Function Caller block to instruct the code generator to generate C functions and function calls in the generated code for encapsulation and portability. A Simulink Function block is a nonreusable subsystem.

With a Simulink Function block and a Function Caller block, you can:

- Use nested function calls to call a function from a function.
- Choose to separate function definitions and calls into different models.
- Specify SIL and PIL simulations.
- Integrate code for multiple top models where the Simulink Function block and Function callers are in different models.
- Use global data to communicate between a server and its parent model. This data uses custom storage classes to customize how the data is communicated.
- Model a client and server application using the export functions modeling style.

Simulink Function blocks and Function Caller blocks do not honor the `MaxStackSize` parameter.

For more information, see "Simulink Functions" (Simulink), "Diagnostics Using a Client-Server Architecture" (Simulink), and Simulink Function block.

Input and Output Arguments

When you set up your model that contains Simulink Function blocks for code generation:

- Do not define the signals entering and leaving Argument Inport blocks and Argument Outport blocks in the Simulink Function definition with a storage class.

- Do not specify Argument Inport and Argument Outport blocks as test points.
- If you specify the data type of signals entering and leaving Argument Inport and Argument Outport blocks as a `Simulink.IntEnumType`, `Simulink.AliasType` or `Simulink.Bus` type, then you must specify the arguments as `Imported` or `Exported`, not `Auto`.
- The Simulink Function block and the Function Caller blocks must agree in data type, complexity, dimension, and number of arguments.

For more information, see Argument Inport and Argument Outport.

Function and Function Caller Definitions Across Models

You can define a Simulink Function block and Function Caller block in different models. When the code generator generates code for a model hierarchy, it can encounter either a Simulink Function block or a Function Caller block first. If the code generator finds the Simulink Function block first, the software uses the function definition from the Simulink Function block. If the code generator then encounters a Function Caller block that does not match the function definition, the code generator issues an error. This error prompts you to either change the Function Caller block to match the Simulink Function block or remove the `slprj` folder. Verify that the arguments and data types in the Function Caller blocks match the arguments and data types in the Simulink Function block. Regenerate code for the models involved.

If the code generator encounters a Function Caller block first, then the code generator uses the function definition derived from the Function Caller block. If the code generator then encounters a Simulink Function block with different arguments and data types from the Function Caller block, the code generator issues a warning message. Verify that the Function Caller blocks match the Simulink Function block. Regenerate the code where you have made changes.

Specifying two Simulink Function blocks with the same name is an error. Modify one of the blocks and remove the `slprj` folder.

Code Generation Files

In the build folders, the code generator creates different files depending on the setting you choose.

When one of the following is true, the code generator creates files as shown in the table.

- The system target file is `grt.tlc`.
- The system target file is `ert.tlc` and you do not have an Embedded Coder license.
- The system target file is `ert.tlc` and you have an Embedded Coder license. For the **Code Generation** > **Code Placement** > **File packaging format** parameter, select `Modular`.

For a model named `model` and a function named `fn1`, the code generator creates files with modular file packaging.

Modular File Packaging of Files for GRT System Target or ERT System Target

File	Folder	Contents
`model.c`	`model_`*`target`*`_rtw`	Calls to the function.
`model.h`	`model_`*`target`*`_rtw`	This header file includes declarations and header files for the function, including `fn1.h` and `fn1_private.h`.
`fn1.c`	`model_`*`target`*`_rtw`	Code for the function.
`fn1.h`	`slprj/`*`target`*`/_sharedutils`	This header file contains the `fn1` function prototype declaration. This header file is included in the code generated for the Function Caller blocks associated with the function. The `fn1.h` file placement is not affected by the **Code Generation** > **Interface** > **Shared code placement** parameter value.
`fn1_private.h`	`model_`*`target`*`_rtw`	This header file includes declarations and header files for the function, including `fn1.h`.

If you have an Embedded Coder license, set the system target file to `ert.tlc`, and set the **File packaging format** parameter to `Compact` or `Compact (with separate data file)`, the code generator creates files with compact file packaging.

Compact File Packaging of Files for ERT System Target

File	Folder	Contents
`model.c`	`model_ert_rtw`	Calls to the function and code for the function.

File	Folder	Contents
`model.h`	`model_ert_rtw`	This header file includes declarations and header files for the function, including `fn1.h`.
`fn1.h`	`slprj\ert\_sharedutils`	This header file contains the `fn1` function prototype declaration. This header file is included in the code generated for the Function Caller blocks associated with the function. The `fn1.h` file placement is not affected by the **Code Generation** > **Interface** > **Shared code placement** parameter value.

For more information, see “Generate Code for Functions and Callers” on page 4-6.

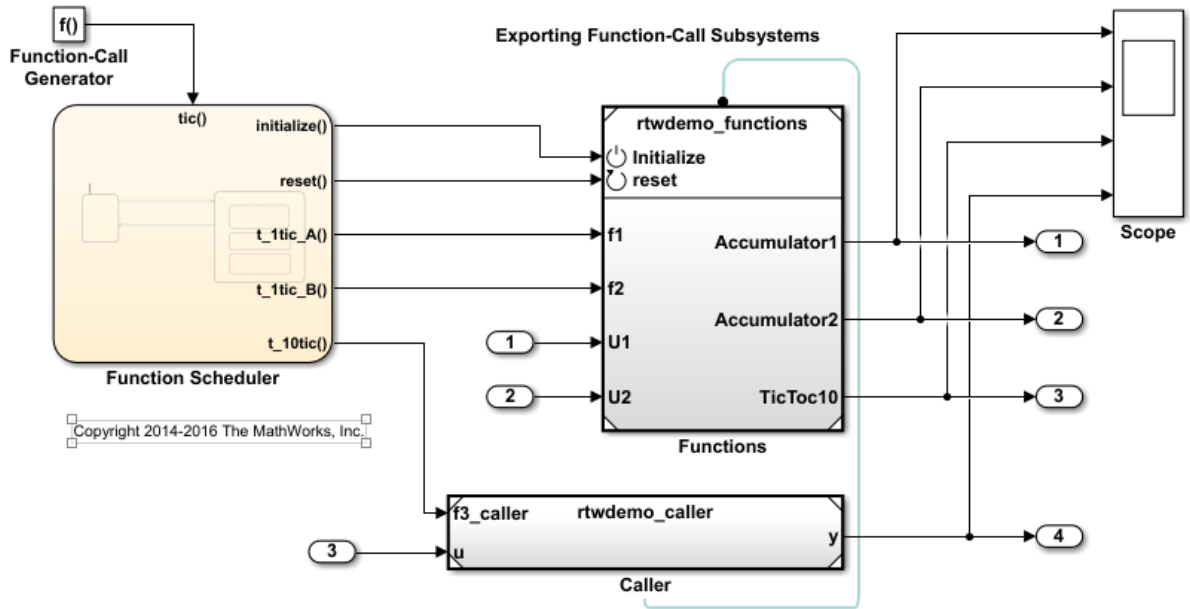
Generate Code for Functions and Callers

In this section...

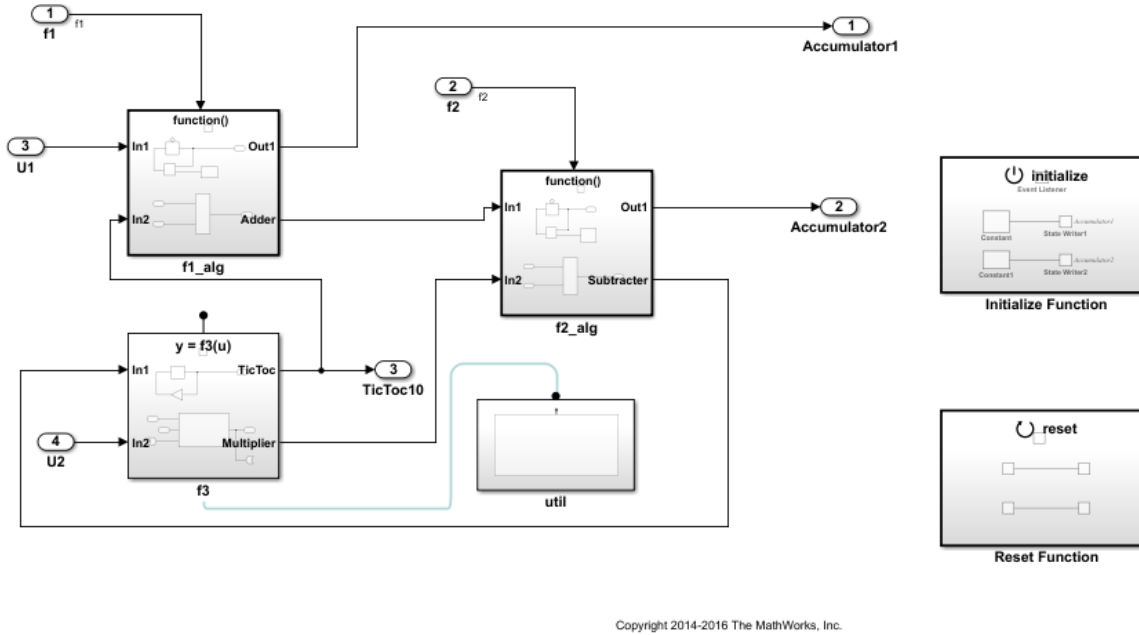
This example shows how the code generator translates Simulink Function blocks and Function Caller blocks into C code.

At the command prompt, type `rtwdemo_export_functions`. This model uses Stateflow software, but this example reviews only the code generated from the referenced models.



Generate Code for the Function Definition

1 Double click `rtwdemo_functions`. The Simulink Function block is the `f3` subsystem defined as `y = f3(u)`.



2 In the model window, press **Ctrl+B**.

The code generator creates `rtwdemo_functions.c`. This file contains the function definition and initialization.

- The initialization function is:

```
void f3_Init(void)
{
  /* InitializeConditions for UnitDelay: '<S5>/Delay' */
  rtDWork.Delay_DSTATE = 1;
}
```

- The primary function is:

```
/* Output and update for Simulink Function: '<Root>/f3' */
void f3(real_T rtu_u, real_T *rty_y)
{
  /* Outport: '<Root>/TicToc10' incorporates:
   *  UnitDelay: '<S5>/Delay'
```

```
   */
  rtY.TicToc10 = rtDWork.Delay_DSTATE;

  /* Gain: '<S5>/Gain' */
  rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

  /* FunctionCaller: '<S5>/Function Caller' incorporates:
   *  Inport: '<Root>/U2'
   *  SignalConversion: '<S5>/TmpLatchAtIn1Outport1'
   *  SignalConversion: '<S5>/TmpSignal ConversionAtuOutport1'
   */
  adder_h(rtB.Subtract, rtU.U2, rtu_u, rtB.FunctionCaller);

  /* SignalConversion: '<S5>/TmpSignal ConversionAtyInport1' */
  *rty_y = rtB.FunctionCaller;
}
/* Output and update for Simulink Function: '<S6>/adder' */
void adder_h(real_T rtu_u1, real_T rtu_u2, real_T rtu_u3, real_T *rty_y)
{
  /* SignalConversion: '<S7>/TmpSignal ConversionAtyInport1' incorporates:
   *  SignalConversion: '<S7>/TmpSignal ConversionAtu1Outport1'
   *  SignalConversion: '<S7>/TmpSignal ConversionAtu2Outport1'
   *  SignalConversion: '<S7>/TmpSignal ConversionAtu3Outport1'
   *  Sum: '<S7>/Sum'
   */
  *rty_y = (rtu_u1 + rtu_u2) + rtu_u3;
}
```

- The shared header file, `f3.h`, contains the primary function prototype declaration.

```
/* Shared type includes */
#include "rtwtypes.h"

extern void f3(real_T rtu_u, real_T *rty_y);
```

Generate Code for the Caller Definition

1. On the `rtwdemo_export_functions` model, click `rtwdemo_caller`.
2. Press **Ctrl+B**.

The code generator creates the files `rtwdemo_caller.h` and `rtwdemo_caller.c` in the folder `rtwdemo_caller_ert_rtw`.

`rtwdemo_caller.h` includes the shared header file, `f3.h`, which contains the function prototype declaration.

`rtwdemo_caller.c` calls the function `f3`.

```
/* Output function for RootInportFunctionCallGenerator: '
        <Root>/RootFcnCall_InsertedFor_t_1Otic_at_outport_1' */
void rtwdemo_caller_t_1Otic(const real_T *rtu_u, real_T *rty_y)
{
  /* RootInportFunctionCallGenerator: '
        <Root>/RootFcnCall_InsertedFor_t_1Otic_at_outport_1' incorporates:
   *  SubSystem: '<Root>/Subsystem'
   */
  /* FunctionCaller: '<S1>/Function Caller' */
  f3(*rtu_u, rty_y);
}
```

Referenced Models in Simulink Coder

Code Generation of Referenced Models

This section describes model referencing considerations that apply specifically to code generation by the Simulink Coder. This section assumes that you understand referenced models and related terminology and requirements, as described in "Overview of Model Referencing" (Simulink) and associated topics.

When generating code for a referenced model hierarchy, the code generator produces a stand-alone executable for the top model, and a library module called a *model reference target* for each referenced model. When the code executes, the top executable invokes the model reference targets to compute the referenced model outputs. Model reference targets are sometimes called *Simulink Coder targets*.

Be careful not to confuse a model reference target (Simulink Coder target) with other types of targets:

- Target hardware — A platform for which the Simulink Coder software generates code
- System target — A file that tells the Simulink Coder software how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with the Simulink Coder product
- Simulation target — A MEX-file that implements a referenced model that executes with Simulink Accelerator™ software

The code generator places the code for the top model of a hierarchy in the code generation folder (Simulink) and places the code for referenced models in an `slprj` folder in the code generation folder (Simulink). Subfolders in `slprj` provide separate places for different types of files. For folder information, see "Manage Build Process Folders" (Simulink Coder).

By default, the product uses *incremental code generation*. When generating code, it compares structural checksums of referenced model files with the generated code files to determine whether to regenerate model reference targets. To control when rebuilds occur, use the configuration parameter **Model Referencing > Rebuild**. For details, see "Rebuild" (Simulink).

In addition to incremental code generation, the Simulink Coder software uses *incremental loading*. The code for a referenced model is not loaded into memory until the code for its parent model executes and needs the outputs of the referenced model. The

product then loads the referenced model target and executes. Once loaded, the target remains in memory until it is no longer used.

Most code generation considerations are the same whether or not a model includes referenced models: the code generator handles the details automatically insofar as possible. This chapter describes topics that you may need to consider when generating code for a model reference hierarchy.

If you have a Embedded Coder license, custom targets must declare themselves to be model reference compliant if they need to support Model blocks. For more information, see “Support Model Referencing” on page 71-83.

Generate Code for Referenced Models

In this section...

About Generating Code for Referenced Models

To generate code for referenced models, you

1. Create a subsystem in an existing model.
2. Convert the subsystem to a referenced model (Model block).
3. Call the referenced model from the top model.
4. Generate code for the top model and referenced model.
5. Explore the generated code and the code generation folder.

You can accomplish some of these tasks automatically with a function called `Simulink.Subsystem.convertToModelReference`.

Create and Configure the Subsystem

In the first part of this example, you define a subsystem for the `vdp` example model, set configuration parameters for the model, and use the `Simulink.Subsystem.convertToModelReference` function to convert it into two new models — the top model (`vdptop`) and a referenced model `vdpmultRM` containing a subsystem you created (`vdpmult`).

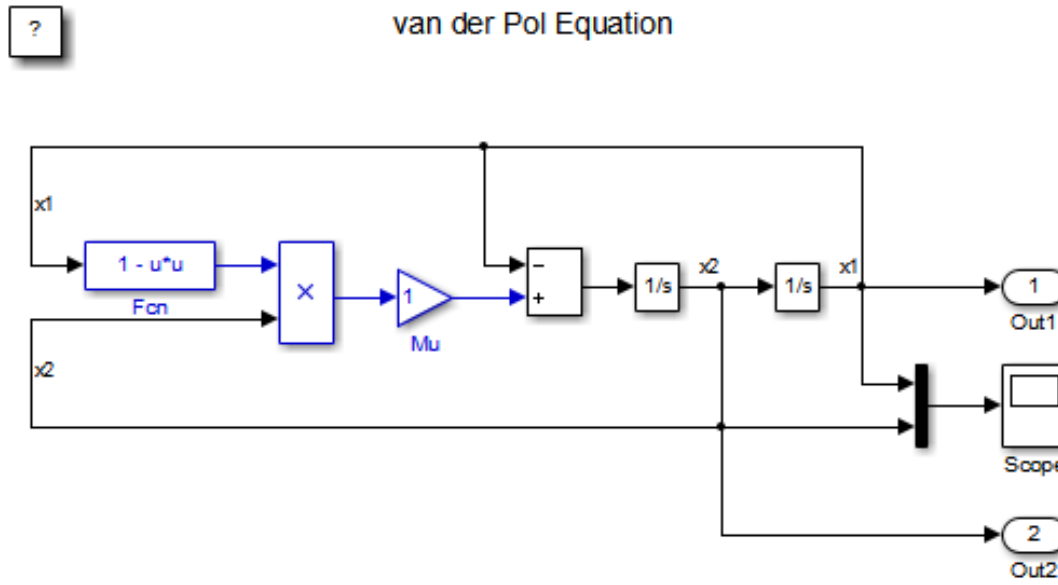
1. In the MATLAB Command Window, create a new working folder wherever you want to work and `cd` into it:

   ```
   mkdir mrexample
   cd mrexample
   ```

2. Open the `vdp` example model by typing:

`vdp`

3 Drag a box around the three blocks outlined in blue below:



4 Choose **Create Subsystem from Selection** from the **Diagram > Subsystem & Model Reference** menu.

A subsystem block replaces the selected blocks.

5 If the new subsystem block is not where you want it, move it to a preferred location.

6 Rename the block `vdpmult`.

7 Right-click the `vdpmult` block and select **Block Parameters (Subsystem)**.

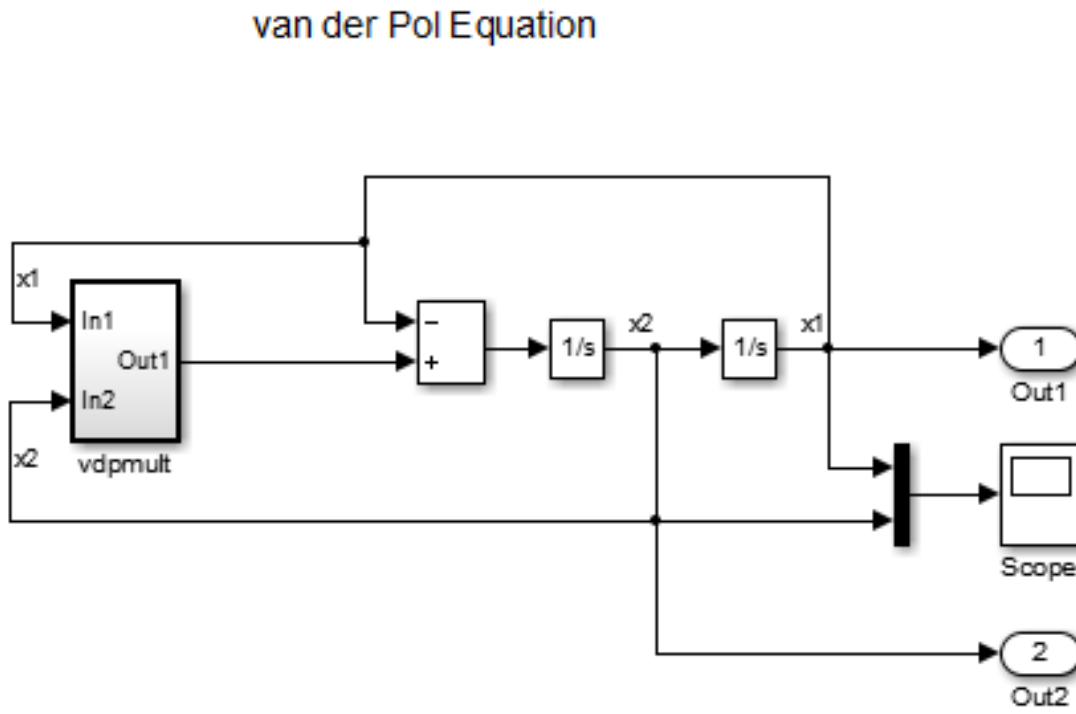
The **Function Block Parameters** dialog box appears.

8 In the **Function Block Parameters** dialog box, select **Treat as atomic unit**, then click **OK**.

The border of the `vdpmult` subsystem thickens to indicate that it is now atomic. An atomic subsystem executes as a unit relative to the parent model: subsystem block execution does not interleave with parent block execution. This property makes it

possible to extract subsystems for use as stand-alone models and as functions in generated code.

The block diagram should now appear as follows:



You must set several properties before you can extract a subsystem for use as a referenced model. To set the properties,

1. Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
2. In the **Model Hierarchy** pane, click the symbol preceding the model name to reveal its components.
3. Click **Configuration (Active)** in the left pane.
4. In the center pane, select **Solver**.
5. In the right pane, under **Solver Options** change the **Type** to `Fixed-step`, then click **Apply**. You must use fixed-step solvers when generating code, although referenced models can use different solvers than top models.

6 In the center pane, select **Diagnostics**. In the right pane, select the **Data Validity** tab. In the **Signals** area, set **Signal resolution** to `Explicit only`. Alternatively, if you do not want to use `Simulink.Signal` objects, set **Signal resolution** to `None`.

7 Click **Apply**.

The model now has the properties that model referencing requires.

8 In the center pane, click **Model Referencing**. In the right pane, set **Rebuild** to `If any changes in known dependencies detected`. Click **Apply**. This setting prevents code regeneration when it is not required.

9 In the `vdp` model window, choose **File** > **Save as**. Save the model as `vdptop` in your working folder. Leave the model open.

Convert Model to Use Model Referencing

In this portion of the example, you use the conversion function `Simulink.SubSystem.convertToModelReference` to extract the subsystem `vdpmult` from `vdptop` and convert `vdpmult` into a referenced model named `vdpmultRM`. To see the complete syntax of the conversion function, type at the MATLAB prompt:

```
help Simulink.SubSystem.convertToModelReference
```

For additional information, type:

```
doc Simulink.SubSystem.convertToModelReference
```

If you want to see an example of `Simulink.SubSystem.convertToModelReference` before using it yourself, type:

```
sldemo_mdlref_conversion
```

Simulink also provides a menu command, **Subsystem & Model Reference** > **Convert Subsystem to** > **Referenced Model**, that you can use to convert a subsystem to a referenced model. The command calls `Simulink.SubSystem.convertToModelReference` with default arguments. For more information, see "Convert a Subsystem to a Referenced Model" (Simulink).

Extract the Subsystem to a Referenced Model

To use `Simulink.SubSystem.convertToModelReference` to extract `vdpmult` and convert it to a referenced model, type:

```
Simulink.SubSystem.convertToModelReference...
('vdptop/vdpmult', 'vdpmultRM',...
'ReplaceSubsystem', true, 'BuildTarget', 'Sim')
```

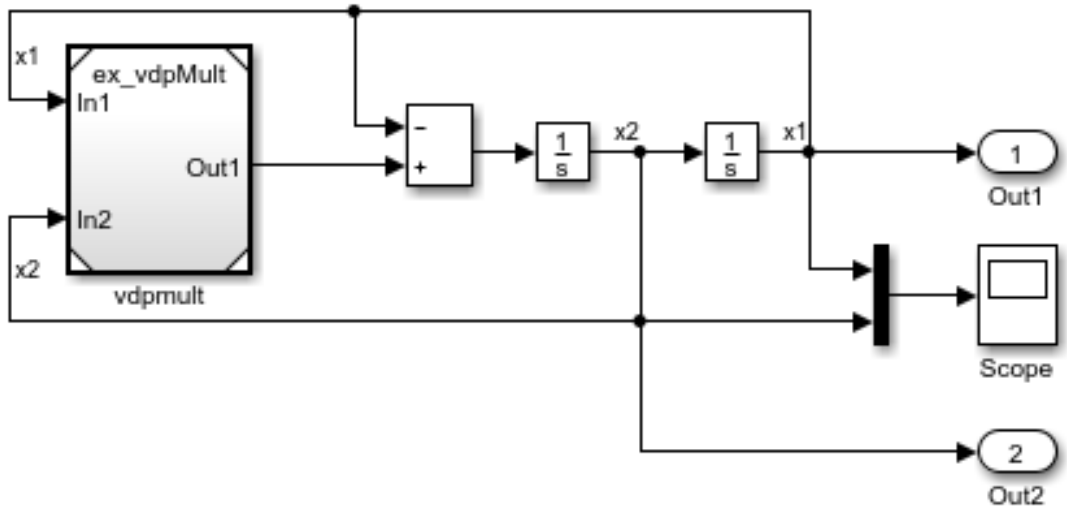
This command:

1. Extracts the subsystem `vdpmult` from `vdptop`.
2. Converts the extracted subsystem to a separate model named `vdpmultRM` and saves the model to the working folder.
3. In `vdptop`, replaces the extracted subsystem with a Model block that references `vdpmultRM`.
4. Creates a simulation target for `vdptop` and `vdpmultRM`.

The converter prints progress messages and terminates with

```
ans =
     1
```

The parent model `vdptop` now looks like this:

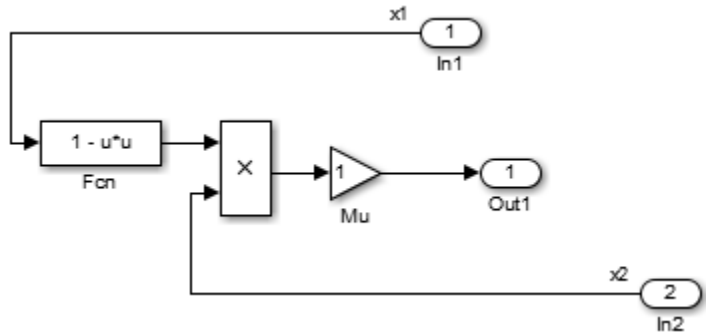


Note the changes in the appearance of the block `vdpmult`. These changes indicate that it is now a Model block rather than a subsystem. As a Model block, it does not have

contents of its own: the previous contents now exist in the referenced model `vdpmultRM`, whose name appears at the top of the Model block. Widen the Model block to expose the complete name of the referenced model.

If the parent model `vdptop` had been closed at the time of conversion, the converter would have opened it. Extracting a subsystem to a referenced model does *not* automatically create or change a saved copy of the parent model. To preserve the changes to the parent model, save `vdptop`.

Right-click the Model block `vdpmultRM` and choose **Open** to open the referenced model. The model looks like this:



Files Created and Changed by the Converter

The files in your working folder now consist of the following (not in this order).

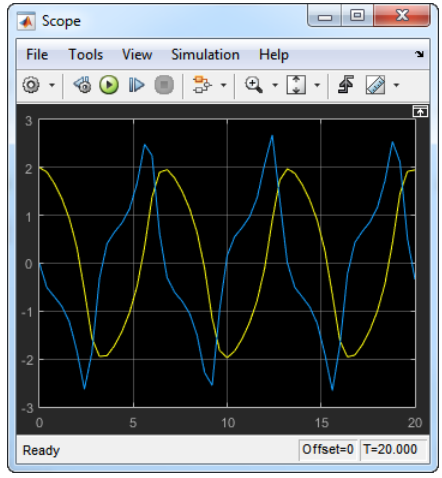
File	Description
`vdptop` model file	Top model that contains a Model block where the `vdpmult` subsystem was
`vdpmultRM` model file	Referenced model created for the `vdpmult` subsystem
`vdpmultRM_msf.mexw64`	Static library file (Microsoft® Windows platforms only). The file extension is system-dependent and may differ. This file executes when the `vdptop` model calls the Model block `vdpmult`. When called, `vdpmult` in turn calls the referenced model `vdpmultRM`.

File	Description
`/slprj`	Folder for generated model reference code

Code for model reference simulation targets is placed in the `slprj/sim` subfolder. Generated code for GRT, ERT, and other Simulink Coder targets is placed in `slprj` subfolders named for those targets. You will inspect some model reference code later in this example. For more information on code generation folders, see "Work with Code Generation Folders" on page 5-12.

Run the Converted Model

Open the Scope block in `vdptop` if it is not visible. In the `vdptop` window, click the **Run** tool or choose **Run** from the **Simulation** menu. The model calls the `vdpmultRM_msf` simulation target to simulate. The output looks like this:



Generate Model Reference Code for a GRT Target

The function `Simulink.SubSystem.convertToModelReference` created the model and the simulation target files for the referenced model `vdpmultRM`. In this part of the example, you generate code for that model and the `vdptop` model, and run the executable you create:

1. Verify that you are still working in the `mrexample` folder.
2. If the model `vdptop` is not open, open it. Make sure it is the active window.

3. Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
4. In the **Model Hierarchy** pane, click the symbol preceding the `vdptop` model to reveal its components.
5. Click **Configuration (Active)** in the left pane.
6. In the center pane, select **Data Import/Export**.
7. In the pane, select **Time** and **Output** and *clear* **Data stores**. Click **Apply**.

   These settings instruct the model `vdptop` (and later its executable) to log time and output data to MAT-files for each time step.
8. Generate GRT code (the default) and an executable for the top model and the referenced model. For example, in the model, press **Ctrl+B**.

The Simulink Coder build process generates and compiles code. The current folder now contains a new file and a new folder:

File	Description
`vdptop.exe`	The executable created by the build process
`vdptop_grt_rtw/`	The build folder, containing generated code for the top model

The build process also generated GRT code for the referenced model and placed it in the `slprj` folder.

To view a model's generated code in **Model Explorer**, the model must be open. To use the **Model Explorer** to inspect the newly created build folder, `vdptop_grt_rtw`:

1. Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
2. In the **Model Hierarchy** pane, click the symbol preceding the model name to reveal its components.
3. Click the symbol preceding `Code for vdptop` to reveal its components.
4. Directly under `Code for vdptop`, click `This Model`.

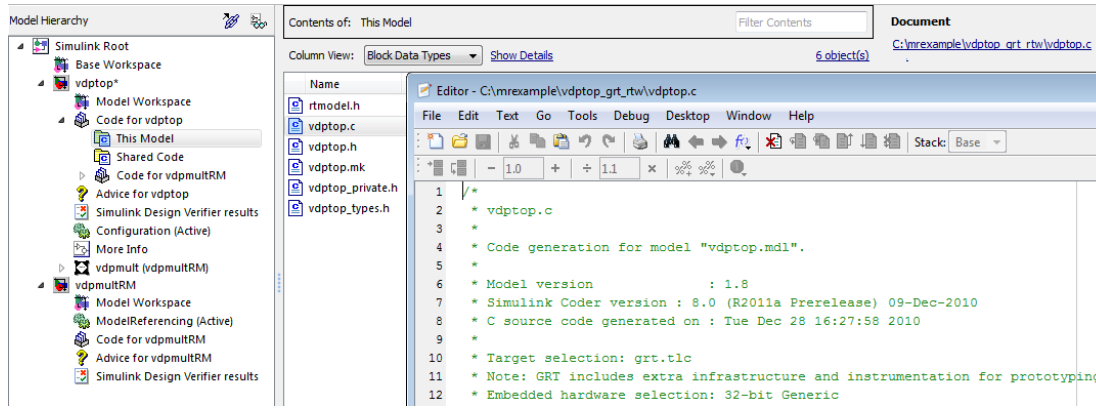
   A list of generated code files for `vdptop` appears in the **Contents** pane:

   ```
   rtmodel.h
   vdptop.c
   vdptop.h
   vdptop.mk
   ```

```
vdptop_private.h
vdptop_types.h
```

You can browse code by selecting a file of interest in the **Contents** pane.

To open a file in a text editor, click a filename, and then click the hyperlink that appears in the gray area at the top of the **Document** pane. The figure below illustrates viewing code for `vdptop.c`, in a text editor. Your code may differ.



To view the generated code in the HTML code generation report, see “Generate a Code Generation Report” (Simulink Coder).

Work with Code Generation Folders

When you view generated code in **Model Explorer**, the files listed in the **Contents** pane can exist either in a build folder or a code generation folder. Model reference code generation folders (located under the `slprj` folder), like build folders, are created in your code generation folder (Simulink). This process implies certain constraints on when and where model reference targets are built and on how they are accessed.

The models referenced by Model blocks can be stored anywhere. A given top model can include models stored on different file systems or in different folders. The same is not true for the simulation targets derived from these models; under most circumstances, models referenced by a given top model must be set up to simulate and generate model reference target code in a single code generation folder. The top and referenced models can exist anywhere on your path, but the code generation folder is assumed to exist in your current folder.

This means that, if you reference the same model from several top models, each stored in a different folder, you must either

- Always work in the same folder and be sure that the models are on your path
- Allow separate code generation folders, simulation targets, and Simulink Coder targets to be generated in each folder in which you work

The files in such multiple code generation folders are generally quite redundant. Therefore, to minimize code regeneration of referenced models, choose a specific working folder and remain in it for all sessions.

As model reference code generated for Simulink Coder targets as well as for simulation targets is placed in code generation folders, the same considerations as above apply even if you are generating target applications only. That is, code for all models referenced from a given model ends up being generated in the same code generation folder, even if it is generated for different targets and at different times.

Related Examples

- “Specify Instance-Specific Parameter Values for Reusable Referenced Model” on page 19-65

Configure Referenced Models

Minimize occurrences of algebraic loops by selecting the **Minimize algebraic loop occurrences** parameter on the **Model Reference** pane. The setting of this option affects only generation of code from the model. For information on how this option affects code generation, see "Configure Run-Time Environment Options" (Simulink Coder). For more information, see "Model Blocks and Direct Feed through" (Simulink).

Use the **Integer rounding mode** parameter on your model's blocks to simulate the rounding behavior of the C compiler that you intend to use to compile code generated from the model. This setting appears on the **Signal Attributes** pane of the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.

For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the Simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see "Precision" (Fixed-Point Designer).

When models contain Model blocks, all models that they reference must be configured to use identical hardware settings. For information on the **Model Referencing** pane options, see "Model Configuration Parameters: Model Referencing" (Simulink) and "Configuration Parameter Requirements" (Simulink).

Build Model Reference Targets

By default, the Simulink engine rebuilds simulation targets before the Simulink Coder software generates model reference targets. You can change the rebuild criteria or specify when the engine rebuilds targets. For more information, see "Rebuild" (Simulink).

The Simulink Coder software generates a model reference target directly from the Simulink model. The product automatically generates or regenerates model reference targets, for example, when they require an update.

You can command the Simulink and Simulink Coder products to generate a simulation target for an Accelerator mode referenced model, and a model reference target for a referenced model, by executing the `slbuild` command with arguments in the MATLAB Command Window.

The Simulink Coder software generates only one model reference target for all instances of a referenced model. See "Reusable Code and Referenced Models" on page 5-26 for details.

Reduce Change Checking Time

You can reduce the time that the Simulink and Simulink Coder products spend checking whether simulation targets and model reference targets need to be rebuilt by setting configuration parameter values as follows:

- In the top model, consider setting the model configuration parameter **Model Referencing** > **Rebuild** to `If any changes in known dependencies detected`. (See "Rebuild" (Simulink).)
- In all referenced models throughout the hierarchy, set the configuration parameter **Diagnostics** > **Data Validity** > **Signal resolution** to `Explicit only` or `None`. (See "Signal resolution" (Simulink).)

These parameter values exist in a referenced model's configuration set, not in the individual Model block. Setting either value for an instance of a referenced model, sets it for all instances of that model.

Simulink Coder Model Referencing Requirements

A model reference hierarchy must satisfy various Simulink Coder requirements, as described in this section. In addition to these requirements, a model referencing hierarchy to be processed by the Simulink Coder software must satisfy:

- The Simulink requirements listed in:
  - "Configuration Requirements for All Referenced Model Simulation" (Simulink)
  - "Model Structure Requirements" (Simulink)
- The Simulink limitations listed in "Limitations on All Model Referencing" (Simulink)
- The Simulink Coder limitations listed in "Simulink Coder Model Referencing Limitations" on page 5-30

Configuration Parameter Requirements

A referenced model uses a configuration set in the same way a top model does, as described in "Manage a Configuration Set" (Simulink). By default, every model in a hierarchy has its own configuration set, which it uses in the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The response of the Simulink Coder software to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, the product ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, the product resolves the conflict silently; resolves it with a warning; or generates an error.
- If an acceptable resolution is not possible, the product generates an error. You must then change parameter values to eliminate the problem.

When a model reference hierarchy contains many referenced models that have incompatible parameter values, or a changed parameter value must propagate to many referenced models, manually eliminating all configuration parameter incompatibilities can be tedious. You can control or eliminate such overhead by using configuration

references to assign an externally-stored configuration set to multiple models. See "Manage a Configuration Reference" (Simulink) for details.

The following tables list configuration parameters that can cause problems if set in certain ways, or if set differently in a referenced model than in a parent model. Where possible, the Simulink Coder software resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

Configuration Requirements for Model Referencing with All System Targets

Dialog Box Pane	Option	Requirement
Solver	**Start time**	Some system targets require the start time of all models to be zero.
Hardware Implementation	All options	Values must be the same for top and referenced models.
Code Generation	**System target file**	Must be the same for top and referenced models.
	Language	Must be the same for top and referenced models.
	Generate code only	Must be the same for top and referenced models.
Symbols	**Maximum identifier length**	Cannot be longer for a referenced model than for its parent model.
Interface	**Code replacement library**	Must be the same for top and referenced models.
	C API options	The C API check boxes must be the same for top and referenced models.
	ASAP2 interface	Can be `on` or `off` in a top model, but must be `off` in a referenced model. If it is not, the Simulink Coder software temporarily sets it to `off` during code generation.

Configuration Requirements for Model Referencing with ERT System Targets (Requires Embedded Coder License)

Dialog Box Pane	Option	Requirement
All Parameters tab	**Ignore custom storage classes**	Must be the same for top and referenced models.
Symbols	**Global variables** **Global types** **Subsystem methods** **Local temporary variables** **Constant macros**	`$R` token must appear.
	Signal naming	Must be the same for top and referenced models.
	M-function	If specified, must be the same for top and referenced models.
	Parameter naming	Must be the same for top and referenced models.
	#define naming	Must be the same for top and referenced models.
Interface	**Support floating-point numbers**	Must be the same for both top and referenced models
	Support non-finite numbers	If `off` for top model, can be `off` or `off` for referenced models. If `on` for top model, must be `on` for referenced models.
	Support complex numbers	If `off` for top model, can be `off` or `off` for referenced models. If `on` for top model, must be `on` for referenced models.
	Suppress error status in real-time model	If `on` for top model, must be `on` for referenced models.
Code Placement	**Use owner from data object for data definition placement**	Must be the same for top and referenced models.

Dialog Box Pane	Option	Requirement
	Signal display level	Must be the same for top and referenced models.
	Parameter tune level	Must be the same for top and referenced models.

Naming Requirements

Within a model that uses model referencing, names of the constituent models can not collide. When you generate code from a model that uses model referencing, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and the name-mangling text. A code generation error occurs if **Maximum identifier length** is not large enough.

When a name conflict occurs between a symbol within the scope of a higher-level model and a symbol within the scope of a referenced model, the symbol from the referenced model is preserved. Name mangling is performed on the symbol from the higher-level model.

Embedded Coder Naming Requirements

The Embedded Coder product lets you control the formatting of generated symbols in much greater detail. When generating code with an ERT target from a model that uses model referencing:

- The `$R` token must be included in the **Identifier format control** parameter specifications (in addition to the `$M` token) except for **Shared utilities**.
- The **Maximum identifier length** must be large enough to accommodate full expansions of the `$R` and `$M` tokens.

See “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder) for more information.

Custom Target Requirements

If you have an Embedded Coder license, a custom target must meet various requirements to support model referencing. For details, see “Support Model Referencing” on page 71-83.

Storage Classes for Signals Used with Model Blocks

Models containing Model blocks can use signals of storage class `Auto` without restriction. However, when you declare signals to be global, you must be aware of how the signal data will be handled.

A global signal is a signal with a storage class other than `Auto`:

- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `Custom`

The above are distinct from `SimulinkGlobal` signals, which are treated as test points with `Auto` storage class.

Global signals are declared, defined, and used as follows:

- An `extern` declaration is generated by all models that use a given global signal.

  As a result, if a signal crosses a Model block boundary, the top model and the referenced model both generate `extern` declarations for the signal.
- For an exported signal, the top model is responsible for defining (allocating memory for) the signal, whether or not the top model itself uses the signal.
- Global signals used by a referenced model are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.

Custom storage classes also follow the above rules. However, certain custom storage classes are not currently supported for use with model reference. For details, see “Custom Storage Class Limitations” on page 23-71.

Storage Classes for Parameters Used with Model Blocks

Storage classes are supported for both simulation and code generation, and all except `Auto` are tunable. The supported storage classes thus include

- `SimulinkGlobal`
- `ExportedGlobal`

- `ImportedExtern`
- `ImportedExternPointer`
- `Custom`

Note the following restrictions on parameters in referenced models:

- Tunable parameters are not supported for noninlined S-functions.
- Tunable parameters set using the Model Parameter Configuration dialog box are ignored.

Note the following considerations concerning how global tunable parameters are declared, defined, and used in code generated for targets:

- A global tunable parameter is a parameter in the base workspace with a storage class other than `Auto`.
- An `extern` declaration is generated by all models that use a given parameter.
- If a parameter is exported, the top model is responsible for defining (allocating memory for) the parameter (whether it uses the parameter or not).
- Global parameters are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.
- Symbols for `SimulinkGlobal` parameters in referenced models are generated using unstructured variables (`rtP_xxx`) instead of being written into the *`model`*`_P` structure. This is so that each referenced model can be compiled independently.

Certain custom storage classes for parameters are not currently supported for model reference. For details, see “Custom Storage Class Limitations” on page 23-71.

Parameters used as Model block arguments must be defined in the referenced model's workspace. For details, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

Signal Name Mismatches Across Model Reference Boundary

Within a parent model, the name and storage class for a signal entering or leaving a Model block might not match those of the signal attached to the root inport or outport within that referenced model. Because referenced models are compiled independently without regard to a parent model, they cannot adapt to the possible variations in how parent models label and store signals.

The Simulink Coder software accepts all cases where input and output signals in a referenced model have `Auto` storage class. When such signals are test pointed or are global, as described above, certain restrictions apply. The following table describes how mismatches in signal labels and storage classes between parent and referenced models are handled:

Relationships of Signals and Storage Classes Across Model Reference Boundary

Referenced Model	Parent Model	Signal Passing Method	Signal Mismatch Checking
`Auto`	Any storage class	Function argument	None
`SimulinkGlobal` or resolved to Signal Object	Any storage class	Function argument	**Signal label mismatch**
`Global`	Auto or `SimulinkGlobal`	Global variable	**Signal label mismatch**
`Global`	`Global`	Global variable	Labels and storage classes must be identical (else error)

To summarize, the following signal resolution rules apply to code generation:

- If the storage class of a root input or output signal in a referenced model is `Auto` (or is `SimulinkGlobal`), the signal is passed as a function argument.
  - When such a signal is `SimulinkGlobal` or resolves to a `Simulink.Signal` object, the **Signal label mismatch** diagnostic is applied.
- If a root input or output signal in a referenced model is global, it is communicated by using direct memory access (global variable). In addition,
  - If the corresponding signal in the parent model is also global, the names and storage classes must match exactly.
  - If the corresponding signal in the parent model is not global, the **Signal label mismatch** diagnostic is applied.

You can set the **Signal label mismatch** diagnostic to `error`, `warning`, or `none` in the **Diagnostics > Connectivity** pane of the Configuration Parameters dialog box.

Inherited Sample Time for Referenced Models

For information about Model block sample time inheritance, see "Sample Times for Model Referencing" (Simulink). In generated code, you can control inheriting sample time by using `ssSetModelReferenceSampleTimeInheritanceRule` in different ways:

- An S-function that precludes inheritance: If the sample time is used in the S-function's run-time algorithm, then the S-function precludes a model from inheriting a sample time. For example, consider the following `mdlOutputs` code:

  ```
  static void mdlOutputs(SimStruct *S, int_T tid)
  {
      const real_T *u = (const real_T*)
      ssGetInputPortSignal(S,0);
      real_T       *y = ssGetOutputPortSignal(S,0);
      y[0] = ssGetSampleTime(S,tid) * u[0];
  }
  ```

  This `mdlOutputs` code uses the sample time in its algorithm, and the S-function therefore should specify

  ```
  ssSetModelReferenceSampleTimeInheritanceRule
  (S, DISALLOW_SAMPLE_TIME_INHERITANCE);
  ```

- An S-function that does not preclude Inheritance: If the sample time is only used for determining whether the S-function has a sample hit, then it does not preclude the model from inheriting a sample time. For example, consider the `mdlOutputs` code from the S-function example `sfun_multirate.c`:

  ```
  static void mdlOutputs(SimStruct *S, int_T tid)
  {
      InputRealPtrsType enablePtrs;
      int               *enabled = ssGetIWork(S);

      if (ssGetInputPortSampleTime
      (S,ENABLE_IPORT)==CONTINUOUS_SAMPLE_TIME &&
      ssGetInputPortOffsetTime(S,ENABLE_IPORT)==0.0) {
          if (ssIsMajorTimeStep(S) &&
          ssIsContinuousTask(S,tid)) {
              enablePtrs =
              ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
              *enabled = (*enablePtrs[0] > 0.0);
          }
      } else {
  ```

```
            int enableTid =
            ssGetInputPortSampleTimeIndex(S,ENABLE_IPORT);
            if (ssIsSampleHit(S, enableTid, tid)) {
                enablePtrs =
                ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
                *enabled = (*enablePtrs[0] > 0.0);
            }
        }

        if (*enabled) {
            InputRealPtrsType uPtrs  =
            ssGetInputPortRealSignalPtrs(S,SIGNAL_IPORT);
            real_T            signal = *uPtrs[0];
            int               i;

            for (i = 0; i < NOUTPUTS; i++) {
                if (ssIsSampleHit(S,
                ssGetOutputPortSampleTimeIndex(S,i), tid)) {
                    real_T *y = ssGetOutputPortRealSignal(S,i);
                    *y = signal;
                }
            }
        }
    } /* end mdlOutputs */
```

The above code uses the sample times of the block, but only for determining whether there is a hit. Therefore, this S-function should set

```
ssSetModelReferenceSampleTimeInheritanceRule
(S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE);
```

Customize Library File Suffix and File Type

You can control the library file suffix and file type extension that the Simulink Coder code generator uses to name generated model reference libraries. Use the model configuration parameter `TargetLibSuffix` to specify the scheme for the suffix and extension. The scheme must include a period (.). If you do not set this parameter, the Simulink Coder software names the libraries as follows:

- On Windows systems, *`model`*`_rtwlib.lib`
- On UNIX or Linux® systems, *`model`*`_rtwlib.a`

For more information, see "Using TargetLibSuffix with the Toolchain Approach" (Simulink Coder).

Reusable Code and Referenced Models

Models that employ model referencing might require special treatment when generating and using reusable code. The following sections identify general restrictions and discuss how reusable functions with inputs or outputs connected to a referenced model's root Inport or Outport blocks can affect code reuse.

General Considerations

You can generate code for subsystems that contain referenced models using the same procedures and options described in "Code Generation of Subsystems" (Simulink Coder). However, the following restrictions apply to such builds:

- A top model that uses single-tasking mode and that has a referenced model that uses multi-tasking mode executes for blocks with the different rates that are not connected. However, you get an error if the blocks with different rates are connected by Rate Transition block (inserted either manually or by Simulink).
- ERT S-functions do not support subsystems that contain a continuous sample time.
- The Simulink Coder S-function target is not supported.
- The Tunable parameters table (set by using the Model Parameter Configuration dialog box) is ignored; to make parameters tunable, you must define them as Simulink parameter objects in the base workspace.
- All other parameters are inlined into the generated code and S-function.

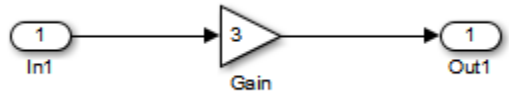
Note You can generate subsystem code using any target configuration available in the System Target File Browser. However, if the S-function target is selected, **Build This Subsystem** and **Build Selected Subsystem** behaves identically to **Generate S-Function**. (See "Automate S-Function Generation with S-Function Builder" on page 11-61.)

Code Reuse and Model Blocks with Root Inport or Outport Blocks

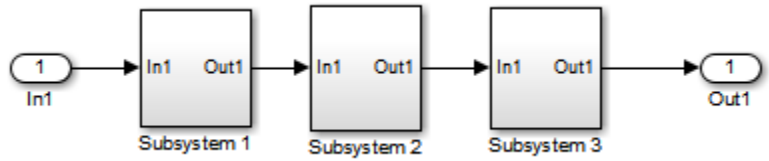
Reusable functions with inputs or outputs connected to a referenced model's root Inport or Outport block can affect code reuse. This means that code for certain atomic subsystems cannot be reused in a model reference context the same way it is reused in a standalone model.

For example, suppose you create the following subsystem and make the following changes to the subsystem's block parameters:

- Select **Treat as an atomic unit**
- Go to the **Code Generation** tab and set **Function packaging** to `Reusable function`



Suppose you then create the following model, which includes three instances of the preceding subsystem.



With the configuration parameter **Default parameter behavior** set to `Inlined` in this stand-alone model, the code generator can optimize the code by generating a single copy of the function for the reused subsystem, as shown below.

```
void reuse_subsys1_Subsystem1(
                   real_T rtu_0,
                   rtB_reuse_subsys1_Subsystem1 *localB)
{

  /* Gain: '<S1>/Gain' */
  localB->Gain_k = rtu_0 * 3.0;
}
```

When generated as code for a Model block (into an `slprj` folder in the code generation folder (Simulink)), the subsystems have three different function signatures:

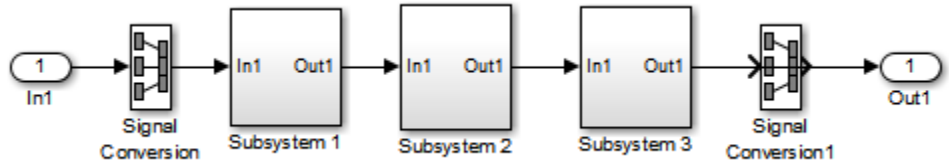
```
/* Output and update for atomic system: '<Root>/Subsystem1' */
void reuse_subsys1_Subsystem1(const real_T *rtu_0,
```

```
rtB_reuse_subsys1_Subsystem1
 *localB)
{
  /* Gain: '<S1>/Gain' */
  localB->Gain_w = (*rtu_0) * 3.0;
}

/* Output and update for atomic system: '<Root>/Subsystem2' */
void reuse_subsys1_Subsystem2(real_T rtu_In1,
rtB_reuse_subsys1_Subsystem2
 *localB)
{
  /* Gain: '<S2>/Gain' */
  localB->Gain_y = rtu_In1 * 3.0;
}

/* Output and update for atomic system: '<Root>/Subsystem3' */
void reuse_subsys1_Subsystem3(real_T rtu_In1, real_T *rty_0)
{
  /* Gain: '<S3>/Gain' */
  (*rty_0) = rtu_In1 * 3.0;
}
```

One way to make all the function signatures the same for code reuse, is to insert Signal Conversion blocks. Place one between the Inport and Subsystem1 and another between Subsystem3 and the Outport of the referenced model.



The result is a single reusable function:

```
void reuse_subsys2_Subsystem1(real_T rtu_In1,
                  rtB_reuse_subsys2_Subsystem1 *localB)
{

  /* Gain: '<S1>/Gain' */
  localB->Gain_g = rtu_In1 * 3.0;
}
```

You can achieve the same result (reusable code) with only one Signal Conversion block. You can omit the Signal Conversion block connected to the Inport block if you select the **Pass fixed-size scalar root inputs by value** check box at the bottom of the **Model Referencing** pane of the Configuration Parameters dialog box. When you do this, you still need to insert a Signal Conversion block before the Outport block.

Simulink Coder Model Referencing Limitations

The following Simulink Coder limitations apply to model referencing. In addition to these limitations, a model reference hierarchy used for code generation must satisfy:

- The Simulink requirements listed in:
  - "Configuration Requirements for All Referenced Model Simulation" (Simulink)
  - "Model Structure Requirements" (Simulink)
- The Simulink limitations listed in "Model Referencing Limitations" (Simulink).
- The Simulink Coder requirements applicable to the code generation target, as listed in "Configuration Parameter Requirements" on page 5-16.

Customization Limitations

- The code generator ignores custom code settings in the Configuration Parameters dialog box and custom code blocks when generating code for a referenced model.
- Data type replacement is not supported for simulation target code generation of referenced models.
- Simulation targets do not include Stateflow target custom code.
- If you have an Embedded Coder license, some restrictions exist on grouped custom storage classes in referenced models. For details, see "Custom Storage Class Limitations" on page 23-71.

Data Logging Limitations

- To Workspace blocks, Scope blocks, and all types of runtime display, such as the display of port values and signal values, are ignored when the Simulink Coder software generates code for a referenced model. The resulting code is the same as if the constructs did not exist.
- Code generated for referenced models cannot log data to MAT-files. If data logging is enabled for a referenced model, the Simulink Coder software disables the option before code generation and re-enables it afterwards.
- If you log states for a model that contains referenced models, the ordering of the states in the output is determined by block sorted order, and might not match between simulation output and generated code MAT-file logging output.

State Initialization Limitation

When a top model uses the **Data Import/Export > Initial state** parameter in the Configuration Parameters dialog box to specify initial conditions, the Simulink Coder software does not initialize the discrete states of the referenced models during code generation.

Reusability Limitations

If a referenced model used for code generation has any of the following properties, the model must specify the configuration parameter **Model Referencing > Total number of instances allowed per top model** as `One`, and no other instances of the model can exist in the hierarchy. If you do not set the parameter to `One`, or more than one instance of the model exists in the hierarchy, an error occurs. The properties are:

- The model references another model which has been set to single instance
- The model contains a state or signal with non-auto storage class
- The model uses any of the following Stateflow constructs:
  - Machine-parented data
  - Machine-parented events
  - Stateflow graphical functions
- The model contains a subsystem that is marked as function
- The model contains an S-function that is:
  - Inlined but has not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`
  - Not inlined
- The model contains a function-call subsystem that:
  - Has been forced by the Simulink engine to be a function
  - Is called by a wide signal

For more information about **Total number of instances allowed per top model**, see "Total number of instances allowed per top model" (Simulink).

S-Function Limitations

- If a referenced model contains an S-function that should be inlined using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target will not inline the S-function unless this flag is set.
- A referenced model cannot use noninlined S-functions generated by the Simulink Coder software.
- The Simulink Coder S-function target does not support model referencing.

For additional information, see "S-Functions with Referenced Models" (Simulink).

Simulink Tool Limitations

- Simulink tools that require access to a model's internal data or configuration (including the Model Coverage tool, the Simulink Report Generator product, the Simulink debugger, and the Simulink profiler) have no effect on code generated by the Simulink Coder software for a referenced model, or on the execution of that code. Specifications made and actions taken by such tools are ignored and effectively do not exist.

Subsystem Limitations

- If a subsystem contains Model blocks, you cannot build a subsystem module by right-clicking the subsystem (or by using **Code > C/C++ Code > Build Selected Subsystem**) unless the model is configured to use an ERT target.
- If you generate code for an atomic subsystem as a reusable function, inputs or outputs that connect the subsystem to a referenced model might prevent code reuse, as described in "Reusable Code and Referenced Models" (Simulink Coder).

Target Limitations

- The Simulink Coder S-function target does not support model referencing.

Other Limitations

- Errors or unexpected behavior can occur if a Model block is part of a cycle, the Model block is a direct feedthrough block, and an algebraic loop results. For details, see "Model Blocks and Direct Feed through" (Simulink).

- The **External mode** option is not supported. If it is enabled, it is ignored during code generation.
- When a model contains a trigger or enable port, you cannot generate standalone Simulink Coder code or PIL code.

6

Combined Models in Simulink Coder

Combine Code Generated for Multiple Models

Techniques

Techniques that you can use to combine code, which the code generator produces for multiple models or multiple instances of a model, into one executable program include:

- Referenced models. See "Overview of Model Referencing" (Simulink) and "Generate Code for Referenced Models" on page 5-4.
- If you have Embedded Coder software, interface the code for multiple models to a common harness program. From the harness program, call the entry-point functions generated for each model. The `ert.tlc` system target file has restrictions, relating to embedded processing, that could be incompatible with your application.
- Generate reusable, multi-instance code that is reentrant. See "Combine Code Generated for Multiple Models or Multiple Instances of a Model" on page 6-3.

The S-function system target (`rtwsfcn.tlc`) does not support combining code generated for multiple models.

Consider using model referencing to combine models for simulation and code generation. Model referencing helps with:

- Symbol naming consistency
- Required scheduling of the overall algorithm
- Model configuration consistency

If you combine code generated for different models (that is, without using referenced models), consider:

- Data is global. Symbol (name) clashes can result.
- Configuration parameter settings for the models must match, including settings such as hardware word sizes.
- Reuse and sharing of code can be suboptimal (for example, duplicate code for shared utility functions, scheduling, and solvers).
- Scheduling can be more complex (for example, models can have periodic sample times that are not multiples of each other, making scheduling from a common timer interrupt more complicated)

- For plant models that use continuous time and state, the continuous time signals connecting models are not handled by a single solver like continuous time signals within a model. This can lead to subtle numeric differences.

Control Ownership of Data

If you have Embedded Coder software, you can specify an *owner* for individual data items such as signals, parameters, and states. The owner of a data item generates the definition (memory allocation and initialization) for the data item. For example, if you apply a custom storage class to a `Simulink.Parameter` object so that it appears as a tunable global variable in the generated code, specify one of the combined models as the owner of the object. The code generated for that model defines the parameter data.

If you use model referencing, you can modularize the generated code and establish clear ownership of data when you work in a team.

If you do not use model referencing, you can prevent generation of duplicate definitions for a data item. For example, suppose you store a `Simulink.Parameter` object in the base workspace and apply the storage class `ExportedGlobal`. If you generate code from two separate models that use the object, each model generates a definition for the corresponding global variable. Instead, you can specify an owner for the object so that only the owner generates a definition.

To specify an owner for a data item:

1. Apply a custom storage class to the data item. See “Introduction to Custom Storage Classes” on page 23-2.
2. Configure the owner of the data item by specifying the **Owner** custom attribute.
3. Select the model configuration parameter **Use owner from data object for data definition placement**.

For more information about controlling ownership and file placement of data definitions and declarations, see “Manage Placement of Data Definitions and Declarations” on page 36-100.

Combine Code Generated for Multiple Models or Multiple Instances of a Model

For each model for which you are combining code, generate the code.

1. Set the system target file to a GRT- or ERT-based system target file. The system target file for the models you combine, must be the same.
2. If you intend to have multiple instances of that model in the application, set the model configuration parameter **Code Generation > Interface > Code interface packaging** to `Reusable function`. If you specified an ERT-based system target file, optionally, you can set the model configuration parameter **Use dynamic memory allocation for model initialization**, depending on whether you want to statically or dynamically allocate the memory for each instance of the model.
3. Generate source code. The code generator includes an allocation function in the generated file *`model`*`.c`. The allocation function dynamically allocates model data for each instance of the model.

After generating source code for each model:

1. Compile the code for each model that you are combining.
2. Combine the makefiles generated for the models into one makefile.
3. Create a combined simulation engine by modifying a main program, such as `rt_malloc_main.c`. The main program initializes and calls the code generated for each model.
4. Run the makefile. The makefile links the object files and the main program into an executable program.

Share Data Across Models

Use unidirectional signal connections between models. This affects the order in which models are called. For example, if you use an output signal from `modelA` as input to `modelB`, the `modelA` output computation should be called first.

Timing Issues

When combining code generated for multiple models or multiple instances of a model:

- Configure the models with the same solver mode (single-tasking or multitasking).
- If the models use continuous states, configure the models with the same solver.

If the base rates for the models differ, the main program (such as `rt_malloc_main.c`) must set up the timer interrupt to occur at the greatest common divisor rate of the models. The main program calls each model at a time interval.

Data Logging and External Mode Support

A multiple-model program can log data to separate MAT-files for each model.

Only one of the models in a multiple-model program can use external mode.

7

Configure Model Parameters for Simulink Coder

Configure Run-Time Environment Options

When you use Simulink software to create and execute a model and use the code generator to produce C or C++ code, consider your configuration for up to three run-time environments:

- The MATLAB development computer run-time environment that runs MathWorks software during application development.
- The production hardware run-time environment in which you deploy an application when it is put into production.
- The test hardware run-time environment in which you test an application under development before deployment.

One run-time environment can serve in multiple capacities, but the run-time environments remain conceptually distinct. Often, the MATLAB development computer is the test hardware. Typically, the production hardware is different from, and less powerful than, the MATLAB development or the test hardware. Many types of production hardware can do little more than run a downloaded executable file.

Provide information about the production hardware board and the compiler that you use with it when:

- You use Simulink software to simulate a model for which you later generate code
- You use the code generator to produce code for deployment on *production* hardware

The software uses the board and compiler information to get bit-true agreement for the results of integer and fixed-point operations performed in simulation and in code generated for the production hardware. The code generator uses the information to create code that executes with maximum efficiency.

When you generate code for testing on *test* hardware, provide information about the test hardware board and the compiler that you use. The code generator uses this information to create code that provides bit-true agreement between results from:

- Integer and fixed-point operations performed in simulation
- Generated code run on the production hardware
- Generated code run on the test hardware

You can achieve bit-true agreement for results even if the production and test hardware are different. Where the C standard does not completely define behavior, the compilers for the two types of hardware can use different defaults.

Configure Production and Test Hardware

You can specify model simulation or code generation for a specific hardware board and its device type. For example, you can set the data size, byte ordering, and compiler behavior, such as integer rounding. You can configure:

- The production hardware and the compiler that you use with it. This information affects simulation and code generation. See "Example Production Hardware Setting That Affects Normal Mode Simulation" on page 7-13.
- The test hardware and the compiler that you use with it. This information affects only code generation.

Configure production hardware by selecting **Configuration Parameters** > **Hardware Implementation**. By default, the Hardware Implementation pane lists **Hardware board**, **Device vendor**, and **Device type** parameter fields only. Unless you have installed hardware support packages, **Hardware board** lists values `None` or `Determine by Code Generation system target file`, and `Get Hardware Support Packages`. After installing a hardware support package, the list also includes the corresponding hardware board name. If you select a hardware board name, parameters for that board appear. To set device details, such as data size and byte ordering, click **Device details**.

Configure test hardware in the Configuration Parameters dialog box, on the **All Parameters** tab. To enable parameters for configuring test hardware details, set `ProdEqTarget` to `off`. Code generated for test hardware executes in the environment specified by the test hardware parameters. The code behaves as if it were executing in the environment specified for the production hardware. For more information, see "Test Hardware Considerations" on page 7-13.

Default values and properties appear as initial values in the **Hardware Implementation** pane when:

- You specify a **System target file** in the **Code Generation** pane.
- The system target file specifies a default microprocessor and its hardware properties.

You cannot change parameters that have only one possible value. Parameters that have more than one possible value provide a list of valid values. If you specify hardware properties manually in **Hardware Implementation** pane, verify that these values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Hardware implementation parameters describe hardware and compiler properties to MATLAB software. The code generator uses the information to produce code for the run-time environment that runs as efficiently as possible. The generated code gives bit-true agreement for the results of integer and fixed-point operations in simulation, production code, and test code.

For details about specific parameters, see "Hardware Implementation Pane" (Simulink). To see an example of **Hardware Implementation** pane capabilities, see the `rtwdemo_targetsettings` example model. For details related to configuring a hardware implementation, see:

Specify Hardware Board

Specify the hardware board that runs the code generated from your model. Select a value for **Configuration Parameters > Hardware Implementation > Hardware board**.

The Hardware Implementation pane identifies the system target file selected on **Configuration Parameters > Code Generation**.

To configure test hardware, use **Configuration Parameters > All Parameters**.

To enable parameters for configuring test hardware details, set `ProdEqTarget` to `off`.

Ways to Specify the Hardware Board

If	Select
The menu *includes* the name of the hardware board that you want to use.	The name of that hardware board.

If	Select
	If you select a hardware board name, parameters for that board appear.
The menu *does not include* the name of the hardware board that you want to use.	`Get Hardware Support Packages`. That value opens the Support Package Installer. Install the support package that you want. After you install the support package, the menu includes relevant hardware board names.
The model configuration *uses* system target file `ert.tlc`, `realtime.tlc`, or `autosar.tlc`.	`None`. No hardware board is specified for the hardware implementation.
The model configuration *does not use* system target file `ert.tlc`, `realtime.tlc`, or `autosar.tlc`.	`Determine by Code Generation system target file`. The code generator uses the specified system target file to determine the hardware implementation.

Specify Device Vendor

To specify the vendor of the microprocessor of the hardware device, use the **Device vendor** parameter. Your selection determines the available microprocessors in the **Device type** menu. If the vendor name does not appear, select `Custom Processor`. Then, use the **Device type** parameter to specify the microprocessor.

- For complete lists of **Device vendor** and **Device type** values, see "Device vendor" (Simulink) and "Device type" (Simulink).
- To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, see "Register More Device Vendor and Device Type Values" on page 7-6.

Specify the Device Type

To specify the microprocessor name from the supported devices listed for your **Device vendor** selection, use the **Device type** parameter. If the microprocessor does not appear in the menu, change **Device vendor** to `Custom Processor`. Then, specify device details for your custom device.

If you select a device type for which the system target file specifies default hardware properties, the properties appear as initial values. You cannot change the value of parameters with only one possible selection. Parameters that have more than one possible value provide a menu. Select values for your hardware.

Register More Device Vendor and Device Type Values

To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, you can use a hardware device registration API provided by the code generator.

To use this API, you create an `sl_customization.m` file, on your MATLAB path, that invokes the `registerTargetInfo` function and fills in a hardware device registry entry with device information. The device information is registered with Simulink software for each subsequent Simulink session. (To register your device information without restarting MATLAB, issue the MATLAB command `sl_refresh_customizations`.)

For example, the following `sl_customization.m` file adds device vendor `MyDevVendor` and device type `MyDevType` to the Simulink device lists.

```
function sl_customization(cm)
  cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device
  thisDev = RTW.HWDeviceRegistry;
  thisDev.Vendor = 'MyDevVendor';
  thisDev.Type = 'MyDevType';
  thisDev.Alias = {};
  thisDev.Platform = {'Prod', 'Target'};
  thisDev.setWordSizes([8 16 32 32 32]);
  thisDev.LargestAtomicInteger = 'Char';
  thisDev.LargestAtomicFloat = 'None';
  thisDev.Endianess = 'Unspecified';
  thisDev.IntDivRoundTo = 'Undefined';
  thisDev.ShiftRightIntArith = true;
  thisDev.setEnabled({'IntDivRoundTo'});
end
```

After device registration, you can select the device in the **Hardware Implementation** pane.

To register multiple devices, specify an array of `RTW.HWDeviceRegistry` objects in your `sl_customization.m` file. For example:

```
function sl_customization(cm)
  cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device

  thisDev(1) = RTW.HWDeviceRegistry;
  thisDev(1).Vendor = 'MyDevVendor';
  thisDev(1).Type = 'MyDevType1';
  ...

  thisDev(4) = RTW.HWDeviceRegistry;
  thisDev(4).Vendor = 'MyDevVendor';
  thisDev(4).Type = 'MyDevType4';
  ...

end
```

You can specify various `RTW.HWDeviceRegistry` properties in the `registerTargetInfo` function call in your `sl_customization.m` file.

Properties for registerTargetInfo Function Call

Property	Description
`Vendor`	Character vector specifying the **Device vendor** value for your hardware device.
`Type`	Character vector specifying the **Device type** value for your hardware device.
`Alias`	Cell array of character vectors specifying aliases or legacy names that can resolve to this device. Specify each alias or legacy name in the format `'Vendor->Type'`. Embedded Coder software provides the utility functions `RTW.isHWDeviceTypeEq` and `RTW.resolveHWDeviceType`. These functions detect and resolve alias values or legacy values when testing user-specified values for the hardware device type.
`Platform`	Cell array of enumerated character vector values specifying whether this device can be listed in the **Production hardware** subpane (`{'Prod'}`), the **Test hardware** subpane (`{'Target'}`), or both (`{'Prod', 'Target'}`).

Property	Description
`setWordSizes`	Array of integer sizes to associate with the **Number of bits** parameters **char**, **short**, **int**, **long**, and **native word size**, respectively.
`LargestAtomicInteger`	Character vector specifying an enumerated value for the **Largest atomic size: integer** parameter: `'Char'`, `'Short'`,`'Int'`, or `'Long'`.
`LargestAtomicFloat`	Character vector specifying an enumerated value for the **Largest atomic size: floating-point** parameter: `'Float'`, `'Double'`, or `'None'`.
`Endianess`	Character vector specifying an enumerated value for the **Byte ordering** parameter: `'Unspecified'`, `'Little'` for little Endian, or `'Big'` for big Endian.
`IntDivRoundTo`	Character vector specifying an enumerated value for the **Signed integer division rounds to** parameter: `'Zero'`, `'Floor'`, or `'Undefined'`.
`ShiftRightIntArith`	Boolean value specifying whether your compiler implements a signed integer right shift as an arithmetic right shift (`true`) or not (`false`).
`setEnabled`	Cell array of character vectors specifying which device properties you can modify in the **Hardware Implementation** pane when you select this device type. This property applies for the `'Endianess'`, `'IntDivRoundTo'`, and `'ShiftRightIntArith'` properties. You can apply this property to individual **Number of bits** parameters by using the property names `'BitPerChar'`, `'BitPerShort'`, `'BitPerInt'`, `'BitPerLong'`, and `'NativeWordSize'`.

Set Bit Lengths for Device Data Types

The **Number of bits** parameters describe the **native word size** of the microprocessor and the bit lengths of **char**, **short**, **int**, and **long** data. For code generation to succeed:

- The bit lengths must be such that **char** <= **short** <= **int** <= **long**.
- Bit lengths must be multiples of 8, with a maximum of 32.

- The bit length for **long** data must not be less than 32.

The `rtwtypes.h` file defines integer type names. The values that you provide must be consistent with the word sizes as defined in the compiler `limits.h` header file. The code generator maps its integer type names to the corresponding Simulink integer type names.

If no ANSI® C type with a matching word size is available, but a larger ANSI C type is available, the code generator uses the larger type for `int8_T`, `uint8_T`, `int16_T`, `uint16_T`, `int32_T`, and `uint32_T`. When the code generator uses a larger type, the resulting logged values (for example, MAT-file logging) can have different data types than logged values for simulation.

An application can use an integer data of length from 1 (unsigned) or 2 (signed) bits up 32 bits. If the integer length matches the length of an available type, the code generator uses that type. If a matching type is not available, the code generator uses the smallest available type that can hold the data, generating code that does not use unnecessary higher-order bits. For example, on hardware that supports 8-bit, 16-bit, and 32-bit integers, for a signal specified as 24 bits, the code generator implements the data as an `int32_T` or `uint32_T`.

Code that uses emulated integer data is not maximally efficient. This code can be useful during application development for emulating integer lengths that are available only on production hardware. Emulation does not affect the results of execution.

During code generation, the software checks the compatibility of model data types with the data types that you specify for production hardware.

- If none of the lengths that you specify for production hardware integers is 32 bits, the software generates an error.
- If the lengths of data types that the model uses are smaller than the available production hardware integer lengths, the software generates a warning.

Mapping of Integer Types from Code Generator to Simulink

Code Generator Integer Type	Simulink Integer Type
`boolean_T`	`boolean`
`int8_T`	`int8`
`uint8_T`	`uint8`
`int16_T`	`int16`

Code Generator Integer Type	Simulink Integer Type
`uint16_T`	`uint16`
`int32_T`	`int32`
`uint32_T`	`uint32`

Set Byte Ordering for Device

The **Byte ordering** parameter specifies whether the hardware uses `Big Endian` (most significant byte first) or `Little Endian` (least significant byte first) byte ordering. If left as `Unspecified`, the code generator produces code that determines the endianness of the hardware. This setting is the least efficient.

Set Quotient Rounding Behavior for Signed Integer Division

ANSI C does not completely define the quotient rounding technique for compilers to use when dividing one signed integer by another. So, the behavior is implementation-dependent. If both integers are positive, or both are negative, the quotient must round down. If either integer is positive and the other is negative, the quotient can round up or down.

The **Signed integer division rounds to** parameter instructs the code generator about how the compiler rounds the result of signed integer division. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize code generated for signed integer division. The parameter values are:

- `Zero` — If the quotient is between two integers, the compiler chooses the integer that is closer to zero as the result.
- `Floor` — If the quotient is between two integers, the compiler chooses the integer that is closer to negative infinity.
- `Undefined` — If `Zero` or `Floor` do not describe the compiler behavior or if that behavior is unknown, choose this value.

Avoid selecting `Undefined`. When the code generator does not know the signed integer division rounding behavior of the compiler, the model build generates extra code.

The compiler quotient rounding behavior varies according to these values.

You can obtain the compiler implementation for signed integer division rounding from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Example Quotient Rounding for Zero, Floor, and Undefined

N	D	Ideal N/D	Zero	Floor	Undefined
33	4	8.25	8	8	8
-33	4	-8.25	-8	-9	-8 or -9
33	-4	-8.25	-8	-9	-8 or -9
-33	-4	8.25	8	8	8 or 9

Set Arithmetic Right Shift Behavior for Signed Integers

ANSI C does not define the behavior of right shifts on negative integers for compilers. So, the behavior is implementation-dependent. The **Shift right on a signed integer as arithmetic shift** option instructs the code generator about how the compiler implements right shifts on negative integers. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize the code generated for arithmetic right shifts.

If the C compiler implements a signed integer right shift as an arithmetic right shift, select the option. Otherwise, clear the option. An arithmetic right shift fills bits vacated by the right shift with the value of the most significant bit, which indicates the sign of the number in two's-complement notation. The option is selected by default. If your compiler handles right shifts as arithmetic shifts, this setting is preferred.

- When you select the option, the code generator produces efficient code whenever the Simulink model performs arithmetic shifts on signed integers.
- When the option is cleared, the code generator produces fully portable but less efficient code to implement right arithmetic shifts.

You can obtain the compiler implementation for arithmetic right shifts from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Update Release 14 Hardware Configuration

If your model was created before Release 14 and you have not updated the model, the **Configure current execution hardware device** parameter (`TargetUnknown`) value is `'on'` by default.

To update your model, clear the box for **Configuration Parameters > All Parameters > Configure current execution hardware device**.Or in the Command Window, type:

```
cs = getActiveConfigSet('your_model_name');
set_param(cs,'TargetUnknown','off');
```

This update to your model:

- Enables the **Test Hardware is the same as production hardware** parameter (`ProdEqTarget`), setting the parameter to `'on'`.
- Copies the **Production device vendor and type** parameter (`ProdHWDeviceType`) value to the **Test device vendor and type** parameter (`TargetHWDeviceType`).

To complete the update:

1. Clear the box for **Configuration Parameters > All Parameters > Test Hardware is the same as production hardware**. Apply this step only if your production and test hardware are different.
2. Set the parameters in **Configuration Parameters > All Parameters > Hardware implementation** to match your production and test systems.
3. Save the model.

Production Hardware Considerations

When you configure production hardware, consider these points:

- Production hardware can have word sizes and other hardware characteristics that differ from the MATLAB development computer. You can prototype code on hardware that is different from the production hardware or the MATLAB development computer. When producing code, the code generator accounts for these differences.
- The Simulink product uses some of the information in the production hardware configuration. That information enables simulations without code generation to give the same results as executing generated code. For example, the results can detect error conditions that arise on the production hardware, such as hardware overflow.
- The code generator produces code that provides bit-true agreement with Simulink results for integer and fixed-point operations. Generated code that emulates unavailable data lengths runs less efficiently than without emulation. The emulation does not affect bit-true agreement with Simulink for integer and fixed-point results.
- If you change run-time environments during application development, before generating or regenerating code, reconfigure the hardware implementation parameters for the new run-time environment. When code executes on hardware for which it was not generated, bit-true agreement is not always achieved for results of integer and fixed-point operations in simulation, production code, and test code.

- To compile code generated from the model, use the **Integer rounding mode** parameter on model blocks to simulate the rounding behavior of the C compiler that you intend. This setting appears on the **Signal Attributes** pane in the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.
- For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see "Precision" (Fixed-Point Designer).
- When models contain Model blocks, configure models that they reference to use identical hardware settings.

Test Hardware Considerations

By default, the test hardware configuration is the same as the configuration for the production hardware. You can use the generated code for testing in an environment that is identical to the production environment.

If the test and production environments differ, you can generate code that runs on test hardware as if it were running on production hardware:

1. In the Configuration Parameters dialog box, on the **All Parameters** tab, enable test hardware parameters by setting `ProdEqTarget` to `off`.
2. Specify device type details through the test hardware (`Target*`) parameters.

If you select a system target file that specifies a default microprocessor and its hardware properties, these default values and properties appear as initial values.

Parameters with only one possible value cannot be changed. If you modify hardware properties, check that their values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Example Production Hardware Setting That Affects Normal Mode Simulation

Changing some production hardware settings, for example, `ProdLongLongMode` and `ProdIntDivRoundTo`, can affect normal mode simulation results. The following example simulates an adder with four inputs. In the first simulation, `ProdLongLongMode` is disabled. In the second simulation, `ProdLongLongMode` is enabled. In the plot of

simulation outputs, you observe small differences between output values in the time step range 125–175.

```
model = 'hwSettingEffect';
new_system(model)
open_system(model)

% Create adder
pos = [140   140   200   340];
add_block('simulink/Math Operations/Add',[model '/sum_int32'], ...
          'Inputs','++++','SaturateOnIntegerOverflow','on','Position',pos)

pos = [75   155   105   175];
add_block('built-in/Inport',[model '/In1'],'Position',pos)
set_param([model '/In1'], 'OutDataTypeStr','int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In1/1','sum_int32/1')

pos = [75   205   105   225];
add_block('built-in/Inport',[model '/In2'],'Position',pos)
set_param([model '/In2'], 'OutDataTypeStr','int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In2/1','sum_int32/2')

pos = [75   255   105   275];
add_block('built-in/Inport',[model '/In3'],'Position',pos)
set_param([model '/In3'], 'OutDataTypeStr','int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In3/1','sum_int32/3')

pos = [75   305   105   325];
add_block('built-in/Inport',[model '/In4'],'Position',pos)
set_param([model '/In4'], 'OutDataTypeStr','int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In4/1','sum_int32/4')

pos = [275   230   305   250];
add_block('built-in/Outport',[model '/Out1'],'Position',pos)
add_line(model, 'sum_int32/1','Out1/1')

% Specify input data
t = 0:200;
peakValue = 1.5e9;
in1 = peakValue * sin(t*2*pi/100);
in2 = peakValue * cos(t*2*pi/70);
in3 = -peakValue * sin(t*2*pi/40);
in4 = -peakValue * cos(t*2*pi/30);
set = Simulink.SimulationData.Dataset;
set = set.addElement(1, timeseries(int32(in1),t,'Name','sig1'));
set = set.addElement(2, timeseries(int32(in2),t,'Name','sig2'));
set = set.addElement(3, timeseries(int32(in3),t,'Name','sig3'));
set = set.addElement(4, timeseries(int32(in4),t,'Name','sig4'));

set_param(model, 'LoadExternalInput', 'on');
set_param(model, 'ExternalInput', 'set');

set_param(model, 'StopTime', '50');

% Disable production hardware setting and run first simulation
```

```
set_param(model, 'ProdLongLongMode', 'off');
[~, ~, y1] = sim(model, 200);

% Enable production hardware setting and run second simulation
set_param(model, 'ProdLongLongMode', 'on');
[~, ~, y2] = sim(model, 200);

plot([y1 y2]);
figure(gcf);
```

The difference in behavior is due to the accumulator data type in the Sum block. The **Accumulator data type** block parameter is set to `Inherit: Inherit via internal rule`. For this example, the resulting accumulator data type is 64 bits wide if the use of the C `long long` data type is enabled. Otherwise, it is 32 bits wide. Depending on the input values for the sum block, the 32-bit accumulator can saturate when the 64-bit accumulator does not. Therefore, normal mode behavior can depend on the `ProdLongLongMode` setting. In both cases, the normal mode behavior and production hardware behavior matches bitwise.

Model Protection in Simulink Coder

Protect a Referenced Model

Protect a model when you want to share a model with a third party without revealing intellectual property. Protecting a model does not use encryption technology unless you use the optional password protection available for read-only view, simulation, and code generation. If you choose password protection for one of these options, the software protects the supporting files using AES–256 encryption.

When you create a protected model (Simulink):

- By default, Simulink creates and stores a protected version of the referenced model in the current working folder. The protected model has the same name as the source model, with a `.slxp` extension.
- The original Model block does not change. However, if the Model block parameter **Model name** does not specify an extension, a protected model, `.slxp`, takes precedence over a model file, `.slx`.
- You can optionally create a harness model which includes the protected model. A shield icon appears in the lower-left corner of the protected model block in the harness model. For more information, see “Harness Model” on page 8-4.
- You can optionally include generated code with the protected model so that a third party can generate code for a model that contains the protected model. For more information, see “Code Generation Support in a Protected Model” on page 8-6.
- If the Model block uses variants, only the active variant is protected. For more information, see “Set up Model Variants” (Simulink).
- If the model defines callbacks, the model protection process does not preserve these callbacks. For more information on creating callbacks for use with a protected model, see “Define Callbacks for Protected Model” (Simulink Coder).
- If you rename a protected model, or change its suffix, the model is unusable until you restore its original name and suffix. You cannot change a protected model file internally because such changes make the file unusable.

Create a protected model using one of the following options.

- The Model block context menu. For more information, see “Create a Protected Model” on page 8-10
- The `Simulink.ModelReference.protect` function.
- The Simulink Editor menu bar. Select **File > Export Model To > Protected Model** to create a protected model from the current model.

Requirements for Protecting a Model

When you create a protected model from a referenced model, the referenced model must meet all requirements listed in "Model Referencing Limitations" (Simulink), as well as these requirements:

- You must have a Simulink Coder license to create a protected model.
- A model that you protect must be available on the MATLAB path and not have unsaved changes.
- A model that you protect cannot reference a protected model directly or indirectly.
- A model that you protect cannot use a non-inlined S-function directly or indirectly.
- To use a protected model that requires passwords across platforms, before you create the protected model, set the MATLAB character set encoding to `'US-ASCII'`. For more information, see `slCharacterEncoding`.

Model protection has certain limitations, as listed in "Limitations on All Model Referencing" (Simulink) and "Limitations on Accelerator Mode Referenced Models" (Simulink).

Harness Model

You can create a harness model for the generated protected model. The harness model opens as a new, untitled model that contains only a Model block that references the protected model. This Model block:

- Specifies the Model block parameter, **Model name**, as the name of the protected model.
- Has a shield icon in the lower-left corner.
- Has the same number of input and output ports as the protected model.
- Defines model reference arguments that the protected model uses, but does not provide values.

To create a harness model, see “Create a Protected Model” on page 8-10. You can use a harness model to test your protected model. For more information, see “Test the Protected Model” on page 8-20. You can also copy the Model block in your harness model to another model, where it is an interface to the protected model.

Protected Model Report

You can generate a protected model report when you create the protected model. The report is included as part of the protected model. The report has:

- A **Summary**, including the following tables:
  - **Environment**, providing the Simulink version and platform used to create the protected model.
  - **Supported functionality**, reporting `On`, `Off`, or `On with password protection` for each possible functionality that the protected model supports.
  - **Licenses**, listing licenses required to run the protected model.
- An **Interface Report**, including model interface information such as input and output specifications, exported function information, interface parameters, and data stores.

When you create the protected model from the Simulink Editor, the protected model report is generated. To generate a report when using the `Simulink.ModelReference.protect` function, set the '`Report`' option to `true`.

If you configure your protected model for multiple targets, the **Summary** includes a list of supported targets in the **Supported functionality** table. When you build a model that references a protected model with multiple targets, the protected model code generation report represents the currently configured target.

To view the protected model report, right-click the protected-model badge icon and select **Display Report**. Or, call the `Simulink.ProtectedModel.open` function with the `report` option.

Code Generation Support in a Protected Model

You can create a protected model that supports code generation. When a protected model includes generated code, a third party can generate code for a model that includes the protected model. If you choose to obfuscate the code, the code is obfuscated before compilation. The protected model file contains only obfuscated headers and binaries. Source code, such as `.c` and `.cpp`, is not present in the protected model file, although the headers are documented in the protected model report. For more information, see "Protected Model File" on page 8-8 and "Protected Model Report" on page 8-5.

In the Create Protected Model dialog box, select the **Use generated code** check box. The appearance of the generated code is determined by the **Content type** list. To enable obfuscated code, select `Obfuscated source code` from the list. For an example on including code generation support, see "Create a Protected Model" on page 8-10.

Protected Model Requirements to Support Code Generation

Contents and configuration of a model might prevent code generation support of the protected model. Interaction between the parent model and the protected model might also prevent code generation.

- Code generation for the protected model is only supported for Normal, Accelerator, Software-in-the-Loop (SIL), and Processor-in-the-Loop (PIL) modes and a single target.
- Source code comments in the **Code Generation > Comments** pane are ignored. Obfuscation of the generated code removes comments because comments might reveal intellectual property.
- Custom code specified in the **Code Generation > Custom Code** pane is obfuscated, but identifiers are not.
- Code generation of a model that includes a protected model causes an error, if:
  - Their interfaces do not match.
  - There are incompatible parameters.
  - A protected model and another model share the same name in the same model reference hierarchy.
- Selecting the **Code Generation > Verification > Measure function execution time** check box is incompatible with model protection. If you have this option selected

when you protect your model, the software turns the parameter off and displays a warning.

Protected Model File

A protected model file (`.slxp`) consists of the model itself and supporting files, depending on the options that you selected when you created the protected model.

If you created a protected model for simulation only and the referencing model is in `Normal` mode, after simulation, the *`model`*`.mexext` file is placed in the build folder.

If you created a protected model for simulation only and the referencing model is in `Accelerator` or `Rapid Accelerator` mode, after simulation, the following files are unpacked:

- `slprj/sim/`*`model`*`/*.h`
- `slprj/sim/`*`model`*`/`*`model`*`lib.a` (or *`model`*`lib.lib`)
- `slprj/sim/`*`model`*`/tmwinternal/*`
- `slprj/sim/_sharedutils/*`

For the protected model report, these additional files are unpacked (but not in the build folder):

- `slprj/sim/`*`model`*`/html/*`
- `slprj/sim/`*`model`*`/buildinfo.mat`

If you opted to include code generation support when you created the protected model, after building your model the following files are unpacked (in addition to the preceding files):

- `slprj/sim/`*`model`*`/*.h`
- `slprj/sim/`*`model`*`/`*`model`*`lib.a` (or *`model`*`lib.lib`)
- `slprj/sim/`*`model`*`/tmwinternal/*`
- `slprj/sim/_sharedutils/*`
- `slprj/`*`target`*`/`*`model`*`/*.h`
- `slprj/`*`target`*`/`*`model`*`/`*`model`*`_rtwlib.a` (or *`model`*`_rtwlib.lib`)
- `slprj/`*`target`*`/`*`model`*`/buildinfo.mat`
- `slprj/`*`target`*`/`*`model`*`/codeinfo.mat`
- `slprj/`*`target`*`/_sharedutils/*`
- `slprj/`*`target`*`/`*`model`*`/tmwinternal/*`

With an Embedded Coder license, you can specify a `Top model` code interface. In this case, if you opted to include code generation support when you created the protected model, after building your model the following files are unpacked:

- `slprj/sim/model/*.h`
- `slprj/sim/model/modellib.a` (or `modellib.lib`)
- `slprj/sim/model/tmwinternal/*`
- `slprj/sim/_sharedutils/*`
- `model_target_rtw/*.h`
- `model_target_rtw/*.objExt`
- `model_target_rtw/buildinfo.mat`
- `model_target_rtw/codeinfo.mat`
- `slprj/target/_sharedutils/*`
- `slprj/target/model/tmwinternal/*`

For the protected model report, after building your model these files are unpacked (in addition to the preceding files):

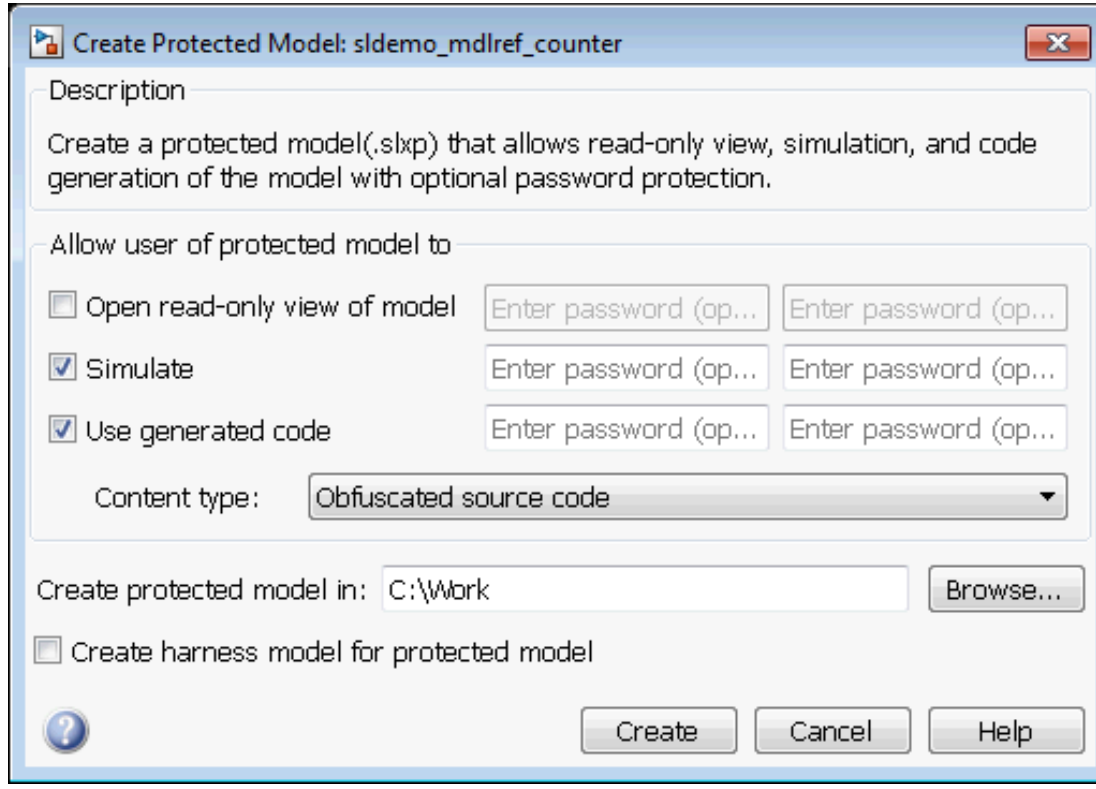
- `slprj/target/model/html/*`
- `slprj/target/model/buildinfo.mat`
- `slprj/target/_sharedutils/html/*`

Note: The `slprj/sim/model/*` files are deleted after they are used.

Create a Protected Model

This example shows how to create a protected model for read-only viewing, simulation, or code generation.

1. Open your model. For this example, `sldemo_mdlref_basic` is used as a demonstration.
2. In the Simulink Editor, right-click the model block that references the model for which you want to generate protected model code. In this example, right-click CounterA.
3. From the context menu, select **Block Parameters (ModelReference)**.
4. In the Block Parameters dialog box, in the **Model name** field, specify the extension for the model, `.slx`. When both the model and the protected model exist in the same folder, `.slxp` takes precedence over `.slx`. In the **Model name** field, if you do not specify an extension, then the original model block in the model becomes protected.
5. Click **OK**.
6. Right-click the model block. From the context menu, select **Subsystem & Model Reference > Create Protected Model for Selected Model Block**.



7 In the Create Protected Model dialog box, select the **Simulate** and **Use generated code** check boxes. If you want to password-protect the functionality of the protected model, enter a password with a minimum of four characters. Each functionality can have a unique password.

8 If you have an Embedded Coder license and specify an ERT based system target file (for example, `ert.tlc`) for the model, the **Code interface** field is visible. From the **Code interface** drop-down list, select one of the following options:

- `Model reference` — Specifies code access through the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model that contains the protected model. In addition, users can run Model block SIL/PIL simulations with the protected model.

- `Top model` — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.

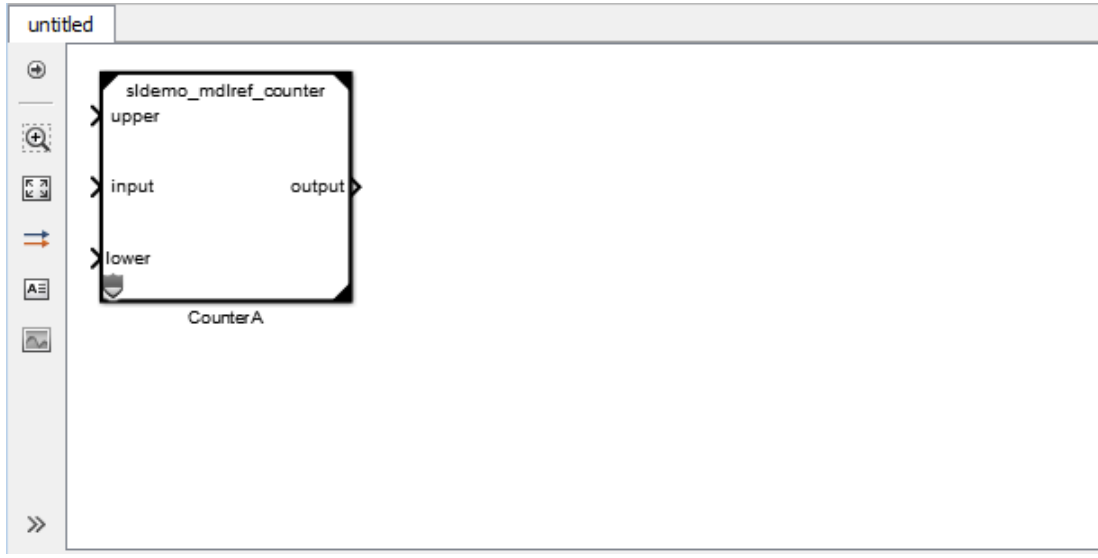
Note: In this example, `sldemo_mdlref_basic` does not specify an ERT based system target file, therefore the Code interface options are not available on the Create Protected Model dialog box.

9 From the **Content type** list, select `Obfuscated source code` to conceal the source code purpose and logic of the protected model.

10 In the **Create protected model in** field, specify the folder path for the protected model. The default value is the current working folder.

11 To create a harness model for the protected model, select the **Create harness model for protected model** check box.

12 Click **Create**. An untitled harness model opens. It contains a model block, which refers to the protected model `sldemo_mdlref_counter.slxp`. The **Simulation mode** for the Model block is set to `Accelerator`. You cannot change the mode.



13 To view the protected model report, right-click the protected-model badge icon on the `CounterA` block and select **Display Report** .

More About

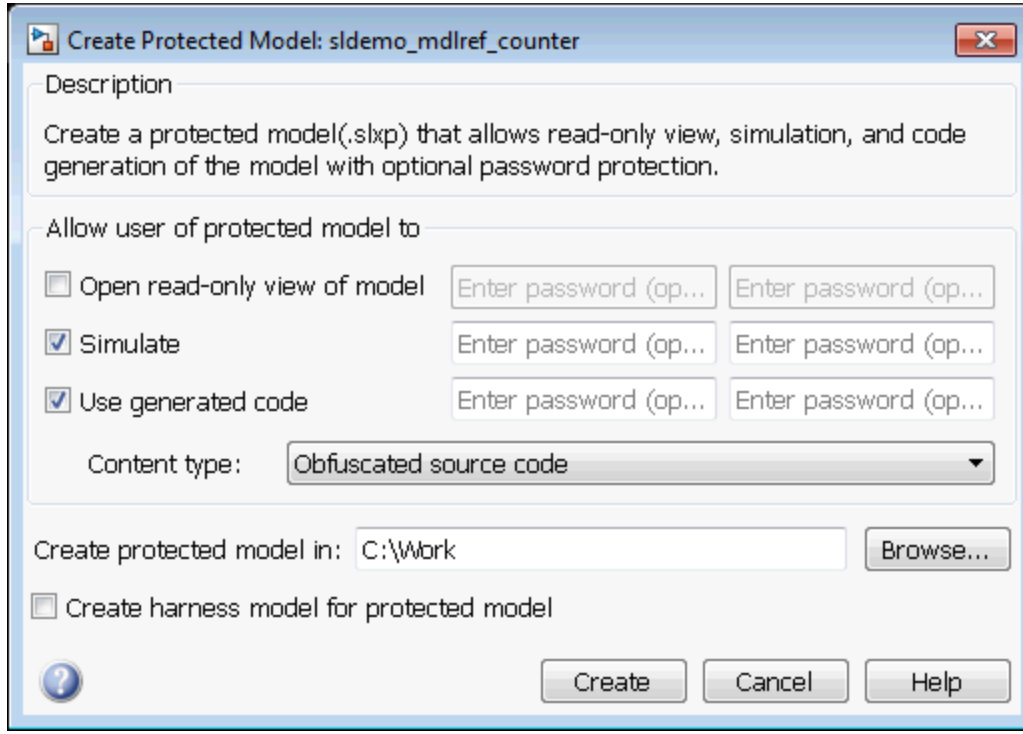
- "Code Generation Support in a Protected Model" on page 8-6
- "Protected Model Creation Settings" on page 8-15
- "Code Interfaces for SIL and PIL" on page 64-6

Protected Model Creation Settings

When you create a protected model, in the Create Protected Model dialog box, you can select which settings you want configured. The settings provide certain functionality permissions when using a protected model. The functionality choices are:

- Read-only viewing
- Simulation
- Code Generation

Password-protection is optional. You must have a minimum of four characters.



Open Read-Only View of Model

If you want to share a view-only version of your model, this option will allows someone using the protected model to open a Web view of the model. The contents and block parameters are viewable in the model Web view.

Simulate

The **Simulate** check box allows someone to simulate a protected model. When you select this check box, the Web view is not inherited. To enable the Web view with simulation functionality, select the **Open Read-Only View of Model** check box. The **Simulate** functionality:

- Enables protected model Simulation Report.
- Sets Mode to Accelerator. You can run Normal Mode and Accelerator simulations.
- Displays only binaries and headers.
- Enables code obfuscation.

Use Generated Code

The **Use generated code** check box allows simulation and code generation for a protected model. To generate code, the **Simulate** check box must also be selected. This functionality:

- Enables protected model Simulation Report and Code Generation Report.
- Sets Mode to enable code generation.
- Enables support for simulation.
- Supports the Model block if you have an Embedded Coder license and specify an ERT system target file (`ert.tlc`) for the model. From the **Code interface** drop-down list, select one of the following options:
  - `Model reference` — Specifies the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model that contains the protected model. In addition, users can run Model block SIL/PIL simulations with the protected model.
  - `Top model` — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.

- Determines the appearance of the generated code by the **Content type** list. The options are:
  - `Binaries`
  - `Obfuscated source code` (default)
  - `Readable source code`, which also includes readable code comments

Create a Protected Model with Multiple Targets

You can create a protected model that supports multiple code generation targets. This example shows how to use command-line functions to create a protected model that supports code generation for GRT and ERT targets.

1. Load a model and save a local copy. This model is configured for a GRT target.

```
sldemo_mdlref_counter
save_system('sldemo_mdlref_counter','mdlref_counter.slx');
```

2. Add a required password for modifying a protected model. If you do not add a password, you are prompted to set a password when you create a modifiable, protected model.

```
Simulink.ModelReference.ProtectedModel.setPasswordForModify(...
'mdlref_counter','password');
```

3. Create a modifiable, protected model with support for code generation.

```
Simulink.ModelReference.protect('mdlref_counter','Mode',...
'CodeGeneration', 'Modifiable',true, 'Report',true);
```

4. Get a list of targets that the protected model supports.

```
 st = Simulink.ProtectedModel.getSupportedTargets('mdlref_counter')
```

```
st =

    'grt'    'sim'
```

5. Configure the unprotected model to support an ERT target.

```
 set_param('mdlref_counter', 'SystemTargetFile', 'ert.tlc');
 save_system('mdlref_counter');
```

6. Add support to the protected model for the ERT target. You are prompted for the modification password.

```
 Simulink.ProtectedModel.addTarget('mdlref_counter');
```

7. Verify that the list of supported targets now includes the ERT target.

```
 st = Simulink.ProtectedModel.getSupportedTargets('mdlref_counter')
```

```
st =

    'ert'    'grt'    'sim'
```

Use a Protected Model with Multiple Targets

When using a protected model with multiple targets, prepare your model for code generation.

1. Get a list of the targets that the protected model supports using the `Simulink.ProtectedModel.getSupportedTargets` function.

   You can also get this information from the protected model report. To view the report, on the protected model block, right-click the badge icon. Select **Display Report**. The **Summary** lists the supported targets.

2. Get the configuration set for your chosen target using the `Simulink.ProtectedModel.getConfigSet` function. You can use the configuration set to verify that the protected model interface is compatible with the parent model.

3. Generate code. The build process selects the corresponding target.

Test the Protected Model

To test a protected model that you created, you use the generated harness model and the procedure described in "Use Protected Model in Simulation" (Simulink).

You can also compare the output of the protected model to the output of the original model. Because you are the supplier, both the original and the protected model might exist on the MATLAB path. In the original model, if the Model block **Model name** parameter names the model without providing a suffix, the protected model takes precedence over the unprotected model. If you need to override this default when testing the output, in the Model block **Model name** parameter, specify the file name with the extension of the unprotected model, `.slx`.

To compare the unprotected and protected versions of a Model block, use the Simulation Data Inspector. This example uses `sldemo_mdlref_basic` and the protected model, `sldemo_mdlref_counter.slxp`, which is created in "Create a Protected Model" on page 8-10.

1. If it is not already open, open `sldemo_mdlref_basic`.
2. Enable logging for the output signal of the Model block, `CounterA`. In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Signal logging** parameter. Click **Apply** and **OK**.
3. Right-click the output signal. From the context menu, select `Properties`. In the Signal Properties dialog box, select **Log signal data**. Click **Apply** and **OK**. For more information, see "Export Signal Data Using Signal Logging" (Simulink).
4. Right-click the `CounterA` block. From the context menu, select `Block Parameters (ModelReference)`. In the Block Parameters dialog box, specify the **Model name** parameter with the name of the unprotected model and the extension, `sldemo_mdlref_counter.slx`. Click **Apply** and **OK**. Repeat this for `CounterB` block and `CounterC` block.
5. In the Simulink Editor, click the **Simulation Data Inspector** button arrow and select **Send Logged Workspace Data to Data Inspector** from the menu.
6. Simulate the model. When the simulation is complete, click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
7. In the Simulation Data Inspector, rename the run to indicate that it is for the unprotected model.
8. In the Simulink Editor, right-click the `CounterA` block. From the context menu, select `Block Parameters (ModelReference)`. In the Block Parameters dialog

box, specify the **Model name** parameter with the name of the protected model, `sldemo_mdlref_counter.slxp`. A shield icon appears on the Model block. Repeat this for `CounterB` block and `CounterC` block.

9. Simulate the model, which now refers to the protected model. When the simulation is complete, a new run appears in the Simulation Data Inspector.
10. In the Simulation Data Inspector, rename the new run to indicate that it is for the protected model.
11. In the Simulation Data Inspector, click the **Compare** tab. From the **Baseline** and **Compare To** lists, select the runs from the unprotected and protected model, respectively. Click **Compare Runs** to compare the runs. For more information about comparing runs, see "Compare Simulation Data" (Simulink).

Save Base Workspace Definitions

Referenced models might use object definitions or tunable parameters that are defined in the MATLAB base workspace. These variables are not saved with the model. When you protect a model, you must obtain the definitions of required base workspace entities and ship them with the model.

The following base workspace variables must be saved to a MAT-file:

- Global tunable parameter
- Global data store
- The following objects used by a signal that connects to a root-level model Inport or Outport:
  - `Simulink.Signal`
  - `Simulink.Bus`
  - `Simulink.Alias`
  - `Simulink.NumericType` that is an alias

For more information, see "Edit and Manage Workspace Variables Used by Models" (Simulink).

Before executing the protected model as a part of a third-party model, the receiver of the protected model must load the MAT-file.

Package a Protected Model

In addition to the protected model file (`.slxp`), you might need to include additional files in the protected model package:

- Harness model file.
- Any required definitions saved in a MAT-file. For more information, see “Save Base Workspace Definitions” on page 8-22.
- Instructions on how to retrieve the files.

Some ways to deliver the protected model package are:

- Provide the `.slxp` file and other supporting files as separate files.
- Combine the files into a ZIP or other container file.
- Combine the files using a manifest. For more information, see “Export Files in a Manifest” (Simulink).
- Provide the files in some other standard or proprietary format specified by the receiver.

Whichever approach you use to deliver a protected model, include information on how to retrieve the original files. One approach to consider is to use the Simulink Manifest Tools, as described in “Analyze Model Dependencies” (Simulink).

Specify Custom Obfuscator for Protected Model

When creating a protected model, you can specify your own postprocessing function for files that the protected model creation process generates. Prior to packaging the protected model files, this function is called by the `Simulink.ModelReference.protect` function. You can use this functionality to run your own custom obfuscator on the generated files by following these steps:

1. Create your postprocessing function. Use this function to call your custom obfuscator. The function must be on the MATLAB path and accept a Simulink.ModelReference.ProtectedModel.HookInfo object as an input variable.
2. In your function, get the files and exported symbol information that your custom obfuscator requires to process the protected model files. To get the files and information, access the properties of your function input variable. The variable is a Simulink.ModelReference.ProtectedModel.HookInfo object with the following properties:

   - `SourceFiles`
   - `NonSourceFiles`
   - `ExportedSymbols`
3. Pass the protected model file information to your custom obfuscator. The following is an example of a postprocessing function for custom obfuscation:

```
function myHook(protectedModelInfo)

    % Get source file list information.
    srcFileList = protectedModelInfo.SourceFiles;
    disp('### Obfuscating...');
    for i=1:length(srcFileList)
        disp(['### Obfuscator: Processing ' srcFileList{i} '...']);
        % call to custom obfuscator
        customObfuscator(srcFileList{i});
    end
end
```

4. Specify your postprocessing function when creating the protected model:

```
Simulink.ModelReference.protect('myModel, 'Mode', 'CodeGeneration', ...
    'CustomPostProcessingHook', ...
    @(protectedModelInfo)myHook(protectedModelInfo))
```

The creator of the protected model also has the option of enabling obfuscation of simulation target code and generated code through the '`ObfuscateCode`' option of the `Simulink.ModelReference.protect` function. Your custom obfuscator runs only on the generated code and not on the simulation target code. If both obfuscators are in use, the custom obfuscator is the last to run on the generated code before the files are packaged.

Define Callbacks for Protected Model

When you create a protected model, you can customize its behavior by defining callbacks. Callbacks specify code that executes when a protected model user views, simulates, or generates code for the protected model. A protected model user cannot view or modify a callback. To create a protected model with callbacks:

1. Define Simulink.ProtectedModel.Callback objects for each callback.
2. To create your protected model, call the `Simulink.ModelReference.protect` function. Use the `'Callbacks'` option to specify a cell array of callbacks to include in the protected model.

In this section...

Creating Callbacks

To create and define a protected model callback, create a Simulink.ProtectedModel.Callback object. Callback objects specify:

- The code to execute for the callback. The code can be a character vector of MATLAB commands or a script on the MATLAB path.
- The event that triggers the callback. The event can be `'PreAccess'` or `'Build'`.
- The protected model functionality that the event applies to. The functionality can be `'CODEGEN'`, `'SIM'`, `'VIEW'`, or `'AUTO'`. If you select `'AUTO'`, and the event is `'PreAccess'`, the callback applies to each functionality. If you select `'AUTO'`, and the event is `'Build'`, the callback applies only to `'CODEGEN'` functionality. If you do not select any functionality, the default behavior is `'AUTO'`.
- The option to override the protected model build process. This option applies only to `'CODEGEN'` functionality.

You can create only one callback per event and per functionality.

Defining Callback Code

You can define the code for a callback by using either a character vector of MATLAB commands or a script on the MATLAB path. When you write callback code, follow these guidelines:

- Callbacks must use MATLAB code (`.m` or `.p`).
- The code can include protected model functions or any MATLAB command that does not require loading the model.
- Callback code must not call out to external utilities unless those utilities are available in the environment where the protected model is used.
- Callback code cannot reference the source protected model unless you are using protected model functions.

You can use the `Simulink.ProtectedModel.getCallbackInfo` function in callback code to get information on the protected model. The function returns a Simulink.ProtectedModel.CallbackInfo object that provides the protected model name and the names of submodels. If the callback is specified for `'CODEGEN'` functionality and `'Build'` event, the object provides the target identifier and model code interface type (`'Top model'` or `'Model reference'`).

Create a Protected Model with Callbacks

This example creates a protected model with a callback for code generation.

1. On the MATLAB path, create a callback script, `pm_callback.m`, containing:

   ```
   s1 = 'Code interface is: ';
   cbinfobj = Simulink.ProtectedModel.getCallbackInfo(...
   'sldemo_mdlref_counter','Build','CODEGEN');
   disp([s1 cbinfobj.CodeInterface]);
   ```

2. Create a callback that uses the script. If the callback code replaces the protected model build process, set the override option.

   ```
   pmCallback = Simulink.ProtectedModel.Callback('Build',...
   'CODEGEN', 'pm_callback.m');
   pmCallback.setOverrideBuild(true);
   ```

3. Create the protected model and specify the code generation callback.

   ```
   Simulink.ModelReference.protect('sldemo_mdlref_counter',...
   ```

```
'Mode', 'CodeGeneration','Callbacks',{pmCallback})
```

4 Build the protected model. In place of the build, the callback displays the code interface.

```
rtwbuild('sldemo_mdlref_basic')
```

Component Initialization, Reset, and Termination in Simulink Coder

Generate Code That Responds to Initialize, Reset, and Terminate Events

To generate code from a modeling component that responds to initialize, reset, and terminate events during execution, use the blocks Initialize Function and Terminate Function. For information on how to use these blocks, see "Create Model to Initialize, Reset, and Terminate State" (Simulink). You can use the blocks anywhere in a model hierarchy.

Examples of when to generate code that responds to initialize, reset, or terminate events include:

- Starting and stopping a component.
- Calculating initial conditions.
- Saving and restoring state from nonvolatile memory.
- Generating reset entry-point functions that respond to external events.

Each nonvirtual subsystem and referenced model can have its own set of initialize, reset, and terminate functions.

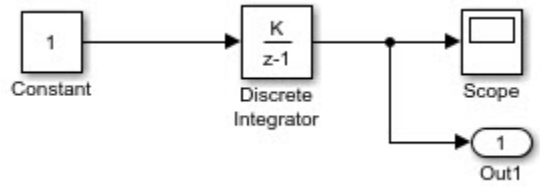
The code generator produces initialization and termination code differently than reset code. For initialization and termination code, the code generator includes your component initialization and termination code in the default entry-point functions, *`model`*`_initialize` and *`model`*`_terminate`. The code generator produces reset code only if you model reset behavior.

Generate Code for Initialize and Terminate Events

When you generate code for a component that includes Initialize Function and Terminate Function blocks, the code generator:

- Includes initialize event code with default initialize code in entry-point function *`model`*`_initialize`.
- Includes terminate event code with default terminate code in entry-point function *`model`*`_terminate`.

Consider the model rtwdemo_irt_base.



For this model, the code generator produces initialize and terminate entry-point functions that other code can interface with.

```
void rtwdemo_irt_base_initialize(void)
void rtwdemo_irt_base_terminate(void)
```

This code appears in the generated file `rtwdemo_irt_base.c`. The initialize function, `rtwdemo_irt_base_initialize`, initializes an error status. The terminate function, `rtwdemo_irt_base_terminate`, requires no code. This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_base_initialize(void)
{
   rtmSetErrorStatus(rtwdemo_irt_base_M, (NULL));

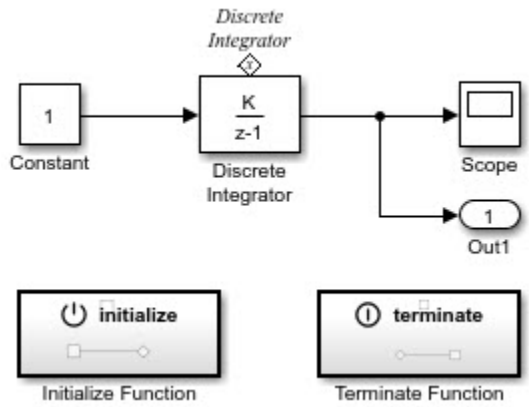
   (void) memset((void *)&rtwdemo_irt_base_DW, 0,
                 sizeof(DW_rtwdemo_irt_base_T));

   rtwdemo_irt_base_Y.Out1 = 0.0;

   rtwdemo_irt_base_DW.DiscreteIntegrator_DSTATE = 0.0;
}

void rtwdemo_irt_base_terminate(void)
{
   /* (no terminate code required) */
}
```

Add Initialize Function and Terminate Function blocks to the model (see `rtwdemo_irt_initterm`). The Initialize Function block uses the State Writer block to set the initial condition of a Discrete Integrator block. The Terminate Function block includes a State Reader block, which reads the state of the Discrete Integrator block.



The **Event type** parameter of the Event Listener block for the initialize and terminate functions is set to `Initialize` and `Terminate`, respectively. The initialize function uses the State Writer block to initialize the input value for the Discrete Integrator block to 10. The terminate function uses the State Reader block to read the state of the Discrete Integrator block.

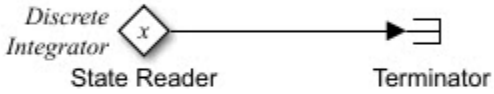
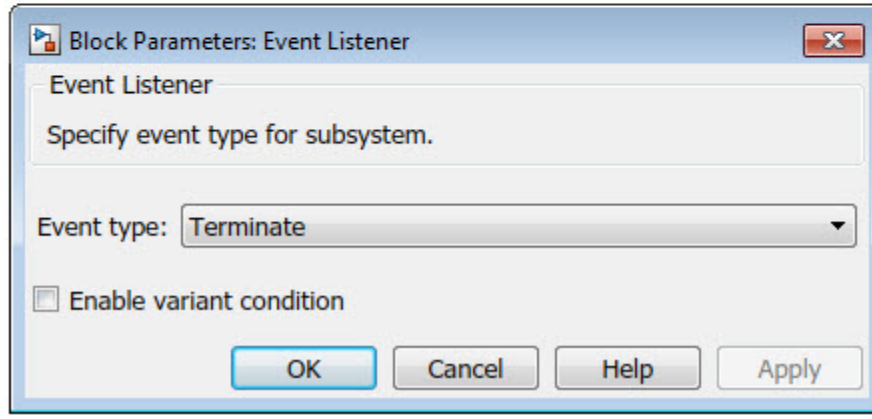
State Writer
Block Parameters: Event Listener
Event Listener
Specify event type for subsystem.
Event type:
Initialize
Enable variant condition
OK
Cancel
Help
Apply





The code generator includes the event code that it produces for the Initialize Function and Terminate Function blocks with standard initialize and terminate code in entry-point functions `rtwdemo_irt_initterm_initialize` and `rtwdemo_irt_initterm_terminate`. This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_initterm_initialize(void)
{
   rtmSetErrorStatus(rtwdemo_irt_initterm_M, (NULL));

   (void) memset((void *)&rtwdemo_irt_initterm_DW, 0,
                 sizeof(DW_rtwdemo_irt_initterm_T));

   rtwdemo_irt_initterm_Y.Out1 = 0.0;
```

```
    rtwdemo_irt_initterm_DW.DiscreteIntegrator_DSTATE = 10.0;
}

void rtwdemo_irt__initterm_terminate(void)
{
    /* (no terminate code required) */
}
```

The initialization code:

- Initializes an error status.
- Allocates memory for block I/O and state parameters.
- Assigns the value of the constant input parameter to the state parameter of the discrete integrator.

The termination code assigns the value of the discrete integrator state parameter to the block I/O parameter.

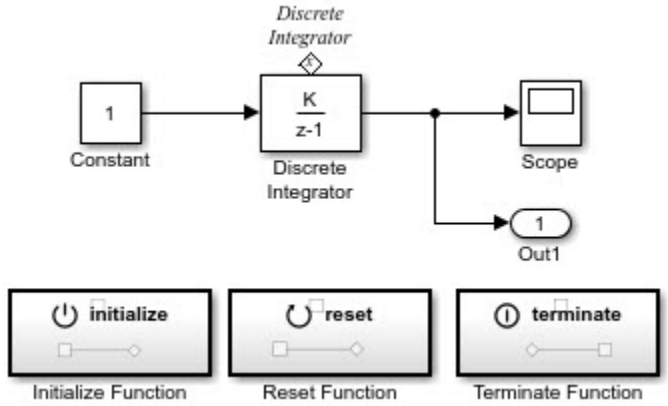
Generate Code for Reset Events

Generate code that responds to a reset event by including an Initialize Function or Terminate Function block in a modeling component. Configure the block for a reset by setting the **Event type** parameter of its Event Listener block to `Reset`. Also set the **Event name** parameter. The default name is `reset`.

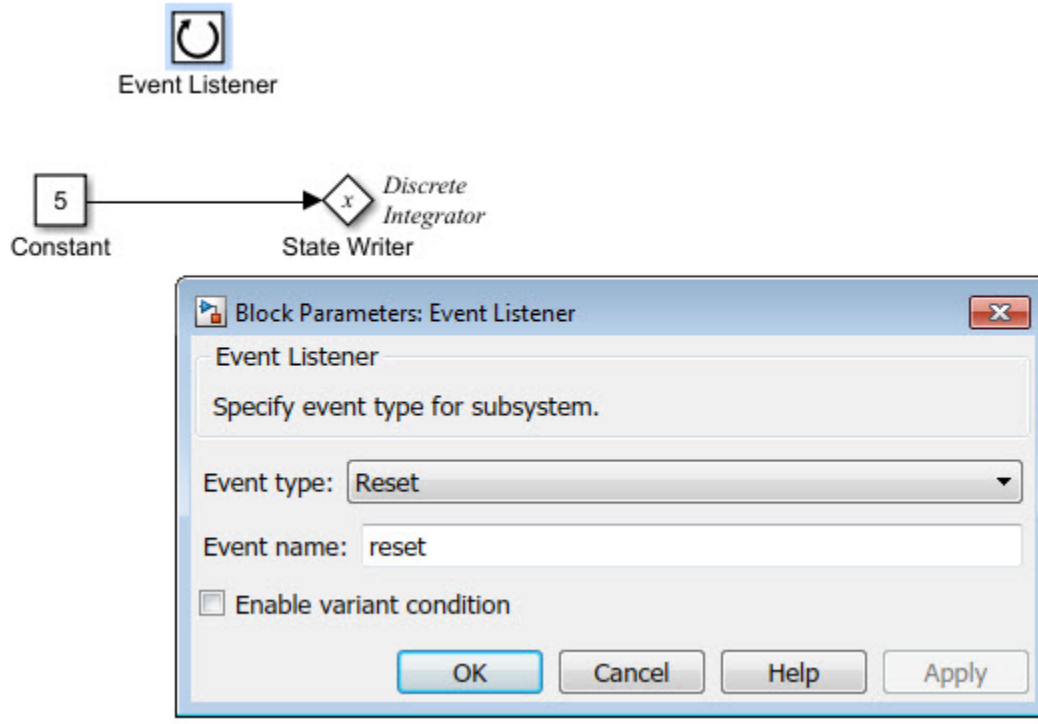
The code generator produces a reset entry-point function *only* if you model reset behavior. If a component contains multiple reset specifications, the code that the code generator produces depends on whether reset functions share an event name. For a given component hierarchy:

- For reset functions with unique event names, the code generator produces a separate entry-point function for each named event. The name of each function is the name of the corresponding event.
- For reset functions that share an event name, the code generator aggregates the reset code into one entry-point function. The code for the reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The name of the function is *`model`*`_reset`. For more information, see “Event Names and Code Aggregation” (Simulink Coder).

Consider the model `rtwdemo_irt_reset`, which includes a Reset Function block derived from an Initialize Function block.



The **Event type** and **Event name** parameters of the Event Listener block are set to `Reset` and `reset`, respectively. The function uses the State Writer block to reset the input value for the Discrete Integrator block to 5.



The code generator produces reset function `rtwdemo_irt_reset_reset`. The code for the function appears in the `Real-time model` section of the *`model`*`.c` file.

```
void rtwdemo_irt_reset_reset(void)

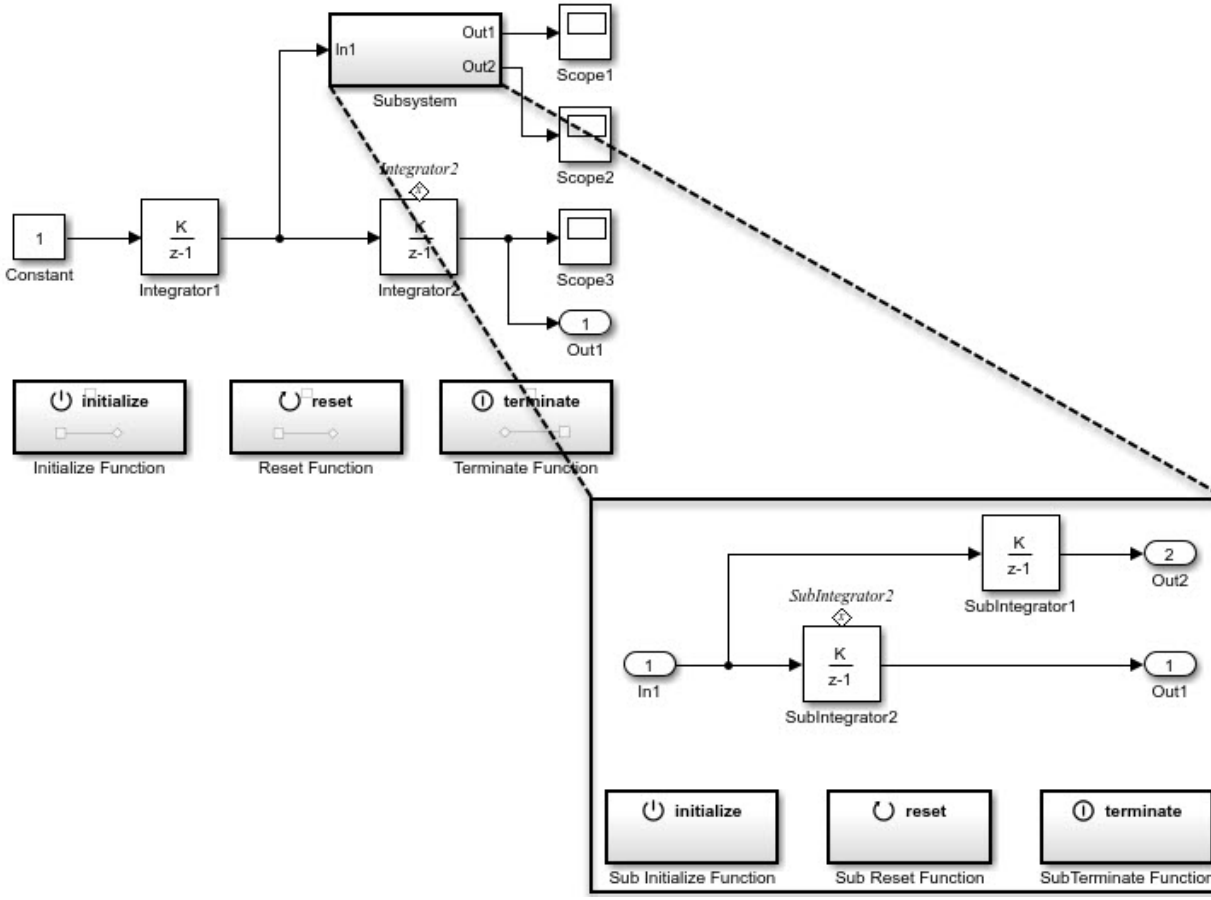
{
  rtwdemo_irt_reset_DW.DiscreteIntegrator_DSTATE = 5.0;
}
```

Event Names and Code Aggregation

Use the Initialize Function and Terminate Function blocks to define multiple initialize, reset, and terminate functions for a component hierarchy. Define only one initialize function and one terminate function per hierarchy level. You can define multiple reset functions for a hierarchy level. The event names that you configure for the functions at a given level must be unique.

When producing code, the code generator aggregates code for functions that have a given event name across the entire component hierarchy into one entry-point function. The code for reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The code generator uses the event name to name the function.

For example, the model `rtwdemo_irt_shared` includes a subsystem that replicates the initialize, reset, and terminate functions that are in the parent model.



Although the model includes multiple copies of the initialize, reset, and terminate functions, the code generator produces one entry-

point function for reset (`rtwdemo_irt_shared_reset`), one for initialize (`rtwdemo_irt_shared_initialize`), and one for terminate (`rtwdemo_irt_shared_terminate`). Within each entry-point function, after listing code for blocks configured with an initial condition (*`model`*`_P.`*`block`*`_IC`), the code generator orders code for components, starting with the lowest level of the hierarchy and ending with the root.

```
.
.
.
void rtwdemo_irt_shared_reset(void)
{
   rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE =
     rtwdemo_irt_shared_P.Constant1_Value;

   rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;

   rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
.
.
.
void rtwdemo_irt_shared_initialize(void)
{
  rtmSetErrorStatus(rtwdemo_irt_shared_M, (NULL));

  (void) memset(((void *)&rtwdemo_irt_shared_DW), 0,
                sizeof(DW_rtwdemo_irt_shared_T));

  rtwdemo_irt_shared_Y.Out1 = 0.0;

  rtwdemo_irt_shared_DW.Integrator1_DSTATE = 0.0;

  rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 2.0;

  rtwdemo_irt_shared_DW.Integrator2_DSTATE = 10.0;
.
.
.
void rtwdemo_irt_shared_terminate(void)
{
   /* (no terminate code required) */
```

```
   }
```

If you rename the event configured for the subsystem reset function to `reset_02`, the code generator produces two reset entry-point functions, `rtwdemo_irt_shared_reset` and `rtwdemo_irt_shared_reset_02`.

```
void rtwdemo_irt_shared_reset(void)
{
   rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}

void rtwdemo_irt_shared_reset_02(void)
{
   rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;
}
```

Limitations

You cannot generate code from a:

- Harness model—a root model that contains a Model block, which exposes initialize, reset, or terminate function ports.
- Model configured for C++ code generation.

Stateflow Blocks in Simulink Coder

Code Generation of Stateflow Blocks

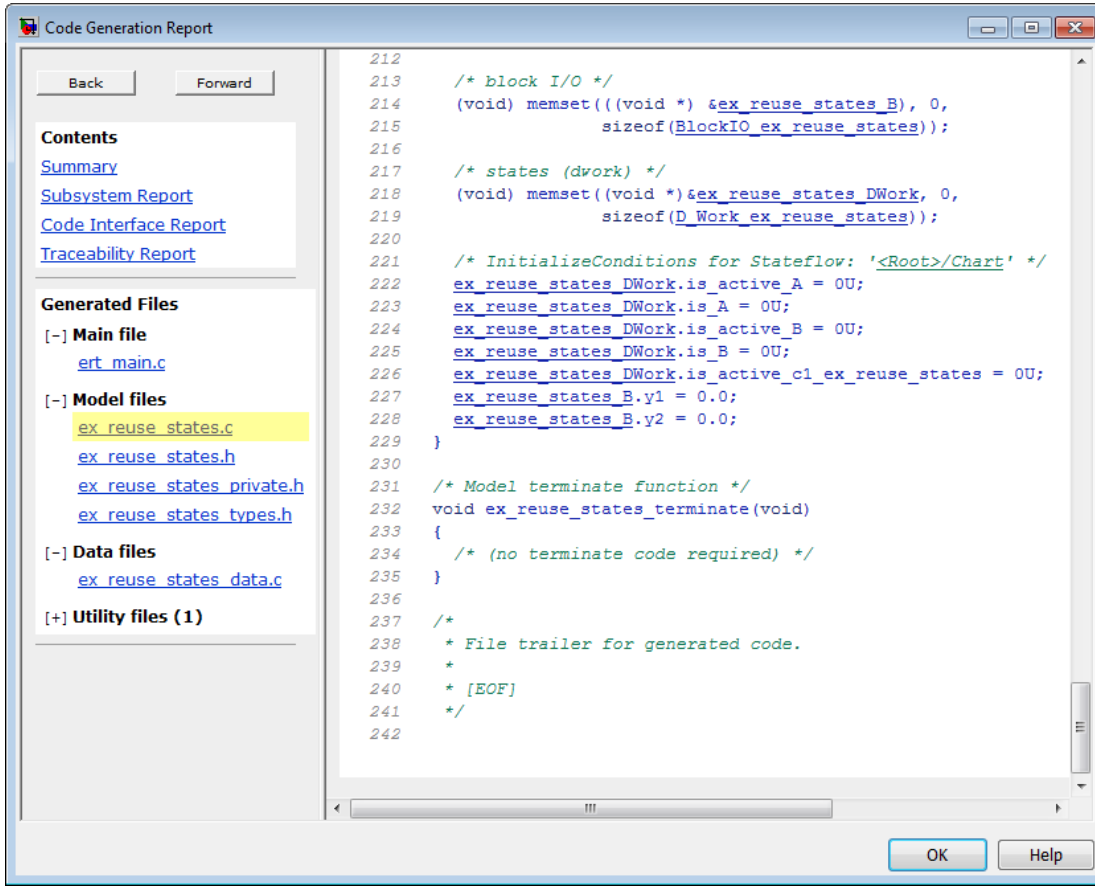
The code generator produces code for Stateflow blocks for rapid prototyping. If you have an Embedded Coder license, you can generate production code for Stateflow blocks.

Comparison of Code Generation Methods

The following sections compare two ways of generating code.

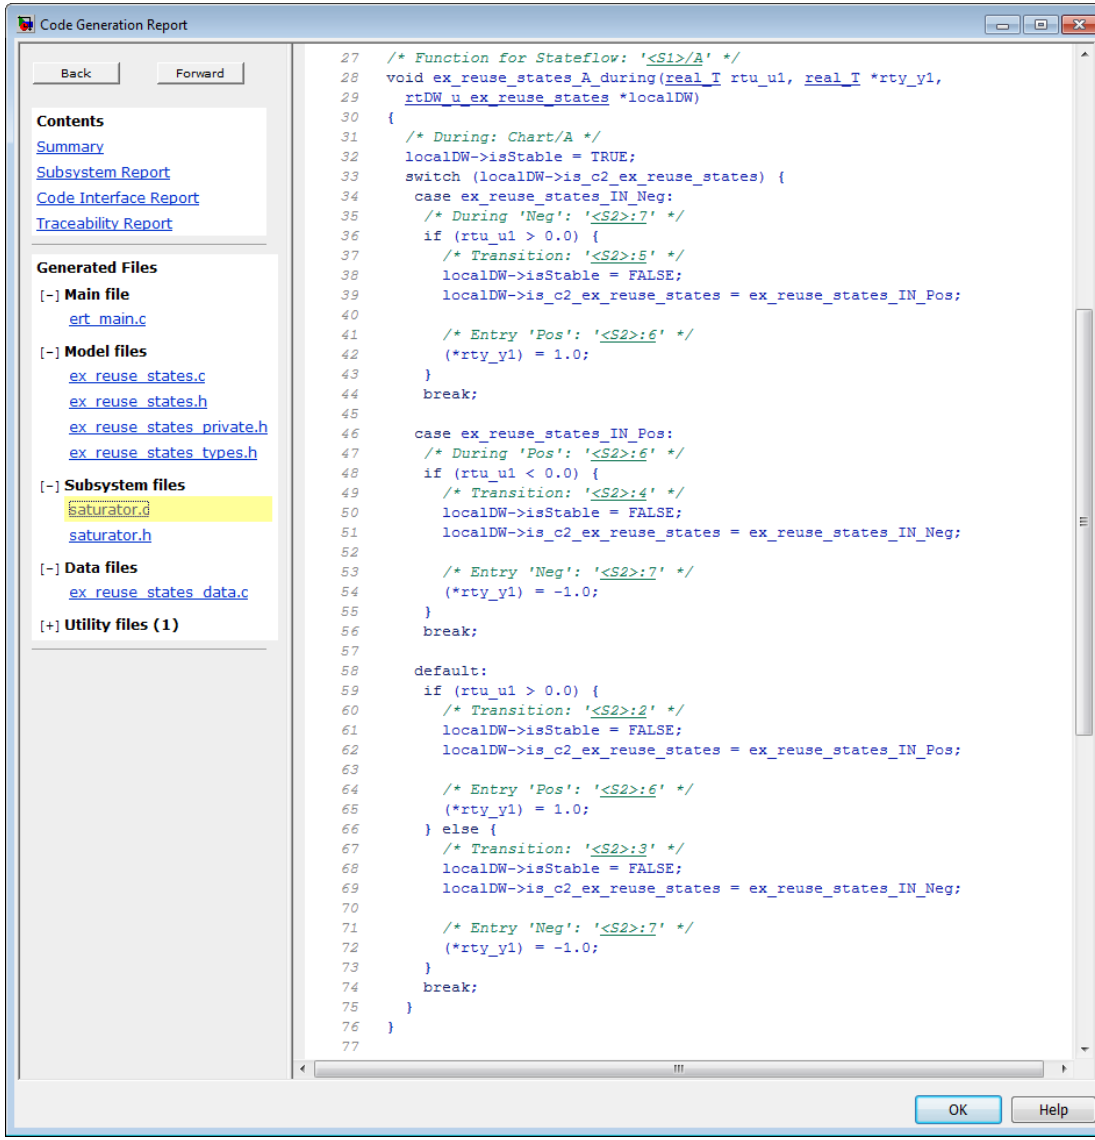
Code Generation Without Atomic Subcharts

You generate code for the entire model in one file and look through that entire file to find code for a specific part of the chart.



Code Generation With Atomic Subcharts

You specify code generation parameters so that code for an atomic subchart appears in a separate file. This method of code generation enables unit testing for a specific part of a chart. You can avoid searching through unrelated code and focus only on the part that interests you.



Note: Unreachable Stateflow states are optimized out and are not included in the generated code.

For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.

Generate Reusable Code for Atomic Subcharts

In this section...

How to Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

1. Open the library model that contains your atomic subchart.
2. Unlock the library.
3. Right-click the library chart and select **Block Parameters**.
4. In the dialog box, specify the following parameters:
   a. On the **Main** tab, select **Treat as atomic unit**.
   b. On the **Code Generation** tab, set **Function packaging** to `Reusable function`.
   c. Set **File name options** to `User specified`.
   d. For **File name**, enter the name of the file with no extension.
   e. Click **OK** to apply the changes.
5. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   b. On the **Code Generation** pane, set **System target file** to `ert.tlc`.
   c. Navigate to the **Code Generation > Symbols** pane.
   d. For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
      - `$R` — root model name
      - `$F` — type of interface function for the atomic subchart
      - `$N` — block name
      - `$H` — subsystem index
      - `$M` — name-mangling text

e Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

How to Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

1 In your chart, right-click the atomic subchart and select **Properties**.

2 In the dialog box, specify the following parameters:

   a Set **Code generation function packaging** to `Reusable function`.

   b Set **Code generation file name options** to `User specified`.

   c For **Code generation file name**, enter the name of the file with no extension.

   d Click **OK** to apply the changes.

3 (OPTIONAL) Customize the generated function names for atomic subcharts:

   a Open the Model Configuration Parameters dialog box.

   b On the **Code Generation** pane, set **System target file** to `ert.tlc`.

   c Navigate to the **Code Generation > Symbols** pane.

   d For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:

      - `$R` — root model name
      - `$F` — type of interface function for the atomic subchart
      - `$N` — block name
      - `$H` — subsystem index
      - `$M` — name-mangling text

   e Click **OK** to apply the changes.

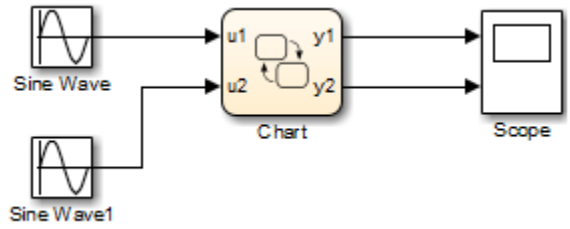
When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.

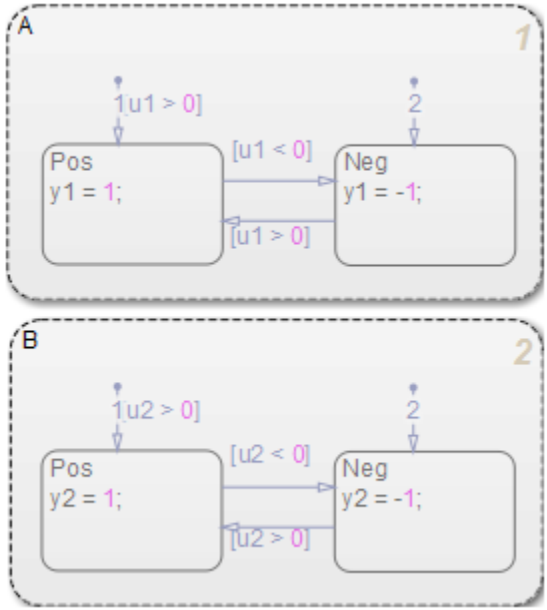
Generate Reusable Code for Unit Testing

In this section...

Goal of the Tutorial

Assume that you have the following model, and the chart has two states:

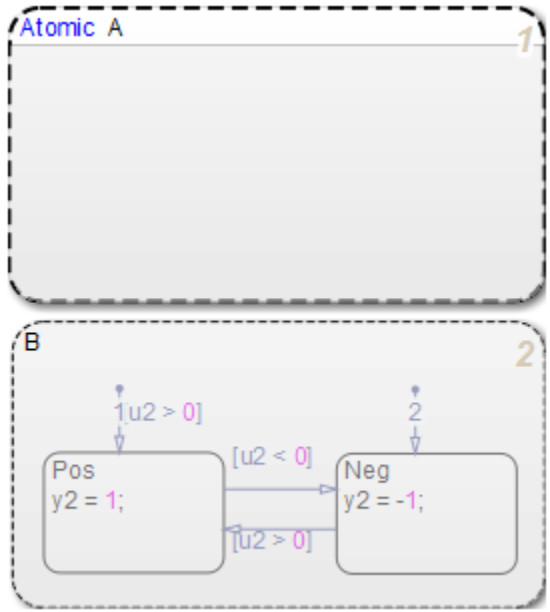




Suppose that you want to generate reusable code so that you can perform unit testing on state A. You can convert that part of the chart to an atomic subchart and then specify a separate file to store the generated code.

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:



Specify Code Generation Parameters

Set Up a Standalone C File for the Atomic Subchart

1. Open the properties dialog box for A.
2. Set **Code generation function packaging** to `Reusable function`.
3. Set **Code generation file name options** to `User specified`.
4. For **Code generation file name**, enter `saturator` as the name of the file.
5. Click **OK**.

Set Up the Code Generation Report

1. Open the Model Configuration Parameters dialog box.
2. In the **Code Generation** pane, set **System target file** to `ert.tlc`.
3. In the **Code Generation** > **Report** pane, select **Create code generation report**.

   This step automatically selects **Open report automatically** and **Code-to-model** on the **All Parameters** tab.

4 Select **Model-to-code** on the **All Parameters** tab.

5 Click **Apply**.

Customize the Generated Function Names

1 In the Model Configuration Parameters dialog box, go to the **Code Generation** > **Symbols** pane.

2 Set **Subsystem methods** to the format scheme `$R$N$M$F`, where:

- `$R` is the root model name.
- `$N` is the block name.
- `$M` is the mangle token.
- `$F` is the type of interface function for the atomic subchart.

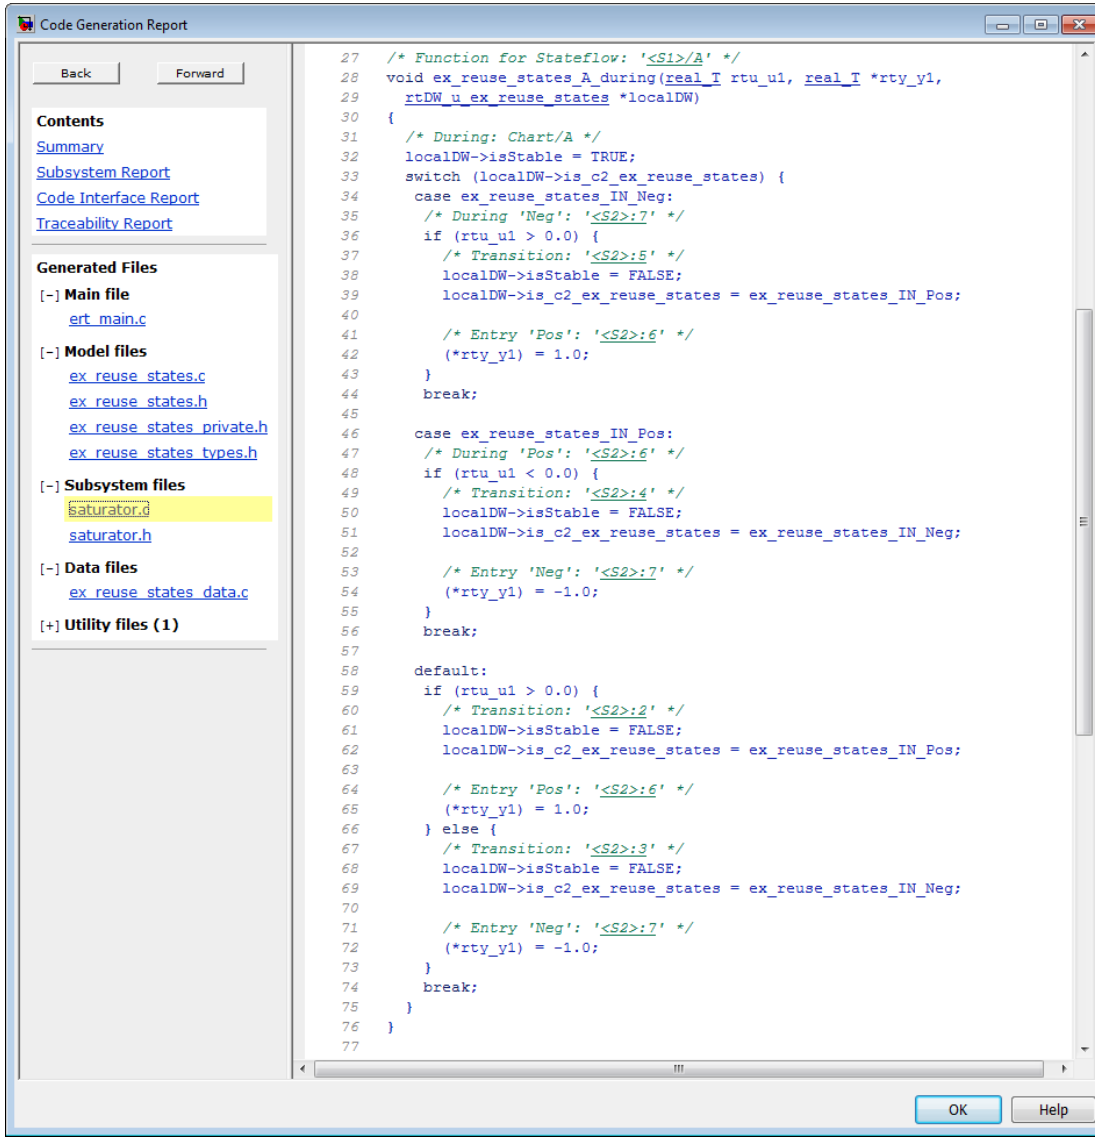
For more information, see "Subsystem methods" (Simulink Coder).

3 Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturator.c`, click the hyperlink in the report to see the following code:



Line 28 shows that the `during` function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme `$R$N$M$F` specified for **Subsystem methods**:

- `$R` is the root model name, `ex_reuse_states`.
- `$N` is the block name, `A`.
- `$M` is the mangle token, which is empty.
- `$F` is the type of interface function for the atomic subchart, `during`.

Note: The line numbers shown can differ from the numbers that appear in your code generation report.

Inline State Functions in Generated Code

In this section...

Inlined Generated Code for State Functions

By default, the code generator uses an internal heuristic to determine whether to inline generated code for state functions. The heuristic takes into consideration an inlining threshold. As code grows and shrinks in size, generated code for state functions can be unpredictable.

If your model includes Stateflow objects and you have rigorous requirements for traceability between generated code and the corresponding state functions, you can override the default behavior. Use the state property `Function Inline Option` to explicitly force or prevent inlining of state functions.

What Happens When You Force Inlining

If you force inlining for a state, the code generator inlines code for state actions into the parent function. The parent function contains code for executing the state actions, outer transitions, and flow charts. It does not include code for empty state actions.

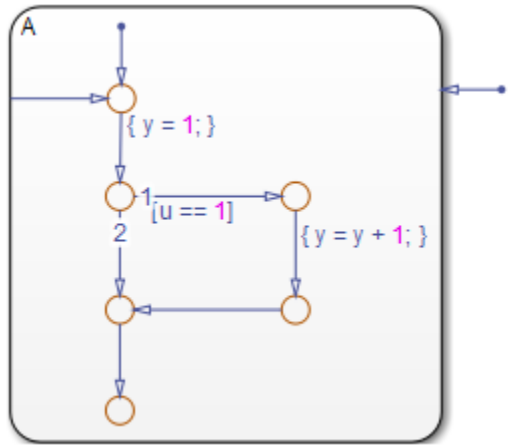
What Happens When You Prevent Inlining

If you prevent inlining for a state, the code generator produces these static functions for state *foo*.

Function	Description
`enter_atomic_`*`foo`*	Marks *`foo`* active and performs entry actions.
`enter_internal_`*`foo`*	Calls default paths.
`inner_default_`*`foo`*	Executes flow charts that originate when an inner transition and default transition reach the same junction inside a state.

Function	Description
	The code generator produces this function only when the flow chart is complex enough to exceed the inlining threshold. In generated code, Stateflow software calls this function from both the `enter_internal_foo` and `foo` functions.
`foo`	Checks for valid outer transitions and if none, performs during actions.
`exit_atomic_foo`	Performs exit actions and marks `foo` inactive.
`exit_internal_foo`	Performs exit actions of the child substates and then exits `foo`.

Suppose the following chart is in model M.



If you prevent inlining for state A, the code generator produces this code.

```
static void M_inner_default_A(void);
static void M_exit_atomic_A(void);
static void M_A(void);
static void M_enter_atomic_A(void);
static void M_enter_internal_A(void);
```

How to Set the State Function Inline Option

To set the function inlining property for a state:

1 Right-click inside the state and, from the context menu, select **Properties**.

The State properties dialog box opens.

2 In the **Function Inline Option** field, select one of these options.

Option	Behavior
Inline	Forces inlining of state functions into the parent function, as long as the function is not part of a recursion. See "What Happens When You Force Inlining" on page 10-14.
Function	Prevents inlining of state functions. Generates up to six static functions for the state. See "What Happens When You Prevent Inlining" on page 10-14.
Auto	Uses internal heuristics to determine whether or not to inline the state functions.

3 Click **Apply**.

Best Practices for Controlling State Function Inlining

To	Set Function Inline Option Property To
Generate a separate function for each action of a state and a separate function for each action of its substates	**Function** for the state and each substate
Generate a separate function for each action of a state, but include code for the associated action of its substates	**Function** for the state and **Inline** for each substate

Air-Fuel Ratio Control System with Stateflow Charts

Generate code for an air-fuel ratio control system designed with Simulink® and Stateflow®.

Figures 1, 2, and 3 show relevant portions of the sldemo_fuelsys model, a closed-loop system containing a plant and controller. The plant validates the controller in simulation early in the design cycle. In this example, you generate code for the relevant controller subsystem, "fuel_rate_control". Figure 1 shows the top-level simulation model.

Open sldemo_fuelsys via rtwdemo_fuelsys and compile the diagram to see the signal data types.

```
rtwdemo_fuelsys
sldemo_fuelsys([],[],[],'compile');
sldemo_fuelsys([],[],[],'term');
```

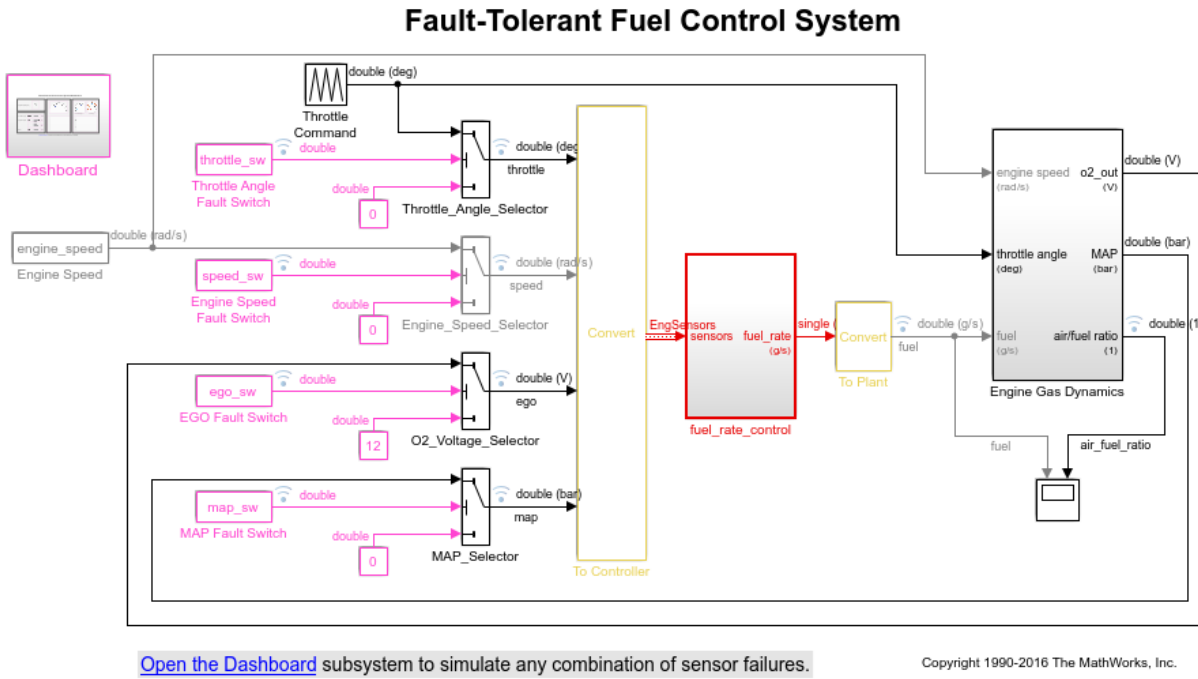


Figure 1: Top-level model of the plant and controller

The air-fuel ratio control system is comprised of Simulink® and Stateflow®. The control system is the portion of the model for which you generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

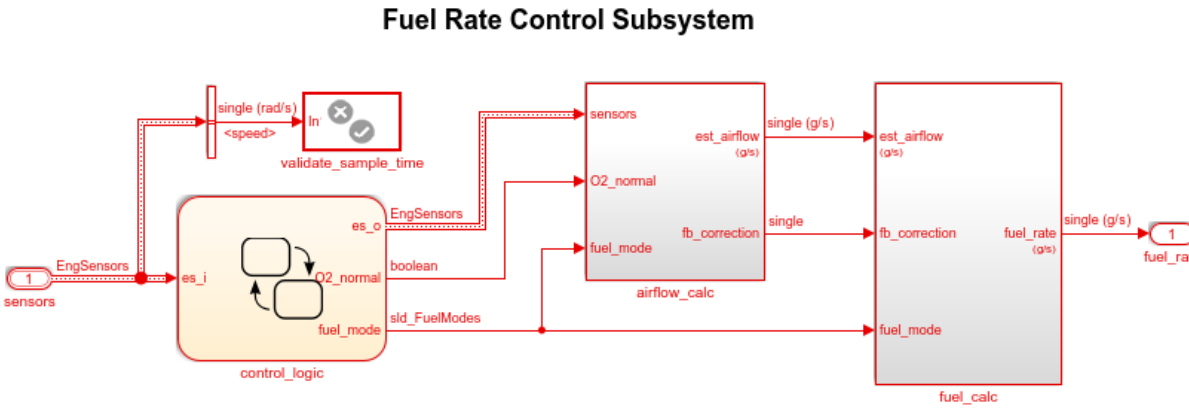

Figure 2: The air-fuel ratio controller subsystem

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

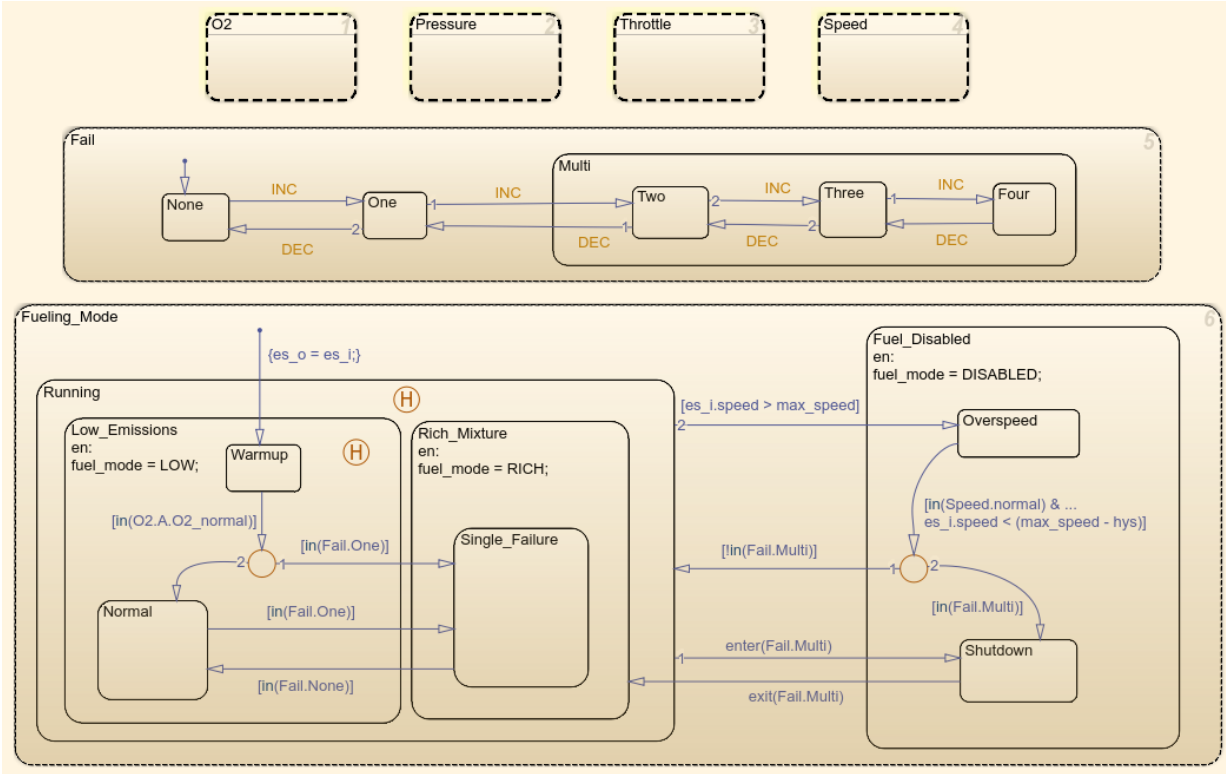

Figure 3: Air-fuel rate controller logic

Close these windows.

```
close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');
```

Configure and Build the Model with Simulink® Coder™

Simulink® Coder™ generates generic ANSI® C code for Simulink® and Stateflow® models via the Generic Real-Time (GRT) target. You can configure a model for code generation programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','GRT');
```

For this example, build only the air-fuel ratio control system. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in fuel_rate_control.c.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Configure and Build the Model with Embedded Coder®

Embedded Coder® generates production ANSI® C/C++ code via the Embedded Real-Time (ERT) target. You can configure a model for code generation programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','ERT');
```

Repeat the build process and inspect the generated code. In the Simulink® Coder™ Report, you can navigate to the relevant code segments interactively by using the **Previous** and **Next** buttons. From the chart context menu (right-click the Stateflow® block), select **Code Generation > Navigate to Code**. Programmatically, use the rtwtrace utility.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
rtwtrace('sldemo_fuelsys/fuel_rate_control/control_logic')
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

View the air-fuel ratio control logic in the generated code.

```
rtwdemodbtype('fuel_rate_control_ert_rtw/fuel_rate_control.c','/* Function for Chart:'
```

```
/* Function for Chart: '<S1>/control_logic' */
static void Fueling_Mode(const int32_T *sfEvent)
```

```
{
  /* During 'Fueling_Mode': '<S3>:21' */
  /* This state interprets the other states in the chart to directly control the fueli
  switch (rtDW.bitsForTID0.is_Fueling_Mode) {
   case IN_Fuel_Disabled:
    rtDW.fuel_mode = DISABLED;

    /* During 'Fuel_Disabled': '<S3>:22' */
    /* The fuel is completely shut off while in this state. */
    switch (rtDW.bitsForTID0.is_Fuel_Disabled) {
     case IN_Overspeed:
      /* Inport: '<Root>/sensors' */
      /* During 'Overspeed': '<S3>:24' */
      /* The speed is dangerously high, so shut off the fuel. */
      if ((rtDW.bitsForTID0.is_Speed == IN_normal) && (rtU.sensors.speed <
           603.0F)) {
        /* Transition: '<S3>:54' */
        if (!(rtDW.bitsForTID0.is_Fail == IN_Multi)) {
          /* Transition: '<S3>:55' */
          rtDW.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
          rtDW.bitsForTID0.is_Fueling_Mode = IN_Running;

          /* Entry Internal 'Running': '<S3>:23' */
          switch (rtDW.bitsForTID0.was_Running) {
           case IN_Low_Emissions:
            if (rtDW.bitsForTID0.is_Running != IN_Low_Emissions) {
              rtDW.bitsForTID0.is_Running = IN_Low_Emissions;
              rtDW.bitsForTID0.was_Running = IN_Low_Emissions;

              /* Entry 'Low_Emissions': '<S3>:25' */
              rtDW.fuel_mode = LOW;
            }

            /* Entry Internal 'Low_Emissions': '<S3>:25' */
            switch (rtDW.bitsForTID0.was_Low_Emissions) {
             case IN_Normal:
              rtDW.bitsForTID0.is_Low_Emissions = IN_Normal;
              rtDW.bitsForTID0.was_Low_Emissions = IN_Normal;
              break;
```

Close the model and code generation report.

```
clear hDemo;
rtwdemoclean;
close_system('sldemo_fuelsys',0);
```

Block Authoring and Code Generation for Simulink Coder

S-Functions and Code Generation

In this section...

You use S-functions to extend Simulink support for simulation and code generation. For example, you can use them to:

- Represent custom algorithms
- Interface existing external code with Simulink and the code generator
- Represent device drivers for interfacing with hardware
- Generate highly optimized code for embedded systems
- Verify code generated for a subsystem as part of a Simulink simulation

The application program interface (API) for writing S-functions allows you to implement generic algorithms in the Simulink environment with a great deal of flexibility. If you intend to use S-functions in a model for code generation, the level of flexibility can vary. For example, it is not possible to access the MATLAB workspace from an S-function that you use with the code generator. This topic explains conditions to be aware of for using S-functions However, using the techniques presented in this topic, you can create S-functions for most applications that work with the generated code.

Although S-functions provide a generic and flexible solution for implementing complex algorithms in a model, the underlying API incurs overhead in terms of memory and computation resources. Most often the additional resources are acceptable for real-time rapid prototyping systems. In many cases, though, additional resources are unavailable in real-time embedded applications. You can minimize memory and computational requirements by using the Target Language Compiler technology provided with the code generator to inline your S-functions. If you are producing an S-function for existing external code, consider using the Legacy Code Tool to generate your S-function and relevant TLC file.

This content assumes that you understand the following concepts:

- Level 2 S-functions

- Target Language Compiler (TLC) scripting
- How the code generator produces and builds C/C++ code

Notes This information is for code generator users. Even if you do not currently use the code generator, follow these practices when writing S-functions, especially if you are creating general-purpose S-functions.

Types of S-Functions

Examples for which you might choose to implement an S-function for simulation and code generation include:

1. "I'm not concerned with efficiency. I just want to write one version of my algorithm and have it work in the Simulink and code generator products automatically."
2. "I want to implement a highly optimized algorithm in the Simulink and code generator products that looks like a built-in block and generates very efficient code."
3. "I have a lot of hand-written code that I need to interface. I want to call my function from the Simulink and code generator products in an efficient manner."

Respectively, the preceding situations map to the following MathWorks terminology:

1. Noninlined S-function
2. Inlined S-function
3. Autogenerated S-function for external code

Noninlined S-Functions

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and generated code. In general, you implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Additional memory and computation resources are required for each instance of a noninlined S-Function block. However, this routine of incorporating algorithms into models and code generation applications is typical during the prototyping phase of a project where efficiency is not important. The advantage gained by forgoing efficiency is the ability to change model parameters and structures rapidly.

Writing a noninlined S-function does not involve TLC coding. Noninlined S-functions are the default case for the build process in the sense that once you build a MEX S-function in your model, there is no additional preparation prior to pressing **Ctrl+B** to build your model.

Some restrictions exist concerning the names and locations of noninlined S-function files when generating makefiles. See "Write Noninlined S-Function and TLC Files" on page 11-66.

Inlined S-Functions

For S-functions to work in the Simulink environment, some overhead code is generated. When the code generator produces code from models that contain S-functions (without `sfunction.tlc` files), it embeds some of this overhead code in the generated code. If you want to optimize your real-time code and eliminate some of the overhead code, you must *inline* (or embed) your S-functions. This involves writing a TLC (`sfunction.tlc`) file that eliminates overhead code from the generated code. The Target Language Compiler processes `sfunction.tlc` files to define how to inline your S-function algorithm in the generated code.

Note The term *inline* should not be confused with the C++ *inline* keyword. Inline means to specify text in place of the call to the general S-function API routines (for example, `mdlOutputs`). For example, when a TLC file is used to inline an S-function, the generated code contains the C/ C++ code that would normally appear within the S-function routines and the S-function itself has been removed from the build process.

A fully inlined S-function builds your algorithm (block) into generated code in a manner that is indistinguishable from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file). The complexity of the TLC file depends on the complexity of your algorithm and the level of efficiency you're trying to achieve in the generated code. TLC files vary from simple to complex in structure.

Autogenerated S-Functions for Legacy or Custom Code

If you need to invoke hand-written C/C++ code in your model, consider using the Simulink Legacy Code Tool. The Legacy Code Tool can automate the generation of a fully inlined S-function and a corresponding TLC file based on information that you register in a Legacy Code Tool data structure.

For more information, see "Integrate C Functions Using Legacy Code Tool" (Simulink) and see "Import Calls to External Code into Generated Code with Legacy Code Tool" on page 11-7.

Files Required for Implementing Noninlined and Inlined S-Functions

This topic briefly describes what files and functions you need to create noninlined and inlined S-functions.

- Noninlined S-functions require the C or C++ MEX S-function source code (*`sfunction`*`.c` or *`sfunction`*`.cpp`).
- Fully inlined S-functions require an *`sfunction`*`.tlc` file. Fully inlined S-functions produce the optimal code for a parameterized S-function. This is an S-function that operates in a specific mode dependent upon fixed S-function parameters that do not change during model execution. For a given operating mode, the *`sfunction`*`.tlc` file specifies the exact code that is generated to implement the algorithm for that mode. For example, the direct-index lookup table S-function in "Write Fully Inlined S-Functions with mdlRTW Routine" on page 11-78 contains two operating modes — one for evenly spaced `x-data` and one for unevenly spaced `x-data`.

  Note: Fully-inlined S-functions that are generated to invoke legacy or custom C/C++ code also require an *`sfunction`*`.tlc` file, which is generated by Legacy Code Tool.

Fully inlined S-functions might require the placement of the `mdlRTW` routine in your S-function MEX-file *`sfunction`*`.c` or *`sfunction`*`.cpp`. The `mdlRTW` routine lets you place information in *`model`*`.rtw`, the record file that specifies a model, and which the code generator invokes the Target Language Compiler to process prior to executing *`sfunction`*`.tlc` when generating code.

Including a `mdlRTW` routine is useful when you want to introduce nontunable parameters into your TLC file. Such parameters are generally used to determine which operating mode is active in a given instance of the S-function. Based on this information, the TLC file for the S-function can generate highly efficient, optimal code for that operating mode.

Guidelines for Writing S-Functions that Support Code Generation

- You can use C/C++ MEX, MATLAB language, and Fortran MEX S-functions with code generation.

- You can inline S-functions for code generation by providing an inlining TLC file. See S-Function Inlining in "Target Language Compiler" (Simulink Coder). MATLAB and Fortran MEX S-functions must be inlined. C/C++ MEX S-functions can be inlined for code efficiency, or noninlined.
- To automatically generate a fully inlined C MEX S-function for invoking legacy or custom code, use the Legacy Code Tool. For more information, see "Integrate C Functions Using Legacy Code Tool" (Simulink) and see "Import Calls to External Code into Generated Code with Legacy Code Tool" (Simulink Coder).
- If code efficiency is not an overriding consideration, for example, if you are rapid prototyping, you can choose not to inline a C/C++ MEX S-function. For more information, see "Write Noninlined S-Function and TLC Files" on page 11-66.

Import Calls to External Code into Generated Code with Legacy Code Tool

In this section...

Legacy Code Tool and Code Generation

You can use the Simulink Legacy Code Tool to generate fully inlined C MEX S-functions for legacy or custom code. The S-functions are optimized for embedded components, such as device drivers and lookup tables, and they call existing C or C++ functions.

Note: The Legacy Code Tool can interface with C++ functions, but not C++ objects. To work around this issue so that the tool can interface with C++ objects, see "Legacy Code Tool Limitations" (Simulink).

You can use the tool to:

- Compile and build the generated S-function for simulation.
- Generate a masked S-Function block that is configured to call the existing external code.

If you want to include these types of S-functions in models for which you intend to generate code, use the tool to generate a TLC block file. The TLC block file specifies how the generated code for a model calls the existing C or C++ function.

If the S-function depends on files in folders other than the folder containing the S-function dynamically loadable executable file, use the tool to generate an

*sFunction*_makecfg.m or rtwmakecfg.m file for the S-function. Generating the file maintains those dependencies when you build a model that includes the S-function. For example, for some applications, such as custom targets, you might want to locate files in a target-specific location. The build process looks for *sFunction*_makecfg.m or rtwmakecfg.m in the same folder as the S-function dynamically loadable executable and calls the function in the file.

For more information, see "Integrate C Functions Using Legacy Code Tool" (Simulink).

Generate Inlined S-Function Files for Code Generation

Depending on the code generation requirements of your application, to generate code for a model that uses the S-function, do either of the following:

- Generate one .cpp file for the inlined S-function. In the Legacy Code Tool data structure, set the value of the Options.singleCPPMexFile field to true before generating the S-function source file from your existing C function. For example:

  ```
  def.Options.singleCPPMexFile = true;
  legacy_code('sfcn_cmex_generate', def);
  ```

- Generate a source file and a TLC block file for the inlined S-function. For example:

  ```
  def.Options.singleCPPMexFile = false;
  legacy_code('sfcn_cmex_generate', def);
  legacy_code('sfcn_tlc_generate', def);
  ```

singleCPPMexFile Limitations

You cannot set the singleCPPMexFile field to true if

- Options.language='C++'
- You use one of the following Simulink objects with the IsAlias property set to true:
  - Simulink.Bus
  - Simulink.AliasType
  - Simulink.NumericType
- The Legacy Code Tool function specification includes a void* or void** to represent scalar work data for a state argument
- HeaderFiles field of the Legacy Code Tool structure specifies multiple header files

Apply Code Style Settings to Legacy Functions

To apply the model configuration parameters for code style to a legacy function:

1. Initialize the Legacy Code Tool data structure. For example:

   ```
   def = legacy_code('initialize');
   ```

2. In the data structure, set the value of the `Options.singleCPPMexFile` field to `true`. For example:

   ```
   def.Options.singleCPPMexFile = true;
   ```

To check the setting, enter:

```
def.Options.singleCPPMexFile
```

singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

Address Dependencies on Files in Different Locations

By default, the Legacy Code Tool assumes that files on which an S-function depends reside in the same folder as the dynamically loadable executable file for the S-function. If your S-function depends on files that reside elsewhere and you are using the template makefile build process, generate an *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file for the S-function. For example, you might generate this file if your Legacy Code Tool data structure defines compilation resources as path names.

To generate the *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file, call the `legacy_code` function with `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` as the first

argument, and the name of the Legacy Code Tool data structure as the second argument. For example:

```
legacy_code('sfcn_makecfg_generate', lct_spec);
```

If you use multiple registration files in the same folder and generate an S-function for each file with a single call to `legacy_code`, the call to `legacy_code` that specifies `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` must be common to all registration files. For more information, see "Handling Multiple Registration Files" (Simulink) in the Simulink documentation.

For example, if you define `defs` as an array of Legacy Code Tool structures, you call `legacy_code` with `'sfcn_makecfg_generate'` once.

```
defs = [defs1(:);defs2(:);defs3(:)];
legacy_code('sfcn_makecfg_generate', defs);
```

For more information, see "Build Support for S-Functions" (Simulink Coder).

Deploy S-Functions for Simulation and Code Generation

You can deploy the S-functions that you generate with the Legacy Code Tool so that other people can use them. To deploy an S-function for simulation and code generation, share the following files:

- Registration file
- Compiled dynamically loadable executable
- TLC block file
- *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file
- Header, source, and include files on which the generated S-function depends

When you use these deployed files:

- Before using the deployed files in a Simulink model, add the folder that contains the S-function files to the MATLAB path.
- If the Legacy Code Tool data structure registers required files as absolute paths and the location of the files changes, regenerate the *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file.

Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The definition of the legacy C++ class in this example is:

```
class adder {
  private:
      int int_state;
  public:
      adder();
      int add_one(int increment);
      int get_val();
};
```

The legacy source code is in the files adder_cpp.h and adder_cpp.cpp.

```
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec  = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles   = {'adder_cpp.h'};
def.SourceFiles   = {'adder_cpp.cpp'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

```
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_adder_cpp.cpp.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_adder_cpp
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional'.
MEX completed successfully.
    mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2013 Professional'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_adder_cpp
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again. Set the first input to 'sfcn_tlc_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_adder_cpp.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block file, you can call the function legacy_code() again. Set the first input to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file that supports

code generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

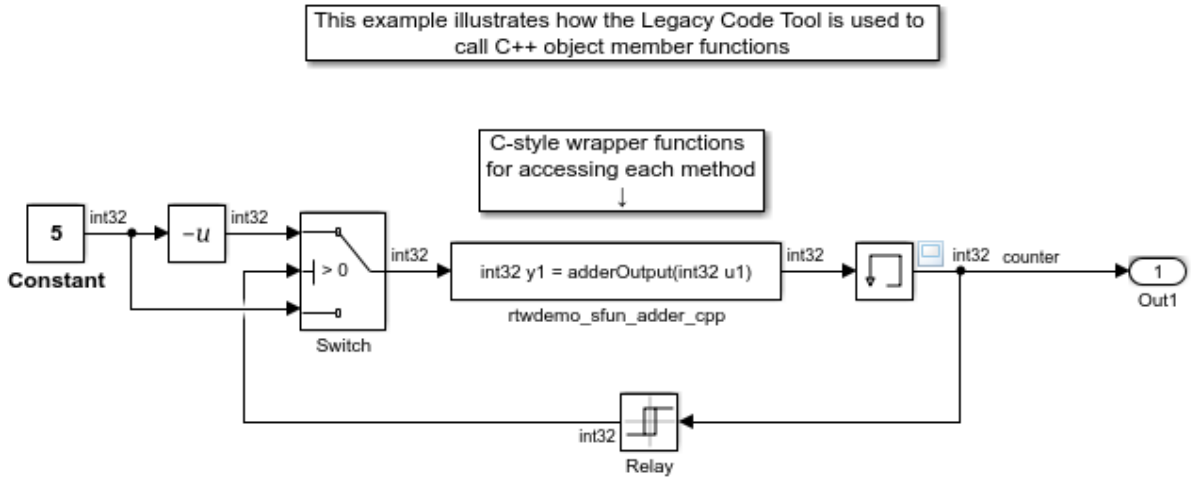
After you compile the C-MEX S-function source, you can call the function legacy_code() again. Set the first input to 'slblock_generate' to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
% legacy_code('slblock_generate', def);
```

Show the Generated Integration with Legacy Code

The model rtwdemo_lct_cpp shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```



Integrate External C++ Objects

The Legacy Code Tool can interface with C++ functions, but not C++ objects. Using the previous example as a starting point, here is an example of how you can work around this limitation.

- Modify the class definition for `adder` in a new file `adder_cpp.hpp`. Add three new macros that dynamically allocate a new `adder` object, invoke the method `add_one()`, and free the memory allocated. Each macro takes a pointer to an `adder` object. Because each function called by the Legacy Code Tool must have a C-like signature,

the pointer is cached and passed as a `void*`. Then you must explicitly cast to `adder*` in the macro. The new class definition for `adder`:

```
#ifndef _ADDER_CPP_
#define _ADDER_CPP_

class adder {
private:
 int int_state;
public:
 adder(): int_state(0) {};
 int add_one(int increment);
 int get_val() {return int_state;};
};

// Method wrappers implemented as macros
#define createAdder(work1) \
    *(work1) = new adder

#define deleteAdder(work1) \
    delete(static_cast(adder*)(*(work1)))

#define adderOutput(work1, u1) \
    (static_cast(adder*) ((work1)))->add_one(u1)

#endif /* _ADDER_CPP_ */
```

- Update `adder_cpp.cpp`. With the class modification, instead of one global instance, each generated S-function manages its own `adder` object.

```
#include "adder_cpp.hpp"

int adder::add_one(int increment)
{
 int_state += increment;
    return int_state;
}
```

- Update `rtwdemo_sfun_adder_cpp.cpp` with the following changes:

  - `StartFcnSpec` calls the macro that allocates a new `adder` object and caches the pointer.

    ```
    def.StartFcnSpec  = 'createAdder(void **work1)';
    ```

- `OutputFcnSpec` calls the macro that invokes the method `add_one()` and provides the S-function specific `adder` pointer object.

  ```
  def.OutputFcnSpec = 'int32 y1 = adderOutput(void *work1, int32 u1)';
  ```

- `TerminateFcnSpec` calls the macro that frees the memory.

  ```
  def.TerminateFcnSpec = 'deleteAdder(void **work1)';
  ```

Legacy Code Tool Examples

Integrate External C Functions That Pass Input Arguments By Value Versus Address

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)
- FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, myfilter.h, filterV1.c, and filterV2.c.

Note the difference in the OutputFcnSpec defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```
defs = [];

% rtwdemo_sfun_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
def.HeaderFiles   = {'myfilter.h'};
def.SourceFiles   = {'filterV1.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles   = {'myfilter.h'};
def.SourceFiles   = {'filterV2.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions in simulation. The source code for the S-functions is in the files rtwdemo_sfun_filterV1.c and rtwdemo_sfun_filterV2.c.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_filterV1
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
```

```
MEX completed successfully.
    mex('rtwdemo_sfun_filterV1.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_filterV1
### Exit

### Start Compiling rtwdemo_sfun_filterV2
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_filterV2.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_filterV2
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are rtwdemo_sfun_filterV1.tlc and rtwdemo_sfun_filterV2.tlc.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an rtwmakecfg.m File for Code Generation

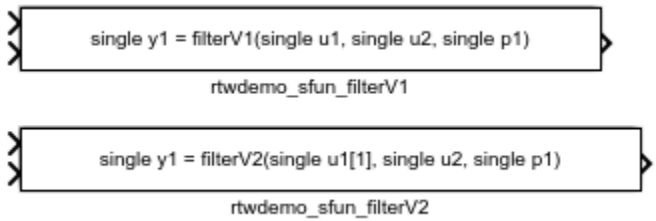
After you create the TLC block files, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

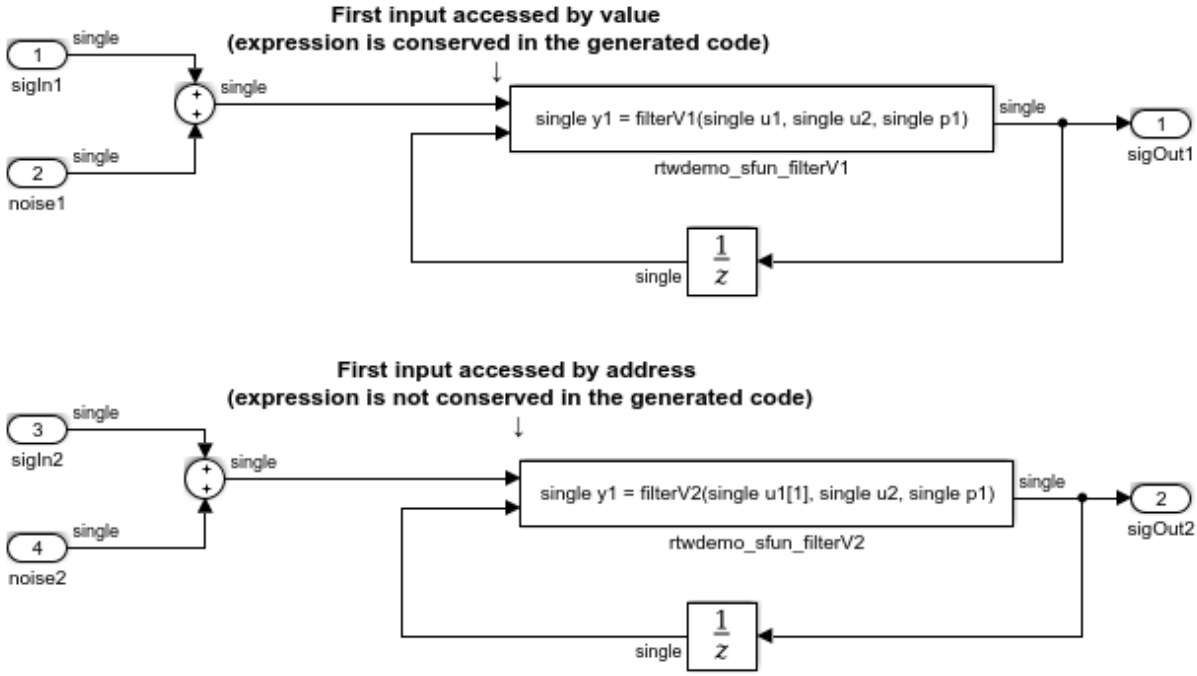
```
legacy_code('slblock_generate', defs);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_filter shows integration of the model with the legacy code. The subsystem TestFilter serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_filter')
open_system('rtwdemo_lct_filter/TestFilter')
sim('rtwdemo_lct_filter')
```



Integrate External C Functions That Pass the Output Argument As a Return Argument

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code()

using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

FLT gainScalar(const FLT in, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, gain.h, and gainScalar.c.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_scalar';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_gain_scalar.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_gain_scalar
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_gain_scalar.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
```

```
### Finish Compiling rtwdemo_sfun_gain_scalar
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_gain_scalar.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

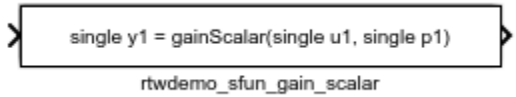
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

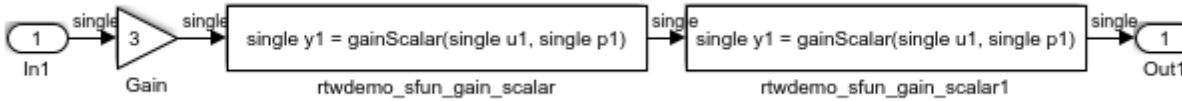
```
legacy_code('slblock_generate', def);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_gain shows integration of the model with the legacy code. The subsystem TestGain serves as a harness for the call to the legacy C function via the generate S-function.

```
open_system('rtwdemo_lct_gain')
open_system('rtwdemo_lct_gain/TestGain')
sim('rtwdemo_lct_gain')
```



Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs by using parameters of fixed-point data type.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)

myFixpt is logically a fixed-point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
```

```
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files timesFixpt.h, and timesS16.c.

```
% rtwdemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles   = {'timesFixpt.h'};
def.SourceFiles   = {'timesS16.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_times_s16.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_times_s16
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_times_s16.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src'
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_times_s16
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_times_s16.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

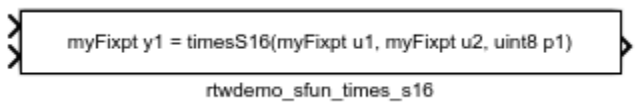
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

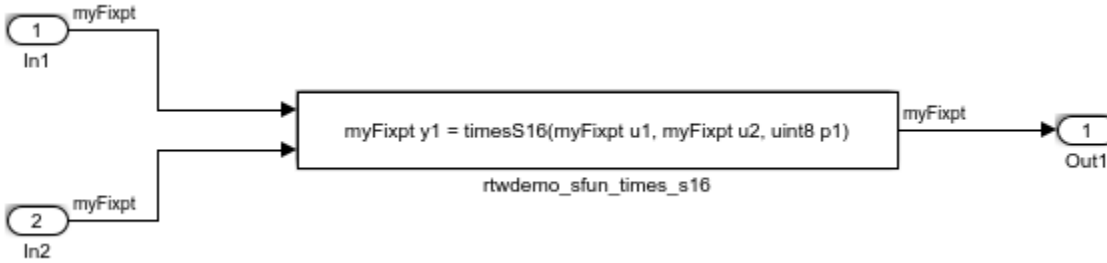


Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_fixpt_signals shows integration of the model with the legacy code. The subsystem TestFixpt serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_signals')
```

```
open_system('rtwdemo_lct_fixpt_signals/TestFixpt')
sim('rtwdemo_lct_fixpt_signals')
```



Integrate External C Functions with Instance-Specific Persistent Memory

Integrate legacy C functions that use instance-specific persistent memory by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

void memory_bus_init(COUNTERBUS *mem, int32_T upper_sat, int32_T lower_sat);

void memory_bus_step(COUNTERBUS *input, COUNTERBUS *mem, COUNTERBUS *output);

mem is an instance-specific persistent memory for applying a one integration step delay. COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files memory_bus.h, and memory_bus.c.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_work
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_work';
def.InitializeConditionsFcnSpec = ...
    'void memory_bus_init(COUNTERBUS work1[1], int32 p1, int32 p2)';
def.OutputFcnSpec = ...
    'void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])';
def.HeaderFiles   = {'memory_bus.h'};
def.SourceFiles   = {'memory_bus.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_work.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_work
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_work.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
```

```
### Finish Compiling rtwdemo_sfun_work
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_work.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

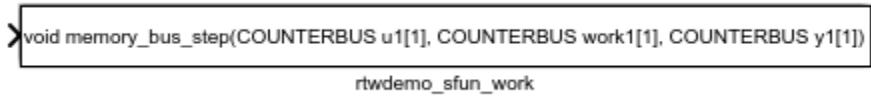
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

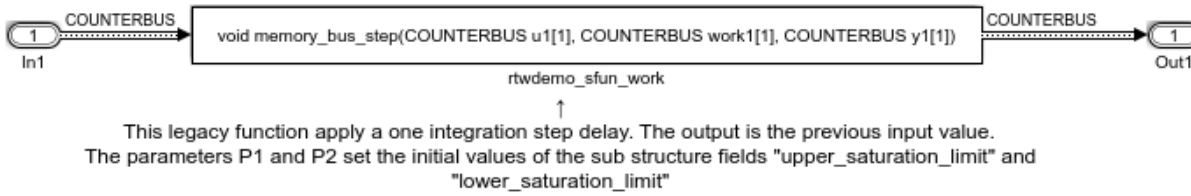
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_work shows integration of the model with the legacy code. The subsystem memory_bus serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_work')
open_system('rtwdemo_lct_work/memory_bus')
sim('rtwdemo_lct_work')
```



Integrate External C Functions That Use Structure Arguments

Integrate legacy C functions with structure arguments that use Simulink® buses with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

counterbusFcn(COUNTERBUS *u1, int32_T u2, COUNTERBUS *y1, int32_T *y2)

COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files counterbus.h, and counterbus.c.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_counterbus
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_counterbus';
def.OutputFcnSpec = ...
    'void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1])';
def.HeaderFiles   = {'counterbus.h'};
def.SourceFiles   = {'counterbus.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_counterbus.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_counterbus
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_counterbus.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_counterbus
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block

file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_counterbus.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

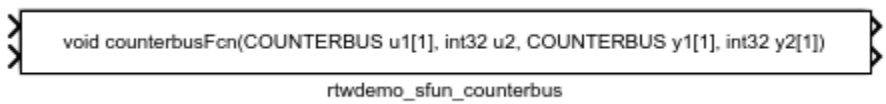
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

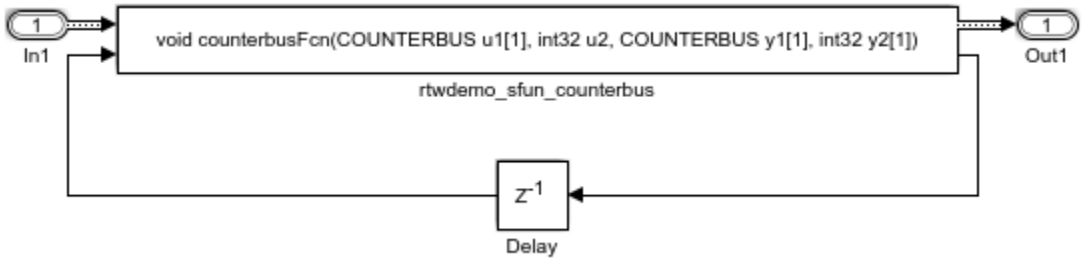
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_bus shows integration of the model with the legacy code. The subsystem TestCounter serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_bus')
open_system('rtwdemo_lct_bus/TestCounter')
sim('rtwdemo_lct_bus')
```



Integrate External C Functions That Pass Input and Output Arguments as Signals with Complex Data

Integrate legacy C functions using complex signals with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

void cplx_gain(creal_T *input, creal_T *gain, creal_T *output);

creal_T is the complex representation of a double. The legacy source code is in the files cplxgain.h, and cplxgain.c.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_cplx_gain';
def.OutputFcnSpec = ...
```

```
    'void cplx_gain(complex<double> u1[1], complex<double> p1[1], complex<double> y1[1]
def.HeaderFiles   = {'cplxgain.h'};
def.SourceFiles   = {'cplxgain.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_cplx_gain.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_cplx_gain
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_cplx_gain.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src'
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_cplx_gain
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_cplx_gain.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

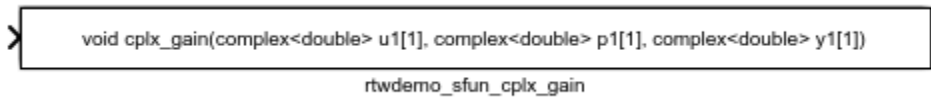
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

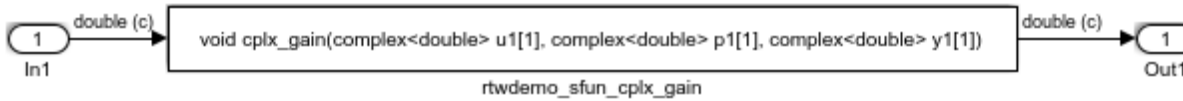
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_cplxgain shows integration of the model with the legacy code. The subsystem complex_gain serves as a harness for the call to the legacy C function via the generate S-function.

```
if isempty(find_system('SearchDepth',0,'Name','rtwdemo_lct_cplxgain'))
    open_system('rtwdemo_lct_cplxgain')
    open_system('rtwdemo_lct_cplxgain/complex_gain')
    sim('rtwdemo_lct_cplxgain')
end
```



Integrate External C Functions That Pass Arguments That Have Inherited Dimensions

This example shows how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)
- void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files mat_ops.h, and mat_ops.c.

```
defs = [];

% rtwdemo_sfun_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_add';
```

```
def.OutputFcnSpec = ['void mat_add(double u1[][], double u2[][], ' ...
                     'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_mat_mult
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_mult';
def.OutputFcnSpec =  ['void mat_mult(double u1[p1][p2], double u2[p2][p3], '...
                     'int32 p1, int32 p2, int32 p3, double y1[p1][p3])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-function is in the files rtwdemo_sfun_mat_add.c and rtwdemo_sfun_mat_mult.c.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_mat_add
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_mat_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
```

```
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_mat_add
### Exit

### Start Compiling rtwdemo_sfun_mat_mult
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_mat_mult.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_mat_mult
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are rtwdemo_sfun_mat_add.tlc and rtwdemo_sfun_mat_mult.tlc.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an rtwmakecfg.m File for Code Generation

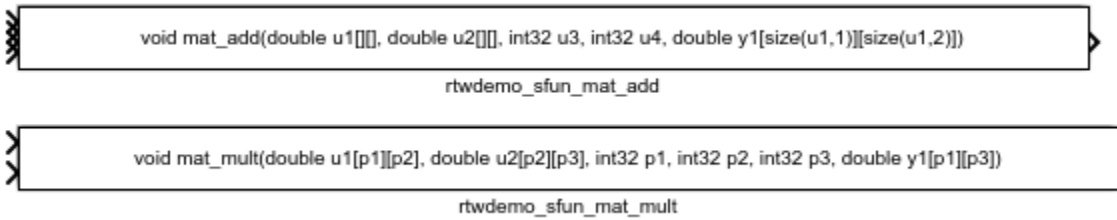
After you create the TLC block files, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model

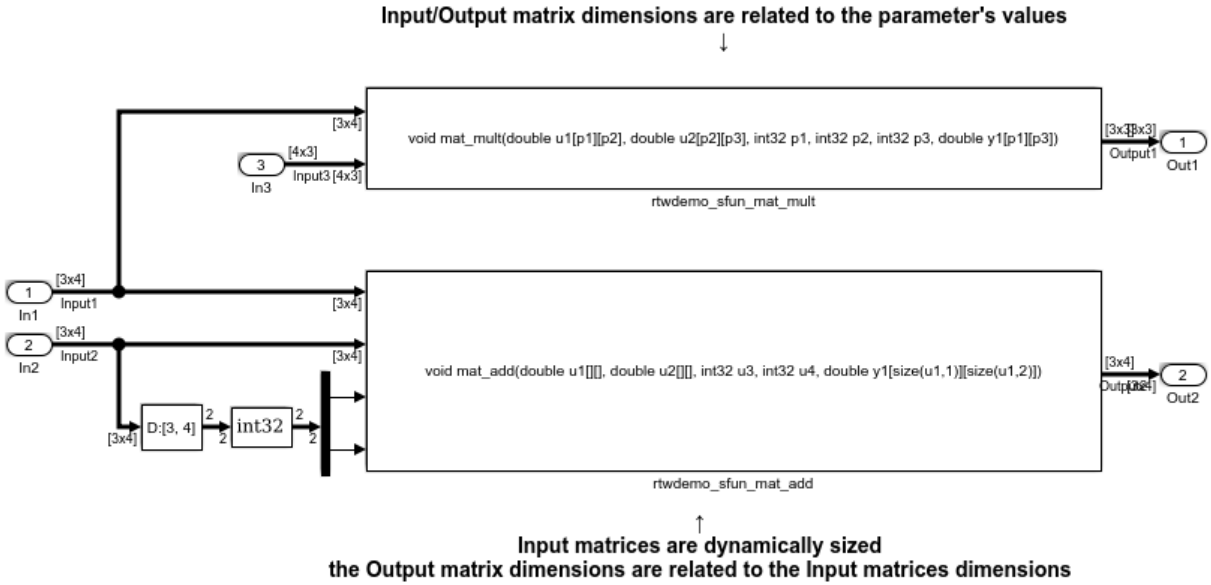
```
legacy_code('slblock_generate', defs);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_inherit_dims shows integration of the model with the legacy code. The subsystem TestMatOps serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_inherit_dims')
open_system('rtwdemo_lct_inherit_dims/TestMatOps')
sim('rtwdemo_lct_inherit_dims')
```



Integrate External C Functions That Implement Start and Terminate Actions

Integrate legacy C functions that have start and terminate actions by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the

properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- void initFaultCounter(unsigned int *counter)
- void openLogFile(void **fid)
- void incAndLogFaultCounter(void *fid, unsigned int *counter, double time)
- void closeLogFile(void **fid)

The legacy source code is in the files your_types.h, fault.h, and fault.c.

```
% rtwdemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_fault';
def.InitializeConditionsFcnSpec  = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec                 = 'openLogFile(void **work1)';
def.OutputFcnSpec                = ...
    'incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)';
def.TerminateFcnSpec             = 'closeLogFile(void **work1)';
def.HeaderFiles                  = {'fault.h'};
def.SourceFiles                  = {'fault.c'};
def.IncPaths                     = {'rtwdemo_lct_src'};
def.SrcPaths                     = {'rtwdemo_lct_src'};
def.Options.useTlcWithAccel      = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_fault.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);

### Start Compiling rtwdemo_sfun_fault
```

```
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_fault.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-I
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_fault
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_fault.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

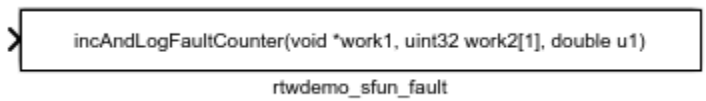
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

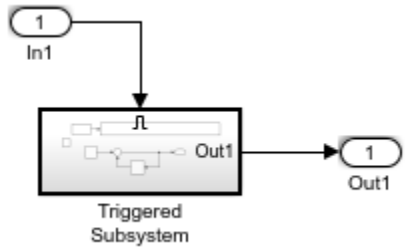
```
legacy_code('slblock_generate', def);
```



Showing the Generated Integration with Legacy Code

The model rtwdemo_lct_start_term shows integration of the model with the legacy code. The subsystem TestFixpt serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```
open_system('rtwdemo_lct_start_term')
open_system('rtwdemo_lct_start_term/TestFault')
sim('rtwdemo_lct_start_term')
```



Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, int32_T nbPages);

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files ndarray_ops.h, and ndarray_ops.c.

```
% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec = ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)],
                     'double u1[][][], double u2[][][], ' ...
                    'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles   = {'ndarray_ops.h'};
def.SourceFiles   = {'ndarray_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

y1 is a 3-D output signal of same dimensions as the 3-D input signal u1. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal u1.

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_ndarray_add.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_ndarray_add
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_ndarray_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
```

```
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_ndarray_add
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_ndarray_add.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

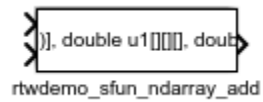
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

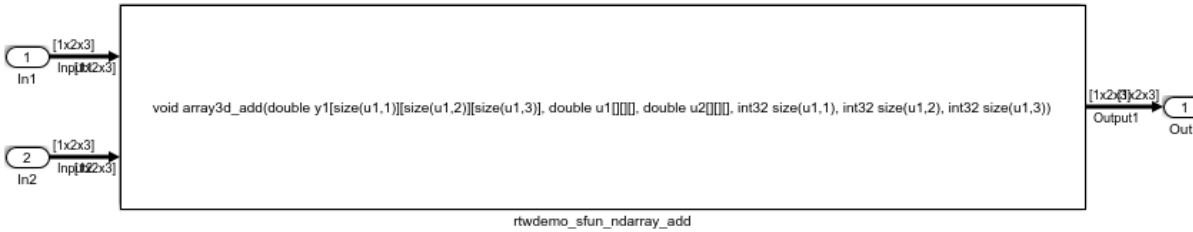
```
legacy_code('slblock_generate', def);
```



Showing the Generated Integration with Legacy Code

The model rtwdemo_lct_ndarray shows integration of the model with the legacy code. The subsystem ndarray_add serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```



```
This legacy function computes the addition of the 2 input signals:
   - Input1 and Input2 are dynamically sized 3D arrays
   - Output1 is a dynamically sized 3D array of same size as Input1
   - the last 3 function's arguments allow to pass the Input1's dimensions to the legacy function
```

Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized

This example shows how to use the Legacy Code Tool to integrate legacy C functions with the block's sample time specified, inherited and parameterized.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

FLT gainScalar(const FLT in, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, gain.h, and gainScalar.c.

```
defs = [];

% rtwdemo_sfun_st_inherited
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_inherited';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_st_fixed
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_fixed';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
def.SampleTime    = [2 1];
defs = [defs; def];

% rtwdemo_sfun_st_parameterized
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_parameterized';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
def.SampleTime    = 'parameterized';
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files rtwdemo_sfun_st_inherited.c and rtwdemo_sfun_st_fixed.c. rtwdemo_sfun_st_parameterized.c.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_st_inherited
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc17a_538369_5
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_st_inherited.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_sr

### Finish Compiling rtwdemo_sfun_st_parameterized
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate

TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are rtwdemo_sfun_st_inherited.tlc and rtwdemo_sfun_st_fixed.tlc. rtwdemo_sfun_st_parameterized.tlc.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an rtwmakecfg.m File for Code Generation

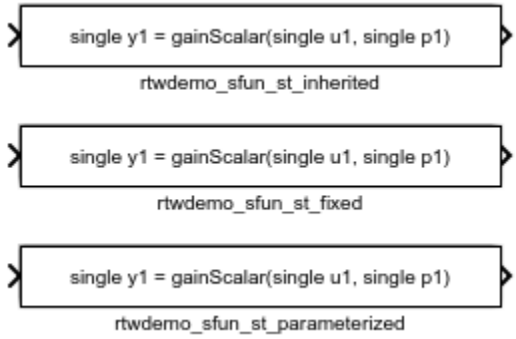
After you create the TLC block files, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

```
legacy_code('slblock_generate', defs);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_sampletime shows integration of the model with the legacy code. The subsystem sample_time serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_sampletime')
open_system('rtwdemo_lct_sampletime/sample_time')
sim('rtwdemo_lct_sampletime')
```

External Code Integration Examples

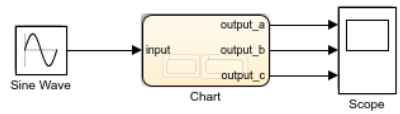
This topic shows various scenarios of external code integration.

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

```
model='rtwdemo_sfcustom';
open_system(model);
```



Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

Include Code - Header that defines functions, structures, and data to be accessible by Stateflow.
Include Path - Path to this include file.
Source Files - c-files that define the functions and data accessible by Stateflow.

Open simulation custom code settings

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

Open Code Generation custom code settings

Build model using Simulink Coder

Calling c-code from Stateflow

Functions
Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

result = my_custom_function(in_args);

Structures
Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

result = my_var.my_field;

To view the custom source for this examplenstration double click the links below.

Open my_header.h

Open my_function.c

Calling C++ code from Stateflow

Custom C++ code can also be integrated into Stateflow and Simulink Coder. Double-click below for a example.

Open rtwdemo_sfcpp

Additional documentation

Additional documentation is available for integrating C and C++ code in your modelby double-clicking the link below.

C-Code integration

C++-Code integration

Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Code Generation/Custom Code');
```

Generate Code

```
rtwbuild('rtwdemo_sfcustom')
```

```
### Starting build procedure for model: rtwdemo_sfcustom
### Successful completion of build procedure for model: rtwdemo_sfcustom
```

Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

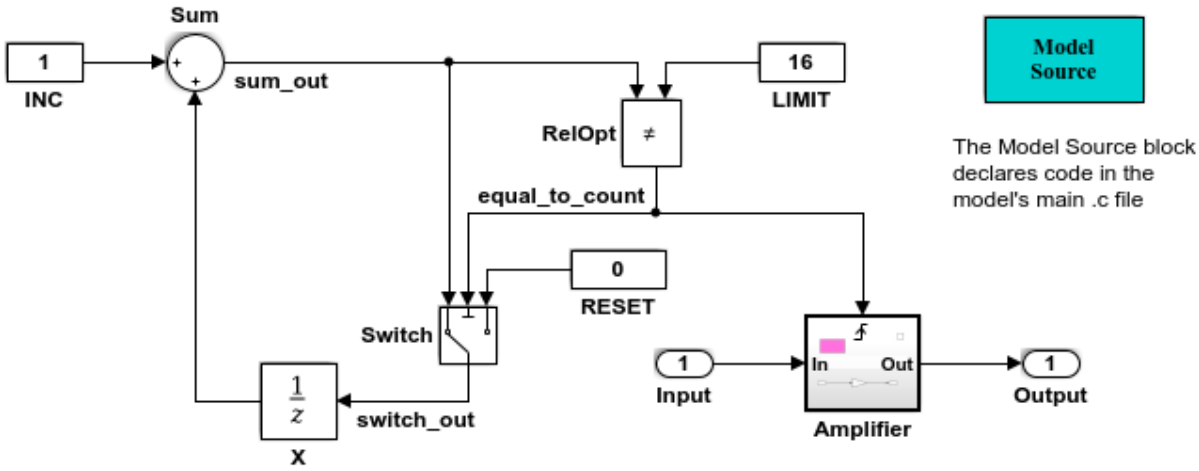
```
rtwdemoclean;
close_system('rtwdemo_sfcustom',0);
```

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```



2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** intializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem `Amplifier`. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the `Amplifier` subsystem. The external code:

- Declares the pointer variable `*intPtr` and intitializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;

int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Output block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;

*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;

*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** intializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem `Amplifier`. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the `Amplifier` subsystem. The external code:

- Declares the pointer variable `*intPtr` and intitializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;

int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Output block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;

*intPtr = -1;
```

```
rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;

*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

```
model='rtwdemo_sfcustom';
open_system(model);
```

Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

Include Code - Header that defines functions, structures, and data to be accessible by Stateflow.
Include Path - Path to this include file.
Source Files - c-files that define the functions and data accessible by Stateflow.

Open simulation custom code settings

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

Open Code Generation custom code settings

Build model using Simulink Coder

Calling c-code from Stateflow

Functions
Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

result = my_custom_function(in_args);

Structures
Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

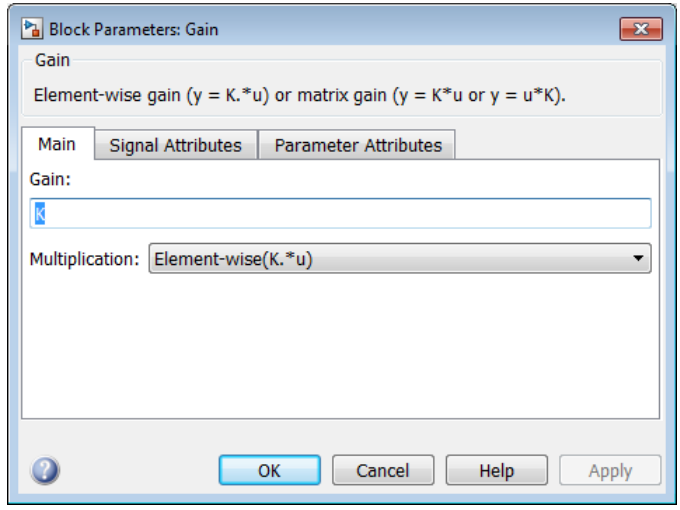
Automate S-Function Generation with S-Function Builder

The **Generate S-function** feature automates the process of generating an S-function from a subsystem. In addition, the **Generate S-function** feature presents a display of parameters used within the subsystem, and lets you declare selected parameters tunable.

As an example, consider `SourceSubsys`, the same subsystem illustrated in the example "Create S-Function Blocks from a Subsystem" on page 46-37. The objective is to automatically extract `SourceSubsys` from the model and build an S-Function block from it, as in the previous example. In addition, the workspace variable `K` , which is the gain factor of the Gain block within `SourceSubsys` (as shown in the Gain block parameter dialog box below), is declared and generated as a tunable variable.



To auto-generate an S-function from `SourceSubsys` with tunable parameter `K`,

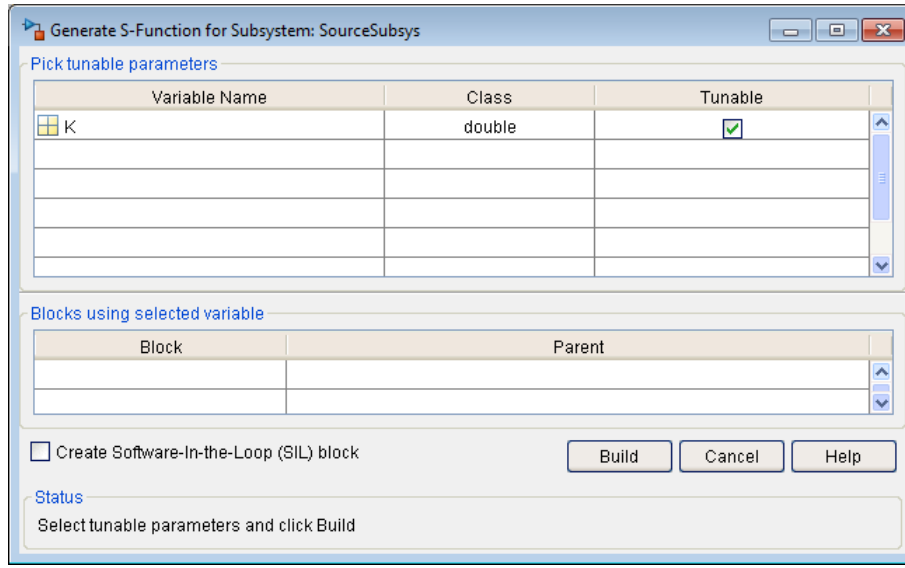
1. With the `SourceSubsys` model open, click the subsystem to select it.
2. From the **Code** menu, select **C/C++ Code** > **Generate S-Function**. This menu item is enabled when a subsystem is selected in the current model.

   Alternatively, you can right-click the subsystem and select **C/C++ Code** > **Generate S-Function** from the subsystem block's context menu.
3. The **Generate S-Function** window is displayed (see the next figure). This window shows variables (or data objects) that are referenced as block parameters in the subsystem, and lets you declare them as tunable.

The upper pane of the window displays three columns:

- **Variable Name**: name of the parameter.
- **Class**: If the parameter is a workspace variable, its data type is shown. If the parameter is a data object, its name and class is shown
- **Tunable**: Lets you select tunable parameters. To declare a parameter tunable, select the check box. In the next figure, the parameter K is declared tunable.

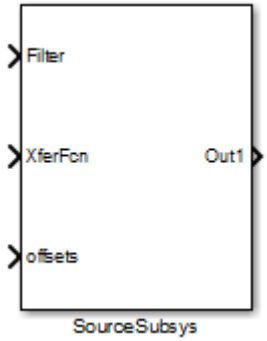
When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter, and the parent system of each such block.



Generate S-Function Window

4 After selecting tunable parameters, click the **Build** button. This initiates code generation and compilation of the S-function, using the S-function target. The **Create New Model** option is automatically enabled.

5 The build process displays status messages in the MATLAB Command Window. When the build completes, the tunable parameters window closes, and a new untitled model window opens.



6 The model window contains an S-Function block with the same name as the subsystem from which the block was generated (in this example, `SourceSubsys`). Optionally, you can save the generated model containing the generated block.

7 The generated code for the S-Function block is stored in the current working folder. The following files are written to the top level folder:

- *`subsys`*`_sf.c` or `.cpp`, where *`subsys`* is the subsystem name (for example, `SourceSubsys_sf.c`)
- *`subsys`*`_sf.h`
- *`subsys`*`_sf.`*`mexext`*, where *`mexext`* is a platform-dependent MEX-file extension (for example, `SourceSubsys_sf.mexw64`)

The source code for the S-function is written to the subfolder *`subsys`*`_sfcn_rtw`. The top-level `.c` or `.cpp` file is a stub file that simply contains an include directive that you can use to interface other C/C++ code to the generated code.

Note: For a list of files required to deploy your S-Function block for simulation or code generation, see "Required Files for S-Function Deployment" on page 46-35.

---

8 The generated S-Function block has inports and outports whose widths and sample times correspond to those of the original model.

The following code, from the `mdlOutputs` routine of the generated S-function code (in `SourceSubsys_sf.c`), shows how the tunable variable `K` is referenced by using calls to the MEX API.

```
static void mdlOutputs(SimStruct *S, int_T tid)
```

```
...

/* Gain: '<S1>/Gain' incorporates:
     *  Sum: '<S1>/Sum'
     */
    rtb_Gain_n[0] = (rtb_Product_p + (*(((const
      real_T**)ssGetInputPortSignalPtrs(S, 2))[0]))) * (*(real_T
      *)(mxGetData(K(S))));
    rtb_Gain_n[1] = (rtb_Product_p + (*(((const
      real_T**)ssGetInputPortSignalPtrs(S, 2))[1]))) * (*(real_T
      *)(mxGetData(K(S))));
```

- In automatic S-function generation, the **Use Value for Tunable Parameters** option is cleared or at the command line is set to `'off'`.
- Use a MEX S-function wrapper only in the MATLAB version in which the wrapper is created.

If you specify paths and files with absolute

Macro Parameters

Suppose that you apply a custom storage class such as `Define` to a `Simulink.Parameter` object so that the parameter appears as a macro in the generated code. If you use the parameter object inside a subsystem from which you generate an ERT S-function, you cannot select the parameter object as a tunable parameter. Instead, the S-function code generator applies the custom storage class to the parameter object. This generation of macros in the S-function code allows you to generate S-functions from subsystems that contain variant elements, such as Variant Subsystem blocks, that you configure to produce preprocessor conditionals in the generated code. However, you cannot change the value of the parameter during simulation of the S-function.

To select the parameter object as a tunable parameter, apply a different storage class or custom storage class. Custom storage classes that treat parameters as macros include `Define`, `ImportedDefine`, `CompilerFlag`, and custom storage classes that you create by setting **Data initialization** to `Macro` in the Custom Storage Class Designer. If you use a non-macro storage class or custom storage class, you cannot use the parameter object as a variant control variable and generate preprocessor conditionals.

If you apply a custom storage class that treats the parameter object as an imported macro, provide the macro definition before you generate the ERT S-function. For example, suppose you apply the custom storage class `ImportedDefine` to a `Simulink.Parameter` object, and use the parameter object as a variant control variable in the subsystem. If you set the custom attribute `HeaderFile` to `'myHdr.h'`, when you

generate the S-function, place the custom header file `myHdr.h` in the current folder. The generated S-function uses the macro value from your header file instead of the value from the `Value` property of the parameter object.

To use a macro that you define through a compiler option, for example by applying the custom storage class `CompilerFlag`, use the model configuration parameter **Configuration Parameters** > **Code Generation** > **Custom Code** > **Additional build information** > **Defines** to specify the compiler option. For more information, see Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

Write S-Function and TLC Files By Hand

You can choose from several approaches for writing S-function and TLC files by hand.

Write Noninlined S-Function and TLC Files

About Noninlined S-Functions

Noninlined S-functions are identified by the *absence* of an `sfunction.tlc` file for your S-function. The filename varies depending on your platform. For example, on a 64–bit Microsoft Windows system, the file name would be `sfunction.mexw64`. Type mexext in the MATLAB Command Window to see which extension your system uses.

Guidelines for Writing Noninlined S-Functions

- The MEX-file cannot call MATLAB functions.
- If the MEX-file uses functions in the MATLAB External Interface libraries, include the header file `cg_sfun.h` instead of `mex.h` or `simulink.c`. To handle this case, include the following lines at the end of your S-function:

```
#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c"  /* MEX-file interface mechanism */
#else
#include "cg_sfun.h"   /* Code generation registration function */
#endif
```

- Use only MATLAB API function that the code generator supports, which include:

```
mxGetEps
mxGetInf
mxGetM
mxGetN
mxGetNaN
mxGetPr
mxGetScalar
mxGetString
mxIsEmpty
mxIsFinite
mxIsInf
```

- MEX library calls are not supported in generated code. To use such calls in MEX-file and not in the generated code, conditionalize the code as follows:

  ```
  #ifdef MATLAB_MEX_FILE
  #endif
  ```

- Use only full matrices that contain only real data.
- Do not specify a return value for calls to `mxGetString` . If you do specify a return value, the MEX-file will not compile. Instead, use the function's second input argument, which returns a pointer to a character vector.
- Make sure that the `#define` *`s-function_name`* statement is correct. The S-function name that you specify must match the S-function's filename.
- Use the data types `real_T` and `int_T` instead of `double` and `int`, if possible. The data types `real_T` and `int_T` are more generic and can be used in multiple environments.
- Provide the build process with the names of the modules used to build the S-function. You can do this by using a template make file, the `set_param` function, or the `S-function modules` field of the S-Function block parameters dialog box. For example, suppose you build your S-function with the following command:

  ```
  mex sfun_main.c sfun_module1.c sfun_module2.c
  ```

  You can then use the following call to `set_param` to include the required modules:

  ```
  set_param(sfun_block, "SFunctionModules","sfun_module1 sfun_module2")
  ```

  When you are ready to generate code, force the code generator to rebuild the top model, as explained in “Control Regeneration of Top Model Code” (Simulink Coder).

Noninlined S-Function Parameter Type Limitations

Parameters to noninlined S-functions can be of the following types only:

- Double precision
- Characters in scalars, vectors, or 2-D matrices

For more flexibility in the type of parameters you can supply to S-functions or the operations in the S-function, inline your S-function and consider using an `mdlRTW` S-function routine.

Use of other functions from the MATLAB `matrix.h` API or other MATLAB APIs, such as `mex.h` and `mat.h`, is not supported. If you call unsupported APIs from an S-function

source file, compiler errors occur. See the files *matlabroot*/rtw/c/src/rt_matrx.h and *matlabroot*/rtw/c/src/rt_matrx.c for details on supported MATLAB API functions.

If you use mxGetPr on an empty matrix, the function does not return NULL; rather, it returns a random value. Therefore, you should protect calls to mxGetPr with mxIsEmpty.

Write Wrapper S-Function and TLC Files

This topic describes how to create S-functions that work seamlessly with the Simulink and code generator products using the *wrapper* concept. This topic begins by describing how to interface your algorithms in Simulink models by writing MEX S-function wrappers (*sfunction*.mex). It finishes with a description of how to direct the code generator to insert your algorithm into the generated code by creating a TLC S-function wrapper (*sfunction*.tlc).

MEX S-Function Wrapper

Creating S-functions using an S-function wrapper allows you to insert C/C++ code algorithms in Simulink models and the generated code with little or no change to your original C/C++ function. A *MEX S-function wrapper* is an S-function that calls code that resides in another module. A *TLC S-function wrapper* is a TLC file that specifies how the code generator should call your code (the same code that was called from the C MEX S-function wrapper).

Note: A MEX S-function wrapper must only be used in the MATLAB version in which the wrapper is created.

Suppose you have an algorithm (that is, a C function) called my_alg that resides in the file my_alg.c. You can integrate my_alg into a Simulink model by creating a MEX S-

function wrapper (for example, `wrapsfcn.c`). Once this is done, a Simulink model can call `my_alg` from an S-Function block. However, the Simulink S-function contains a set of empty functions that the Simulink engine requires for various API-related purposes. For example, although only `mdlOutputs` calls `my_alg`, the engine calls `mdlTerminate` as well, even though this S-function routine performs no action.

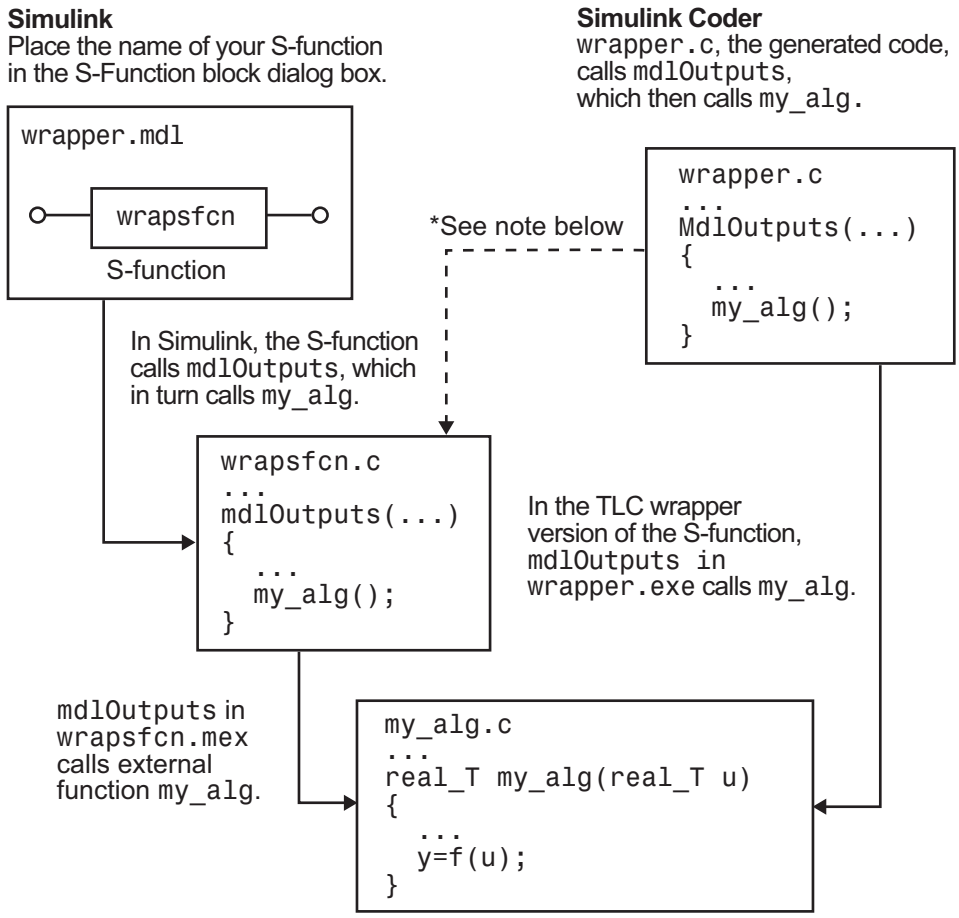
You can integrate `my_alg` into generated code (that is, embed the call to `my_alg` in the generated code) by creating a TLC S-function wrapper (for example, `wrapsfcn.tlc`). The advantage of creating a TLC S-function wrapper is that the empty function calls can be eliminated and the overhead of executing the `mdlOutputs` function and then the `my_alg` function can be eliminated.

Wrapper S-functions are useful when you are creating new algorithms that are procedural in nature or when you are integrating legacy code into a Simulink model. However, if you want to create code that is

- Interpretive in nature (that is, highly parameterized by operating modes)
- Heavily optimized (that is, no extra tests to decide what mode the code is operating in)

then you must create a *fully inlined TLC file* for your S-function.

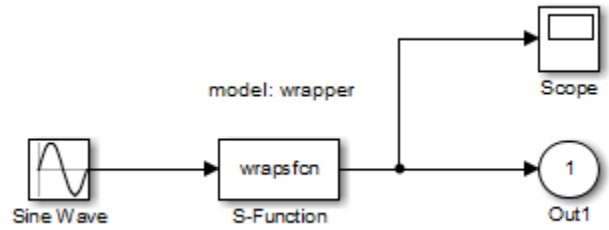
The next figure shows the wrapper S-function concept.



*The dotted line is the path taken if the S-function does not have a TLC wrapper file. If there is no TLC wrapper file, the generated code calls `mdlOutputs`.

Using an S-function wrapper to import algorithms in your Simulink model means that the S-function serves as an interface that calls your C/C++ algorithms from `mdlOutputs`. S-function wrappers have the advantage that you can quickly integrate large standalone C /C++ programs into your model without having to make changes to the code.

The following sample model includes an S-function wrapper.



There are two files associated with the `wrapsfcn` block, the S-function wrapper and the C/C++ code that contains the algorithm. The S-function wrapper code for `wrapsfcn.c` appears below. The first three statements do the following:

1. Defines the name of the S-function (what you enter in the Simulink S-Function block dialog).
2. Specifies that the S-function is using the level 2 format.
3. Provides access to the `SimStruct` data structure, which contains pointers to data used during simulation and code generation and defines macros that store data in and retrieve data from the `SimStruct`.

For more information, see "Templates for C S-Functions" (Simulink).

```
#define S_FUNCTION_NAME wrapsfcn
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"

extern real_T my_alg(real_T u);  /* Declare my_alg as extern */

/*
 * mdlInitializeSizes - initialize the sizes array
 */
static void mdlInitializeSizes(SimStruct *S)
{

    ssSetNumSFcnParams( S, 0); /*number of input arguments*/

    if (!ssSetNumInputPorts(S, 1)) return;
    ssSetInputPortWidth(S, 0, 1);
    ssSetInputPortDirectFeedThrough(S, 0, 1);

    if (!ssSetNumOutputPorts(S,1)) return;
    ssSetOutputPortWidth(S, 0, 1);

    ssSetNumSampleTimes( S, 1);
}

/*
```

```
 * mdlInitializeSampleTimes - indicate that this S-function runs
 * at the rate of the source (driving block)
 */
static void mdlInitializeSampleTimes(SimStruct *S)
{
    ssSetSampleTime(S, 0, INHERITED_SAMPLE_TIME);
    ssSetOffsetTime(S, 0, 0.0);
}

/*
 * mdlOutputs - compute the outputs by calling my_alg, which
 * resides in another module, my_alg.c
 */
static void mdlOutputs(SimStruct *S, int_T tid)
{
    InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
    real_T            *y    = ssGetOutputPortRealSignal(S,0);
    *y = my_alg(*uPtrs[0]); /* Call my_alg in mdlOutputs */
 }
/*
 * mdlTerminate - called when the simulation is terminated.
 */
static void mdlTerminate(SimStruct *S)
{
}

#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
```

The S-function routine `mdlOutputs` contains a function call to `my_alg`, which is the C function containing the algorithm that the S-function performs. This is the code for `my_alg.c`:

```
#ifdef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
real_T my_alg(real_T u)
{
return(u * 2.0);
}
```

For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

The wrapper S-function `wrapsfcn` calls `my_alg`, which computes `u * 2.0`. To build `wrapsfcn.mex`, use the following command:

```
mex wrapsfcn.c my_alg.c
```

TLC S-Function Wrapper

This topic describes how to inline the call to `my_alg` in the `mdlOutputs` section of the generated code. In the above example, the call to `my_alg` is embedded in the `mdlOutputs` section as

```
*y = my_alg(*uPtrs[0]);
```

When you are creating a TLC S-function wrapper, the goal is to embed the same type of call in the generated code.

It is instructive to look at how the code generator executes S-functions that are not inlined. A noninlined S-function is identified by the absence of the file *`sfunction`*`.tlc` and the existence of *`sfunction`*`.mex`. When generating code for a noninlined S-function, the code generator produces a call to `mdlOutputs` through a function pointer that, in this example, then calls `my_alg`.

The wrapper example contains one S-function, `wrapsfcn.mex`. You must compile and link an additional module, `my_alg`, with the generated code. To do this, specify

```
set_param('wrapper/S-Function','SFunctionModules','my_alg')
```

Code Overhead for Noninlined S-Functions

The code generated when using `grt.tlc` as the system target file *without* `wrapsfcn.tlc` is

```
<Generated code comments for wrapper model with noninlined wrapsfcn S-function>

#include <math.h>
#include <string.h>
#include "wrapper.h"
#include "wrapper.prm"

/* Start the model */
void mdlStart(void)
{
  /* (start code not required) */
}

/* Compute block outputs */
void mdlOutputs(int_T tid)
{
  /* Sin Block: <Root>/Sin */
  rtB.Sin = rtP.Sin.Amplitude *
    sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

  /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
```

```
  {
    /* Noninlined S-functions create a SimStruct object and
     * generate a call to S-function routine mdlOutputs
     */
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnOutputs(rts, tid);
  }

  /* Outport Block: <Root>/Out */
  rtY.Out = rtB.S_Function;
}

/* Perform model update */
void mdlUpdate(int_T tid)
{
  /* (update code not required) */
}

/* Terminate function */
void mdlTerminate(void)
{
  /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
  {
/* Noninlined S-functions require a SimStruct object and
     * the call to S-function routine mdlTerminate
     */
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnTerminate(rts);
  }
}

#include "wrapper.reg"

/* [EOF] wrapper.c */
```

In addition to the overhead outlined above, the `wrapper.reg` generated file contains the initialization of the `SimStruct` for the wrapper S-Function block. There is one child `SimStruct` for each S-Function block in your model. You can significantly reduce this overhead by creating a TLC wrapper for the S-function.

How to Inline

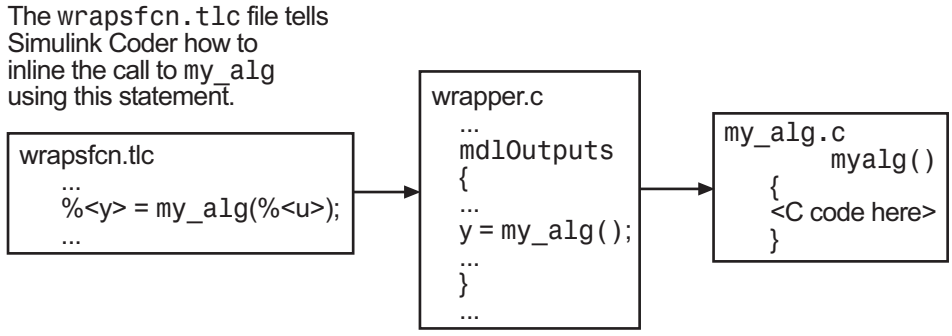
The generated code makes the call to your S-function, `wrapsfcn.c`, in `mdlOutputs` by using this code:

```
SimStruct *rts = ssGetSFunction(rtS, 0);
sfcnOutputs(rts, tid);
```

This call has computational overhead associated with it. First, the Simulink engine creates a `SimStruct` data structure for the S-Function block. Second, the code generator constructs a call through a function pointer to execute `mdlOutputs`, then `mdlOutputs`

calls `my_alg`. By inlining the call to your C/C++ algorithm, `my_alg`, you can eliminate both the `SimStruct` and the extra function call, thereby improving the efficiency and reducing the size of the generated code.

Inlining a wrapper S-function requires an *`sfunction`*`.tlc` file for the S-function (see the "Target Language Compiler" (Simulink Coder) for details). The TLC file must contain the function call to `my_alg`. The following figure shows the relationships between the algorithm, the wrapper S-function, and the *`sfunction`*`.tlc` file.



To inline this call, you have to place your function call in an *`sfunction`*`.tlc` file with the same name as the S-function (in this example, `wrapsfcn.tlc`). This causes the Target Language Compiler to override the default method of placing calls to your S-function in the generated code.

This is the `wrapsfcn.tlc` file that inlines `wrapsfcn.c`.

```
%% File    : wrapsfcn.tlc
%% Abstract:
%%      Example inlined tlc file for S-function wrapsfcn.c
%%

%implements "wrapsfcn" "C"

%% Function: BlockTypeSetup ===================================================
%% Abstract:
%%      Create function prototype in model.h as:
%%      "extern real_T my_alg(real_T u);"
%%
%function BlockTypeSetup(block, system) void
  %openfile buffer
    extern real_T my_alg(real_T u); /* This line is placed in wrapper.h */
  %closefile buffer
```

```
  %<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup

%% Function: Outputs ============================================================
%% Abstract:
%%      y = my_alg( u );
%%
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %assign u = LibBlockInputSignal(0, "", "", 0)
  %assign y = LibBlockOutputSignal(0, "", "", 0)
  %% PROVIDE THE CALLING STATEMENT FOR "algorithm"
  %% The following line is expanded and placed in mdlOutputs within wrapper.c
  %<y> = my_alg(%<u>);

%endfunction %% Outputs
```

The first section of this code inlines the `wrapsfcn` S-Function block and generates the code in C:

```
%implements "wrapsfcn" "C"
```

The next task is to tell the code generator that the routine `my_alg` needs to be declared external in the generated `wrapper.h` file for any `wrapsfcn` S-Function blocks in the model. You only need to do this once for all `wrapsfcn` S-Function blocks, so use the `BlockTypeSetup` function. In this function, you tell the Target Language Compiler to create a buffer and cache the `my_alg` as `extern` in the `wrapper.h` generated header file.

The final step is the inlining of the call to the function `my_alg`. This is done by the `Outputs` function. In this function, you access the block's input and output and place a direct call to `my_alg`. The call is embedded in `wrapper.c`.

The Inlined Code

The code generated when you inline your wrapper S-function is similar to the default generated code. The `mdlTerminate` function does not contain a call to an empty function and the `mdlOutputs` function now directly calls `my_alg`.

```
void mdlOutputs(int_T tid)
{
  /* Sin Block: <Root>/Sin */
  rtB.Sin = rtP.Sin.Amplitude *
    sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

  /* S-Function Block: <Root>/S-Function */
  rtB.S_Function = my_alg(rtB.Sin); /* Inlined call to my_alg */

  /* Outport Block: <Root>/Out */
```

```
  rtY.Out = rtB.S_Function;
}
```

In addition, `wrapper.reg` does not create a child `SimStruct` for the S-function because the generated code is calling `my_alg` directly. This eliminates over 1 KB of memory usage.

Write Fully Inlined S-Functions

Using the example from "Write Wrapper S-Function and TLC Files" (Simulink Coder), you could eliminate the call to `my_alg` entirely by specifying the explicit code (that is, `2.0 * u`) in `wrapsfcn.tlc`. This is referred to as a *fully inlined S-function*. While this can improve performance, if you are working with a large amount of C/C++ code, this can be a lengthy task. In addition, you now have to maintain your algorithm in two places, the C/C++ S-function itself and the corresponding TLC file. However, the performance gains might outweigh the disadvantages. To inline the algorithm used in this example, in the `Outputs` section of your `wrapsfcn.tlc` file, instead of writing

```
%<y> = my_alg(%<u>);
```

use

```
%<y> = 2.0 * %<u>;
```

This is the code produced in `mdlOutputs`:

```
void mdlOutputs(int_T tid)
{
  /* Sin Block: <Root>/Sin */
  rtB.Sin = rtP.Sin.Amplitude *
    sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

  /* S-Function Block: <Root>/S-Function */
  rtB.S_Function = 2.0 * rtB.Sin; /* Explicit embedding of algorithm */

  /* Outport Block: <Root>/Out */
  rtY.Out = rtB.S_Function;
}
```

The Target Language Compiler has replaced the call to `my_alg` with the algorithm itself.

Multiport S-Function

A more advanced multiport inlined S-function example is `sfun_multiport.c` and `sfun_multiport.tlc`. This S-function illustrates how to create a fully inlined TLC

file for an S-function that contains multiple ports. You might find that looking at this example helps you to understand fully inlined TLC files.

Write Fully Inlined S-Functions with mdlRTW Routine

You can inline more complex S-functions that use the S-function `mdlRTW` routine. The purpose of the `mdlRTW` routine is to provide the code generation process with more information about how the S-function is to be inlined, by creating a parameter record of a nontunable parameter for use with a TLC file. The `mdlRTW` routine does this by placing information in the *`model`*`.rtw` file. The `mdlRTW` function is described in the text file *`matlabroot`*`/simulink/src/sfuntmpl_doc.c`.

As an example of how to use the `mdlRTW` function, this topic discusses the steps you must take to create a direct-index lookup S-function. Lookup tables are collections of ordered data points of a function. Typically, these tables use some interpolation scheme to approximate values of the associated function between known data points. To incorporate the example lookup table algorithm into a Simulink model, the first step is to write an S-function that executes the algorithm in `mdlOutputs`. To produce the most efficient code, the next step is to create a corresponding TLC file to eliminate computational overhead and improve the speed of the lookup computations.

For your convenience, the Simulink product provides support for two general-purpose lookup 1-D and 2-D algorithms. You can use these algorithms as they are or create a custom lookup table S-function to fit your requirements. This topic illustrates how to create a 1-D lookup S-function, `sfun_directlook.c`, and its corresponding inlined `sfun_directlook.tlc` file (see “Target Language Compiler” (Simulink Coder) for more details). This 1-D direct-index lookup table example illustrates the following concepts that you need to know to create your own custom lookup tables:

- Error checking of S-function parameters
- Caching of information for the S-function that doesn't change during model execution
- How to use the `mdlRTW` function to customize the code generator to produce the optimal code for a given set of block parameters
- How to generate an inlined `TLC` file for an S-function in a combination of the fully inlined form and/or the wrapper form

- “S-Function RTWdata” on page 11-79
- “Direct-Index Lookup Table Algorithm” on page 11-79

S-Function RTWdata

There is a property of blocks called `RTWdata`, which can be used by the Target Language Compiler when inlining an S-function. `RTWdata` is a structure of character vectors that you can attach to a block. It is saved with the model and placed in the *`model`*`.rtw` file when generating code. For example, this set of MATLAB commands,

```
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(gcb,'RTWdata',mydata)
get_param(gcb,'RTWdata')
```

produces this result:

```
ans =

    field1: 'information for field1'
    field2: 'information for field2'
```

Inside the *`model`*`.rtw` file for the associated S-Function block is this information.

```
Block {
  Type                    "S-Function"
  RTWdata {
    field1                  "information for field1"
    field2                  "information for field2"
  }
```

Note: `RTWdata` is saved in the model file for S-functions that are not linked to a library. However, `RTWdata` is **not persistent** for S-Function blocks that are linked to a library.

Direct-Index Lookup Table Algorithm

The 1-D lookup table block provided in the Simulink library uses interpolation or extrapolation when computing outputs. This extra accuracy might not be required. In this example, you create a lookup table that directly indexes the output vector (*y*-data vector) based on the current input (*x*-data) point.

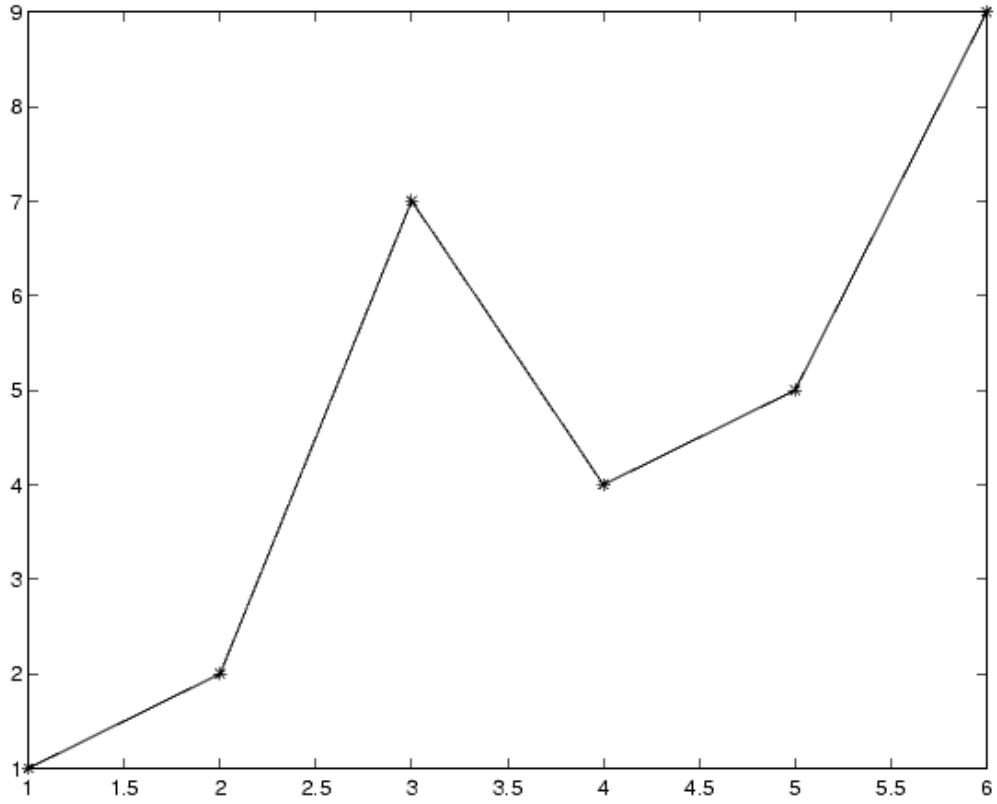
This direct 1-D lookup example computes an approximate solution *p(x)* to a partially known function *f(x)* at *x=x0*, given data point pairs *(x,y)* in the form of an *x*-data vector and a *y*-data vector. For a given data pair (for example, the *i'th* pair), *y_i = f(x_i)*. It is assumed that the *x*-data values are monotonically increasing. If *x0* is outside the range of the *x*-data vector, the first or last point is returned.

The parameters to the S-function are

```
XData, YData, XEvenlySpaced
```

`XData` and `YData` are double vectors of equal length representing the values of the unknown function. `XDataEvenlySpaced` is a scalar, `0.0` for false and `1.0` for true. If the `XData` vector is evenly spaced, `XDataEvenlySpaced` is `1.0` and more efficient code is generated.

The following graph shows how the parameters `XData=[1:6]` and `YData=[1,2,7,4,5,9]` are handled. For example, if the input (*x*-value) to the S-Function block is 3, the output (*y*-value) is 7.



Direct-Index Lookup Table Example

This topic shows how to improve the lookup table by inlining a direct-index S-function with a TLC file. This direct-index lookup table S-function does not require a TLC file. Here the example uses a TLC file for the direct-index lookup table S-function to reduce the code size and increase efficiency of the generated code.

Implementation of the direct-index algorithm with inlined TLC file requires the S-function main module, `sfun_directlook.c`, and a corresponding `lookup_index.c` module. The `lookup_index.c` module contains the `GetDirectLookupIndex` function that is used to locate the index in the `XData` for the current `x` input value when the `XData` is unevenly spaced. The `GetDirectLookupIndex` routine is called from both the S-function and the generated code. Here the example uses the wrapper concept for sharing C/C++ code between Simulink MEX-files and the generated code.

If the `XData` is evenly spaced, then both the S-function main module and the generated code contain the lookup algorithm (not a call to the algorithm) to compute the *y*-value of a given *x*-value, because the algorithm is short. This illustrates the use of a fully inlined S-function for generating optimal code.

The inlined TLC file, which either performs a wrapper call or embeds the optimal C/C++ code, is `sfun_directlook.tlc` (see the example in “mdlRTW Usage” on page 11-82).

Error Handling

In this example, the `mdlCheckParameters` routine verifies that

- The new parameter settings are valid.
- `XData` and `YData` are vectors of the same length containing real finite numbers.
- `XDataEvenlySpaced` is a scalar.
- The `XData` vector is a monotonically increasing vector and evenly spaced.

The `mdlInitializeSizes` function explicitly calls `mdlCheckParameters` after it verifies the number of parameters passed to the S-function. After the Simulink engine calls `mdlInitializeSizes`, it then calls `mdlCheckParameters` whenever you change the parameters or there is a need to reevaluate them.

User Data Caching

The `mdlStart` routine shows how to cache information that does not change during the simulation (or while the generated code is executing). The example caches the value

of the `XDataEvenlySpaced` parameter in `UserData`, a field of the `SimStruct`. The following line in `mdlInitializeSizes` tells the Simulink engine to disallow changes to `XDataEvenlySpaced`.

```
ssSetSFcnParamTunable(S, iParam, SS_PRM_NOT_TUNABLE);
```

During execution, `mdlOutputs` accesses the value of `XDataEvenlySpaced` from `UserData` rather than calling the `mxGetPr` MATLAB API function.

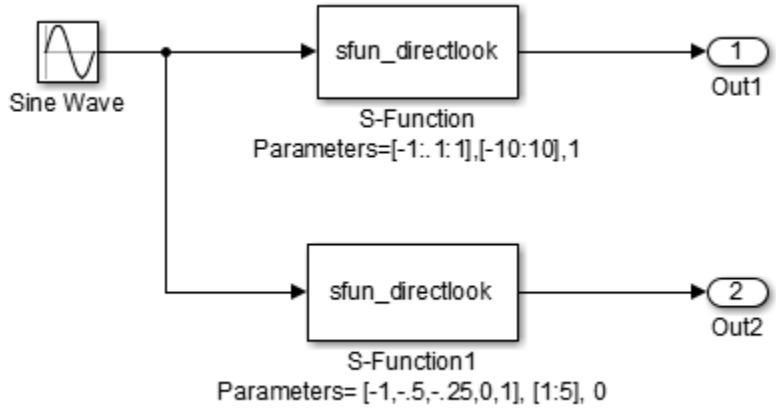
mdlRTW Usage

The code generator calls the `mdlRTW` routine while generating the *`model`*`.rtw` file. To produce optimal code for your Simulink model, you can add information to the *`model`*`.rtw` file about the mode in which your S-Function block is operating.

The following example adds parameter settings to the *`model`*`.rtw` file. The parameter settings do not change during execution. In this case, the `XDataEvenlySpaced` S-function parameter cannot change during execution (`ssSetSFcnParamTunable` was specified as false (`0`) for it in `mdlInitializeSizes`). The example writes it out as a parameter setting (`XSpacing`) using the function `ssWriteRTWParamSettings`.

Because `xData` and `yData` are registered as run-time parameters in `mdlSetWorkWidths`, the code generator handles writing to the *`model`*`.rtw` file automatically.

Before examining the S-function and the inlined TLC file, consider the generated code for the following model.



The model uses evenly spaced `XData` in the top S-Function block and unevenly spaced `XData` in the bottom S-Function block. When creating this model, you need to specify the following for each S-Function block.

```
set_param(`sfun_directlook_ex/S-Function','SFunctionModules','lookup_index')
set_param(`sfun_directlook_ex/S-Function1','SFunctionModules','lookup_index')
```

This informs the build process to use the module `lookup_index.c` when creating the executable.

When generating code for this model, the code generator uses the S-function `mdlRTW` method to generate a *`model`*`.rtw` file with the value `EvenlySpaced` for the `XSpacing` parameter for the top S-Function block, and the value `UnEvenlySpaced` for the `XSpacing` parameter for the bottom S-Function block. The TLC-file uses the value of `XSpacing` to determine what algorithm to include in the generated code. The generated code contains the lookup algorithm when the `XData` is evenly spaced, but calls the `GetDirectLookupIndex` routine when the `XData` is unevenly spaced. The generated *`model`*`.c` or *`model`*`.cpp` code for the lookup table example model is similar to the following:

```
/*
 * sfun_directlook_ex.c
 *
 * Code generation for Simulink model
 * "sfun_directlook_ex.slx".
 *
...
 */

#include "sfun_directlook_ex.h"

Guidelines for Writing Inlined S-Functions

- Consider using the block property `RTWdata` (see "S-Function RTWdata" (Simulink Coder)). This property is a structure of character vectors that you can associate with a block. The code generator saves the structure with the model in the *`model`*`.rtw` file and makes the `.rtw` file more readable. For example, suppose you enter the following commands in the MATLAB Command Window:

  ```
  mydata.field1 = 'information for field1';
  mydata.field2 = 'information for field2';
  set_param(sfun_block, 'RTWdata', mydata);
  ```

  The `.rtw` file that the code generator produces for the block includes the comments specified in the structure `mydata`.
- Consider using the `mdlRTW` function to inline your C MEX S-function in the generated code. This is useful when you want to
  - Rename tunable parameters in the generated code
  - Introduce nontunable parameters into a TLC file

S-Functions That Support Expression Folding

About S-Functions that Support Expression Folding

This topic describes how you can take advantage of expression folding to increase the efficiency of code generated by your own inlined S-Function blocks, by calling macros provided in the S-Function API. This topic assumes that you are familiar with:

- Writing inlined S-functions (see "S-Function Basics" (Simulink)).
- "Target Language Compiler" (Simulink Coder)

The S-Function API lets you specify whether a given S-Function block should nominally accept expressions at a given input port. A block should not always accept expressions. For example, if the address of the signal at the input is used, expressions should not be accepted at that input, because it is not possible to take the address of an expression.

The S-Function API also lets you specify whether an expression can represent the computations associated with a given output port. When you request an expression at a block's input or output port, the Simulink engine determines whether or not it can honor that request, given the block's context. For example, the engine might deny a block's request to output an expression if the destination block does not accept expressions at its input, if the destination block has an update function, or if multiple output destinations exist.

The decision to honor or deny a request to output an expression can also depend on the category of output expression the block uses (see "Categories of Output Expressions" on page 11-98).

The topics that follow explain

- When and how you can request that a block accept expressions at an input port
- When and how you can request that a block generate expressions at an outport
- The conditions under which the Simulink engine will honor or deny such requests

To take advantage of expression folding in your S-functions, you should understand when to request acceptance and generation of expressions for specific blocks. You do not have to understand the algorithm by which the Simulink engine chooses to accept or deny these requests. However, if you want to trace between the model and the generated code, it is helpful to understand some of the more common situations that lead to denial of a request.

Categories of Output Expressions

When you implement a C MEX S-function, you can specify whether the code corresponding to a block's output is to be generated as an expression. If the block generates an expression, you must specify that the expression is *constant*, *trivial*, or *generic*.

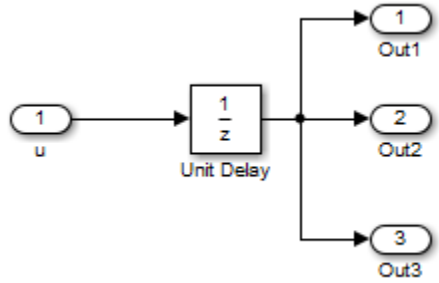
A *constant* output expression is a direct access to one of the block's parameters. For example, the output of a Constant block is defined as a constant expression because the output expression is simply a direct access to the block's `Value` parameter.

A *trivial* output expression is an expression that can be repeated, without a performance penalty, when the output port has multiple output destinations. For example, the output of a Unit Delay block is defined as a trivial expression because the output expression is simply a direct access to the block's state. Because the output expression does not have computations, it can be repeated more than once without degrading the performance of the generated code.

A *generic* output expression is an expression that should be assumed to have a performance penalty if repeated. As such, a generic output expression is not suitable for repeating when the output port has multiple output destinations. For instance, the output of a Sum block is a generic rather than a trivial expression because it is costly to recompute a Sum block output expression as an input to multiple blocks.

Examples of Trivial and Generic Output Expressions

Consider the following block diagram. The Delay block has multiple destinations, yet its output is designated as a trivial output expression, so that it can be used more than once without degrading the efficiency of the code.



The following code excerpt shows code generated from the Unit Delay block in this block diagram. The three root outputs are directly assigned from the state of the Unit Delay block, which is stored in a field of the global data structure `rtDWork`. Since the assignment is direct, without expressions, there is no performance penalty associated with using the trivial expression for multiple destinations.

```
void MdlOutputs(int_T tid)
{
   ...
  /* Outport: <Root>/Out1 incorporates:

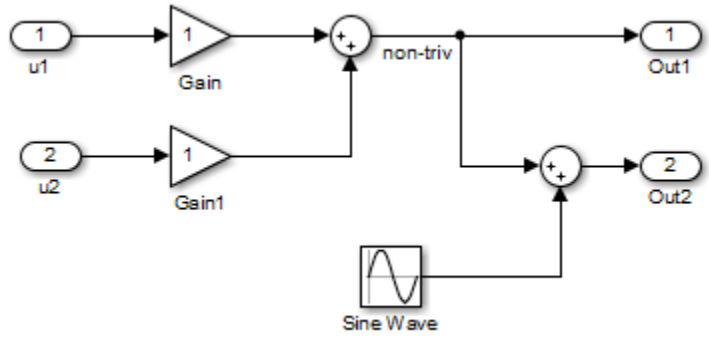
   *   UnitDelay: <Root>/Unit Delay */
  rtY.Out1 = rtDWork.Unit_Delay_DSTATE;

  /* Outport: <Root>/Out2 incorporates:
   *   UnitDelay: <Root>/Unit Delay */
  rtY.Out2 = rtDWork.Unit_Delay_DSTATE;

  /* Outport: <Root>/Out3 incorporates:
   *   UnitDelay: <Root>/Unit Delay */
  rtY.Out3 = rtDWork.Unit_Delay_DSTATE;
```

```
    ...
}
```

On the other hand, consider the Sum blocks in the following model:



The upper Sum block in the preceding model generates the signal labeled `non_triv`. Computation of this output signal involves two multiplications and an addition. If the Sum block's output were permitted to generate an expression even when the block had multiple destinations, the block's operations would be duplicated in the generated code. In the case illustrated, the generated expressions would proliferate to four multiplications and two additions. This would degrade the efficiency of the program. Accordingly the output of the Sum block is not allowed to be an expression because it has multiple destinations

The code generated for the previous block diagram shows how code is generated for Sum blocks with single and multiple destinations.

The Simulink engine does not permit the output of the upper Sum block to be an expression because the signal `non_triv` is routed to two output destinations. Instead, the result of the multiplication and addition operations is stored in a temporary variable `(rtb_non_triv)` that is referenced twice in the statements that follow, as seen in the code excerpt below.

In contrast, the lower Sum block, which has only a single output destination (`Out2`), does generate an expression.

```
void MdlOutputs(int_T tid)
{
  /* local block i/o variables */
  real_T rtb_non_triv;
```

```
  real_T rtb_Sine_Wave;

  /* Sum: <Root>/Sum incorporates:
   *   Gain: <Root>/Gain
   *   Inport: <Root>/u1
   *   Gain: <Root>/Gain1
   *   Inport: <Root>/u2
   *
   * Regarding <Root>/Gain:
   *   Gain value: rtP.Gain_Gain
   *
   * Regarding <Root>/Gain1:
   *   Gain value: rtP.Gain1_Gain
   */
  rtb_non_triv = (rtP.Gain_Gain * rtU.u1) + (rtP.Gain1_Gain *
rtU.u2);

  /* Outport: <Root>/Out1 */
  rtY.Out1 = rtb_non_triv;

  /* Sin Block: <Root>/Sine Wave */

  rtb_Sine_Wave = rtP.Sine_Wave_Amp *
 sin(rtP.Sine_Wave_Freq * rtmGetT(rtM_model) +
 rtP.Sine_Wave_Phase) + rtP.Sine_Wave_Bias;

  /* Outport: <Root>/Out2 incorporates:
   *   Sum: <Root>/Sum1
   */
  rtY.Out2 = (rtb_non_triv + rtb_Sine_Wave);
}
```

Specify the Category of an Output Expression

The S-Function API provides macros that let you declare whether an output of a block should be an expression, and if so, to specify the category of the expression. The following table specifies when to declare a block output to be a constant, trivial, or generic output expression.

Types of Output Expressions

Category of Expression	When to Use
Constant	Use only if block output is a direct memory access to a block parameter.
Trivial	Use only if block output is an expression that can appear multiple times in the code without reducing efficiency (for example, a direct memory access to a field of the `DWork` vector, or a literal).
Generic	Use if output is an expression, but not constant or trivial.

You must declare outputs as expressions in the `mdlSetWorkWidths` function using macros defined in the S-Function API. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx:` zero-based index of the output port.
- `bool value:` pass in TRUE if the port generates output expressions.

The following macros are available for setting an output to be a constant, trivial, or generic expression:

- `void ssSetOutputPortConstOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortOutputExprInRTW(SimStruct *S, int idx, bool value)`

The following macros are available for querying the status set by prior calls to the macros above:

- `bool ssGetOutputPortConstOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortOutputExprInRTW(SimStruct *S, int idx)`

The set of generic expressions is a superset of the set of trivial expressions, and the set of trivial expressions is a superset of the set of constant expressions.

Therefore, when you query an output that has been set to be a constant expression with `ssGetOutputPortTrivialOutputExprInRTW`, it returns `True`. A constant expression is considered a trivial expression, because it is a direct memory access that can be repeated without degrading the efficiency of the generated code.

Similarly, an output that has been configured to be a constant or trivial expression returns `True` when queried for its status as a generic expression.

Acceptance or Denial of Requests for Input Expressions

A block can request that its output be represented in code as an expression. Such a request can be denied if the destination block cannot accept expressions at its input port. Furthermore, conditions independent of the requesting block and its destination blocks can prevent acceptance of expressions.

This topic discusses block-specific conditions under which requests for input expressions are denied. For information on other conditions that prevent acceptance of expressions, see “Denial of Block Requests to Output Expressions” on page 11-104.

A block should not be configured to accept expressions at its input port under the following conditions:

- The block must take the address of its input data. It is not possible to take the address of most types of input expressions.
- The code generated for the block references the input more than once (for example, the Abs or Max blocks). This would lead to duplication of a potentially complex expression and a subsequent degradation of code efficiency.

If a block refuses to accept expressions at an input port, then a block that is connected to that input port is not permitted to output a generic or trivial expression.

A request to output a constant expression is not denied, because there is no performance penalty for a constant expression, and the software can take the parameter’s address.

S-Function API to Specify Input Expression Acceptance

The S-Function API provides macros that let you:

- Specify whether a block input should accept nonconstant expressions (that is, trivial or generic expressions)
- Query whether a block input accepts nonconstant expressions

By default, block inputs do not accept nonconstant expressions.

You should call the macros in your `mdlSetWorkWidths` function. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's SimStruct.
- `int idx:` zero-based index of the input port.
- `bool value:` pass in TRUE if the port accepts input expressions; otherwise pass in FALSE.

The macro available for specifying whether or not a block input should accept a nonconstant expression is as follows:

```
void ssSetInputPortAcceptExprInRTW(SimStruct *S, int portIdx, bool value)
```

The corresponding macro available for querying the status set by any prior calls to `ssSetInputPortAcceptExprInRTW` is as follows:

```
bool ssGetInputPortAcceptExprInRTW(SimStruct *S, int portIdx)
```

Denial of Block Requests to Output Expressions

Even after a specific block requests that it be allowed to generate an output expression, that request can be denied for generic reasons. These reasons include, but are not limited to

- The output expression is nontrivial, and the output has multiple destinations.
- The output expression is nonconstant, and the output is connected to at least one destination that does not accept expressions at its input port.
- The output is a test point.
- The output has been assigned an external storage class.
- The output must be stored using global data (for example is an input to a merge block or a block with states).
- The output signal is complex.

You do not need to consider these generic factors when deciding whether or not to utilize expression folding for a particular block. However, these rules can be helpful when you are examining generated code and analyzing cases where the expression folding optimization is suppressed.

Expression Folding in a TLC Block Implementation

To take advantage of expression folding, you must modify the TLC block implementation of an inlined S-Function such that it informs the Simulink engine whether it generates or accepts expressions at its

- Input ports, as explained in "S-Function API to Specify Input Expression Acceptance" on page 11-103.
- Output ports, as explained in "Categories of Output Expressions" on page 11-98.

This topic discusses required modifications to the TLC implementation.

Expression Folding Compliance

In the `BlockInstanceSetup` function of your S-function, register your block to be compliant with expression folding. Otherwise, expression folding requested or allowed at the block's outputs or inputs will be disabled, and temporary variables will be used.

To register expression folding compliance, call the TLC library function `LibBlockSetIsExpressionCompliant(block)`, which is defined in matlabroot/rtw/c/tlc/lib/utillib.tlc. For example:

```
%% Function: BlockInstanceSetup ===========================================
%%
%function BlockInstanceSetup(block, system) void
  %%
  %<LibBlockSetIsExpressionCompliant(block)>
  %%
%endfunction
```

You can conditionally disable expression folding at the inputs and outputs of a block by making the call to this function conditionally.

If you override one of the TLC block implementations provided by the code generator with your own implementation, you should not make the preceding call until you have updated your implementation, as described by the guidelines for expression folding in the following topics.

Output Expressions

The `BlockOutputSignal` function is used to generate code for a scalar output expression or one element of a nonscalar output expression. If your block outputs an expression, you should add a `BlockOutputSignal` function. The prototype of the `BlockOutputSignal` is

```
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
```

The arguments to `BlockOutputSignal` are as follows:

- `block`: the record for the block for which an output expression is being generated
- `system`: the record for the system containing the block
- `portIdx`: zero-based index of the output port for which an expression is being generated
- `ucv`: user control variable defining the output element for which code is being generated
- `lcv`: loop control variable defining the output element for which code is being generated
- `idx`: signal index defining the output element for which code is being generated
- `retType`: character vector defining the type of signal access desired:

  `"Signal"` specifies the contents or address of the output signal.

`"SignalAddr"` specifies the address of the output signal

The `BlockOutputSignal` function returns a character vector for the output signal or address. The character vector should enforce the precedence of the expression by using opening and terminating parentheses, unless the expression consists of a function call. The address of an expression can only be returned for a constant expression; it is the address of the parameter whose memory is being accessed. The code implementing the `BlockOutputSignal` function for the Constant block is shown below.

```
%% Function: BlockOutputSignal ================================================
%% Abstract:
%%      Return the reference to the parameter.  This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
  %switch retType
    %case "Signal"
      %return LibBlockParameter(Value,ucv,lcv,idx)
    %case "SignalAddr"
      %return LibBlockParameterAddr(Value,ucv,lcv,idx)
    %default
      %assign errTxt = "Unsupported return type: %<retType>"
      %<LibBlockReportError(block,errTxt)>
  %endswitch
%endfunction
```

The code implementing the `BlockOutputSignal` function for the Relational Operator block is shown below.

```
%% Function: BlockOutputSignal ================================================
%% Abstract:
%%      Return an output expression.  This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
%assign logicOperator = ParamSettings.Operator
 %if ISEQUAL(logicOperator, "~=")
 %assign op = "!="
elseif ISEQUAL(logicOperator, "==") %assign op = "=="
  %else
%assign op = logicOperator
%endif
 %assign u0 = LibBlockInputSignal(0, ucv, lcv, idx)
%assign u1 = LibBlockInputSignal(1, ucv, lcv, idx)
  %return "(%<u0> %<op> %<u1>)"
 %default
 %assign errTxt = "Unsupported return type: %<retType>"
 %<LibBlockReportError(block,errTxt)>
%endswitch
```

```
%endfunction
```

Expression Folding for Blocks with Multiple Outputs

When a block has a single output, the `Outputs` function in the block's TLC file is called only if the output port is not an expression. Otherwise, the `BlockOutputSignal` function is called.

If a block has multiple outputs, the `Outputs` function is called if any output port is not an expression. The `Outputs` function should guard against generating code for output ports that are expressions. This is achieved by guarding sections of code corresponding to individual output ports with calls to `LibBlockOutputSignalIsExpr()`.

For example, consider an S-Function with two inputs and two outputs, where

- The first output, y0, is equal to two times the first input.
- The second output, y1, is equal to four times the second input.

The `Outputs` and `BlockOutputSignal` functions for the S-function are shown in the following code excerpt.

```
%% Function: BlockOutputSignal ================================================
%% Abstract:
%%      Return an output expression.  This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
   %assign u = LibBlockInputSignal(portIdx, ucv, lcv, idx)
 %case "Signal"
 %if portIdx == 0
  %return "(2 * %<u>)"
%elseif portIdx == 1
 %return "(4 * %<u>)"
%endif
%default
%assign errTxt = "Unsupported return type: %<retType>"
 %<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
%%
%% Function: Outputs ==========================================================
%% Abstract:
%%      Compute output signals of block
%%
%function Outputs(block,system) Output
%assign rollVars = ["U", "Y"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%assign u0 = LibBlockInputSignal(0, "", lcv, sigIdx)
 %assign u1 = LibBlockInputSignal(1, "", lcv, sigIdx)
```

```
 %assign y0 = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %assign y1 = LibBlockOutputSignal(1, "", lcv, sigIdx)
%if !LibBlockOutputSignalIsExpr(0)
%<y0> = 2 * %<u0>;
%endif
%if !LibBlockOutputSignalIsExpr(1)
 %<y1> = 4 * %<u1>;
%endif
%endroll
%endfunction
```

Comments for Blocks That Are Expression-Folding-Compliant

In the past, blocks preceded their outputs code with comments of the form

```
/* %<Type> Block: %<Name> */
```

When a block is expression-folding-compliant, the initial line shown above is generated automatically. You should not include the comment as part of the block's TLC implementation. Additional information should be registered using the `LibCacheBlockComment` function.

The `LibCacheBlockComment` function takes a character vector as an input, defining the body of the comment, except for the opening header, the final newline of a single or multiline comment, and the closing trailer.

The following TLC code illustrates registering a block comment. Note the use of the function `LibBlockParameterForComment`, which returns a character vector, suitable for a block comment, specifying the value of the block parameter.

```
%openfile commentBuf
  $c(*) Gain value: %<LibBlockParameterForComment(Gain)>
  %closefile commentBuf
  %<LibCacheBlockComment(block, commentBuf)>
```

S-Functions That Specify Port Scope and Reusability

You can use the following `SimStruct` macros in the `mdlInitializeSizes` method to specify the scope and reusability of the memory used for your S-function's input and output ports:

- `ssSetInputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function input port
- `ssSetOutputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function output port
- `ssSetInputPortOverWritable`: Specify whether one of your S-function's input ports can be overwritten by one of its output ports

- `ssSetOutputPortOverwritesInputPort`: Specify whether an output port can share its memory buffer with an input port

You declare an input or output as local or global, and indicate its reusability, by passing one of the following four options to the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros:

- `SS_NOT_REUSABLE_AND_GLOBAL`: Indicates that the input and output ports are stored in separate memory locations in the global block input and output structure
- `SS_NOT_REUSABLE_AND_LOCAL`: Indicates that the code generator can declare individual local variables for the input and output ports
- `SS_REUSABLE_AND_LOCAL`: Indicates that the code generator can reuse a single local variable for these input and output ports
- `SS_REUSABLE_AND_GLOBAL`: Indicates that these input and output ports are stored in a single element in the global block input and output structure

---

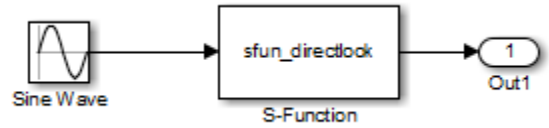
Note Marking an input or output port as a local variable does not imply that the code generator uses a local variable in the generated code. If your S-function accesses the inputs and outputs only in its `mdlOutputs` routine, the code generator declares the inputs and outputs as local variables. However, if the inputs and outputs are used elsewhere in the S-function, the code generator includes them in the global block input and output structure.

The reusability setting indicates if the memory associated with an input or output port can be overwritten. To reuse input and output port memory:

1. Indicate the ports are reusable using either the `SS_REUSABLE_AND_LOCAL` or `SS_REUSABLE_AND_GLOBAL` option in the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros
2. Indicate the input port memory is overwritable using `ssSetInputPortOverWritable`
3. If your S-function has multiple input and output ports, use `ssSetOutputPortOverwritesInputPort` to indicate which output and input ports share memory

The following example shows how different scope and reusability settings affect the generated code. The following model contains an S-function block pointing to the C

MEX S-function *matlabroot*`/toolbox/simulink/simdemos/simfeatures/src/sfun_directlook.c`, which models a direct 1-D lookup table.



The S-function's `mdlInitializeSizes` method declares the input port as reusable, local, and overwritable and the output port as reusable and local, as follows:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* snip */
    ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);
    ssSetInputPortOverWritable(S, 0, TRUE);

/* snip */
    ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);

/* snip */
}
```

The generated code for this model stores the input and output signals in a single local variable `rtb_SFunction`, as shown in the following output function:

```
static void sl_directlook_output(int_T tid)
{
  /* local block i/o variables */
  real_T rtb_SFunction[2];

  /* Sin: '<Root>/Sine Wave' */
  rtb_SFunction[0] = sin(((real_T)sl_directlook_DWork.counter[0] +
    sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
    sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[0] +
    sl_directlook_P.SineWave_Bias;
  rtb_SFunction[1] = sin(((real_T)sl_directlook_DWork.counter[1] +
    sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
    sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[1] +
    sl_directlook_P.SineWave_Bias;

  /* S-Function Block: <Root>/S-Function */
  {
    const real_T *xData = &sl_directlook_P.SFunction_XData[0];
    const real_T *yData = &sl_directlook_P.SFunction_YData [0];
    real_T spacing = xData[1] - xData[0];
    if (rtb_SFunction[0] <= xData[0] ) {
      rtb_SFunction[0] = yData[0];
    } else if (rtb_SFunction[0] >= yData[20] ) {
```

```
      rtb_SFunction[0] = yData[20];
    } else {
      int_T idx = (int_T)( ( rtb_SFunction[0] - xData[0] ) / spacing );
      rtb_SFunction[0] = yData[idx];
    }

    if (rtb_SFunction[1] <= xData[0] ) {
      rtb_SFunction[1] = yData[0];
    } else if (rtb_SFunction[1] >= yData[20] ) {
      rtb_SFunction[1] = yData[20];
    } else {
      int_T idx = (int_T)( ( rtb_SFunction[1] - xData[0] ) / spacing );
      rtb_SFunction[1] = yData[idx];
    }
  }

  /* Outport: '<Root>/Out1' */
  sl_directlook_Y.Out1[0] = rtb_SFunction[0];
  sl_directlook_Y.Out1[1] = rtb_SFunction[1];
  UNUSED_PARAMETER(tid);
}
```

The following table shows variations of the code generated for this model when using the generic real-time target (GRT). Each row explains a different setting for the scope and reusability of the S-function's input and output ports.

Scope and reusability	S-function `mdlInitializeSizes` code	Generated code

Inputs: Local, reusable, overwritable
 	
Outputs: Local, reusable
	`ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);`
	
	`ssSetInputPortOverWritable(S, 0, TRUE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);`
		The *`model`*`.c` file declares a local variable in the output function.
		
		`/* local block i/o variables */`
		`  real_T rtb_SFunction[2];`

Inputs: Global, reusable, overwritable
 	
Outputs: Global, reusable
	`ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_GLOBAL);`
	
	`ssSetInputPortOverWritable(S, 0, TRUE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_GLOBAL);`
		The *`model`*`.h` file defines a block signals structure with a single element to store the S-function's input and output.
		
		`/* Block signals (auto storage) */`
		`typedef struct {`
		`  real_T SFunction[2];`
		`} BlockIO_sl_directlook;`
		The *`model`*`.c` file uses this element of the structure in calculations of the S-function's input and output signals.
		
		`/* Sin: '<Root>/Sine Wave' */`

Scope and reusability	S-function `mdlInitializeSizes` code	Generated code

		`sl_directlook_B.SFunction[0] = sin ...`
		`/* snip */`
		`/*S-Function Block:<Root>/S-Function*/`
		`{`
		`const real_T *xData =`
		`  &sl_directlook_P.SFunction_XData[0]`

Inputs: Local, not reusable
 	
Outputs: Local, not reusable
	`ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);`
	
	`ssSetInputPortOverWritable(S, 0, FALSE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);`
		The *`model`*`.c` file declares local variables for the S-function's input and output in the output function
		
		`/* local block i/o variables */`
		`  real_T rtb_SineWave[2];`
		`  real_T rtb_SFunction[2];`

Inputs: Global, not reusable
 	
Outputs: Global, not reusable
	`ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);`
	
	`ssSetInputPortOverWritable(S, 0, FALSE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);`
		The *`model`*`.h` file defines a block signal structure with individual elements to store the S-function's input and output.
		
		`/* Block signals (auto storage) */`
		`typedef struct {`

		`/* snip */`
		`/*S-Function Block:<Root>/S-Function*/`
		`{`
		`const real_T *xData =`
		`  &sl_directlook_P.SFunction_XData[0]`

S-Functions That Specify Sample Time Inheritance Rules

For the Simulink engine to determine whether a model can inherit a sample time, the S-functions in the model need to specify how they use sample times. You can specify this information by calling the macro `ssSetModelReferenceSampleTimeInheritanceRule` from `mdlInitializeSizes` or `mdlSetWorkWidths`. To use this macro:

1 Check whether the S-function calls any of the following macros:

- `ssGetSampleTime`
- `ssGetInputPortSampleTime`
- `ssGetOutputPortSampleTime`
- `ssGetInputPortOffsetTime`
- `ssGetOutputPortOffsetTime`
- `ssGetSampleTimePtr`
- `ssGetInputPortSampleTimeIndex`
- `ssGetOutputPortSampleTimeIndex`
- `ssGetSampleTimeTaskID`
- `ssGetSampleTimeTaskIDPtr`

2 Check for the following in your S-function TLC code:

- `LibBlockSampleTime`
- `CompiledModel.SampleTime`
- `LibBlockInputSignalSampleTime`
- `LibBlockInputSignalOffsetTime`
- `LibBlockOutputSignalSampleTime`
- `LibBlockOutputSignalOffsetTime`

3 Depending on your search results, use `ssSetModelReferenceSampleTimeInheritanceRule` as indicated in the following table.

If...	Use...
None of the macros or functions are present, the S-function does not preclude the model from inheriting a sample time.	`ssSetModelReferenceSampleTimeInheritanceRule (S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE)`
Any of the macros or functions are used for • Throwing errors if sample time is inherited, continuous, or constant	`ssSetModelReferenceSampleTimeInheritanceRule... (S,USE_DEFAULT_FOR_DISCRETE_INHERITANCE)`

If...	Use...
• Checking `ssIsSampleHit` • Checking whether sample time is inherited in either `mdlSetInputPortSampleTime` or `mdlSetOutputPortSampleTim` before setting	
The S-function uses its sample time for computing parameters, outputs, and so on	`ssSetModelReferenceSampleTimeInheritanceRule (S, DISALLOW_SAMPLE_TIME_INHERITANCE)`

Note If an S-function does not set the `ssSetModelReferenceSampleTimeInheritanceRule` macro, by default the Simulink engine assumes that the S-function does not preclude the model containing that S-function from inheriting a sample time. However, the engine issues a warning indicating that the model includes S-functions for which this macro is not set.

You can use settings on the **All Parameters** pane of the Configuration Parameters dialog box or Model Explorer to control how the Simulink engine responds when it encounters S-functions that have unspecified sample time inheritance rules. Toggle the **Unspecified inheritability of sample time** diagnostic to `none`, `warning`, or `error`. The default is `warning`.

S-Functions That Support Code Reuse

You can reuse the generated code for identical subsystems that occur in multiple instances within a model and across referenced models. For more information about code generation of subsystems for code reuse, see "Code Generation of Subsystems" (Simulink Coder). If you want your S-function to support code reuse for a subsystem, the S-function must meet the following requirements:

- The S-function must be inlined.
- Code generated from the S-function must not use static variables.
- The S-function must initialize its pointer work vector in `mdlStart` and not before.
- The S-function must not be a sink that logs data to the workspace.

- The S-function must register its parameters as run-time parameters in `mdlSetWorkWidths`. (It must not use `ssWriteRTWParameters` in its `mdlRTW` function for this purpose.)
- The S-function must not be a device driver.

In addition to meeting the preceding requirements, your S-function must set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag (see the description of `ssSetOptions` in the Simulink Writing S-Function documentation). This flag indicates that your S-function meets the requirements for subsystem code reuse.

S-Functions for Multirate Multitasking Environments

About S-Functions for Multirate Multitasking Environments

S-functions can be used in models with multiple sample rates and deployed in multitasking target environments. Likewise, S-functions themselves can have multiple rates at which they operate. The code generator produces code for multirate multitasking models using an approach called *rate grouping*. In code generated for ERT-based targets, rate grouping generates separate *`model`*`_step` functions for the base rate task and each subrate task in the model. Although rate grouping is a code generation feature found in ERT targets only, your S-functions can use it in other contexts when you code them as explained below.

Rate Grouping Support in S-Functions

To take advantage of rate grouping, you must inline your multirate S-functions if you have not done so. You need to follow certain Target Language Compiler protocols to exploit rate grouping. Coding TLC to exploit rate grouping does not prevent your inlined S-functions from functioning properly in GRT. Likewise, your inlined S-functions will still generate valid ERT code even if you do not make them rate-grouping-compliant. If you do so, however, they will generate more efficient code for multirate models.

For instructions and examples of Target Language Compiler code illustrating how to create and upgrade S-functions to generate rate-grouping-compliant code, see "Rate Grouping Compliance and Compatibility Issues" on page 49-17.

For each multirate S-function that is not rate grouping-compliant, the code generator issues the following warning when you build:

```
Warning:  Simulink Coder: Code of output function for multirate block
'<Root>/S-Function' is guarded by sample hit checks rather than being rate
grouped. This will generate the same code for all rates used by the block,
possibly generating dead code. To avoid dead code, you must update the TLC
file for the block.
```

You will also find a comment such as the following in code generated for each noncompliant S-function:

```
/* Because the output function of multirate block
   <Root>/S-Function is not rate grouped,
   the following code might contain unreachable blocks of code.
   To avoid this, you must update your block TLC file. */
```

The words “update function” are substituted for “output function” in these warnings.

Create Multitasking, Multirate, Port-Based Sample Time S-Functions

The following instructions show how to support both data determinism and data integrity in multirate S-functions. They do not cover cases where there is no determinism nor integrity. Support for frame-based processing does not affect the requirements.

Note The slow rates must be multiples of the fastest rate. The instructions do not apply when two rates being interfaced are not multiples or when the rates are not periodic.

Rules for Properly Handling Fast-to-Slow Transitions

The rules that multirate S-functions should observe for inputs are

- The input should only be read at the rate that is associated with the input port sample time.
- Generally, the input data is written to `DWork`, and the `DWork` can then be accessed at the slower (downstream) rate.

The input can be read at every sample hit of the input rate and written into `DWork` memory, but this `DWork` memory cannot then be directly accessed by the slower rate. `DWork` memory that will be read by the slow rate must only be written by the fast rate when there is a *special sample hit*. A special sample hit occurs when both this input port rate and rate to which it is interfacing have a hit. Depending on their requirements and design, algorithms can process the data in several locations.

The rules that multirate S-functions should observe for outputs are

- The output should not be written by a rate other than the rate assigned to the output port, except in the optimized case described below.
- The output should always be written when the sample rate of the output port has a hit.

If these conditions are met, the S-Function block can specify that the input port and output port can both be made local and reusable.

You can include an optimization when little or no processing needs to be done on the data. In such cases, the input rate code can directly write to the output (instead of by using DWork) when there is a special sample hit. If you do this, however, you must declare the outport port to be *global* and *not reusable*. This optimization results in one less `memcpy` but does introduce nonuniform processing requirements on the faster rate.

Whether you use this optimization or not, the most recent input data, as seen by the slower rate, is the value when both the faster and slower rate had their hits (and possible earlier input data as well, depending on the algorithm). Subsequent steps by the faster rate and the associated input data updates are not seen by the slower rate until the next hit for the slow rate occurs.

Pseudocode Examples of Fast-to-Slow Rate Transition

The pseudocode below abstracts how you should write your C MEX code to handle fast-to-slow transitions, illustrating with an input rate of 0.1 second driving an output rate of one second. A similar approach can be taken when inlining the code. The block has following characteristics:

- File: `sfun_multirate_zoh.c`, Equation: `y = u(tslow)`
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSepcialSampleHit("1")) {
        DWork = u;
    }
}
if (ssIsSampleHit("1")) {
    y = DWork;
}
```

An alternative, slightly optimized approach for simple algorithms:

- Input: local and reusable
- Output: global and not reusable because it needs to persist between special sample hits
- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        y = u;
    }
}
```

Example adding a simple algorithm:

- File: `sfun_multirate_avg.c`; Equation: `y = average(u)`
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

  (Assume `DWork[0:10]` and `DWork[mycounter]` are initialized to zero)

```
OutputFcn
if (ssIsSampleHit(".1")) {
    /* In general, processing on 'u' could be done here,
        it runs on every hit of the fast rate. */
    DWork[DWork[mycounter]++] = u;
    if (ssIsSpecialSampleHit("1")) {
    /* In general, processing on DWork[0:10] can be done
       here, but it does cause the faster rate to have
       nonuniform processing requirements (every 10th hit,
       more code needs to be run).*/
        DWork[10] = sum(DWork[0:9])/10;
        DWork[mycounter] = 0;
    }
}
if (ssIsSampleHit("1")) {
    /* Processing on DWork[10] can be done here before
       outputing. This code runs on every hit of the
       slower task. */
    y = DWork[10];
}
```

Rules for Properly Handling Slow-to-Fast Transitions

When output rates are faster than input rates, input should only be read at the rate that is associated with the input port sample time, observing the following rules:

- Always read input from the update function.
- Use no special sample hit checks when reading input.
- Write the input to a DWork.
- When there is a special sample hit between the rates, copy the DWork into a second DWork in the output function.
- Write the second DWork to the output at every hit of the output sample rate.

The block can request that the input port be made local but it cannot be set to reusable. The output port can be set to local and reusable.

As in the fast-to-slow transition case, the input should not be read by a rate other than the one assigned to the input port. Similarly, the output should not be written to at a rate other than the rate assigned to the output port.

An optimization can be made when the algorithm being implemented is only required to run at the slow rate. In such cases, you use only one DWork. The input still writes to the DWork in the update function. When there is a special sample hit between the rates, the output function copies the same DWork directly to the output. You must set the output port to be global and not reusable in this case. This optimization results in one less `memcpy` operation per special sample hit.

In either case, the data that the fast rate computations operate on is always delayed, that is, the data is from the previous step of the slow rate code.

Pseudocode Examples of Slow-to-Fast Rate Transition

The pseudocode below abstracts what your S-function needs to do to handle slow-to-fast transitions, illustrating with an input rate of one second driving an output rate of 0.1 second. The block has following characteristics:

- File: `sfun_multirate_delay.c`, Equation: `y = u(tslow-1)`
- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1") {
    if (ssIsSpecialSampleHit("1") {
        DWork[1] = DWork[0];
```

```
    }
    y = DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
    DWork[0] = u;
}
```

An alternative, optimized approach can be used by some algorithms:

- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: global and not reusable because it needs to persist between special sample hits.
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1") {
    if (ssIsSpecialSampleHit("1") {
        y = DWork;
    }
}
UpdateFcn
if (ssIsSampleHit("1")) {
    DWork = u;
}
```

Example adding a simple algorithm:

- File: `sfun_multirate_modulate.c`, Equation: `y = sin(tfast) + u(tslow-1)`
- Input: Set to local, will be local if output/update are combined (an ERT feature) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1") {
    if (ssIsSpecialSampleHit("1") {
    /* Processing not likely to be done here. It causes
     * the faster rate to have nonuniform processing
     * requirements (every 10th hit, more code needs to
     * be run).*/
        DWork[1] = DWork[0];
    }
    /* Processing done at fast rate */
    y = sin(ssGetTaskTime(".1")) + DWork[1];
```

```
}
UpdateFcn
if (ssIsSampleHit("1")) {
    /* Processing on 'u' can be done here. There is a delay of
       one slow rate period before the fast rate sees it.*/
    DWork[0] = u;}
```

MAAB Guidelines

The MathWorks Automotive Advisory Board (MAAB) involves major automotive OEMs and suppliers in the process of evolving MathWorks controls, simulation, and code generation products, including Simulink, Stateflow, and Simulink Coder. An important result of the MAAB has been the "MAAB Control Algorithm Modeling" (Simulink) guidelines.

If you have a Simulink Verification and Validation product license, you can check that your Simulink model or subsystem, and the code that you generate from it, complies with MAAB guidelines. To check your model or subsystem, open the Simulink Model Advisor (Simulink). Navigate to **By Product > Simulink Verification and Validation > Modeling Standards > MathWorks Automotive Advisory Board Checks** and run the MathWorks Automotive Advisory Board checks (Simulink Verification and Validation).

For more information on using the Model Advisor, see "Run Model Checks" (Simulink).

MISRA C Guidelines

The Motor Industry Software Reliability Association (MISRA[2]) has established "Guidelines for the Use of the C Language in Critical Systems" (MISRA C).

For information about MISRA C, see www.misra.org.uk.

In 1998, MIRA Ltd. published MISRA C (MISRA C:1998) to provide a restricted subset of a standardized, structured language that met Safety Integrity Level (SIL) 2 and higher. A major update based on feedback was published in 2004 (MISRA C:2004), followed by a minor update in 2007 known as Technical Corrigendum (TC1).

In 2007, MIRA Ltd. published the MISRA AC AGC standard, "MISRA AC AGC: Guidelines for the Application of MISRA-C:2004 in the Context of Automatic Code Generation." MISRA AC AGC does not change MISRA C:2004 rules, rather it modifies the adherence recommendation.

In 2013, MIRA Ltd. published the MISRA C:2012 standard, "Guidelines for the use of the C language in critical systems." MISRA C:2012 provides improvements based on user feedback and includes guidance on automatic code generation.

Embedded Coder and Simulink offer capabilities to minimize the potential for MISRA C rule violations.

To configure a model or subsystem so that the code generator is most likely to produce MISRA C:2012 compliant code, use the Code Generation Advisor. For more information, see "Configure Model for Code Generation Objectives by Using Code Generation Advisor" on page 29-2.

The Model Advisor (Simulink) also checks that you developed your model or subsystem to increase the likelihood of generating MISRA C:2012 compliant code. To check your model or subsystem:

1. Open the Model Advisor.
2. Navigate to **By Task > Modeling Guidelines for MISRA C:2012**.
3. Run the checks in the folder.

For more information about using the Model Advisor, see "Run Model Checks" (Simulink).

2. MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.

For information about using Embedded Coder software within MISRA C guidelines, see Technical Solution 1-1IFP0W on the MathWorks website.

IEC 61508 Standard

In this section...

Apply Simulink and Embedded Coder to the IEC 61508 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. IEC 61508, Functional safety of electrical/electronic/programmable electronic safety related systems, is such a standard. Because the standard was published when most software was coded by hand, the standard needs to be mapped to Model-Based Design technologies. For further information about MathWorks support for IEC 61508, see IEC 61508 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 61508 standard. For more information, see http://www.mathworks.com/products/iec-61508/.

Check for IEC 61508 Standard Compliance Using the Model Advisor

If you have a Simulink Verification and Validation product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 61508 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for IEC 61508** and run the "IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks" (Simulink Verification and Validation).

For more information on using the Model Advisor, see "Run Model Checks" (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Traceability” (Simulink Verification and Validation) that is available if you have a Simulink Verification and Validation license.
Trace model blocks and subsystems to generated code	The **Model-to-code** traceability option on page 61-8 when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The **Code-to-model** traceability option on page 61-6 when generating an HTML report during the code generation or build process.

Develop a Model that Complies with the IEC 61508 Standard

This example shows how to use Model Advisor checks for the IEC 61508 standard to develop a model and code that comply with the standard.

The IEC 61508 checks identify issues with a model that impede deployment in safety-related applications or limit traceability.

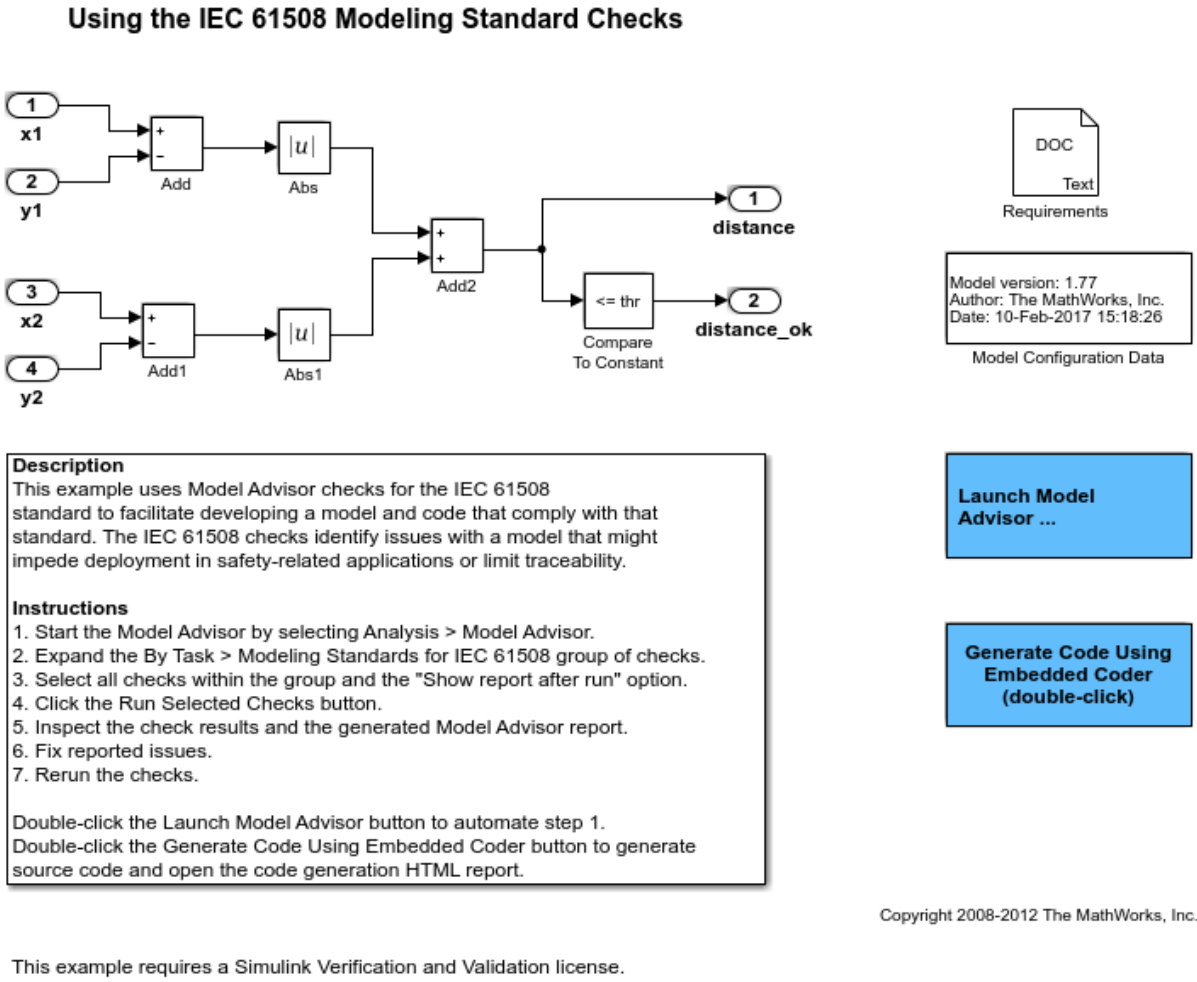
Understanding the Model

According to the functional requirements, a model shall be created that checks whether the 1-norm distance between points `(x1,x2)` and `(y1,y2)` is less than or equal to a given threshold `thr`. For two points `(x1,x2)` and `(y1,y2)`, the 1-norm distance is given as:

$$\sum_{i=1}^{2} |x_i - y_i|$$

The rtwdemo_iec61508 model implements the preceding requirement. Open and get familiar with the model.

```
model='rtwdemo_iec61508';
open_system(model)
```



Apply the IEC 61508 Modeling Standard Checks

To deploy the model in a safety-related software component that must comply with the IEC 61508 safety standard, check the model for issues that might impede deployment in such an environment or limit traceability between the model and generated source code.

To identify possible compliance issues with the model:

1. Start the Model Advisor by selecting **Analysis > Analysis > Model Advisor** or by entering modeladvisor('rtwdemo_IEC61508') at the MATLAB command line.
2. In the **Task Hierarchy**, expand **By Task > Modeling Standards for IEC 61508**.
3. Select the checks within the group.
4. Select **Show report after run** to generate an HTML report that shows the check results.
5. Click **Run Selected Checks**. Model Advisor processes the IEC 61508 checks and displays the results.

To review the check results and make changes:

1. Review the **Summary** in the **Report** section of the right pane.
2. In the **Task Hierarchy**, select a check that did not pass. Review the results that appear in the right pane for that check. For more information on the check and on how to resolve reported issues, with the check selected, click **Help**.
3. Click the **Generate Code Using Embedded Coder** button in the model to inspect the generated code and the traceability report.
4. Resolve the reported issues and rerun the checks.
5. Review the generated HTML report of the check results by clicking the link in the **Report** box.
6. Print the generated HTML report. You can use the report as evidence in the IEC 61508 compliance example process.

IEC 62304 Standard

Apply Simulink and Embedded Coder to the IEC 62304 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. Standard: IEC 62304, Medical device software - Software life cycle processes, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 62304 standard. For more information, see http://www.mathworks.com/products/iec-61508/.

Check for IEC 62304 Standard Compliance Using the Model Advisor

If you have a Simulink Verification and Validation product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 62304 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for IEC 62304** and run the "IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks" (Simulink Verification and Validation).

For more information on using the Model Advisor, see "Run Model Checks" (Simulink).

ISO 26262 Standard

In this section...

Apply Simulink and Embedded Coder to the ISO 26262 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined functional safety standards. ISO 26262, Road Vehicles - Functional Safety, is such a standard. For further information about MathWorks support for ISO 26262, see ISO 26262 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to qualify MathWorks code generation and verification tools for projects based on the ISO 26262 standard. For more information, see http://www.mathworks.com/products/iso–26262/.

Check for ISO 26262 Standard Compliance Using the Model Advisor

If you have a Simulink Verification and Validation product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the ISO 26262 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for ISO 26262** and run the "IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks" (Simulink Verification and Validation).

For more information on using the Model Advisor, see "Run Model Checks" (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The "Requirements Traceability" (Simulink Verification and Validation) that is available if you have a Simulink Verification and Validation license.

To...	Use...
Trace model blocks and subsystems to generated code	The **Model-to-code** traceability option on page 61-8 when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The **Code-to-model** traceability option on page 61-6 when generating an HTML report during the code generation or build process.

EN 50128 Standard

In this section...

Apply Simulink and Embedded Coder to the EN 50128 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. EN 50128, Railway applications — Software for railway control and protection systems, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the EN 50128 standard. For more information, see http://www.mathworks.com/products/iec-61508/.

Check for EN 50128 Standard Compliance Using the Model Advisor

If you have a Simulink Verification and Validation product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the EN 50128 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for EN 50128** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Verification and Validation).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...

DO-178C Standard

In this section...

Apply Simulink and Embedded Coder to the DO-178C Standard

Applying Model-Based Design to a high-integrity system requires extra consideration and rigor so that the system adheres to defined safety standards. DO-178C Software Considerations in Airborne Systems and Equipment Certification is such a standard. A supplement to DO-178C, DO-331, provides guidance on the use of Model-Based Design technologies. MathWorks provides a DO Qualification Kit product that you can use to qualify MathWorks verification tools for projects based on the DO-178C, DO-331, and related standards. For more information, see http://www.mathworks.com/products/do-178/.

For information about Model-Based Design and MathWorks support of aerospace and defense industry standards, see http://www.mathworks.com/aerospace-defense/ .

Check for Standard Compliance Using the Model Advisor

If you have a Simulink Verification and Validation product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the DO-178C standard by running the Simulink Model Advisor (Simulink). Navigate to **By Product > Simulink Verification and Validation > Modeling Standards > DO-178C/DO-331 Checks** or **By Task > Modeling Standards for DO-178C/DO-331** and run the DO-178C/DO-331 checks (Simulink Verification and Validation).

For more information on using the Model Advisor, see "Run Model Checks" (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Traceability” (Simulink Verification and Validation) that is available if you have a Simulink Verification and Validation license.
Trace model blocks and subsystems to generated code	The **Model-to-code** traceability option on page 61-8 when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The **Code-to-model** traceability option on page 61-6 when generating an HTML report during the code generation or build process.

Patterns for C Code in Embedded Coder

Prepare a Model for Code Generation

In this section...

Several standard methods are available for setting up a model to generate specific C constructs in your code. For preparing your model for code generation, some of these methods include: configuring signals and ports, initializing states, and setting up configuration parameters for code generation. Depending on the components of your model, some of these methods are optional. Methods for configuring a model to generate specific C constructs are organized by category, for example, the Control Flow category includes constructs `if-else`, `switch`, `for`, and `while`. Refer to the name of a construct to see how you should configure blocks and parameters in your model. Different modeling methodologies are available, such as Simulink blocks, Stateflow charts, and MATLAB Function blocks, to implement a C construct.

Model examples in “Modeling Patterns for C Code” have the following naming conventions:

Model Components	Naming Convention
Inputs	`u1`, `u2`, `u3`, and so on
Outputs	`y1`, `y2`, `y3`, and so on
Parameters	`p1`, `p2`, `p3`, and so on
States	`x1`, `x2`, `x3`, and so on

Input ports are named to reflect the signal names that they propagate.

Configure a Signal

1 Create a model in Simulink. For more information, see “Model Editing Fundamentals” (Simulink).

2 Right-click a signal line. Select **Properties**. For more information about the Signal Properties dialog box, see "Signal Properties" (Simulink).

3 Enter a signal name for the **Signal name** parameter.

4 On the same Signal Properties dialog box, select the **Code Generation** tab. Use the drop down menu for the **Storage class** parameter to specify a storage class. Examples in this chapter use `ExportedGlobal`.

Note: Alternatively, on the Signal Properties dialog box, select **Signal name must resolve to Simulink signal object**. Then create a signal data object in the base workspace with the same name as the signal. See "Create Data Objects for Code Generation with Data Object Wizard" on page 24-2 for more information on creating data objects in the base workspace. (Examples use `Simulink.Signal` and specify the **Storage class** as `ExportedGlobal`.)

Configure Input and Output Ports

1 In your model,

Double-click an Inport or Outport block. A Block Parameters dialog box opens.

2 Select the **Signal Attributes** tab.

3 Specify the **Port dimensions** and **Data type**. Examples leave the default value for **Port dimensions** as –1 (for inherited) and **Data type** as `Inherit: auto`.

Initialize States

1 Double-click a block.

2 In the Block Parameters dialog box, select the **Main** tab.

3 Specify the **Initial conditions** and **Sample time**. For more information, see "Specify Sample Time" (Simulink).

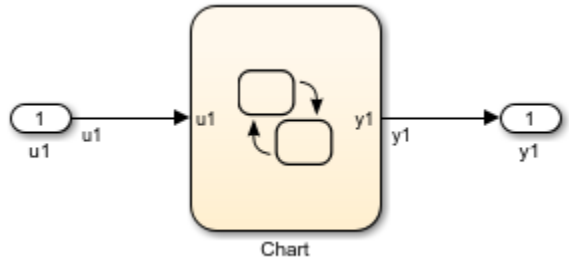
4 Select the **State Attributes** pane. Specify the state name. See "Discrete Block State Naming in Generated Code" (Simulink Coder).

5 You can also use the Data Object Wizard for creating data objects. A part of this process initializes states. See "Create Data Objects for Code Generation with Data Object Wizard" on page 24-2.

Set Up Configuration Parameters for Code Generation

1. Open the Configuration Parameter dialog box by selecting **Simulation** > **Model Configuration parameters**. You can also use the keyboard shortcut `Ctrl+E`.
2. Open the **Solver** pane and select
   - **Solver type**: `Fixed-Step`
   - **Solver**: `discrete (no continuous states)`
3. Open the **Optimization** > **Signals and Parameters** pane, and set **Default parameter behavior** to `Inlined`.
4. Open the **Code Generation** pane, and specify `ert.tlc` as the **System Target File**.
5. Clear **Generate makefile**.
6. Select **Generate code only**.
7. Enable the HTML report generation by opening the **Code Generation** > **Report** pane and selecting **Create code generation report** and **Launch report automatically**. On the **All Parameters** tab, select **Code-to-model**. Enabling the HTML report generation is optional.
8. Click **Apply** and then **OK** to exit.

Set Up an Example Model With a Stateflow Chart



Follow this general procedure to create a simple model containing a Stateflow chart.

1. From the **Stateflow > Chart** library, add a Stateflow chart to your model .
2. Add Inport blocks and Outport blocks according to the example model.

3 Open the **Stateflow Editor** by performing one of the following:

- Double-click the Stateflow chart.
- Press **Ctrl+R**.

4 Select **Chart > Add Inputs & Outputs > Data Input from Simulink** to add the inputs to the chart. A Data dialog box opens for each input.

5 Specify the **Name** (`u1, u2, ...`) and the **Type** (`Inherit: Same as Simulink`) for each input, unless specified differently in the example. Click **OK**.

Click **Apply** and close each dialog box.

6 Select **Chart > Add Inputs & Outputs > Data Output from Simulink** to add the outputs to the chart. A Data dialog opens for each output.

7 Specify the **Name** (`y1, y2, ...`) and **Type** (`Inherit: Same as Simulink`) for each output, unless specified differently in the example. Click **OK**.

8 Click **Apply** and close each dialog box.

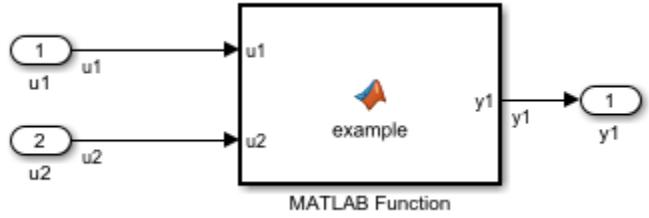
9 In the **Stateflow Editor**, create the Stateflow diagram specific to the example.

10 The inputs and outputs appear on the chart in your model.

11 Connect the Inport and Outport blocks to the Stateflow Chart.

12 Configure the input and output signals; see “Configure a Signal” on page 13-3.

Set Up an Example Model With a MATLAB Function Block



1 Add the number of Inport and Outport blocks according to a C construct example included in this chapter.

2 From the Simulink User-defined Functions library drag a MATLAB Function block into the model.

3. Double-click the block. The MATLAB Function Block Editor opens. Edit the function to implement your application.
4. Click **File > Save** and close the MATLAB Function Block Editor.
5. Connect the Inport and Outport blocks to the MATLAB Function block. See "Configure a Signal" on page 13-3.
6. Save your model.

Definition, Initialization, and Declaration of Parameter Data

This example shows how to export the definition, initialization, and declaration of a global variable that the generated code uses as a parameter.

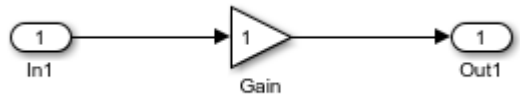
C Construct

```
int32 myParam = 3;

extern int32 myParam;
```

Procedure

1. Create the `ex_defn_decl` model by using a Gain block.



2. In the Gain block dialog box, set **Gain** to `myParam`. Click **Apply**.
3. Click the button ⋮ next to the parameter value. Select **Create Variable**.
4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`. Click **Create**.

   A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 3.
5. In the Simulink.Parameter property dialog box, set **Data type** to `int32`.
6. Set **Storage class** to `ExportToFile`.
7. Set **HeaderFile** to `myDecls.h`.
8. Set **DefinitionFile** to `myDefns.c`. Click **OK**.
9. Generate code from the model.

Results

The generated header file `myDecls.h` declares the global variable `myParam` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */
extern int32_T myParam;
```

The generated source file `myDefns.c` defines and initializes `myParam`.

```
/* Definition for custom storage class: ExportToFile */
int32_T myParam = 3;
```

Related Examples

Definition and Declaration of Signal Data

This example shows how to export the definition and declaration of a global variable that the generated code uses as a signal.

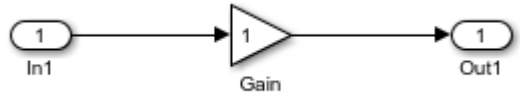
C Construct

```
float mySig;

extern float mySig;
```

Procedure

1. Create the `ex_defn_decl` model by using a Gain block.



2. In the model, select **View** > **Model Data**.
3. In the Model Data Editor, view the **Inports/Outports** tab.
4. From the **Change View** drop-down list, select `Design`.
5. In the model, select the Inport block.
6. In the Model Data Editor, for the Inport block, set **Signal Name** to `mySig`.
7. Set **Data Type** to `single`.
8. From the **Change View** drop-down list, select `Code`.
9. For the Inport block, set **Storage Class** to `ExportToFile`.
10. Set **Header File** to `myDecls.h`.
11. Set **Definition File** to `myDefns.c`.
12. Generate code from the model.

Results

The generated header file `myDecls.h` declares the global variable `mySig` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */
extern real32_T mySig;
```

The generated source file `myDefns.c` defines the variable `mySig`.

```
/* Definition for custom storage class: ExportToFile */
real32_T mySig;
```

Data Type Conversion

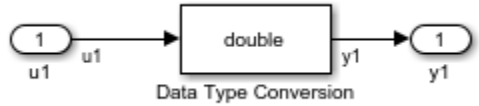
C Construct

```
y1 = (double)u1;
```

Modeling Patterns

Modeling Pattern for Data Type Conversion — Simulink Block

One method to create a data type conversion is to use a Data Type Conversion block from the **Simulink > Commonly Used Blocks** library.



ex_data_type_SL

1. From the **Commonly Used Blocks** library, drag a Data Type Conversion block into your model and connect to the Inport and Outport blocks.
2. Double-click on the Data Type Conversion block to open the Block Parameters dialog box.
3. Select the **Output data type** parameter as `double`.
4. Press **Ctrl+B** to build the model and generate code.

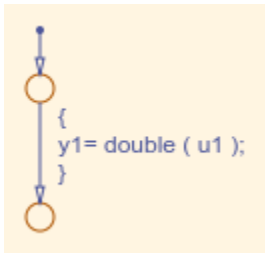
The generated code appears in `ex_data_type_SL.c`, as follows:

```
int32_T u1;
real_T y1;
```

```
void ex_data_type_SL_step(void)
{
 y1 = (real_T)u1;
}
```

The code generator type definition for `double` is `real_T`.

Modeling Pattern for Data Type Conversion — Stateflow Chart



Stateflow Chart Type Conversion

Procedure

1. Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 13-5 . This example contains one Inport block and one Outport block.
2. Name the example model `ex_data_type_SF`.
3. Double-click the Inport block and select the **Signal Attributes** tab. Specify the **Data Type** as `int32` from the drop down menu.
4. Double-click the Outport block and select the **Signal Attributes** tab. Specify the **Data Type** as `Inherit: auto` from the drop down menu.
5. Press **Ctrl+B** to build the model and generate code.

Results

The generated code appears in `ex_data_type_SF.c`, as follows:

```
int32_T u1;
real_T y1;
RT_MODEL_ex_data_type_SF ex_data_type_SF_M_;
RT_MODEL_ex_data_type_SF *const ex_data_type_SF_M = &ex_data_type_SF_M_;
void ex_data_type_SF_step(void)
{
  y1 = u1;
}
```

Modeling Pattern for Data Type Conversion — MATLAB Function Block

Procedure

1. Follow the steps for "Set Up an Example Model With a MATLAB Function Block" on page 13-6 . This example model contains one Inport block and one Outport block.
2. Name the model `ex_data_type_ML_Func`.
3. In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = typeconv(u1)
y1 = double(u1);
end
```

4. Press **Ctrl+B** to build the model and generate code.

Results

The generated code appears in `ex_data_type_ML_func.c`, where `real32_T` is a `float` and `real_T` is a `double`. Type conversion occurs across assignments.

```
real32_T u1;
real_T y1;

void ex_data_type_ML_func_step(void)
{
     y1 = u1;
}
```

Other Type Conversions in Modeling

Type conversions can also occur on the output of blocks where the output variable is specified as a different data type. For example, in the Gain block, you can select the **Inherit via internal rule** parameter to control the output signal data type. Another example of type conversion can occur at the boundary of a Stateflow chart. You can specify the output variable as a different data type.

See Also

Data Type Conversion

Type Qualifiers

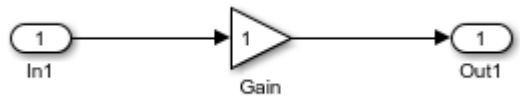
This example shows how to apply the `const` and `volatile` keywords to a global variable that represents parameter data.

C Construct

```
const volatile double myParam = 9.8;
```

Procedure

1. Create the `ex_const_volatile` model by using a Gain block.



2. In the Gain block dialog box, set **Gain** to `myParam`. Click **Apply**.
3. Click the button ⋮ next to the parameter value. Select **Create Variable**.
4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)`. Click **Create**.

   A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 9.8.
5. In the Simulink.Parameter property dialog box, set **Storage class** to `ConstVolatile`. Click **OK**.

   Alternatively, to apply only one of the keywords, you can use the storage classes `Const` or `Volatile`.
6. Generate code from the model.

Results

The generated source file `ex_const_volatile.c` defines `myParam` by using the `const` and `volatile` keywords.

```
/* Definition for custom storage class: ConstVolatile */
```

```
const volatile real_T myParam = 9.8;
```

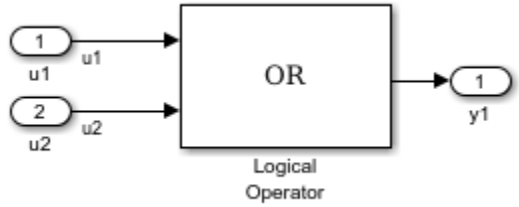
Relational and Logical Operators

Modeling Patterns for Relational and Logical Operators

Modeling Pattern for Relational or Logical Operators — Simulink Blocks



ex_logical_SL

Procedure

1. From the **Logic and Bit Operations** library, drag a Logical Operator block into your model.
2. Double-click the block to configure the logical operation. Set the **Operator** field to `OR`.
3. Name the blocks, as shown in the model `ex_logical_SL`.
4. Connect the blocks and name the signals, as shown in the model `ex_logical_SL`.
5. Press **Ctrl+B** to build the model and generate code.

Note: You can use the above procedure to implement relational operators by replacing the Logical Operator block with a Relational Operator block.

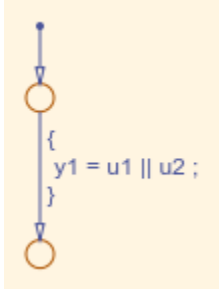
Results

Code implementing the logical operator `OR` is in the `ex_logical_SL_step` function in `ex_logical_SL.c`:

```
/* Exported block signals */
   boolean_T u1;                         /* '<Root>/u1' */
   boolean_T u2;                         /* '<Root>/u2' */
   boolean_T y1;                         /* '<Root>/Logical Operator'*/

   /* Logic: '<Root>/Logical Operator' incorporates:
    *  Inport: '<Root>/u1'
    *  Inport: '<Root>/u2'
    */
    y1 = (u1 || u2);
```

Modeling Pattern for Relational and Logical Operators – Stateflow Chart



ex_logical_SF/Logical Operator Stateflow Chart

Procedure

1. Follow the steps for "Set Up an Example Model With a Stateflow Chart" on page 13-5. This example model contains two Inport blocks and one Outport block.
2. Name the example model `ex_logical_SF`.
3. In the **Stateflow Editor**, specify the **Data Type** for `y1` as `Boolean`.
4. In the **Stateflow Editor**, create the Stateflow diagram as shown. The relational or logical operation actions are on the transition from one junction to another. Relational statements specify conditions to conditionally allow a transition. In that case, the statement would be within square brackets.

5 Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the logical operator OR is in the `ex_logical_SF_step` function in `ex_logical_SF.c`:

```
boolean_T u1;                /* '<Root>/u1' */
boolean_T u2;                /* '<Root>/u2' */
boolean_T y1;                /* '<Root>/Chart' */

void ex_logical_SF_step(void)
{
    y1 = (u1 || u2);
}
```

Modeling Pattern for Relational and Logical Operators — MATLAB Function Block

This example demonstrates the MATLAB Function block method for incorporating operators into the generated code using a relational operator.

Procedure

1 Follow the steps for "Set Up an Example Model With a MATLAB Function Block" on page 13-6 . This example model contains two Inport blocks and one Outport block.

2 Name the example model `ex_rel_operator_ML`.

3 In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2)
y1 = u1 > u2;
end
```

4 Press **Ctrl+B** to build the model and generate code.

Results

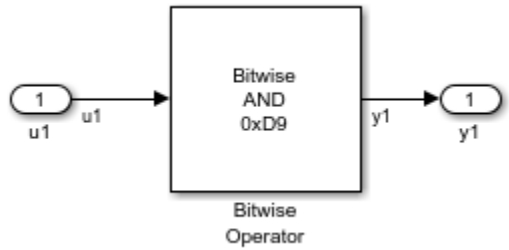
Code implementing the relational operator `'>'` is in the `ex_rel_operator_ML_step` function in `ex_rel_operator_ML.c`:

```
real_T u1;                          /* '<Root>/u1' */
real_T u2;                          /* '<Root>/u2' */
boolean_T y;                        /* '<Root>/MATLAB Function' */
```

```
void ex_rel_operator_ML_step(void)
{
  y = (u1 > u2);
 }
```

Bitwise Operations

Simulink Bitwise-Operator Block



ex_bit_logic_SL

Procedure

1. Drag a Bitwise Operator block from the **Logic and Bit Operations** library into your model.
2. Double-click the block to open the Block Parameters dialog.
3. Select the type of **Operator**. In this example, select `AND`.
4. In order to perform Bitwise operations with a bit-mask, select **Use bit mask**.

   Note: If another input uses Bitwise operations, clear the **Use bit mask** parameter and enter the number of input ports.
5. In the **Bit Mask** field, enter a decimal number. Use `bin2dec` or `hex2dec` to convert from binary or hexadecimal. In this example, enter `hex2dec('D9')`.
6. Name the blocks, as shown in, model `ex_bit_logic_SL`.
7. Connect the blocks and name the signals, as shown in, model `ex_bit_logic_SL`.
8. Press **Ctrl+B** to build the model and generate code.

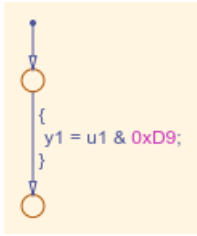
Results

Code implementing the logical operator OR is in the `ex_bit_logic_SL_step` function in `ex_bit_logic_SL.c`:

```
uint8_T u1;
uint8_T y1;

void ex_bit_logic_SL_step(void)
{
  y1 = (uint8_T)(u1 & 217);
}
```

Stateflow Chart



ex_bit_logic_SF/Bit_Logic Stateflow Chart

Procedure

1. Follow the steps for "Set Up an Example Model With a Stateflow Chart" on page 13-5. This example contains one Inport block and one Outport block.
2. Name the example model `ex_bit_logic_SF`.
3. From the **Stateflow Editor**, select **Tools > Explore** to open the Model Explorer.
4. In the Model Explorer, on the right pane, select **Enable C-bit operations**.
5. In the **Stateflow Editor**, create the Stateflow diagram, `ex_bit_logic_SF/Bit_Logic`.
6. Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the logical operator OR is in the `ex_bit_logic_SF_step` function in `ex_bit_logic_SF.c`:

```
uint8_T u1;
uint8_T y1;

void bit_logic_SF_step(void)
```

```
{
   y1 = (uint8_T)(u1 & 0xD9);
}
```

MATLAB Function Block

In this example, to demonstrate the MATLAB Function block method for implementing bitwise logic into the generated code, use the bitwise OR, '|'.

Procedure

1. Follow the steps for "Set Up an Example Model With a MATLAB Function Block" on page 13-6. This example model contains two Inport blocks and one Outport block.
2. Name your model `ex_bit_logic_ML`.
3. In the MATLAB Function Block Editor enter the function, as follows:

   ```
   function y1 = fcn(u1, u2)

   y1 = bitor(u1, u2);
   end
   ```
4. Press **Ctrl+B** to build the model and generate code.

Results

Code implementing the bitwise operator OR is in the `ex_bit_logic_ML_step` function in `ex_bit_logic_ML.c`:

```
uint8_T u1;
uint8_T u2;
uint8_T y1;

void ex_bit_logic_ML_step(void)
{
 y1 = (uint8_T)(u1 | u2);
}
```

Enumeration

To generate an enumerated data type, define an enumeration class in a MATLAB file. Then, use the enumeration class as the data type of signals, block parameters, and states in a model.

C Construct

```
typedef enum {
  Choice1 = 0,
  Choice2
} myEnumType;
```

Procedure

In your current folder, create the MATLAB file `myEnumType.m`. The file defines an enumeration class `myEnumType`.

```
classdef myEnumType < Simulink.IntEnumType

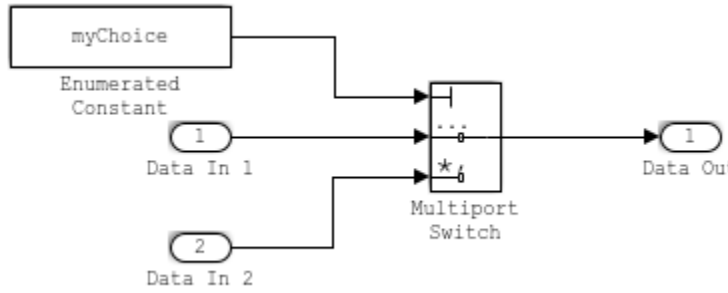
    enumeration
        Choice1(0)
        Choice2(1)
    end %enumeration

    methods (Static)
        function retVal = getHeaderFile()
            retVal = 'myEnumHdr.h';
        end %function
        function retVal = getDataScope()
            retVal = 'Exported';
        end %function
    end %methods

end %classdef
```

Create the model `ex_pattern_enum` by using an Enumerated Constant block and a Multiport Switch block.

```
open_system('ex_pattern_enum')
```



In the base workspace, create a `Simulink.Parameter` object `myChoice`. Use the enumeration member `Choice1` to set the value of the parameter object.

```
myChoice = Simulink.Parameter(myEnumType.Choice1);
```

Set the storage class of the parameter object to `ExportedGlobal` so that the object appears in the generated code as a global variable.

```
myChoice.CoderInfo.StorageClass = 'ExportedGlobal';
```

In the Enumerated Constant block dialog box, set:

- **Output data type** to `Enum: myEnumType`.
- **Value** to `myChoice`.

In the Multiport Switch block dialog box, set:

- **Data port order** to `Specify indices`.
- **Data port indices** to `enumeration('myEnumType')`. This expression returns all of the enumeration members of `myEnumType`.

Generate code from the model.

```
rtwbuild('ex_pattern_enum');
```

```
### Starting build procedure for model: ex_pattern_enum
### Successful completion of build procedure for model: ex_pattern_enum
```

Results

View the generated header file `myEnumHdr.h`. The file defines the enumerated data type.

```
file = fullfile('ex_pattern_enum_ert_rtw','myEnumHdr.h');
rtwdemodbtype(file,'typedef enum {','} myEnumType;',1,1)
```

```
typedef enum {
  Choice1 = 0,                          /* Default value */
  Choice2
} myEnumType;
```

View the source file `ex_pattern_enum.c`. The file defines the variable `myChoice`. The algorithm in the `step` function uses `myChoice` to route one of the input signals to the output signal.

```
file = fullfile('ex_pattern_enum_ert_rtw','ex_pattern_enum.c');
rtwdemodbtype(file,'myEnumType myChoice = Choice1;','/* Variable: myChoice',1,1)
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)
```

```
myEnumType myChoice = Choice1;          /* Variable: myChoice

/* Model step function */
void ex_pattern_enum_step(void)
{
  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   *  Constant: '<S1>/Constant'
   */
  if (myChoice == Choice1) {
    /* Outport: '<Root>/Data Out' incorporates:
     *  Inport: '<Root>/Data In 1'
     */
    rtY.DataOut = rtU.DataIn1;
  } else {
    /* Outport: '<Root>/Data Out' incorporates:
     *  Inport: '<Root>/Data In 2'
     */
    rtY.DataOut = rtU.DataIn2;
  }

  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}
```

If-Else

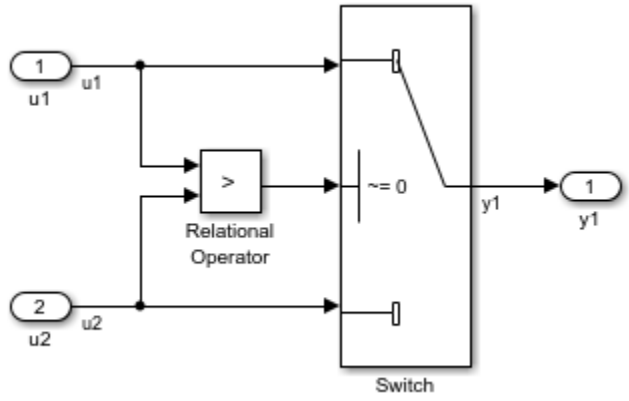
C Construct

```
if (u1 > u2)
{
  y1 = u1;
}
else
{
  y1 = u2;
}
```

Modeling Patterns

Modeling Pattern for If-Else: Switch block

One method to create an `if-else` statement is to use a Switch block from the **Simulink > Signal Routing** library.



Model ex_if_else_SL

Procedure

1. Drag the Switch block from the **Simulink>Signal Routing** library into your model.
2. Connect the data inputs and outputs to the block.
3. Drag a Relational Operator block from the Logic & Bit Operations library into your model.
4. Connect the signals that are used in the if-expression to the Relational Operator block. The order of connection determines the placement of each signal in the if-expression.
5. Configure the Relational Operator block to be a greater than operator.
6. Connect the controlling input to the middle input port of the Switch block.
7. Double-click the Switch block and set **Criteria for passing first input** to `u2~=0`. The software selects `u1` if `u2` is `TRUE`; otherwise `u2` passes.
8. Enter `Ctrl+B` to build the model and generate code.

Results

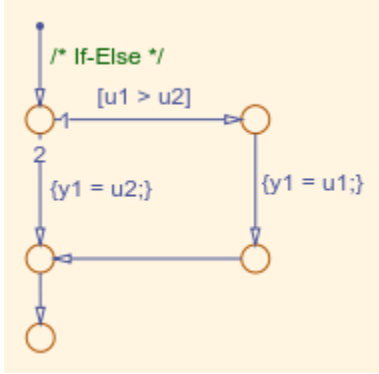
The generated code includes the following `ex_if_else_SL_step` function in the file `ex_if_else_SL.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SL_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   *  Outport: '<Root>/y1'
   *  RelationalOperator: '<Root>/Relational Operator'
   */
 if (U.u1 > U.u2) {
    Y.y1 = U.u1;
  } else {
    Y.y1 = U.u2;
  }
}
```

Modeling Pattern for If-Else: Stateflow Chart



ex_if_else_SF/Chart

Procedure

1. Follow the steps for "Set Up an Example Model With a Stateflow Chart" on page 13-5. This example model contains two Inport blocks and one Outport block.
2. Name your model `ex_if_else_SF`.
3. When configuring your Stateflow chart, select **Chart** > **Add Patterns** > **Decision** > **If-Else**. The Stateflow Pattern dialog opens. Fill in the fields as follows:

Description	`If-Else` (optional)
If condition	`u1 > u2`
If action	`y1 = u1`
Else action	`y1 = u2`

4. Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_if_else_SF_step` function in the file `If_Else_SF.c`:

```
 /* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;
```

```
/* Model step function */
void ex_If_Else_SF_step(void)
{
  /* Chart: '<Root>/Chart' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  /* Gateway: Chart */
  /* During: Chart */
  /* Entry Internal: Chart */
  /* Transition: '<S1>:15' */
  /*  If-Else */
  if (U.u1 > U.u2) {
    /* Outport: '<Root>/y1' */
    /* Transition: '<S1>:16' */
    /* Transition: '<S1>:18' */
    Y.y1 = U.u1;

    /* Transition: '<S1>:19' */
  } else {
    /* Outport: '<Root>/y1' */
    /* Transition: '<S1>:17' */
    Y.y1 = U.u2;
  }

  /* End of Chart: '<Root>/Chart' */
  /* Transition: '<S1>:20' */
}
```

Modeling Pattern for If-Else: MATLAB Function Block

Procedure

1. Follow the steps for "Set Up an Example Model With a MATLAB Function Block" on page 13-6. This example model contains two Inport blocks and one Outport block.
2. Name your model `ex_if_else_ML`.
3. In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2)
if u1 > u2;
  y1 = u1;
else y1 = u2;
end
```

4. Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_if_else_ML_step` function in the file `ex_if_else_ML.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_ML_step(void)
{
  /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   *  Outport: '<Root>/y1'
   */
  /* MATLAB Function 'MATLAB Function': '<S1>:1' */
  if (U.u1 > U.u2) {
    /* '<S1>:1:4' */
    /* '<S1>:1:5' */
    Y.y1 = U.u1;
  } else {
    /* '<S1>:1:6' */
    Y.y1 = U.u2;
  }
}
```

Switch

C Construct

```
switch (u1)
{
 case 2:
   y1 = u2;
   break;
 case 3:
   u3;
   break;
 default:
   y1 = u4;
   break;
}
```

Modeling Patterns

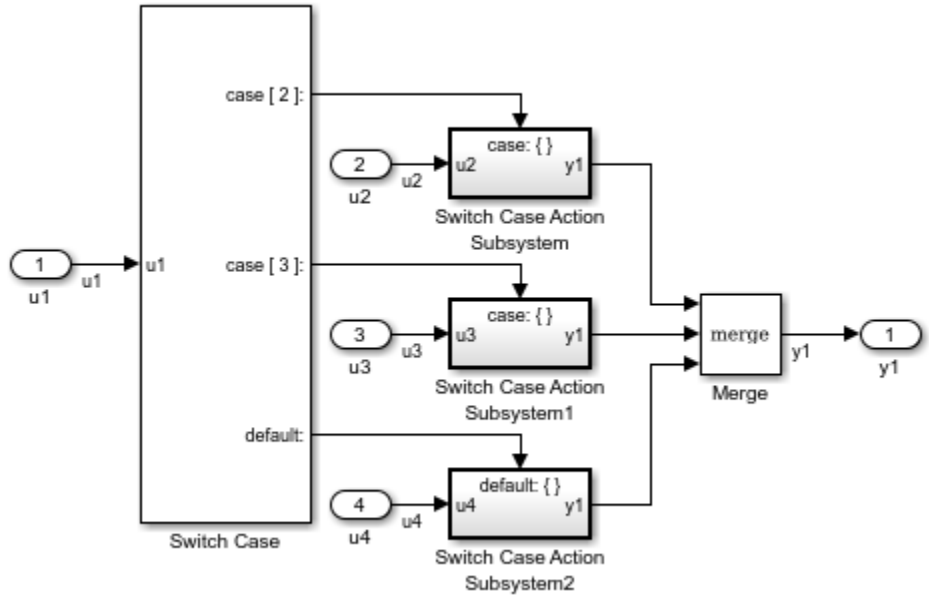
Modeling Pattern for Switch: Switch Case block

One method for creating a `switch` statement is to use a Switch Case block from the **Simulink > Ports and Subsystems** library.



Model ex_switch_SL

Procedure

1. Drag a Switch Case block from the **Simulink > Ports and Subsystems** library into your model.
2. Double-click the block. In the Block Parameters dialog box, fill in the **Case Conditions** parameter. In this example, the two cases are: `{2,3}`.
3. Select the **Show default case** parameter. The default case is optional in a `switch` statement.
4. Connect the condition input `u1` to the input port of the Switch block.
5. Drag Switch Case Action Subsystem blocks from the **Simulink>Ports and Subsystems** library to correspond with the number of cases.

6 Configure the Switch Case Action Subsystem (Simulink) subsystems.

7 Drag a Merge block from the **Simulink > Signal Routing** library to merge the outputs.

8 The Switch Case block takes an integer input, therefore, the input signal `u1` is type cast to an `int32`.

9 Enter `Ctrl+B` to build the model and generate code.

Results

The generated code includes the following `ex_switch_SL_step` function in the file `ex_switch_SL.c`:

```
/* Exported block signals */
 int32_T u1;                            /* '<Root>/u1' */

 /* External inputs (root inport signals with auto storage) */
 ExternalInputs U;

 /* External outputs (root outports fed by signals with auto storage) */
 ExternalOutputs Y;

 /* Model step function */
 void ex_switch_SL_step(void)
 {
   /* SwitchCase: '<Root>/Switch Case' incorporates:
    *  ActionPort: '<S1>/Action Port'
    *  ActionPort: '<S2>/Action Port'
    *  ActionPort: '<S3>/Action Port'
    *  Inport: '<Root>/u1'
    *  SubSystem: '<Root>/Switch Case Action Subsystem'
    *  SubSystem: '<Root>/Switch Case Action Subsystem1'
    *  SubSystem: '<Root>/Switch Case Action Subsystem2'
    */
   switch (u1) {
    case 2:
     /* Inport: '<S1>/u2' incorporates:
      *  Inport: '<Root>/u2'
      *  Outport: '<Root>/y1'
      */
     Y.y1 = U.u2;
     break;

    case 3:
     /* Inport: '<S2>/u3' incorporates:
      *  Inport: '<Root>/u3'
      *  Outport: '<Root>/y1'
      */
     Y.y1 = U.u3;
     break;

    default:
     /* Inport: '<S3>/u4' incorporates:
      *  Inport: '<Root>/u4'
      *  Outport: '<Root>/y1'
      */
     Y.y1 = U.u4;
```

```
    break;
  }
}
```

Modeling Pattern for Switch: MATLAB Function block

Procedure

1. Follow the steps for "Set Up an Example Model With a MATLAB Function Block" on page 13-6. This example model contains four Inport blocks and one Outport block.
2. Name your model `ex_switch_ML`.
3. In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1, u2, u3, u4)

switch u1
    case 2
        y1 = u2;
    case 3
        y1 = u3;
    otherwise
        y1 = u4;
end
```

4. Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_switch_ML_step` function in the file `ex_switch_ML.c`:

```
/* External inputs (root inport signals with auto storage) */
   ExternalInputs U;

   /* External outputs (root outports fed by signals with auto storage) */
   ExternalOutputs Y;

   /* Model step function */
   void ex_switch_ML_step(void)
   {
     /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
      *  Inport: '<Root>/u1'
      *  Inport: '<Root>/u2'
      *  Inport: '<Root>/u3'
      *  Inport: '<Root>/u4'
      *  Outport: '<Root>/y1'
      */
     /* MATLAB Function 'MATLAB Function': '<S1>:1' */
     /* '<S1>:1:4' */
     switch (U.u1) {
      case 2:
       /* '<S1>:1:6' */
       Y.y1 = U.u2;
       break;
```

```
    case 3:
     /* '<S1>:1:8' */
     Y.y1 = U.u3;
     break;

    default:
     /* '<S1>:1:10' */
     Y.y1 = U.u4;
     break;
   }
}
```

Convert If-Elseif-Else to Switch statement

If a MATLAB Function block or a Stateflow chart uses `if-elseif-else` decision logic, you can convert it to a `switch` statement by using a configuration parameter. In the Configuration Parameters dialog box, on the **Code Generation > Code Style** pane, select the "Convert if-elseif-else patterns to switch-case statements" parameter. For more information, see "Converting If-Elseif-Else Code to Switch-Case Statements" (Simulink). For more information on this conversion using a Stateflow chart, see "Enhance Readability of Code for Flow Charts" on page 36-127.

For Loop

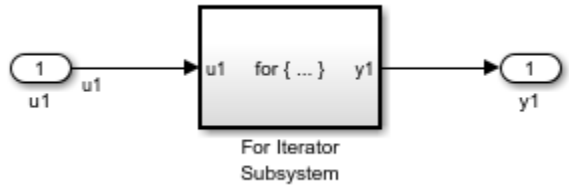
C Construct

```
y1 = 0;
for(inx = 0; inx <10; inx++)
{
  y1 = u1[inx] + y1;
}
```

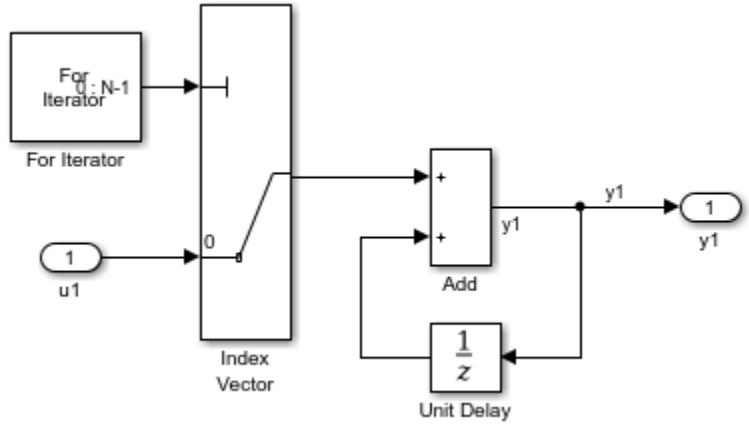
Modeling Patterns:

Modeling Pattern for For Loop: For-Iterator Subsystem block

One method for creating a `for` loop is to use a For Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.



Model ex_for_loop_SL



For Iterator Subsystem

Procedure

1. Drag a For Iterator Subsystem (Simulink) block from the **Simulink > Ports and Subsystems** library into your model.
2. Connect the data inputs and outputs to the For Iterator Subsystem block.
3. Open the Inport block.

4. In the Block Parameters dialog box, select the **Signal Attributes** pane and set the **Port dimensions** parameter to 10.
5. Double-click the For Iterator Subsystem block to open the subsystem.
6. Drag an Index Vector block from the Signal-Routing library into the subsystem.
7. Open the For Iterator block. In the Block Parameters dialog box set the **Index-mode** parameter to `Zero-based` and the **Iteration limit** parameter to 10.
8. Connect the controlling input to the topmost input port of the Index Vector block, and the other input to the second port.
9. Drag an Add block from the **Math Operations** library into the subsystem.
10. Drag a Unit Delay block from **Commonly Used Blocks** library into the subsystem.
11. Double-click the Unit Delay block and set the **Initial Conditions** parameter to `0`. This parameter initializes the state to zero.
12. Connect the blocks as shown in the model diagram.
13. Save the subsystem and the model.
14. Enter `Ctrl+B` to build the model and generate code.

Results

The generated code includes the following `ex_for_loop_SL_step` function in the file `ex_for_loop_SL.c`:

```
  /* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SL_step(void)
{
  int32_T s1_iter;
  int32_T rtb_y1;

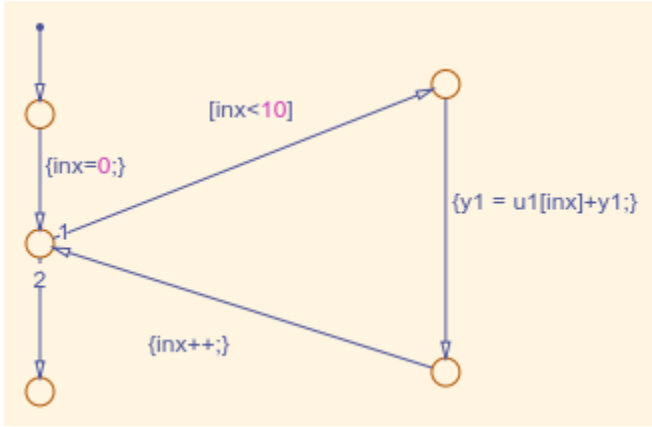
  /* Outputs for iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:
   *  ForIterator: '<S1>/For Iterator'
   */
  for (s1_iter = 0; s1_iter < 10; s1_iter++) {
    /* Sum: '<S1>/Add' incorporates:
     *  Inport: '<Root>/u1'
     *  MultiPortSwitch: '<S1>/Index Vector'
     *  UnitDelay: '<S1>/Unit Delay'
     */
    rtb_y1 = U.u1[s1_iter] + DWork.UnitDelay_DSTATE;

    /* Update for UnitDelay: '<S1>/Unit Delay' */
    DWork.UnitDelay_DSTATE = rtb_y1;
  }
```

```
  /* end of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */

  /* Outport: '<Root>/y1' */
  Y.y1 = rtb_y1;
}
```

Modeling Pattern for For Loop: Stateflow Chart



Model ex_for_loop_SF

Procedure

1. Follow the steps for "Set Up an Example Model With a Stateflow Chart" on page 13-5. This example model contains one Inport block and one Outport block.
2. Name the model `ex_for_loop_SF`.
3. Enter `Ctrl+R` to open the Model Explorer.
4. In the Model Explorer, select the output variable, `u1`, and in the right pane, select the **General** tab and set the **Initial Value** to `0`.
5. In the **Stateflow Editor**, select **Chart** > **Add Patterns** > **Loop** > **For**. The Stateflow Pattern dialog opens.
6. Fill in the fields in the Stateflow Pattern dialog box as follows:

Description	`For Loop` (optional)
Initializer expression	`inx = 0`
Loop test expression	`inx < 10`
Counting expression	`inx++`
For loop body	`y1 = u1[inx] + y1`

The Stateflow diagram is shown.

7 Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_for_loop_SF_step` function in the file `ex_for_loop_SF.c`:

```
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SF_step(void)
{
  int32_T inx;

  /* Chart: '<Root>/Chart' */
  /* Gateway: Chart */
  /* During: Chart */
  /* Entry Internal: Chart */
  /* Transition: '<S1>:13' */
  /* Transition: '<S1>:14' */
  for (inx = 0; inx < 10; inx++) {
    /* Outport: '<Root>/y1' incorporates:
     *  Inport: '<Root>/u1'
     */
    /* Transition: '<S1>:11' */
    /* Transition: '<S1>:12' */
    Y.y1 += U.u1[inx];

    /* Transition: '<S1>:10' */
  }

  /* End of Chart: '<Root>/Chart' */
  /* Transition: '<S1>:9' */
}
```

Modeling Pattern for For Loop: MATLAB Function block

Procedure

1. Follow the directions for "Set Up an Example Model With a MATLAB Function Block" on page 13-6. This example model contains one Inport block and one Outport block.
2. Name your model `ex_for_loop_ML`.
3. In the MATLAB Function Block Editor enter the function, as follows:

```
function y1 = fcn(u1)

y1 = 0;

for inx=1:10
    y1 = u1(inx) + y1 ;
end
```

4. Press **Ctrl+B** to build the model and generate code.

Results

The generated code includes the following `ex_for_loop_ML_step` function in the file `ex_for_loop_ML.c`:

```
/* Exported block signals */
real_T u1[10];                         /* '<Root>/u1' */
real_T y1;                             /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_for_loop_ML_step(void)
{
  int32_T inx;

  /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
   *  Inport: '<Root>/u1'
   */
  /* MATLAB Function 'MATLAB Function': '<S1>:1' */
  /* '<S1>:1:3' */
  y1 = 0.0;
  for (inx = 0; inx < 10; inx++) {
    /* '<S1>:1:5' */
    /* '<S1>:1:6' */
    y1 = u1[inx] + y1;
  }
}
```

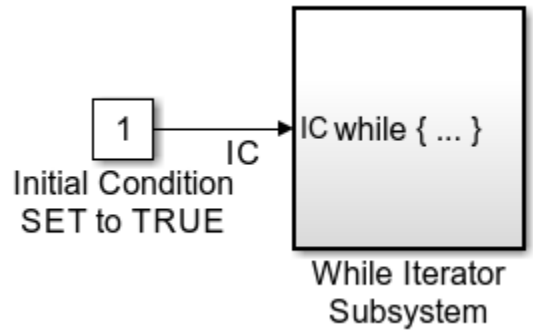
  flag = func ();
  num_iter ++;
}
```

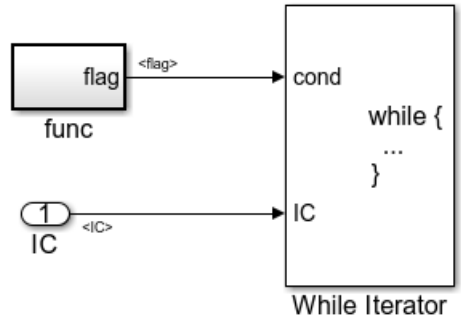
Modeling Patterns

Modeling Pattern for While Loop: While Iterator Subsystem block

One method for creating a `while` loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.



Model ex_while_loop_SL

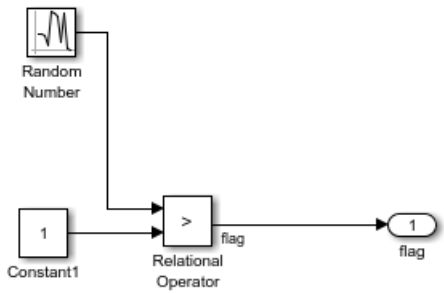


ex_while_loop_SL/While Iterator Subsystem

Procedure

1. Drag a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library into the model.
2. Drag a Constant block from the **Simulink > Commonly Used Blocks** library into the model. In this case, set the **Initial Condition** to `1` and the **Data Type** to `Boolean`. You do not have to set the initial condition to `FALSE`. The initial condition can be dependent on the input to the block.

3. Connect the Constant block to the While Iterator Subsystem block.
4. Double-click the While Iterator Subsystem block to open the subsystem.
5. Place a Subsystem block next to the While Iterator block.
6. Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
7. Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
8. Select the **Code Generation** tab. From the **Function packaging** list, select the option, `Nonreusable function`.
9. From the **Function name options** list, select the option, `User specified`. The **Function name** parameter is displayed.
10. Specify the name as `func`.
11. Click **Apply**.
12. Double-click the `func` subsystem block. In this example, function `func()` has an output `flag` set to `0` or `1` depending on the result of the algorithm in func( ). Create the func() algorithm as shown in the following diagram:



func

13. Double-click the While Iterator block to set the **Maximum number of iterations** to 100.
14. Connect blocks as shown in the model and subsystem diagrams.

Results

The generated code includes the following `ex_while_loop_SL_step` function in the file `ex_while_loop_SL.c`:

```
/* Model step function */
void ex_while_loop_SL_step(void)
{
  int32_T s1_iter;
  boolean_T loopCond;

  /* Constant: '<Root>/Initial Condition SET to TRUE' */
  IC = P.InitialConditionSETtoTRUE_Value;

  /* Outputs for Iterator SubSystem: '<Root>/While Iterator Subsystem' incorporates:
   *  WhileIterator: '<S1>/While Iterator'
   */
  s1_iter = 1;

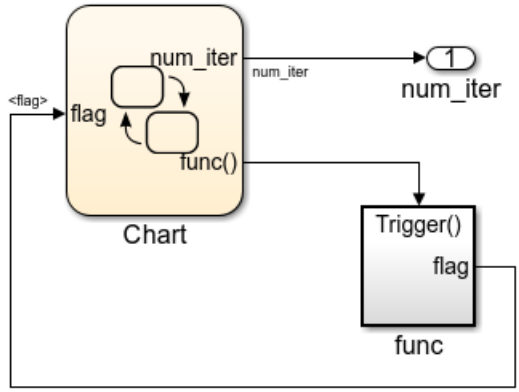
  /* InitializeConditions for Atomic SubSystem: '<S1>/func' */
  func_Init();

  /* End of InitializeConditions for SubSystem: '<S1>/func' */
  loopCond = IC;
  while (loopCond && (s1_iter <= 100)) {
    /* Outputs for Atomic SubSystem: '<S1>/func' */
    func();

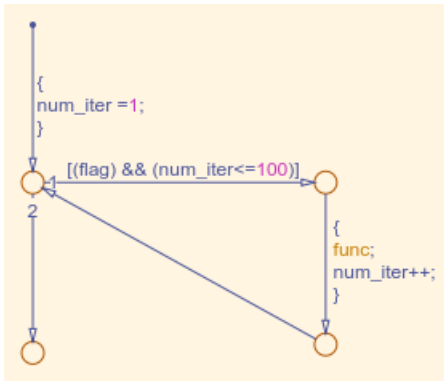
    /* End of Outputs for SubSystem: '<S1>/func' */
    loopCond = flag;
    s1_iter++;
  }

  /* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */
}
```

Modeling Pattern for While Loop: Stateflow Chart



Model ex_while_loop_SF



ex_while_loop_SF/Chart Executes the desired while-loop

Procedure

1. Add a Stateflow Chart to your model from the **Stateflow > Chart** library.
2. Double-click the chart.
3. Add the input, `flag`, and output, `func`, to the chart and specify their data type.
4. Connect the data input and output to the Stateflow chart as shown in the model diagram.

5 In the Model Explorer, select the output variable, then, in the right pane, select the **General** tab and set the **Initial Value** to `0`.

6 Select **Chart** > **Add Patterns** > **Loop** > **While**. The Stateflow Pattern dialog opens.

7 Fill in the fields for the Stateflow Pattern dialog box as follows:

Description	`While Loop` (optional)
While condition	`(flag) && (num_iter<=100)`
Do action	`func; num_iter++;`

8 Place a Subsystem block in your model.

9 Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.

10 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.

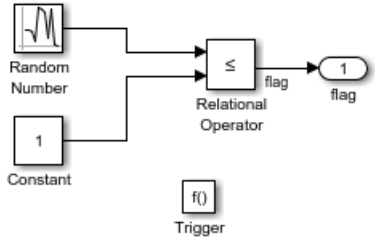
11 Select the **Code Generation** tab. From the **Function packaging** list, select the option, `Nonreusable function`.

12 From the **Function name options** list, select the option, `User specified`. The **Function name** parameter is displayed.

13 Specify the name as `func`.

14 Click **Apply** to apply the changes.

15 Double-click the `func` subsystem block. In this example, function `func` has an output `flag` set to `0` or `1` depending on the result of the algorithm in func( ). The Trigger block parameter **Trigger type** is `function-call`. Create the func() algorithm, as shown in the following diagram:



ex_while_loop_SF/func A function that updates the flag

16 Save and close the subsystem.

17 Connect blocks to the Stateflow chart as shown in the model diagram for `ex_while_loop_SF`.

18 Save your model.

Results

The generated code includes the following `ex_while_loop_SF_step` function in the file `ex_while_loop_SF.c`:

```
/* Exported block signals */
int32_T num_iter;                      /* '<Root>/Chart' */
boolean_T flag;                        /* '<S2>/Relational Operator' */

/* Block states (auto storage) */
D_Work DWork;

/* Model step function */
void ex_while_loop_SF_step(void)
{
  /* Chart: '<Root>/Chart' */
  /* Gateway: Chart */
  /* During: Chart */
  /* Entry Internal: Chart */
  /* Transition: '<S1>:2' */
  num_iter = 1;
  while (flag && (num_iter <= 100)) {
    /* Outputs for Function Call SubSystem: '<Root>/func' */

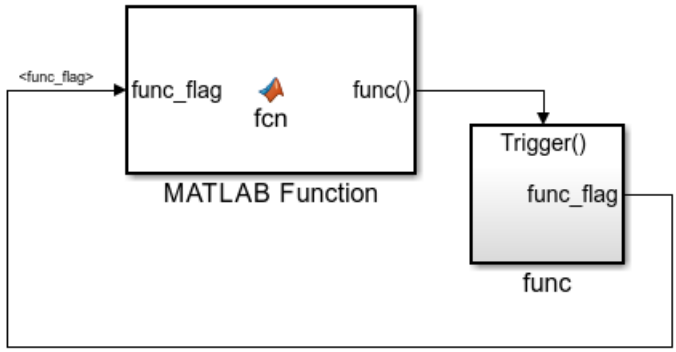
    /* Transition: '<S1>:3' */
    /* Transition: '<S1>:4' */
    /* Event: '<S1>:12' */
    func();

    /* End of Outputs for SubSystem: '<Root>/func' */
    num_iter++;

    /* Transition: '<S1>:5' */
  }

  /* End of Chart: '<Root>/Chart' */
  /* Transition: '<S1>:1' */
}
```

Modeling Pattern for While Loop: MATLAB Function Block



Model ex_while_loop_ML

Procedure

1. In the Simulink Library Browser, click **Simulink > User Defined Functions**, and drag a MATLAB Function block into your model.
2. Double-click the MATLAB Function block. The MATLAB Function Block Editor opens.
3. In the MATLAB Function Block Editor enter the function, as follows:

```
function fcn(func_flag)

flag = true;
num_iter = 1;

while(flag && (num_iter<=100))
    func;
    flag = func_flag;
    num_iter = num_iter + 1;
end
```

4. Select **Edit Data** on the Editor tab. The Ports and Data Manager opens.
5. Select **Add > Function Call Output**. Change the name of the function call output to `func`.
6. Click **Save** and close the MATLAB Function Block Editor.

7 Place a Subsystem block in your model, right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.

8 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.

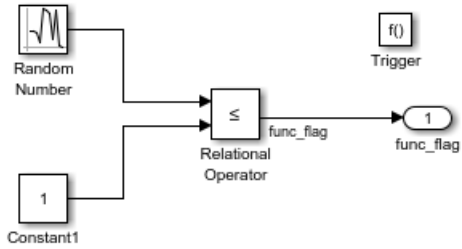
9 Select the **Code Generation** tab. From the **Function packaging** list, select the option, `Nonreusable function`.

10 From the **Function name options** list, select the option, `User specified`. The **Function name** parameter is displayed.

11 Specify the name as `func`.

12 Click **Apply**.

13 Double-click the `func()` subsystem block. In this example, function `func()` has an output `flag` set to `0` or `1` depending on the result of the algorithm in func( ). The Trigger block parameter **Trigger type** is `function-call`. Create the func() algorithm, as shown in the following diagram:



Model ex_while_loop_ML_func

14 Save and close the subsystem.

15 Connect the MATLAB Function block to the `func()` subsystem.

16 Save your model.

Results

The generated code includes the following `while_loop_ML_step` function in the file `while_loop_ML.c`. In some cases an equivalent `for` loop might be generated instead of a `while` loop.

```
/* Model step function */
void ex_while_loop_ML_step(void)
```

```
{
  boolean_T func_flag_0;
  boolean_T flag;
  int32_T num_iter;

  /* MATLAB Function: '<Root>/MATLAB Function' */
  func_flag_0 = func_flag;

  /* MATLAB Function 'MATLAB Function': '<S1>:1' */
  /* '<S1>:1:3' */
  flag = true;

  /* '<S1>:1:4' */
  num_iter = 1;
  while (flag && (num_iter <= 100)) {
    /* Outputs for Function Call SubSystem: '<Root>/func' */

    /* '<S1>:1:6' */
    /* '<S1>:1:7' */
    func();

    /* End of Outputs for SubSystem: '<Root>/func' */

    /* '<S1>:1:8' */
    flag = func_flag_0;

    /* '<S1>:1:9' */
    num_iter++;
  }

  /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

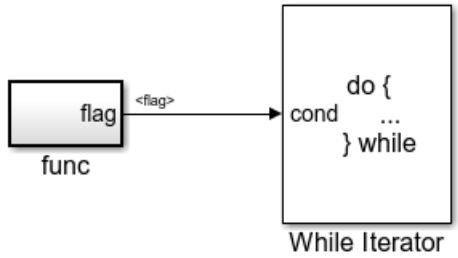
Modeling Pattern for Do While Loop: While Iterator Subsystem block

One method for creating a `while` loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

ex_do_while_loop_SL



ex_do_while_loop_SL/While Iterator Subsystem

Procedure

1. Drag a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library into the model.
2. Double-click the While Iterator Subsystem block to open the subsystem.
3. Place a Subsystem block next to the While Iterator block.
4. Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
5. Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.

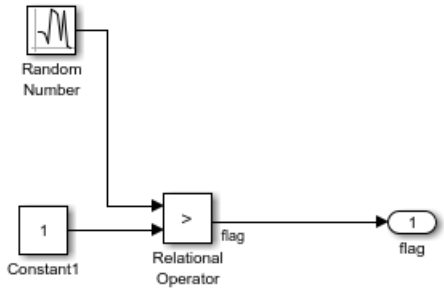
6 Select the **Code Generation** tab. From the **Function packaging** list, select the option, `Nonreusable function`.

7 From the **Function name options** list, select the option, `User specified`. The **Function name** parameter is displayed.

8 Specify the name as `func`.

9 Click **Apply**.

10 Double-click the `func` subsystem block. In this example, function `func` has an output `flag` set to `0` or `1` depending on the result of the algorithm in func. Create the `func` algorithm as shown in the following diagram:



ex_do_while_loop_SL/While Iterator Subsystem/func

11 Double-click the While Iterator block. This opens the Block Parameters dialog.

12 Set the **Maximum number of iterations** to 100.

13 Specify the **While loop type** as `do-while`.

14 Connect blocks as shown in the model and subsystem diagrams.

15 Enter `Ctrl+B` to generate code.

Results

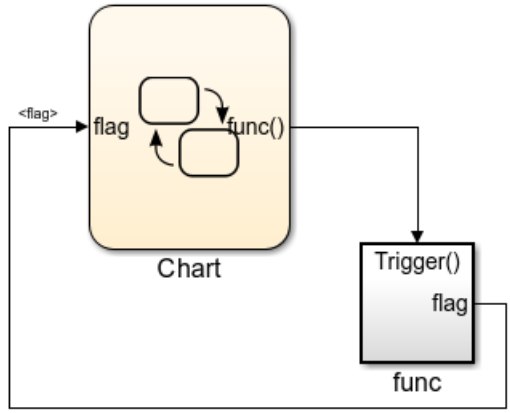
```
void func(void)
{
   flag = (DWork.NextOutput > (real_T)P.Constant1_Value);
   DWork.NextOutput =
      rt_NormalRand(&DWork.RandSeed) * P.RandomNumber_StdDev +
      P.RandomNumber_Mean;
}

void ex_do_while_loop_SL_step(void)
{
   int32_T s1_iter;
```

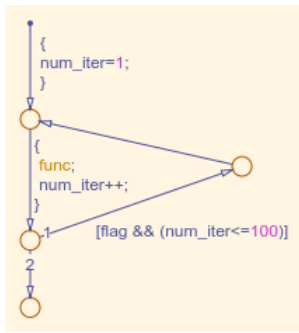
```
    s1_iter = 1;
    do {
       func();
       s1_iter++;
    } while (flag && (s1_iter <= 100));

}
```

Modeling Pattern for Do While Loop: Stateflow Chart



ex_do_while_loop_SF



ex_do_while_loop_SF/Chart

1. Add a Stateflow Chart to your model from the **Stateflow > Chart** library.
2. Double-click the chart to open it.
3. Add the inputs and outputs to the chart and specify their data type.
4. Connect the data input and output to the Stateflow chart.
5. In the Model Explorer, select the output variable, then, in the right pane, select the **General** tab and set the **Initial Value** to 0.

6 Select **Chart > Add Patterns > Loop > While**. The Stateflow Pattern dialog opens.

7 Fill in the fields for the Stateflow Pattern dialog box as follows:

Description	`While Loop` (optional)
While condition	`(flag) && (num_iter<=100)`
Do action	`func; num_iter++;`

8 Place a Subsystem block in your model.

9 Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.

10 Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.

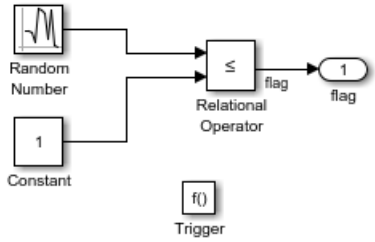
11 Select the **Code Generation** tab. From the **Function packaging** list, select the option, `Nonreusable function`.

12 From the **Function name options** list, select the option, `User specified`. The **Function name** parameter is displayed.

13 Specify the name as `func`.

14 Click **Apply** to apply the changes.

15 Double-click the `func` subsystem block. In this example, function `func` has an output `flag` set to `0` or `1` depending on the result of the algorithm in func. The Trigger block parameter **Trigger type** is `function-call`. Create the func algorithm, as shown in the following diagram:



ex_do_while_loop_SF/func Updates the flag

16 Save and close the subsystem.

17 Connect blocks to the Stateflow chart as shown in the model diagram for `ex_do_while_loop_SF`.

18 Save your model.

Results

```
void ex_do_while_loop_SF_step(void)
{
   int32_T sf_num_iter;
   num_iter = 1;
   do {
      func();
      num_iter++;
    } while (flag && (sf_num_iter <= 100));

}
```

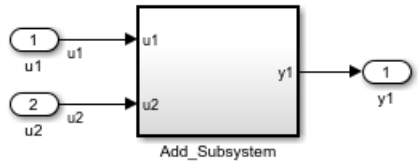
Function Call

To generate a function call, add a subsystem, which implements the operations that you want.

C Construct

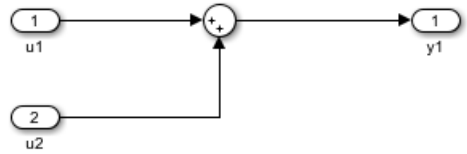
```
void add_function(void)
{
   y1 = u1 + u2;
}
```



ex_function_call

Procedure

1. Create a model containing a subsystem. In this example, the subsystem has two inputs and returns one output.
2. Double-click the subsystem. Create `Add_Subsystem`, as shown.



ex_function_call/Add_Subsystem

3. Right-click the subsystem and select **Block Parameters (Subsystem)** to open the Subsystem Parameters dialog box.

4 Select the **Treat as atomic unit** parameter. This enables parameters on the **Code Generation** tab.

   Select the **Code Generation** tab. For the **Function packaging** parameter, from the drop-down list, select `Nonreusable function`.

5 For the **Function name options** parameter, from the drop-down list, select `User specified`.

6 In the **Function name** field, enter the subsystem name, `add_function`.

7 In the **File name options** field, select `Use function name`.

8 Click **Apply** and **OK**.

9 Press **Ctrl+B** to build and generate code.

Results

In `ex_function_call.c`, the function is called from `ex_function_call_step`:

```
void ex_function_call_step(void)
{
   add_function();
}
```

The function prototype is externed through the subsystem file, `add_function.h`.

```
extern void add_function(void);
```

The function definition is in the subsystem file `add_function.c`:

```
void add_function(void)
{
   function_call_Y.y1 = u1 + u2;
}
```

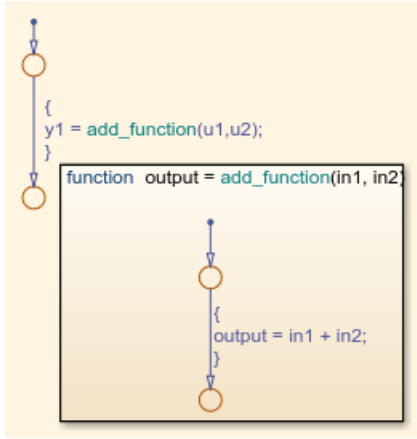
```
double add_function(double u1, double u2)
{
   return u1 + u2;
}
```

Modeling Patterns

Function Call Using Graphical Functions

Procedure

1. Follow the steps for "Set Up an Example Model With a Stateflow Chart" on page 13-5. This example model contains two Inport blocks and one Outport block.
2. Name the example model `ex_func_SF`.
3. In the **Stateflow Editor**, create a graphical function by clicking the ***fx*** button and placing a graphical function into the Stateflow chart.
4. Edit the graphical function signature to: `output = add_function(u1, u2)`.
5. Add the transition action, as shown in the following diagram.



ex_func_SF/Chart

In the Stateflow chart is an example of a simple transition that calls `add_function`.

6 Open the Model Explorer. From the Model Hierarchy tree, select **ex_func_SF > Chart > f()add_function**. On the right pane, specify the **Function Inline Option** as `Function`.

7 From the Model Hierarchy tree, click **Chart** and on the right pane select the **Export Chart Level Functions (Make Global)** parameter. This makes the function available globally to the entire model.

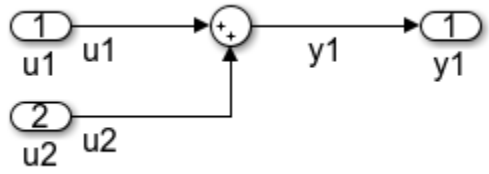
8 Press **Ctrl+B** to build the model and generate code.

Results

`ex_func_SF.c` contains the generated code:

```
real_T add_function(real_T in1, real_T in2)
{
   return in1 + in2;
}
.
.
.
void ex_func_SF_step(void)
{
   y1 = add_function(u1, u2);
}
```

Control Function Prototype of the *model*_step Function



ex_control_step_function

Procedure

1. Create the model, `ex_control_step_function`. See "Configure a Signal" on page 13-3 and "Configure Input and Output Ports" on page 13-4, for more information.
2. Press **Ctrl+E** to open the Configuration Parameters dialog box.
3. On the **Code Generation > Interface** pane, click **Configure Model Functions** to open the Model Interface dialog box.
4. Specify the **Function specification** parameter as `Model specific C prototypes`.
5. Click **Get Default Configuration** to update the **Configure model initialize and step functions** section and list the input and output arguments.
6. To configure the function output argument to pass a pointer, in the **Step function arguments** table, specify the **Category** for the Outport as a `Pointer`. In addition, you can specify the step function arguments order and type qualifiers.
7. To validate your changes, click **Validate**.
8. Press **Ctrl+B** to build the model and generate code.

Results

`ex_control_step_function.c` contains the generated code:

```
void ex_control_step_function_custom(real_T arg_u1, real_T arg_u2, ...
                                     real_T *arg_y1)
{
    (*arg_y1) = arg_u1 + arg_u2;
}
```

Related Examples

- "About Function Prototype Control" on page 26-2

External C Functions

C Construct

```
extern double add(double, double);
```

```
#include "add.h"
double add(double u1, double u2)
{
   double y1;
   y1 = u1 + u2;
   return (y1);
}
```

Modeling Patterns

There are several methods for integrating legacy C functions into the generated code. These methods either create an S-function or make a call to an external C function. For more information on S-functions, see "S-Functions and Code Generation" (Simulink Coder).

- "Use the Legacy Code Tool to Create S-functions" on page 13-71
- "Use a Stateflow Chart to Make Calls to C Functions" on page 13-73
- "Using a MATLAB Function Block to Make Calls to C Functions" on page 13-75

Use the Legacy Code Tool to Create S-functions

This method uses the Legacy Code Tool to create an S-function and generate a TLC file. The code generation software uses the TLC file to generate code from this S-function. The advantage of using the Legacy Code Tool is that the generated code is fully inlined and does not need wrapper functions to access the custom code.

Procedure

1. Create a C header file named `add.h` that contains the function signature:

   ```
   extern double add(double, double);
   ```

2. Create a C source file named `add.c` that contains the function body:

```
double add(double u1, double u2)
{
   double y1;
   y1 = u1 + u2;
   return (y1);
}
```

3 To build an S-function for use in both simulation and code generation, run the following script or execute each of these commands at the MATLAB command line:

```
%% Initialize legacy code tool data structure
def = legacy_code('initialize');

%% Specify Source File
def.SourceFiles = {'add.c'};

%% Specify Header File
def.HeaderFiles = {'add.h'};

%% Specify the Name of the generated S-function
def.SFunctionName = 'add_function';

%% Create a c-mex file for S-function
legacy_code('sfcn_cmex_generate', def);

%% Define function signature and target the Output method
def.OutputFcnSpec = ['double y1 = add(double u1, double u2)'];

%% Compile/Mex and generate a block that can be used in simulation
legacy_code('generate_for_sim', def);

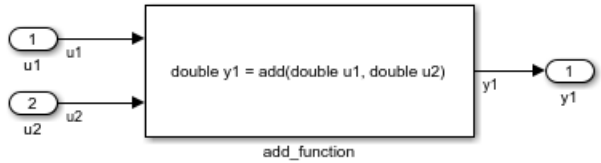
%% Create a TLC file for Code Generation
legacy_code('sfcn_tlc_generate', def);

%% Create a Masked S-function Block
legacy_code('slblock_generate', def);
```

The output of this script produces:

- A new model containing the S-function block
- A TLC file named `add_function.tlc`.
- A C source file named `add_function.c`.
- A mexw32 dll file named `add_function.mexw32`

4 Add inport blocks and an outport block and make the connections, as shown in the model.



ex_function_call_lct

5 Name and save your model. In this example, the model is named `ex_function_call_lct`.

6 Press **Ctrl+B** to build the model and generate code.

Results

The following code is generated in `ex_function_call_lct.c`:

```
real_T u1;
real_T u2;
real_T y1;
void ex_function_call_lct_step(void)
{
   y1 = add(u1, u2);
}
```

The user-specified header file, `add.h`, is included in `ex_function_call_lct.h`:

```
#include "add.h"
```

Use a Stateflow Chart to Make Calls to C Functions

Procedure

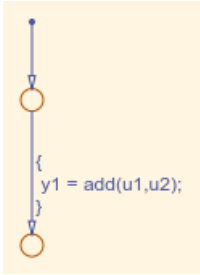
1 Create a C header file named `add.h` that contains the example function signature.

2 Create a C source file named `add.c` that contains the function body.

3 Follow the steps for "Set Up an Example Model With a Stateflow Chart" on page 13-5. This example model contains two Inport blocks and one Outport block.

4 Name the example model `ex_exfunction_call_SF`.

5 Double-click the Stateflow chart and edit the chart as shown. Place the call to the `add` function within a transition action.



ex_exfunction_call_SF/Chart

6 On the **Stateflow Editor**, select **Simulation** > **Model Configuration Parameters**.

7 On the Configuration Parameters dialog box, select **Simulation Target** > **Custom Code**. In the **Include custom C code in generated** section, on the left pane, select **Header file** and in the **Header file** field, enter the `#include` statement:

```
#include "add.h"
```

8 In the **Include list of additional** section, select **Source files** and in the **Source files** field, enter `add.c`.

9 On the Configuration Parameters dialog box, select **Code Generation** > **Custom Code**.

10 Select **Use the same custom code settings as Simulation Target** .

11 Press **Ctrl+B** to build the model and generate code.

Results

`ex_exfunction_call_SF.c` contains the following code in the step function:

```
real_T u1;
real_T u2;
real_T y1;

void exfunction_call_SF_step(void)
{
  y1 = (real_T)add(u1, u2);
}
```

`ex_exfunction_call_SF.h` contains the include statement for `add.h`:

```
#include "add.h"
```

Using a MATLAB Function Block to Make Calls to C Functions

Procedure

1. Create a C header file named `add.h` that contains the example function signature.
2. Create a C source file named `add.c` that contains the function body.
3. In the Simulink Library Browser, click **Simulink** > **User Defined Functions**, and drag a MATLAB Function block into your model.
4. Double-click the MATLAB Function block. The MATLAB Function Block Editor opens.
5. Edit the function to include the statement:

```
function y1 = add_function(u1, u2)

% Set the class and size of output
y1 = u1;

% Call external C function
y1 = coder.ceval('add',u1,u2);

end
```

6. Open the Configuration Parameters dialog box, and select **Simulation Target** > **Custom Code**.
7. In the **Include custom C code in generated** section, on the left pane, select **Header file** and in the **Header file** field, enter the statement, :

```
#include "add.h"
```

8. In the **Include list of additional** section, select **Source files** and in the **Source files** field, enter `add.c`.
9. Add two Inport blocks and one Outport block to the model and connect to the MATLAB Function block.
10. Configure the signals: `u1`, `u2`, and `y1`, as described in “Configure a Signal” on page 13-3.
11. Save the model as `ex_exfunction_call_ML`.
12. Press **Ctrl+B** to build the model and generate code.

Results

`ex_exfunction_call_ML.c` contains the following code:

```
real_T u1;
real_T u2;
real_T y1;

void ex_exfunction_call_ML_step(void)
{
     y1 = add(u1, u2);
}
```

`ex_exfunction_call_ML.h` contains the `#include` statement for `add.h`:

```
#include "add.h"
```

Macro Definitions (#define)

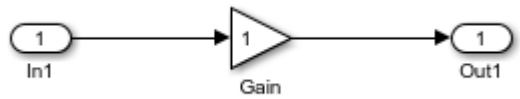
C Construct

```
#define myParam 9.8;
```

Export Generated Macro Definition

Procedure

1. Create the `ex_param_macro` model by using a Gain block.



2. In the Gain block dialog box, set **Gain** to `myParam`. Click **Apply**.
3. Click the button ⋮ next to the parameter value. Select **Create Variable**.
4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)`. Click **Create**.

   A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 9.8.
5. In the Simulink.Parameter property dialog box, set **Storage class** to `Define`. Click **OK**.
6. Generate code from the model.

Results

The generated header file `ex_param_macro.h` defines `myParam` as a macro.

```
/* Definition for custom storage class: Define */
#define myParam                             9.8
```

Reuse Macro from Handwritten Code

Procedure

1. Follow the steps in “Export Generated Macro Definition” on page 13-77.

2 At the command prompt, change the custom storage class of `myParam` from `Define` to `ImportedDefine`.

```
myParam.CoderInfo.CustomStorageClass = 'ImportedDefine';
```

3 Configure the code generator to import the macro definition from a custom header file named `external_params.h`.

```
myParam.CoderInfo.CustomAttributes.HeaderFile = 'external_params.h';
```

4 In your current folder, create the C header file `external_params.h`, which contains the `#define` statement.

```
#ifndef _EXTERNAL_PARAMS
#define _EXTERNAL_PARAMS

#define myParam 9.8

#endif

/* EOF */
```

5 Generate code from the model.

Results

The generated header file `ex_param_macro.h` does not define the macro. Instead, the file includes (`#include`) the custom header file `external_params.h`.

```
/* Includes for objects with custom storage classes. */
#include "external_params.h"
```

The source file `ex_param_macro.c` contains a guard to check that a definition for `myParam` exists.

```
/*
* Check that imported macros with storage class "ImportedDefine" are defined
*/
#ifndef myParam
#error The variable for the parameter "myParam" is not defined
#endif
```

Related Examples

- “Exchange and Reuse Parameter Data Between Generated Code and Existing Code” on page 23-11

- “Control Data Representation by Applying Custom Storage Classes” on page 23-58

Conditional Inclusions (#if / #endif)

You can generate preprocessor conditional directives in your code by implementing variant blocks (Model Variants block or Variant Subsystem block) in your model. In the generated code, preprocessor conditional directives select a section of code to execute at compile time. To implement variants in your model, see “Create a Simple Variant Model” (Simulink). To generate code for variants, see “Generate Preprocessor Conditionals for Variant Systems” on page 14-33.

Typedef

C Construct

```
typedef float float_32;
```

Procedure

To create a data type alias in Simulink, use a `Simulink.AliasType`. The code generator creates a `typedef` statement.

The built-in Simulink data type `single` corresponds to the C data type `float`.

1. At the command prompt, create a `Simulink.AliasType` object named `float_32` that represents an alias of `single`.

   ```
   float_32 = Simulink.AliasType('single')
   ```

2. Create the `ex_typedef` model by using a Gain block.

3. In the model, select **View** > **Model Data**.
4. In the Model Data Editor, view the **Inports/Outports** tab.
5. From the **Change View** drop-down list, select `Design`.
6. In the model, select the Inport block.
7. In the Model Data Editor, for the Inport block, set **Data Type** to `float_32`.
8. From the **Change View** drop-down list, select `Code`.
9. For the Inport block, set **Signal Name** to `mySig`.
10. Set **Storage Class** to `ExportedGlobal`.

    With this setting, the Inport block appears in the generated code as a separate global variable.
11. Generate code from the model.

Results

The generated header file `ex_typedef.h` defines the data type alias `float_32`.

```
#ifndef DEFINED_TYPEDEF_FOR_float_32_
#define DEFINED_TYPEDEF_FOR_float_32_

typedef real32_T float_32;

#endif
```

By default, the code generator also creates the alias `real32_T`, which corresponds to the C data type `float`. You can see the `typedef` statement in the generated header file `rtwtypes.h`.

```
typedef float real32_T;
```

The generated source file `ex_typedef.c` uses `float_32` to define the global variable `mySig`.

```
/* Exported block signals */
float_32 mySig;                        /* '<Root>/In1' */
```

- “Structures of Signals” on page 13-87

Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

C Construct

```
typedef struct {
  double G1;
  double G2;
} myStructType;

myStructType myStruct = {
  2.0,
  -2.0
} ;
```

Procedure

At the command prompt, create a structure named `myStruct` with two fields.

```
myStruct.G1 = 2;
myStruct.G2 = -2;
```

Store the structure in a `Simulink.Parameter` object.

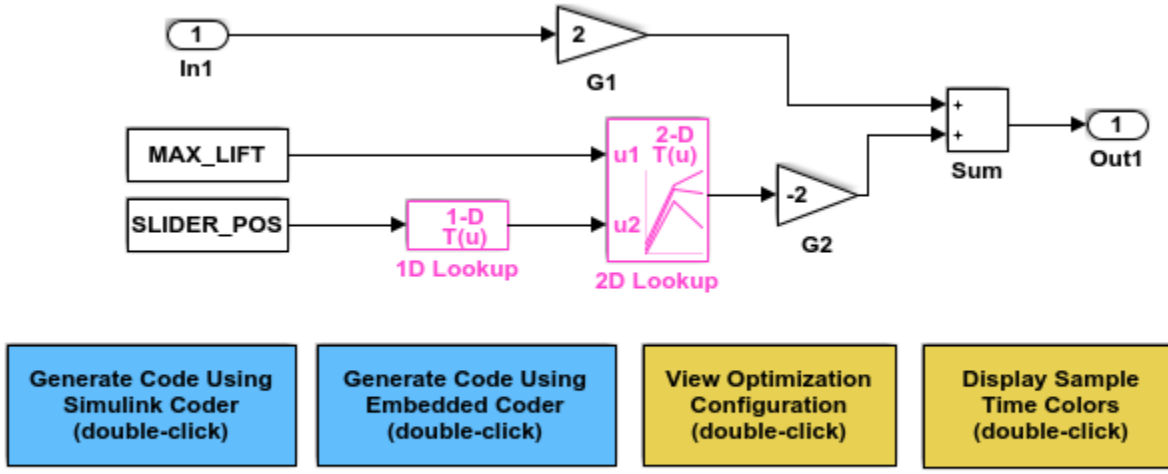
```
myStruct = Simulink.Parameter(myStruct);
```

Apply the storage class `ExportedGlobal` so that the structure appears in the generated code as a global variable.

```
myStruct.CoderInfo.StorageClass = 'ExportedGlobal';
```

Open the example model `rtwdemo_paraminline`.

```
rtwdemo_paraminline
```



In the G1 block dialog box, set **Gain** to `myStruct.G1`.

```
set_param('rtwdemo_paraminline/G1','Gain','myStruct.G1')
```

In the G2 block dialog box, set **Gain** to `myStruct.G2`.

```
set_param('rtwdemo_paraminline/G2','Gain','myStruct.G2')
```

Results

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated header file `rtwdemo_paraminline_types.h` defines a structure type with a randomized name.

```
file = fullfile('rtwdemo_paraminline_grt_rtw',...
    'rtwdemo_paraminline_types.h');
```

```
rtwdemodbtype(file,'typedef struct {','} struct_6h72eH5WFuEIyQr5YrdGuB;',...
    1,1)
```

```
typedef struct {
  real_T G1;
  real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,'struct_6h72eH5WFuEIyQr5YrdGuB myStruct',...
    '/* Variable: myStruct',1,1)
```

```
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
  2.0,
  -2.0
} ;                                    /* Variable: myStruct
```

Specify Name of Structure Type

Optionally, specify a name to use for the structure type definition (`struct`).

Create a `Simulink.Bus` object that represents the structure type.

```
Simulink.Bus.createObject(myStruct.Value);
```

The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

```
myStructType = slBus1.copy;
```

Use the bus object as the data type of the parameter object.

```
myStruct.DataType = 'Bus: myStructType';
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
rtwdemodbtype(file,'myStructType myStruct = {','/* Variable: myStruct',...
    1,1)
```

```
myStructType myStruct = {
  2.0,
  -2.0
} ;                                    /* Variable: myStruct
```

Related Examples

- "Organize Block Parameter Values into Structures in the Generated Code" on page 19-97

Structures of Signals

C Construct

```
typedef struct {
   double signal1;
   double signal2;
   double signal3;
} my_signals_type;
```

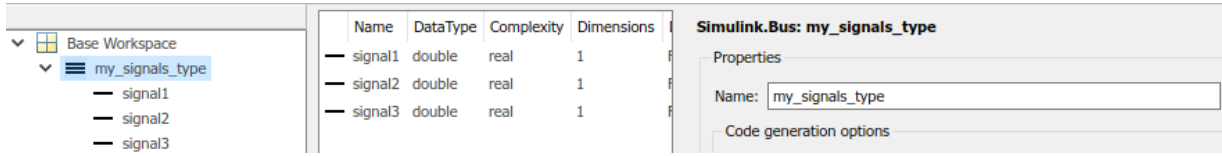
Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

1. Create the `ex_signal_struct` model with Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

   To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

2. In the model, select **Edit** > **Bus Editor**.
3. Use the Bus Editor to create a `Simulink.Bus` object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. To create bus objects with the Bus Editor, see "Create Bus Objects with the Bus Editor" (Simulink).



This bus object represents the structure type that you want the generated code to use.

4 In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

5 Select **Output as nonvirtual bus**. Click **OK**.

A nonvirtual bus appears in the generated code as a structure.

6 In the model, select **View** > **Model Data**.

7 In the Model Data Editor, on the **Signals** tab, from the **Change View** drop-down list, select `Code`.

8 In the model, click the output signal of the Bus Creator block.

9 In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

10 Set **Storage Class** to `ExportedGlobal`.

With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

11 Generate code from the model.

Results

The generated header file `ex_signal_struct.h` defines the structure type `my_signals_type`.

```
typedef struct {
  real_T signal1;
  real_T signal2;
  real_T signal3;
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */
my_signals_type sig_struct_var;        /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm uses `sig_struct_var` and the fields of `sig_struct_var`.

See Also

Simulink.Bus

Related Examples

- “Group Signals into Structures in the Generated Code Using Buses” on page 19-139
- “Combine Buses into an Array of Buses” (Simulink)

Nested Structures of Signals

C Construct

```
typedef struct {
  double signal1;
  double signal2;
  double signal3;
} B_struct_type;

typedef struct {
  double signal1;
  double signal2;
} C_struct_type;

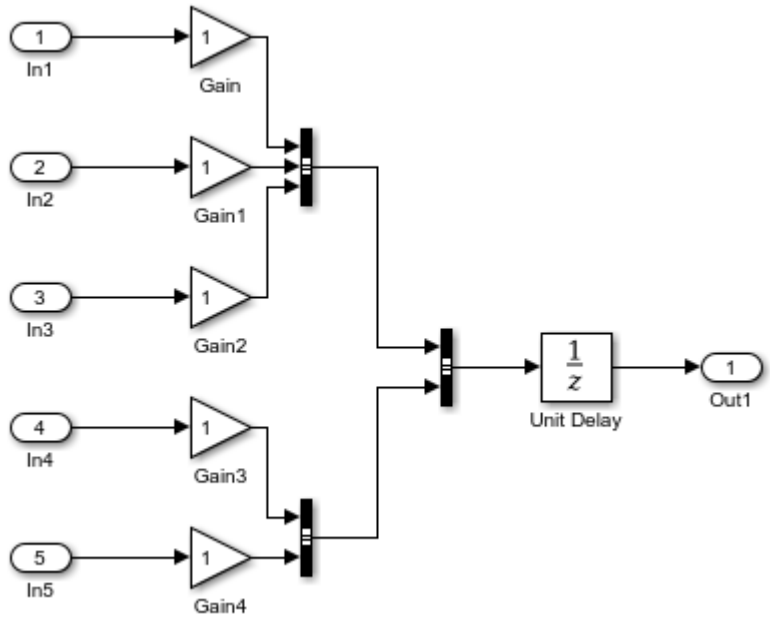
typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

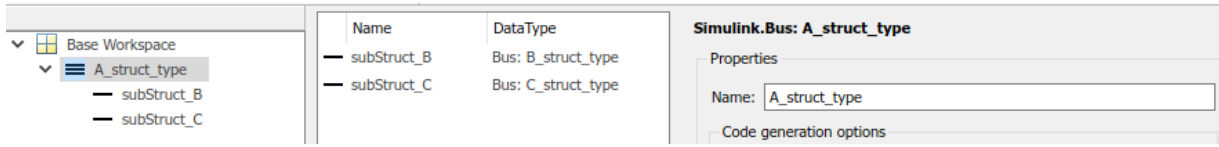
1. Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.



To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

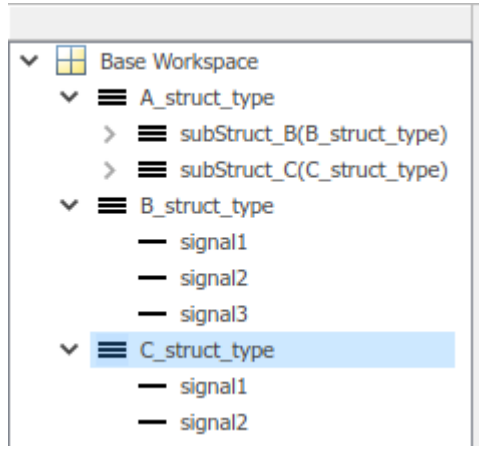
2. In the model, select **Edit** > **Bus Editor**.
3. Use the Bus Editor to create a `Simulink.Bus` object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see "Create Bus Objects with the Bus Editor" (Simulink).

   This bus object represents the top-level structure type that you want the generated code to use.
4. For the `subStruct_B` element, set **DataType** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`.



Each signal element in `A_struct_type` uses another bus object as a data type. Now these elements represent substructures.

5 Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).



6 In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to `Bus: B_struct_type`. Click **Apply**.

7 Select **Output as nonvirtual bus**. Click **OK**.

8 In the dialog box of the other subordinate Bus Creator block, set **Output data type** to `Bus: C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

9 In the last Bus Creator block dialog box, set **Output data type** to `Bus: A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

10 In the model, select **View** > **Model Data**.

11 In the Model Data Editor, on the **Signals** tab, from the **Change View** drop-down list, select `Code`.

12 In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

13 In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

14 Set **Storage Class** to `ExportedGlobal`.

   With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

15 Generate code from the model.

Results

The generated header file `ex_signal_nested_struct.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
  real_T signal1;
  real_T signal2;
  real_T signal3;
} B_struct_type;

typedef struct {
  real_T signal1;
  real_T signal2;
} C_struct_type;

typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is Bus Creator2.

```
/* Exported block signals */
A_struct_type sig_struct_var;          /* '<Root>/Bus Creator2' */
```

In the same file, in the model `step` function, the algorithm uses `sig_struct_var` and the fields of `sig_struct_var`.

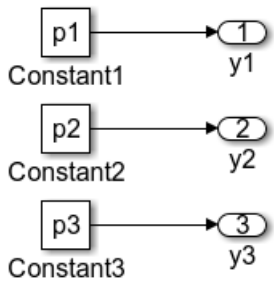
Bitfields

C Construct

```
typedef struct {
   unsigned int p1 : 1;
   unsigned int p2 : 1;
   unsigned int p3 : 1;
} my_struct_type
```

Procedure

1 Create the `ex_struct_bitfield_CSC` model with three Constant blocks and three Outport blocks. In each Constant block, set **Constant value** to `p1`, `p2`, or `p3`.



2 Create a `Simulink.Parameter` object in the base workspace for each Constant block, `p1`, `p2`, and `p3`. At the command prompt, enter:

```
p1 = Simulink.Parameter(false);
p2 = Simulink.Parameter(true);
p3 = Simulink.Parameter(false);
```

Each object stores a Boolean value (`true` or `false`) and uses the data type `boolean`.

3 Apply the custom storage class `BitField` to each parameter object.

```
p1.CoderInfo.StorageClass = 'Custom';
p1.CoderInfo.CustomStorageClass = 'BitField';

p2.CoderInfo.StorageClass = 'Custom';
p2.CoderInfo.CustomStorageClass = 'BitField';
```

```
p3.CoderInfo.StorageClass = 'Custom';
p3.CoderInfo.CustomStorageClass = 'BitField';
```

4 Configure each object to use the same structure type.

```
p1.CoderInfo.CustomAttributes.StructName = 'my_struct';

p2.CoderInfo.CustomAttributes.StructName = 'my_struct';

p3.CoderInfo.CustomAttributes.StructName = 'my_struct';
```

5 Generate code from the model.

Results

The generated header file `ex_struct_bitfield_CSC.h` defines the structure type `my_struct_type`.

```
/* Type definition for custom storage class: BitField */
typedef struct my_struct_tag {
  uint_T p1 : 1;
  uint_T p2 : 1;
  uint_T p3 : 1;
} my_struct_type;
```

The generated source file `ex_struct_bitfield_CSC.c` defines and initializes the structure variable `my_struct`.

```
/* Definition for custom storage class: BitField */
my_struct_type my_struct = {
  /* p1 */
  0,

  /* p2 */
  1,

  /* p3 */
  0
};
```

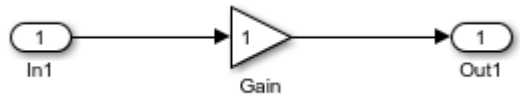
Arrays for Parameters

C Construct

```
float myParams[5]= {1.0F,2.0F,3.0F,4.0F,5.0F};
```

Procedure

1 Create the `ex_param_array` model by using a Gain block.



2 In the Gain block dialog box, set **Gain** to `myParams`. Click **Apply**.

3 Click the button ⋮ next to the parameter value. Select **Create Variable**.

4 In the Create New Data dialog box, set **Value** to `Simulink.Parameter([1 2 3 4 5])`. Click **Create**.

A `Simulink.Parameter` object, `myParams`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter.

5 In the Simulink.Parameter property dialog box, set **Storage class** to `ExportedGlobal`.

With this setting, `myParams` appears in the generated code as a separate global variable.

6 Set **Data type** to `single`. Click **OK**.

7 Generate code from the model.

Results

The generated source file `ex_param_array.c` defines and initializes the global variable `myParams`.

```
/* Exported block parameters */
real32_T myParams[5] = { 1.0F, 2.0F, 3.0F, 4.0F, 5.0F } ;/* Variable: myParams
```

```
* Referenced by: '<Root>/Gain'
*/
```

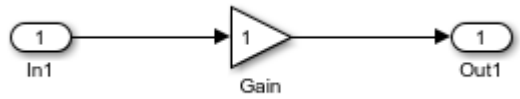
Arrays for Signals

C Construct

```
double myIn[5];
double myOut[5];
```

Procedure

1. Create the `ex_signal_array` model by using a Gain block.



2. In the model, select **View** > **Model Data**.
3. In the Model Data Editor, view the **Inports/Outports** tab.
4. From the **Change View** drop-down list, select `Design`.
5. In the model, select the Inport block.
6. In the Model Data Editor, for the Inport block, set **Signal Name** to `myIn`.
7. Set **Dimensions** to `[5 1]`.
8. For the Outport block, set **Signal Name** to `myOut`.
9. From the **Change View** drop-down list, select `Code`.
10. For the Inport block and the Outport block, set **Storage Class** to `ExportedGlobal`.

    With this setting, the blocks appear in the generated code as separate global variables.
11. Generate code from the model.

Results

The generated source file `ex_signal_array.c` defines the global variables `myIn` and `myOut` as arrays with 5 elements each.

```
/* Exported block signals */
```

```
real_T myIn[5];                         /* '<Root>/In1' */
real_T myOut[5];                        /* '<Root>/Out1' */
```

Pointers

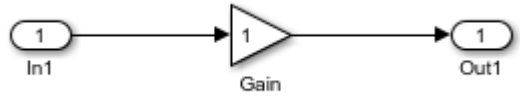
When your handwritten code allocates memory for signal, state, or parameter data, you can generate code that accesses that data through a pointer. Apply a storage class such as `ImportedExternPointer` to a data item in the model. Your handwritten code provides the pointer definition.

C Construct

```
extern double *myIn;
```

Procedure

1. Create the `ex_pointer` model by using a Gain block.



2. In the model, select **View** > **Model Data**.
3. In the Model Data Editor, view the **Inports/Outports** tab.
4. From the **Change View** drop-down list, select `Code`.
5. In the model, select the Inport block.
6. In the Model Data Editor, for the Inport block, set **Signal Name** to `myIn`.
7. Set **Storage Class** to `ImportedExternPointer`.
8. Generate code from the model.

Results

The generated header file `ex_pointer.h` declares the pointer.

```
/* Imported (extern) pointer block signals */
extern real_T *myIn;                   /* '<Root>/In1' */
```

In the generated source file `ex_pointer.c`, in the model `step` function, the algorithm dereferences the pointer, `myIn`.

```
/* Model step function */
void ex_pointer_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtY.Out1 = *myIn;
}
```

Variant Systems in Embedded Coder

Implement Dimension Variants for Array Sizes in Generated Code

Dimension Variants

Use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. Set up your model with dimensions that you specify as symbols in blocks and data objects. These symbols propagate throughout the model during simulation, and then go into the generated code. Modeling constraints for symbols during simulation (for example, `C=A+B`) are output as preprocessor conditionals in either the `model.h` or the *`model`* `_types.h` file.

You can directly specify dimension information as a symbol or a numeric constant for these blocks and data objects:

- Inport
- Outport
- Signal Specification
- Data Store Memory
- Interpreted MATLAB Function
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.BusElement`
- `AUTOSAR.Parameter`

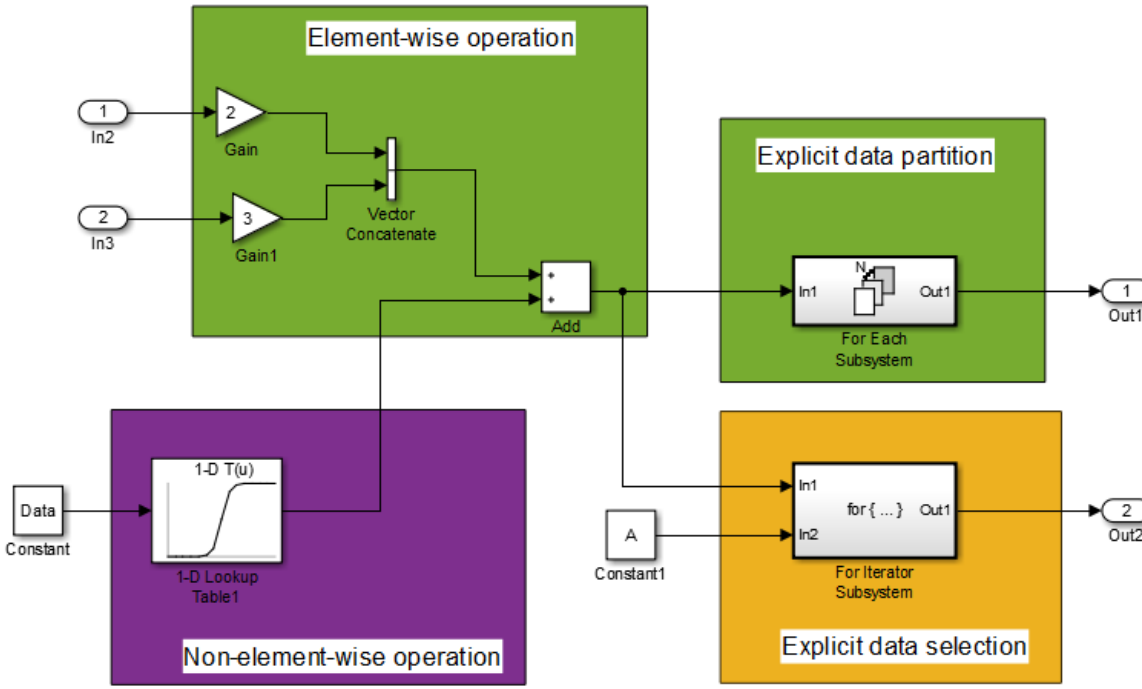
The Data Store Memory and Interpreted MATLAB Function blocks also support variable dimension signals. For these blocks, the symbolic dimensions control the maximum allowed size.

You use `Simulink.Parameter` objects to specify dimension information as symbols. For more information on signal dimensions, see “Signal Dimensions” (Simulink).

Note: The dimension variants feature is on by default. You can turn off this feature by clearing the “Allow symbolic dimension specification” (Simulink) parameter on the **All Parameters** tab of the Configuration Parameters dialog box.

Define Symbolic Dimensions

This example uses the model `rtwdemo_dimension_variants` to show how to implement symbolic dimensions. This model has four modeling patterns involving vectors and matrices.



1. Open the model matlab:rtwdemo_dimension_variants.
2. Open the Model Explorer. Select the base workspace pane.
3. In the base workspace, there are four `Simulink.Parameter` objects for specifying symbolic dimensions. These `Simulink.Parameter` objects have the names `A`, `B`, `C`, and `D`.
4. Select the `Simulink.Parameter` object `A`. Review the information in the Simulink.Parameter dialog box. `A` has a storage class of `CompilerFlag`.
5. Repeat Step 4 for each of the `Simulink.Parameter` objects `B`, `C`, and `D`.

6 For `Simulink.Parameter` objects with an `ImportedDefine` custom storage class, provide a header file on the MATLAB path. Insert the name of the header file in the **HeaderFile** field in the Simulink.Parameter dialog box.

To use a Simulink.Parameter object for dimension specification, it must have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

You can use MATLAB expressions to specify symbolic dimensions. For a list of supported MATLAB expressions, see the section Operators and Operands in Variant Condition Expressions in "Introduction to Variant Controls" (Simulink).

Specify Symbolic Dimensions for Blocks and Data Objects

1 Open the Source Block Parameters dialog box of Inport Block `In2`. In the **Signal Attributes** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object `A`. For Inport blocks, you specify symbolic dimensions in the **Port Dimensions** field.

2 Open the Source Block Parameters dialog box of Inport block `In3`. In the **Signal Attributes** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object `B`.

3 In the base workspace, select the `Simulink.Parameter` object `Data`. In the Simulink.Parameter dialog box for `Data`, the Dimension field has the character vector `'[1,C]'` , which is equivalent to `'[1,5]'` because `C` has a value of `5`. The **Value** field contains an array with `5` values, so the dimensions of `C` are consistent with the dimension of the `Data` object. The dimensions of the `Data` object must always be consistent with the value of the `Simulink.Parameter` object that is in the `Data` object **Dimensions** field. `Data` has a **Storage class** of `ImportedExtern`. A `Simulink.Parameter` object that uses a `Simulink.Parameter` for symbolic dimension specification must have a storage class of either `ImportedExtern` or `ImportedExternPointer`.

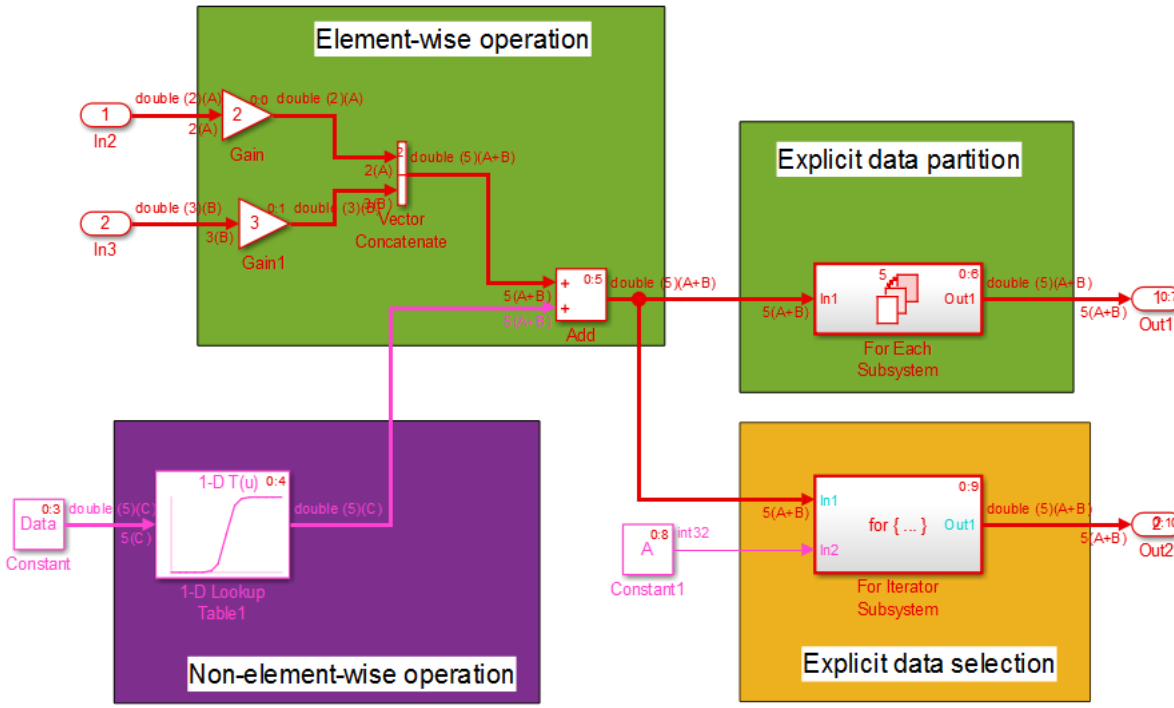
4 Open the Block Parameters dialog box of the `1-D Lookup Table1` block. The **Table data** field contains the `Simulink.Parameter`, `PT`. The **Breakpoints 1** field contains the `Simulink.Parameter`, `PB`.

5 In the base workspace, view the information in the Simulink.Parameter dialog boxes for `PB` and `PT`. These parameters contain the character vector `'[1,D]'` in their

Dimensions field and are arrays consisting of 15 values. The dimension of `D` are consistent with the dimension of the `PB` and `PT` parameters because `D` has a value of `15` .

6 Simulate the model. Simulink propagates the dimensions symbolically in the diagram. During propagation, Simulink establishes modeling constraints among symbols. Simulink then checks for consistency with these constraints based on current numerical assignments. One modeling constraint for `rtwdemo_dimension_variants` is that `C=A+B`. The **Diagnostic Viewer** produces a warning for any violations of constraints.

7 Change the dimension specification to a different configuration and simulate the model again.



Though not shown in this example, you can specify an n-D dimension expression with one or more of the dimensions being a symbol (for example, `'[A,B,C]'` or `'[1,A,3]'`).

Generate Code for a Model with Dimension Variants

Once you have verified dimension specifications through model simulation, generate code for `rtwdemo_dimension_variants`.

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
model='rtwdemo_dimension_variants';
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_dimension_variants
### Successful completion of build procedure for model: rtwdemo_dimension_variants
```

View the generated code. In the `rtwdemo_dimension_variants.h` file, symbolic dimensions are in data declarations.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'/* External inputs', '/* Real-time', 1, 0);
```

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  real_T In2[A];                       /* '<Root>/In2' */
  real_T In3[B];                       /* '<Root>/In3' */
} ExtU;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  real_T Out1[A + B];                  /* '<Root>/Out1' */
  real_T Out2[A + B];                  /* '<Root>/Out2' */
} ExtY;
```

The `rtwdemo_dimension_variants.h` file contains data definitions and preprocessor conditionals that define constraints established among the symbols during simulation. One of these constraints is that the value of a symbolic dimension must be greater than 1. This file also includes the user-provided header file for any `Simulink.Parameter` objects with an `ImportedDefine` custom storage class.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.h');
```

```
rtwdemodbtype(hfile,'#ifndef A', '/* Macros for accessing', 1, 0);

#ifndef A
#error The variable for the parameter "A" is not defined
#endif

#ifndef B
#error The variable for the parameter "B" is not defined
#endif

#ifndef C
#error The variable for the parameter "C" is not defined
#endif

#ifndef D
#error The variable for the parameter "D" is not defined
#endif

/*
 * Constraints for division operations in dimension variants
 */
#if (1 == 0) || (((A+B) % 1) != 0)
# error "The preprocessor definition '1' must not be equal to zero and the division of
#endif

/*
 * Registered constraints for dimension variants
 */
/* Constraint 'C == (A+B)' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if C != (A+B)
# error "The preprocessor definition 'C' must be equal to '(A+B)'"
#endif

#if A <= 1
# error "The preprocessor definition 'A' must be greater than '1'"
#endif

#if B <= 1
# error "The preprocessor definition 'B' must be greater than '1'"
#endif

/* Constraint 'D > 1' registered by:
```

```
 * '<Root>/1-D Lookup Table1'
 */
#if D <= 1
# error "The preprocessor definition 'D' must be greater than '1'"
#endif

/* Constraint 'C > 1' registered by:
 * '<S2>/Assignment'
 */
#if C <= 1
# error "The preprocessor definition 'C' must be greater than '1'"
#endif
```

In the `rtwdemo_dimension_variants.c` file, symbolic dimensions participate in loop bound calculations, array size and index offset calculations, and a parameterized utility function (for example, Lookup Table block) calculation.

```
cfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_dimension_variants_step(void)
{
  /* local scratch DWork variables */
  int32_T ForEach_itr;
  int32_T iU;
  real_T rtb_VectorConcatenate[A + B];
  int32_T s2_iter;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In2'
   */
  for (iU = 0; iU <= (int32_T)(A - 1); iU++) {
    rtb_VectorConcatenate[iU] = 2.0 * rtU.In2[iU];
  }

  /* End of Gain: '<Root>/Gain' */

  /* Gain: '<Root>/Gain1' incorporates:
   *  Inport: '<Root>/In3'
   */
  for (iU = 0; iU <= (int32_T)(B - 1); iU++) {
    rtb_VectorConcatenate[(int32_T)(A + iU)] = 3.0 * rtU.In3[iU];
```

```
}

/* End of Gain: '<Root>/Gain1' */
for (iU = 0; iU <= (int32_T)(C - 1); iU++) {
  /* Sum: '<Root>/Add' incorporates:
   *  Constant: '<Root>/Constant'
   *  Lookup_n-D: '<Root>/1-D Lookup Table1'
   */
  rtb_VectorConcatenate[iU] += look1_binlx(Data[iU], PB, PT, (uint32_T)
    ((uint32_T)D - 1U));
}

/* Outputs for Iterator SubSystem: '<Root>/For Each Subsystem' incorporates:
 *  ForEach: '<S1>/For Each'
 */
for (ForEach_itr = 0; ForEach_itr < (int32_T)(A + B); ForEach_itr++) {
  /* ForEachSliceAssignment: '<S1>/ImpAsg_InsertedFor_Out1_at_inport_0' incorporates
   *  ForEachSliceSelector: '<S1>/ImpSel_InsertedFor_In1_at_outport_0'
   *  MATLAB Function: '<S1>/MATLAB Function'
   */
  /* MATLAB Function 'For Each Subsystem/MATLAB Function': '<S3>:1' */
  /* '<S3>:1:4' y = 2*u; */
  rtY.Out1[ForEach_itr] = 2.0 * rtb_VectorConcatenate[ForEach_itr];
}

/* End of Outputs for SubSystem: '<Root>/For Each Subsystem' */

/* Outputs for Iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:

 */
/* Constant: '<Root>/Constant1' */
for (s2_iter = 0; s2_iter < ((int32_T)A); s2_iter++) {
  /* Assignment: '<S2>/Assignment' incorporates:
   *  Constant: '<S2>/Constant'
   *  Outport: '<Root>/Out2'
   *  Product: '<S2>/Product'
   *  Selector: '<S2>/Selector'
   */
  if (s2_iter == 0) {
    for (iU = 0; iU <= (int32_T)((int32_T)(A + B) - 1); iU++) {
      rtY.Out2[iU] = rtb_VectorConcatenate[iU];
    }
  }
```

```
    rtY.Out2[s2_iter] = rtb_VectorConcatenate[s2_iter] * 2.0;

    /* End of Assignment: '<S2>/Assignment' */
  }

  /* End of Constant: '<Root>/Constant1' */
  /* End of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Code Generation Optimization Considerations

When you create a model with symbolic dimensions, be aware of the following optimization considerations:

- The code generator reuses buffers only if dimension propagation establishes equivalence among buffers.
- Two loops with symbolic loop bound calculations are fused together only if they share equivalent symbolic expression.
- Optimizations do not eliminate a symbolic expression or condition check based on the current value of a symbolic dimension.

Backward Compatibility

If an existing model uses `Simulink.Parameter` objects to specify dimensions, it can be incompatible with dimension variants. Here are two common scenarios:

- Only a subset of blocks accepts symbolic dimension specifications. If a block is not compatible with symbolic dimensions, it causes an update diagram error.
- `Simulink.Parameter` objects that you use to define symbolic dimensions or have symbolic dimensions must have one of the storage classes described in this example. If these specifications are not met, the build procedure for the model fails during code generation.

You can address these backward compatibility issues by doing the following:

- Turn off dimension variants feature by clearing the **Allow symbolic dimension specification** parameter on the **All Parameters** tab in the Configuration Parameters dialog box.
- Update `Simulink.Parameter` objects that define symbolic dimensions or have symbolic dimension specifications.
- Update the model so that only supported blocks have symbolic dimensions or propagate symbolic dimensions.

Supported Blocks

For a list of supported blocks, see the Block Support Table. To access the information in this table, enter `showblockdatatypetable` at the MATLAB command prompt. Unsupported blocks (for example, MATLAB Function) can still work in a model containing symbolic dimensions as long as these blocks do not directly interact with symbolic dimensions.

In the following cases, supported blocks do not propagate symbolic dimensions.

- For `Unit Delay` blocks, you specify a `Simulink.Signal` object that has symbolic dimensions for the **Block Parameters** > **State Attributes** > **State name** parameter.
- For Assignment and Selector blocks, you set the **Block Parameters** > **Index Option** parameter to `Index vector (dialog)`. For Selector and Assignment blocks, if you specify a symbolic dimension for the Index parameter, the code generator does not honor the symbolic dimension in the generated code.
- For the Sum block, you specify `|+` for the **Block Parameters** > **List of signs** parameter, and you set the **Block Parameters** > **Sum over** parameter to `Specified dimension`.
- For the Product block, you specify a value of `1` for the **Block Parameters** > **Number of inputs** parameter, and you set the **Multiply over** parameter to **Specified dimensions**.
- For the ForEach block, you specify a symbolic dimension for the **Partition Width** parameter.

Note that the following modeling patterns are among those modeling patterns that can cause Simulink to error out:

- For Switch blocks, an input signal or the **Threshold** parameter has symbolic dimensions, and you select **Allow different data input sizes (Results in variable-size output signal)**.
- A Data Store Read block selects elements of a `Simulink.Bus` signal that has symbolic dimensions.
- For Lookup Table blocks, on the **Block Parameters** > **Algorithm** tab, you select the parameter **Use one input port for all input data**.

Limitations

The following products and software capabilities support dimension variants in that they act on the numeric value of a symbolic dimension. These features do not support the propagation of symbolic dimensions during model simulation and the preservation of symbolic dimensions in the generated code.

- Code Replacement for Lookup Tables
- Software-in-the-Loop (SIL) and Processor-in-the-Loop (PIL) simulations
- Accelerator and rapid accelerator simulation modes
- Scope and simulation observation (for example, logging, SDI, and so on)
- Model coverage
- Simulink Design Verifier
- Fixed-Point Designer
- Data Dictionary
- Simulink PLC Coder
- HDL Coder

The following do not support dimension variants:

- System Object
- Stateflow
- Physical modeling
- Discrete-event simulation
- Frame data
- MATLAB functions

The following limitations also apply to models that utilize symbolic dimensions.

- For simulation, the size of a symbolic dimension can equal 1. For code generation, the size of a symbolic dimension must be greater than `1`.
- If a symbolic dimension is a MATLAB expression that contains an arithmetic expression and either a relational or logical expression, you must add `+0` after the relational or logical part of the MATLAB expression. If you do not add `+0`, the model errors out during simulation because you cannot mix a `boolean` data type with integer or `double` data types. Adding `+0` converts the data type of the relational or logical part of the expression from a `boolean` to a `double`.

  For example, suppose in the Inport block parameters dialog box, the **Port dimensions** parameter has the expression `[(C==8)*D+E,3]`. The **Data type** parameter is set to `double`. Since `C==8` is a relational expression, you must change the expression to `[((C==8)+0)*D+E,3]` to prevent the model from producing an error during simulation.
- Simulink propagates symbolic dimensions for an entire structure or matrix, but not for a part of a structure or matrix. For example, the `Simulink.Parameter` `P` is a `2x3` matrix with symbolic dimensions `[Dim,Dim1]`.

  ```
  p=Simulink.Parameter(struct('A',[1 2 3;4 5 6]))
  p.DataType='Bus:bo'
  bo=Simulink.Bus
  bo.Elements(1).Name='A'
  bo.Elements(1).Dimensions='[Dim,Dim1]'
  Dim=Simulink.Parameter(2)
  Dim1=Simulink.Parameter(3)
  p.CoderInfo.StorageClass='Custom'
  p.CoderInfo.CustomStorageClass='Define'
  Dim.CoderInfo.StorageClass='Custom'
  Dim.CoderInfo.CustomStorageClass='Define'
  Dim1.Coderinfo.StorageClass='Custom'
  Dim1.CoderInfo.CustomStorageClass='Define'
  ```

  If you specify `p.A` for a dimensions parameter, Simulink propagates the symbolic dimensions `[Dim,Dim1]`. If you specify `p.A(1,:)`, Simulink propagates the numeric dimension `3` but not the symbolic dimension, `Dim1`.
- The MATLAB expression `A(:)` does not maintain symbolic dimension information. Use `A` instead.
- The MATLAB expression `P(2:A)` does not maintain symbolic dimension information. Use the Selector block instead.

- The MATLAB expression `P(2,:)` is not a tunable expression, so it does not maintain symbolic dimension information.
- Suppose that you set the value of a mask parameter, `myMaskParam`, by using a field of a structure or by using a subset of the structures in an array of structures. You store the structure or array of structures in a `Simulink.Parameter` object so that you can use a `Simulink.Bus` object to apply symbolic dimensions to the structure fields. Under the mask, you configure a block parameter to use one of the fields that have symbolic dimensions. The table shows some example cases.

Description	Value of mask parameter (`myMaskParam`)	Value of block parameter
`myStruct` is a structure with field `gains`, which uses symbolic dimensions.	`myStruct.gains`	`myMaskParam`
`myStruct` is a structure with field hierarchy `myStruct.subStruct.gai` The field `gains` uses symbolic dimensions.	`myStruct.subStruct`	`myMaskParam.gains`
`myStructs` is an array of structures. Each structure has a field `gains`, which uses symbolic dimensions.	`myStructs(2)`	`myMaskParam.gains`

In these cases, you cannot generate code from the model. As a workaround, choose one of these techniques:

- Use the entire structure (`myStruct`) or array of structures (`myStructs`) as the value of the mask parameter. Under the mask, configure the block parameter to dereference the target field from the mask parameter by using an expression such as `myMaskParam.subStruct.gains`.
- Use literal dimensions instead of symbolic dimensions for the target field (`gains`).

This limitation also applies when you use a field of a structure or a subset of the structures in an array of structures as the value of a model argument in a Model block.

Code Generation for Variant Blocks

The code generator produces code from a Simulink model containing one or more Variant Subsystem, Variant Source, and Variant Sink blocks. To learn how to create a model containing variant blocks, see "Create a Simple Variant Model" (Simulink).

Code is generated for different variant choices, the active variant, and the default variant. To generate code for variants, set the following conditions in the Variant Subsystem, Variant Source, or Variant Sink block:

- Clear the option **Override variant conditions and use the following variant**.
- Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

Code generated for Variant Subsystem blocks is surrounded by C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Code generated for Variant Source and Variant Sink blocks is surrounded by C preprocessor conditionals `#if` and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

To construct model reference variants and generate preprocessor directives in the generated code, see the example "Use Model Variants to Generate Code That Uses C Preprocessor Conditionals".

To construct variant subsystems and generate preprocessor directives in the generated code, see the example "Use Subsystem Variants To Generate Code That Uses C Preprocessor Conditionals".

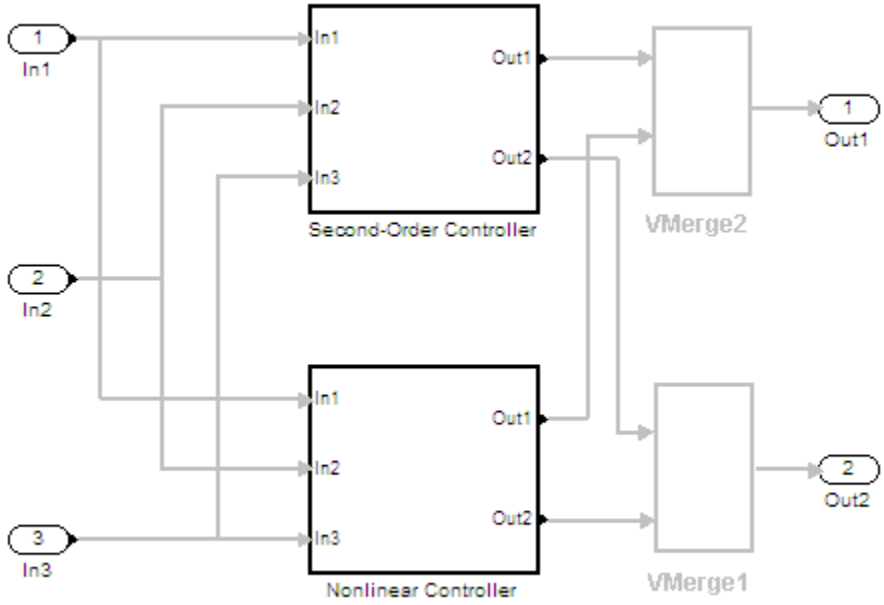
To construct models with variant sources and sinks and generate preprocessor directives in the generated code, see the example "Represent Variant Source and Sink Blocks in Generated Code" on page 14-37

Restrictions on Variant Subsystem Code Generation

To generate preprocessor conditionals, the types of blocks that you can place within the child subsystems of a Variant Subsystem block are limited. Connections are not allowed in the Variant Subsystem block diagram. However, during the code generation process, one `VariantMerge` block is placed at the input of each Outport block within the Variant Subsystem block diagram. All of the child subsystems connect to each of the `VariantMerge` blocks.

In the figure below, the code generation process makes the following connections and adds `VariantMerge` blocks to the sldemo_variant_subsystems model.

When compared to a generic Merge block the `VariantMerge` block can have only one parameter which is the number of Inputs. The `VariantMerge` block is used for code generation in variant subsystems internally, and is not available externally to be used in models. The number of inputs for `VariantMerge` is determined and wired as shown in the figure below.



The child subsystems of the Variant Subsystem block must be atomic subsystems. Select **Treat as atomic unit** parameter in the Subsystem block parameters dialog, to make the subsystems atomic. The `VariantMerge` blocks are inserted at the outport of the subsystems if more than one child subsystems are present. If the source block of a `VariantMerge` block input is nonvirtual, an error message will be displayed during code generation. You must make the source block contiguous, by inserting Signal Conversion blocks inside the variant choices. The signals that enter a Variant Subsystem block must have the same signal properties (for example, signal dimensions, port width, and storage class). The `VariantMerge` block does not support different signal properties because the

input ports and output ports share the same memory. You can use symbolic dimensions to generate code for a variant subsystem with child subsystems of different output signal dimensions.

Generated Code Components Not Compiled Conditionally

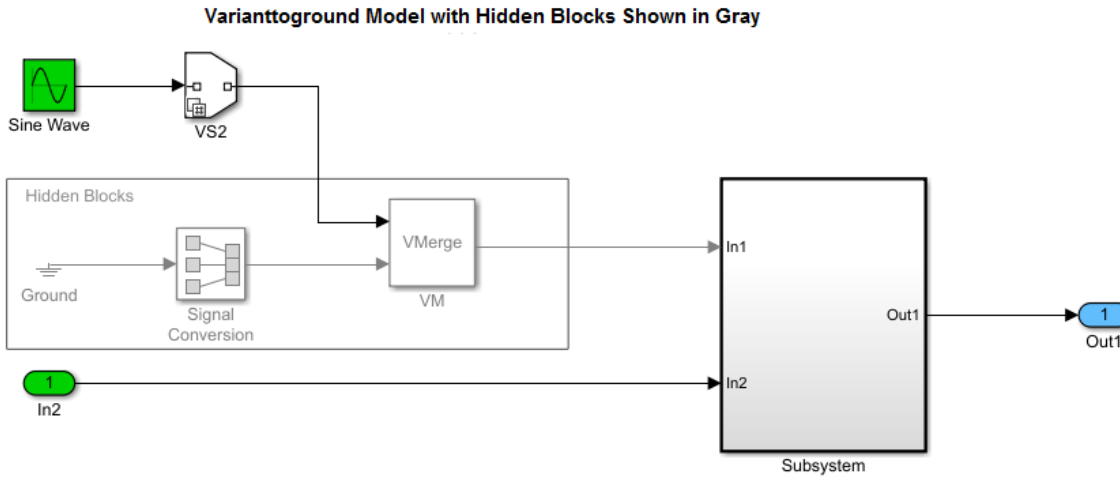
The following components are not conditionally compiled even if only code for variant subsystems or models that are conditionally compiled reference them.

- `rtModel` data structure fields
- `#include`'s of utility files
- Global non-constant parameter structure fields; when the configuration parameter **Optimization** > **Signals and Parameters** > **Parameter structure** is set to `NonHierarchical`
- Global constant parameter structure fields that are referenced by multiple subsystems activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are referenced by multiple subsystems that are activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are used by variant model blocks

Code Generation for Variant Blocks with One Variant Choice

For modeling patterns in which a Root Inport block connects to a Variant block with one variant choice, Simulink inserts a hidden block combination of a Ground block, Signal Conversion block, and a Variant Merge block. If the variant choice evaluates to false, this block combination produces an output of `0.0`.

For example, the model `Varianttoground` contains a Variant Source block with one variant choice. When the Variant Control `SYSCONST_A==6` evaluates to true, the input to `Subsystem` is a sine wave. When `SYSCONST_A==6` evaluates to false, the input to `Subsystem` is `0.0`.



The `varianttoground.c` file contains this code:

```
/* Sin: '<Root>/Sine Wave' */
#if SYSCONST_A == 6

  varianttoground_B.VM_Conditional_Signal_Subsystem_0_r64 = sin
    (varianttoground_M->Timing.t[0]);

#endif                                 /* SYSCONST_A == 6 */

  /* End of Sin: '<Root>/Sine Wave' */

  /* SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
#if SYSCONST_A != 6

  varianttoground_B.VM_Conditional_Signal_Subsystem_0_r64 = 0.0;

#endif                                 /* SYSCONST_A != 6 */

  /* End of SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
```

The comments in the generated code indicate the presence of the hidden signal conversion block. The code does not contain a comment for the Variant Merge block

because this block does not have associated generated code. The Variant Merge block is used internally and is not in the Simulink library.

Represent Subsystem and Model Variants in Generated Code

In this section...

Required products: Simulink, Embedded Coder, Simulink Coder

Using Simulink, you can create models that are based on a modular design platform that comprises a fixed common structure with a finite set of variable components. The variability helps you develop a single, fixed master design with variable components. For more information, see "What Are Variants and When to Use Them" (Simulink) (Simulink). When you implement variants in the generated code, you can:

- Reuse generated code from a set of application models that share functionality with minor variations.
- Share generated code with a third party that activates one of the variants in the code.
- Validate the supported variants for a model and then choose to activate one variant for a particular application, without regenerating and re-validating the code.
- Generate code for the default variant that is selected when an active variant does not exist.

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

This example shows how to represent variant choices in a Simulink model and then prepare the model so that those variant choices are represented in generated code.

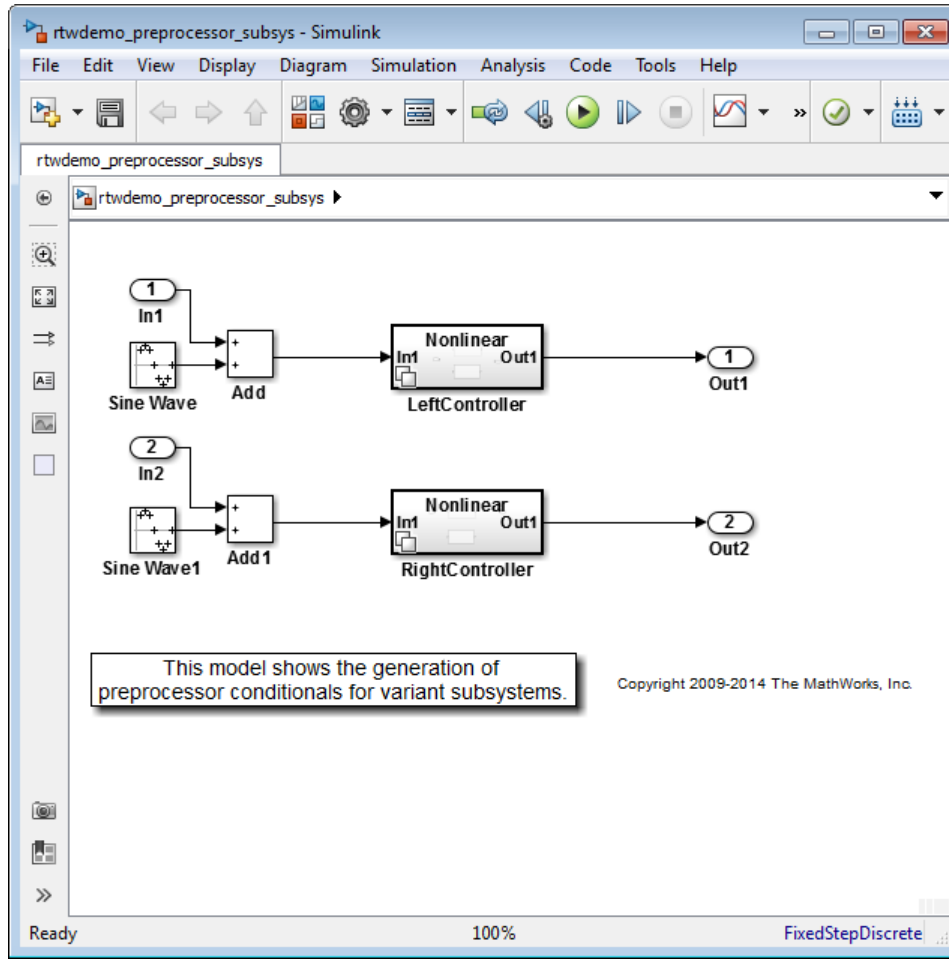
Step 1: Represent Variant Choices in Simulink

Variant choices are two or more configurations of a component in your model. This example uses the model `rtwdemo_preprocessor_subsys` to illustrate how to represent

variant choices inside Variant Subsystem blocks. For other ways to represent variant choices, see “Options for Representing Variants in Simulink” (Simulink) (Simulink).

1 Open the model `rtwdemo_preprocessor_subsys`.

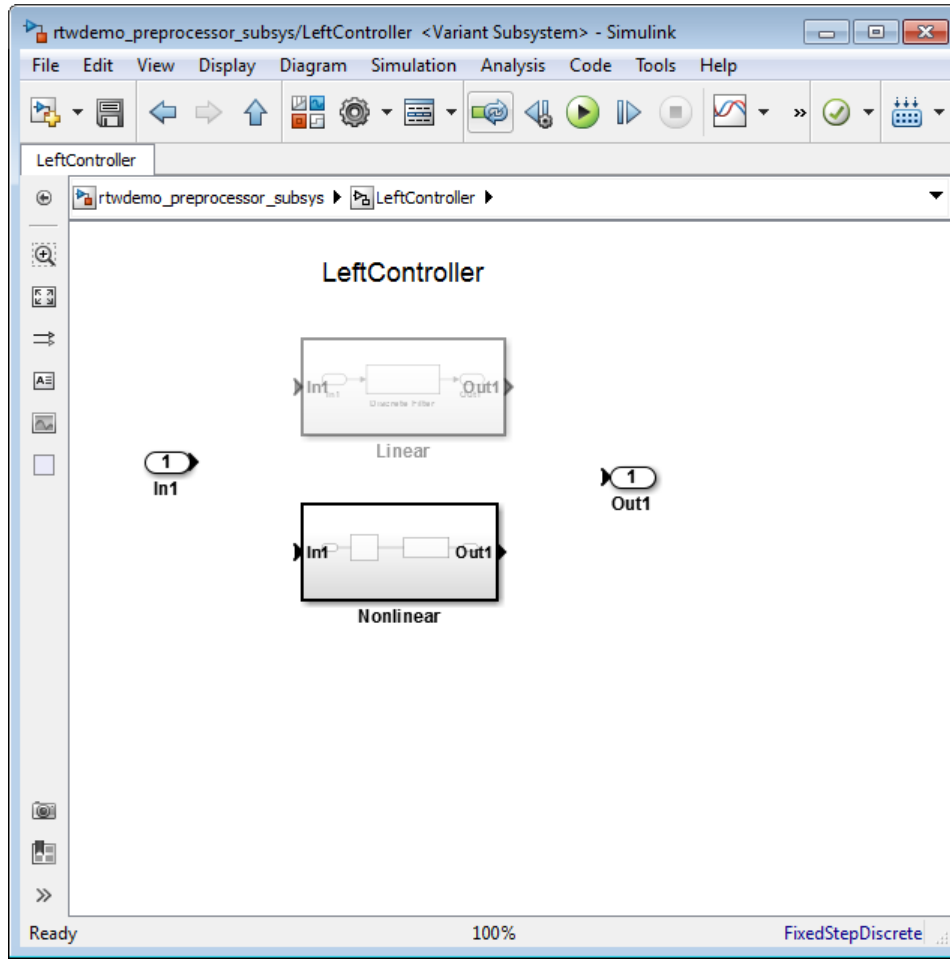
```
open_system('rtwdemo_preprocessor_subsys')
```



The model contains two Variant Subsystem blocks: **LeftController** and **RightController**.

Note: You can only add Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

2 Open the **LeftController** block.



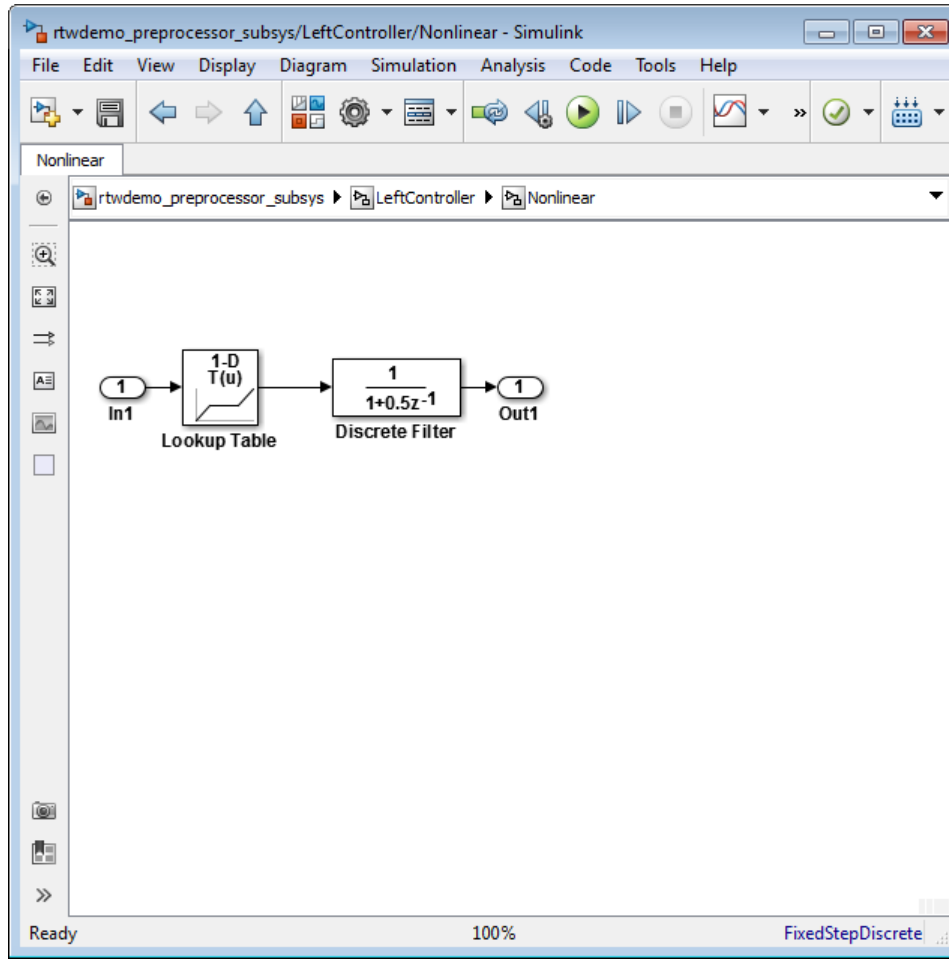
The **LeftController** block serves as the container for the variant choices. It contains two variant choices represented using Subsystem blocks **Nonlinear** and **Linear**.

The nonlinear controller subsystems implement hysteresis, whereas the linear controller subsystems act as simple low-pass filters.

The Subsystem blocks have the same number of inports and outports as the containing Variant Subsystem block.

Variant choices can have different numbers of inports and outports. See “Mapping Inports and Outports of Variant Choices” (Simulink) (Simulink).

3 Open the **Nonlinear** block.



The **Nonlinear** block represents one variant choice that Simulink activates when a condition is satisfied. The **Linear** block represents another variant choice.

Tip: When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside a Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

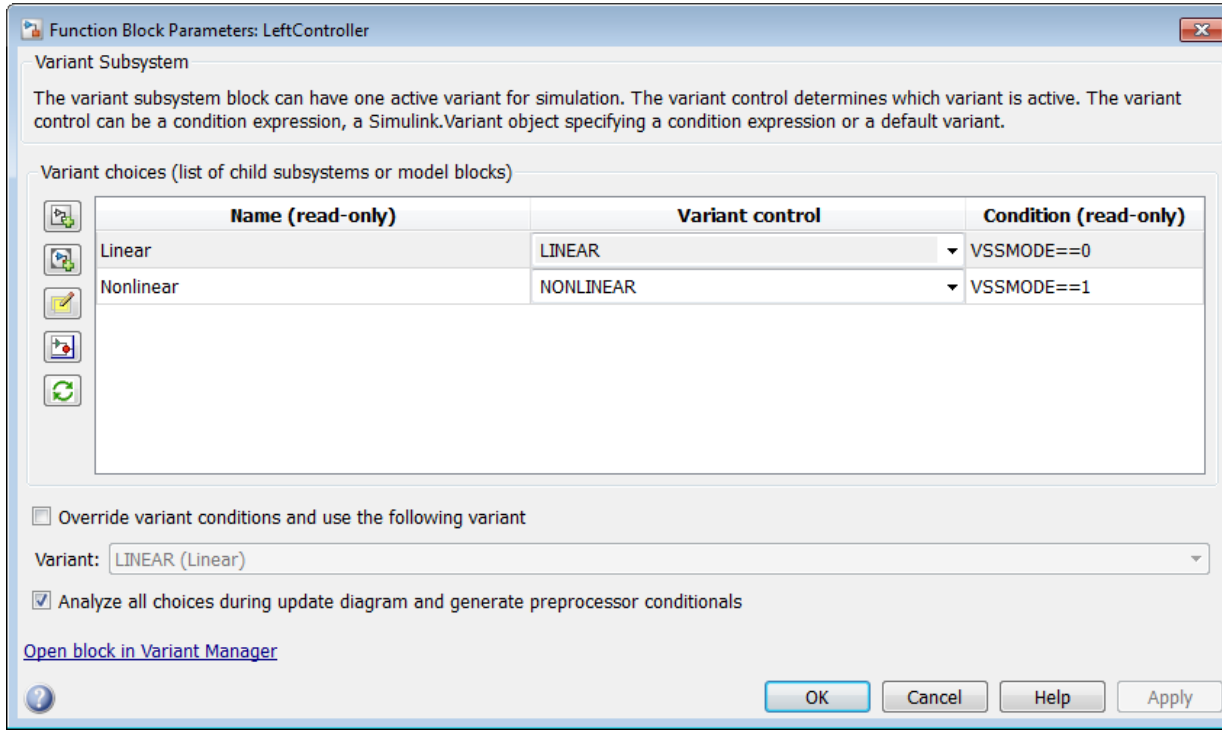
Step 2: Specify Conditions That Control Variant Choice Selection

You can switch between variant choices by constructing conditional expressions called variant controls for each variant choice represented in a Variant Subsystem block. Variant controls determine which variant choice is active, and changing the value of a variant control causes the active variant choice to switch.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

For more information, see "Introduction to Variant Controls" (Simulink) (Simulink).

1 Right-click the **LeftController** block and select **Block Parameters (Subsystem)**.



The **Condition** column displays the Boolean expression that when `true` activates each variant choice. In this example, these conditions are specified using `Simulink.Variant` objects `LINEAR` and `NONLINEAR`.

2 Use these commands to specify a variant control using a `Simulink.Variant` object.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Here, `VSSMODE` is called a variant control variable that can be specified in one of the ways listed in "Approaches for Specifying Variant Controls" (Simulink) (Simulink).

3 Define the variant control variable `VSSMODE`.

You can define `VSSMODE` as a scalar variable. However, to generate code, specify variant control variables as `Simulink.Parameter` objects. In addition to enabling the specification of parameter value, `Simulink.Parameter` objects allow you to specify other attributes such as data type that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- Your own custom storage class that defines data as a macro

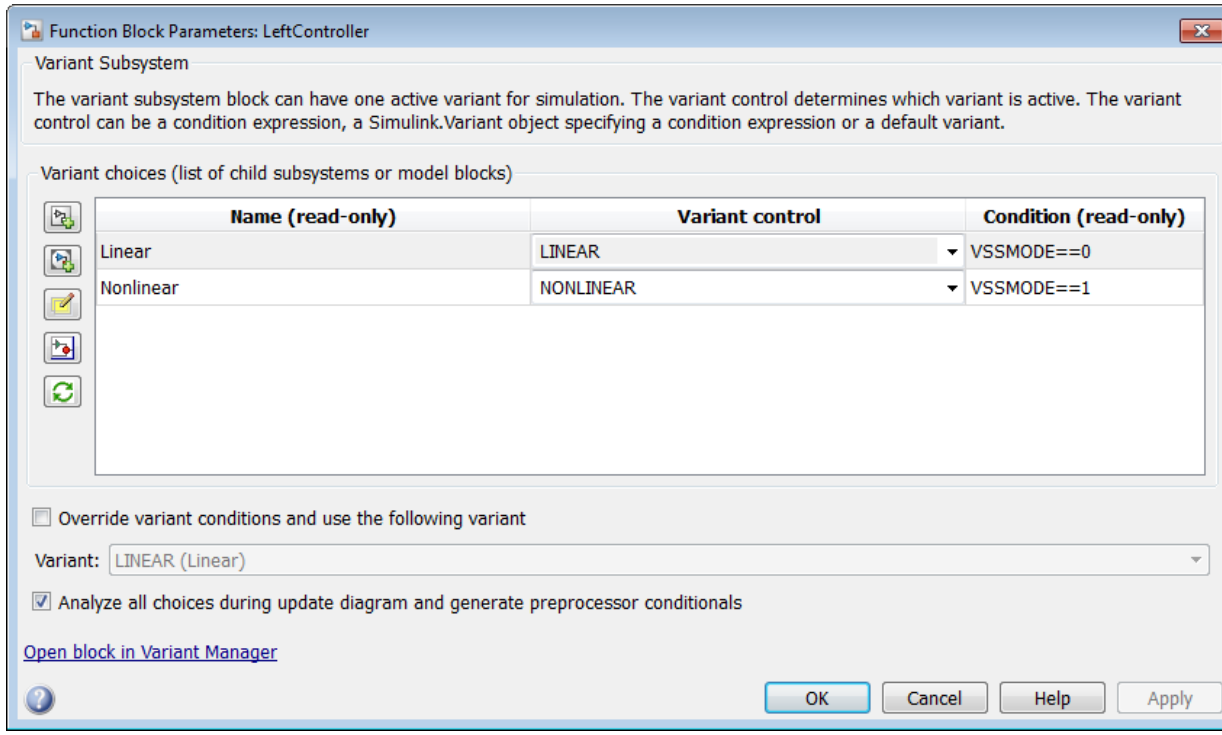
You can also convert a scalar variant control variable into a `Simulink.Parameter` object. See "Convert Variant Control Variables into Simulink.Parameter Objects" (Simulink) (Simulink).

Step 3: Configure Model for Generating Preprocessor Conditionals

Code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation** > **Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
3. In the **Report** pane, select **Create code generation report**.
4. On the **All Parameters** tab of the Configuration Parameters dialog box, clear **Ignore custom storage classes** and click **Apply**.
5. In your model, right-click the **LeftController** block and select **Block Parameters (Subsystem)**.

6 Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.



When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

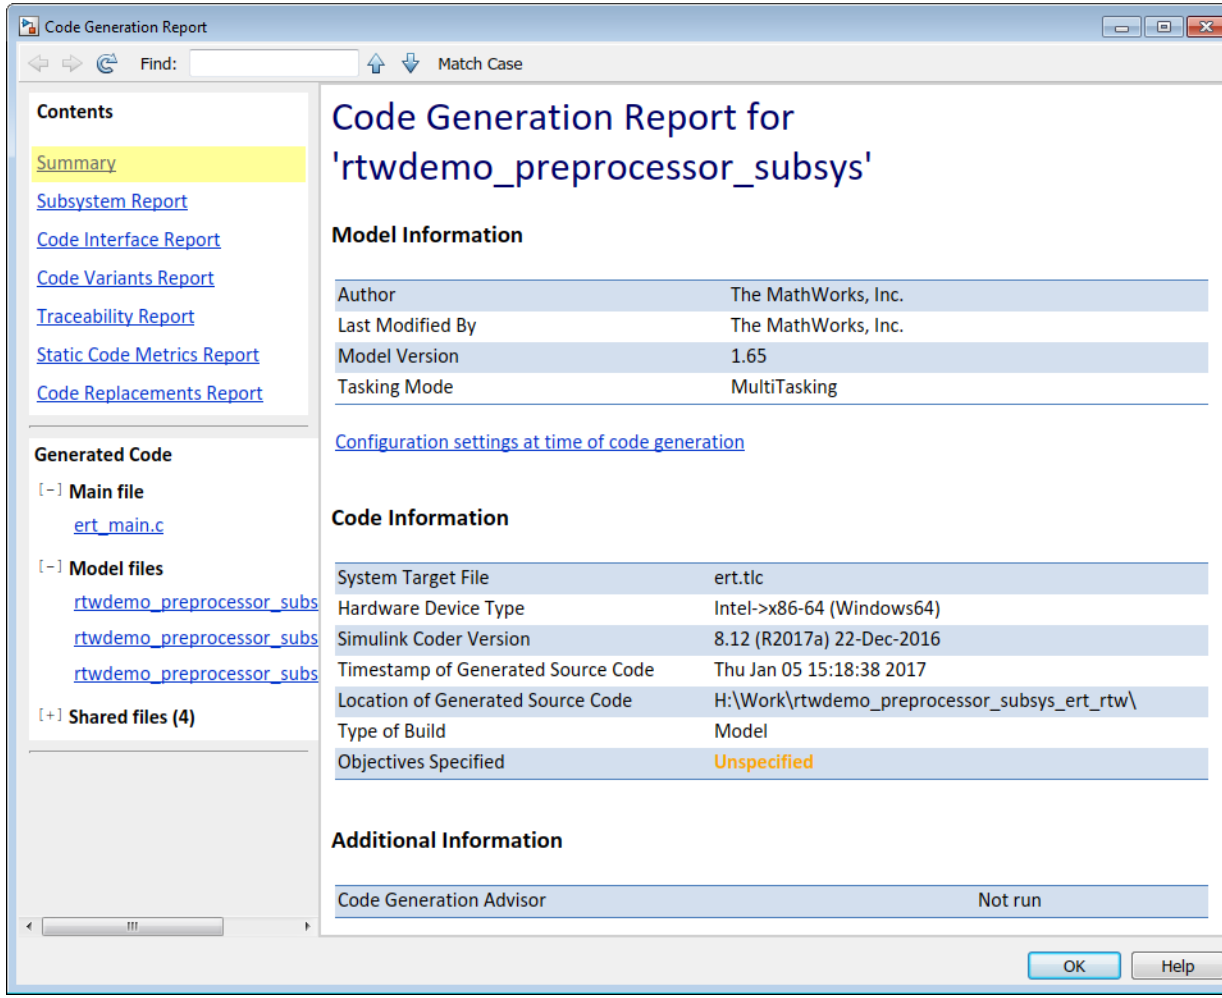
7 Clear the option **Override variant conditions and use following variant**.

8 Build the model.

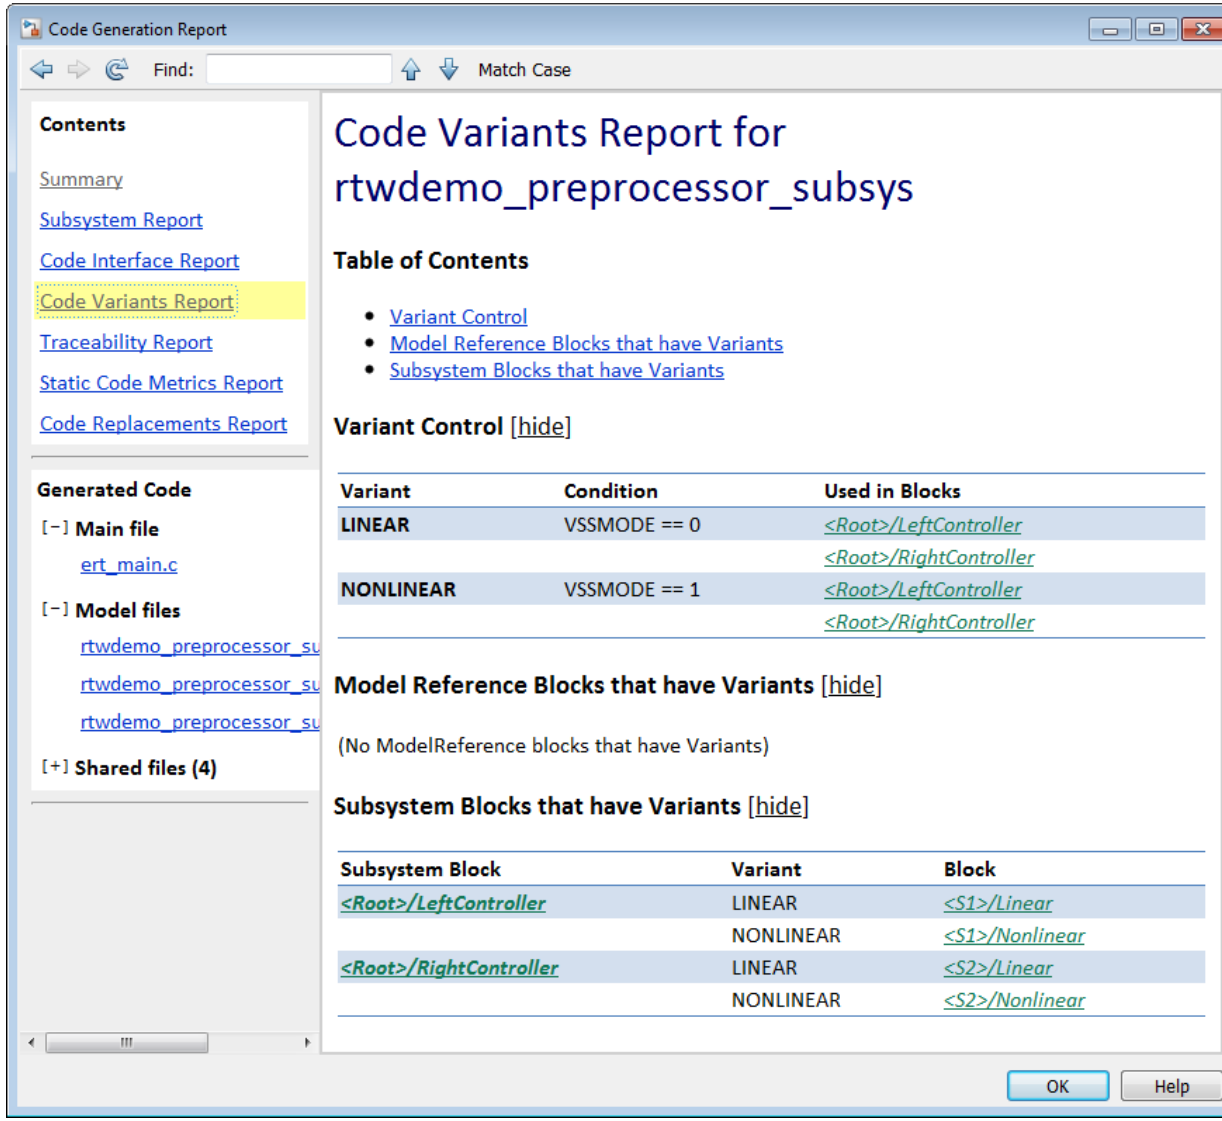
Step 4: Review Generated Code

The code generation report contains a section dedicated to the subsystems that have variants controlled by preprocessor conditionals.

1 To open the Code Generation Report click **Code > C/C++ Code > Code Generation Report > Open Model Report**.



2 Select the **Code Variant Report** from the left.



In this example, the generated code includes references to the `Simulink.Variant` objects `LINEAR` and `NONLINEAR`. The code also includes the definitions of macros corresponding to those variants. The definitions depend on the value of `VSSMODE`,

which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `LINEAR` and `NONLINEAR`.

3 Select the `rtwdemo_preprocessor_subsys_types.h` file from the left.

This file contains the definitions of macros `LINEAR` and `NONLINEAR`.

```
#ifndef LINEAR
 #define LINEAR      (VSSMODE == 0)
#endif

#ifndef NONLINEAR
 #define NONLINEAR   (VSSMODE == 1)
#endif
```

4 Select the `rtwdemo_preprocessor_subsys.c` file from the left.

In this file, calls to the step and initialization functions of each variant are conditionally compiled.

```
 /* Outputs for Atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
 /* Output and update for atomic system: '<S1>/Linear' */
 ...
#elif NONLINEAR
 /* Output and update for atomic system: '<S1>/Nonlinear' */
 ...
#endif
```

Limitations

- When you are generating code for Model Variants blocks and Variant Subsystem blocks, the blocks cannot have:
  - Mass matrices
  - Function call ports
  - Outports with constant sample time
  - Simscape blocks
- The Model Variants block and its referenced models must have the same number of inports and outports.

- The port numbers and names for each active child subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.

Generate Preprocessor Conditionals for Variant Systems

In this section...

Define Variant Controls

For variant systems, conditional expressions called variant controls determine which variant choice is active. This example shows how to define variant controls for generating code.

1. Open the Model Explorer. Select the **base workspace**.
2. A variant control can be a condition expression, a Simulink.Variant class (Simulink) object specifying a condition expression or a Simulink.Parameter object. In the Model Explorer, select **Add** > **Simulink Parameter**. Specify a name for the new parameter.
3. Use the function `Simulink.VariantManager.findVariantControlVars` to find and convert MATLAB variables used in variant control expressions into `Simulink.Parameter` objects. For an example, see "Convert Variant Control Variables into Simulink.Parameter Objects" (Simulink).
4. On the `Simulink.Parameter` property dialog box, specify the **Value** and **Data type**.
5. Select one of these **Storage class** values.
   - `Define`
   - `ImportedDefine(Custom)`
   - `CompilerFlag(Custom)`
   - A storage class created using the Custom Storage Class Designer. Your storage class must have the **Data initialization** parameter set to `Macro` and the **Data scope** parameter set to `Imported`. See "Use Custom Storage Class Designer" on page 23-35 for more information.
6. Specify the value of the variant control. If the storage class is `ImportedDefine(Custom)`, do the following:

a Specify the **Header File** parameter as an external header file in the Custom Attributes section of the `Simulink.Parameter` property dialog box.

b Enter the values of the variant controls in the external header file.

Note: The generated code refers to a variant control as a user-defined macro. The generated code does not contain the value of the macro. The value of the variant control determines the active variant in the compiled code.

If the variant control is a `CompilerFlag` custom storage class, the value of the variant control is set at compile time. Use the **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** parameter to add a list of variant controls (macro definitions) to the compiler command line. For example, for variant control `VSSMODE`, in the text field for the **Defines** parameter, enter:

```
-DVSSMODE=1
```

If you want to modify the value of the variant control after generating a makefile, use a makefile option when compiling your code. For example, at a command line outside of MATLAB, enter:

```
makecommand -f model.mk DEFINES_CUSTOM="-DVSSMODE=1"
```

Note: You can define the variant controls using `Simulink.Parameter` object of enumerated type. This approach provides meaningful names and improves the readability of the conditions. The generated code includes preprocessor conditionals to check that the variant condition contains valid values of the enumerated type.

Configure Model for Generating Preprocessor Conditional Directives

1 Open the Configuration Parameters dialog box.

2 Select the **Code Generation** pane, and set **System target file** as `ert.tlc`.

3 In the **Report** pane, select **Create code generation report**.

4 On the **All Parameters** tab, clear "Ignore custom storage classes" (Simulink Coder). In order to generate preprocessor conditionals, you must use custom storage classes.

5. In the Model Variants block parameter dialog box, select the **Generate preprocessor conditionals** parameter option. In the Variant Subsystem, Variant Source, or Variant Sink block parameter dialog boxes, select the **Analyze all choices during update diagram and generate preprocessor conditionals** option.
6. In both cases, clear the option to **Override variant conditions and use following variant**.
7. Generate code.

Special Considerations for Generating Preprocessor Conditionals

- The code generation process checks that the inports and outports of a Model Variants block are identical (same port numbers and names) to the corresponding inports and outports of its variants. The build process for simulation does not make this check. Therefore, if your variant block contains mismatched inports or outports, the code generation process issues an error.
- The port numbers and names for each child variant subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.
- The code generation process checks that there is at least one active variant by using the variant control values stored in the base workspace. The variant control that evaluates to `true` becomes the active variant. If none of the variant controls evaluates to `true`, the default variant, if specified, becomes the active variant. The code generation process issues an error if an active variant does not exist.
- Implement the condition expressions of the variant objects such that only one evaluates to `true`. The generated code includes a test of the variant objects to determine that there is only one active variant. If this test fails, your code will not compile.
- If you comment out child subsystems listed in the **Variant Choices** table in the Variant Subsystem block parameter dialog box, the code generator does not generate code for the commented out subsystems.
- If the sample time for a default variant differs from that of the other variant choices, the `#else` preprocessor conditional is not generated for the default variant. Instead, an `#if !(`*`<variant conditions>`*`)` is generated.
- For Variant Subsystems, the `model_private.h` file contains conditional parameter definitions. For example, if the value of a Constant block is a `Simulink.Parameter` with an `ImportedDefine` custom storage class, and the Constant block is in a Variant Subsystem, the conditional definition of the `Simulink.Parameter` is in the `model_private.h` file.

Represent Variant Source and Sink Blocks in Generated Code

In this section...

You can use Variant Source and Variant Sink blocks to perceive multiple implementations of a model in a single, unified block diagram. Each implementation depends on conditions that you set for Variant Source and Variant Sink blocks. Simulink propagates these conditions to upstream and downstream blocks including root input and root output ports.

You can generate:

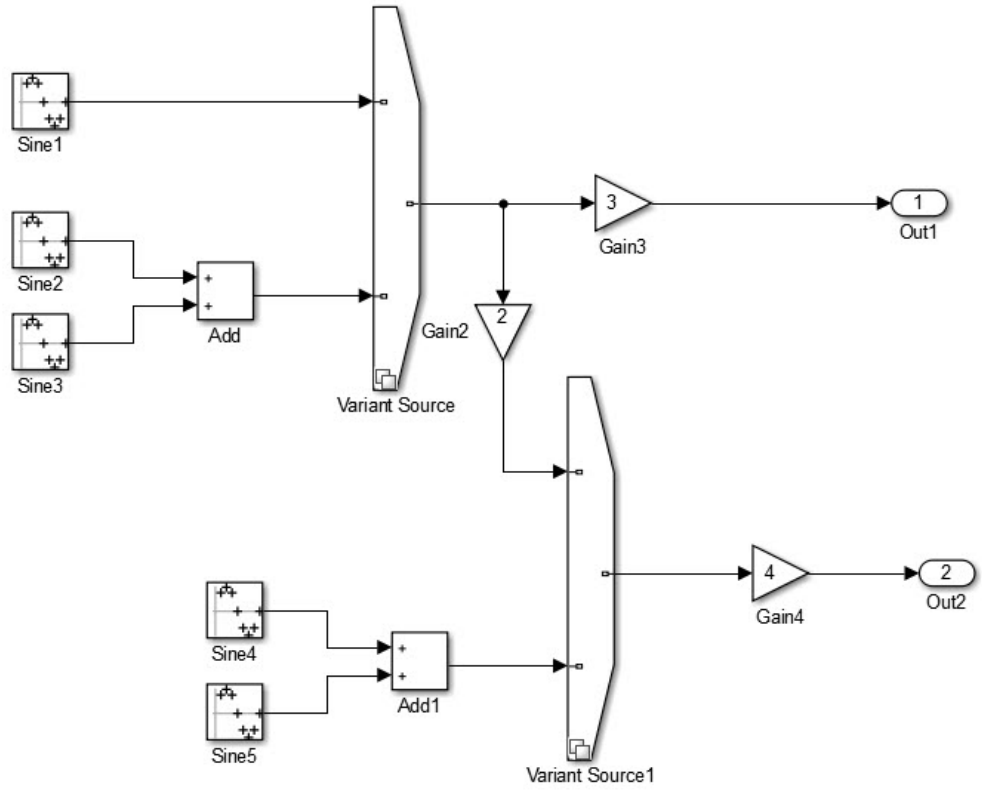
- Code from a Simulink model containing Variant Sink and Variant Source blocks.
- Code that contains preprocessor conditionals that control the activation of each variant choice.
- Preprocessor conditionals that allow for no active variant choice.

Represent Variant Source and Variant Sink blocks in Simulink

This example shows how Variant Source blocks make model elements conditional.

1. From the Simulink Block Library, add 1 Sine Wave Function block, two Add blocks, three Gain blocks, two Outports, and two Variant Source blocks into a new model.

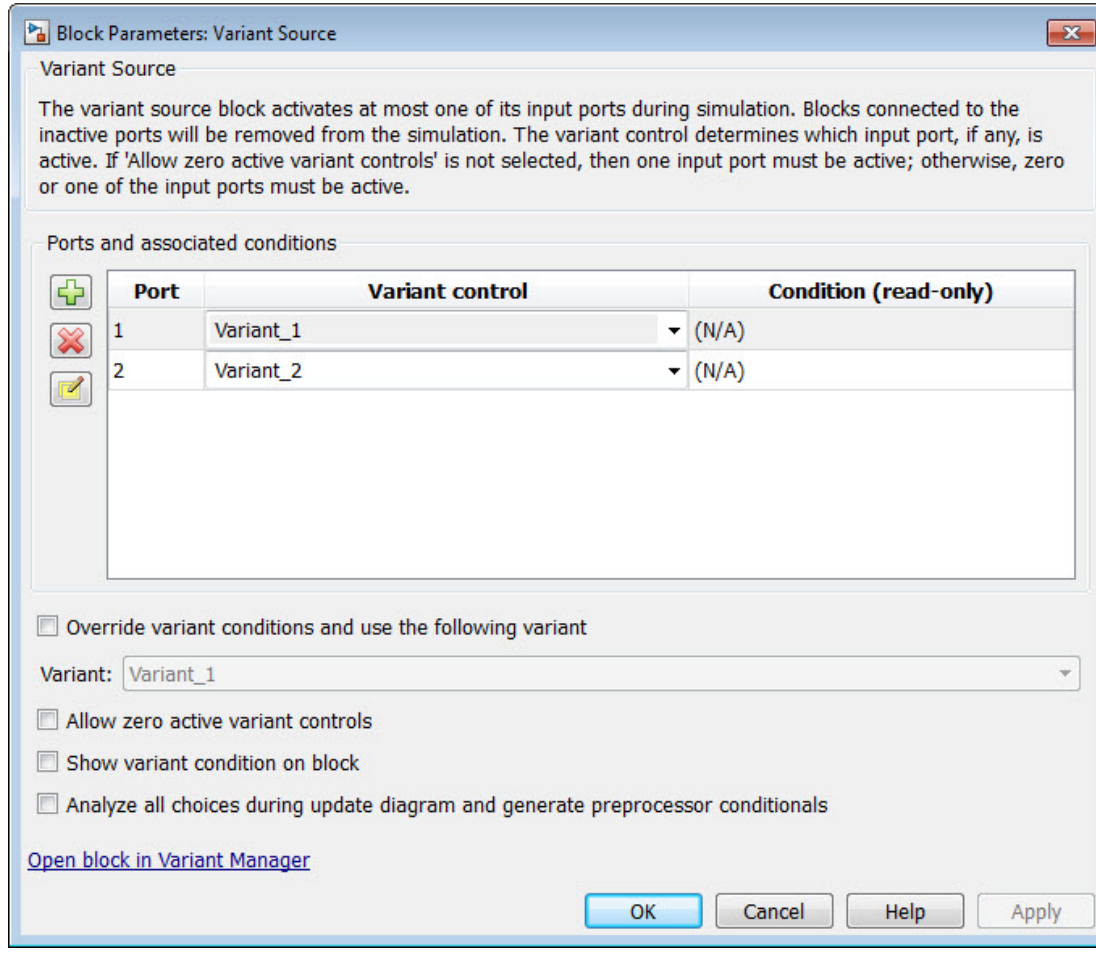
2. Open the Sine Wave Function block. For the **Sine type** parameter, select `Sample based`. For the **Time (t)** parameter, select `Use simulation time`. For the **Sample time** parameter, insert a value of `0.2`.
3. Make four copies of the Sine Wave Function block.
4. Connect and name the blocks as shown.



5 Insert values of `2`, `3`, and `4` in the `Gain2`, `Gain3`, and `Gain4` blocks, respectively.

6 Give the model the name `inline_variants_example`.

7 Open the Block Parameters dialog box for `Variant Source`.



8 In the **Variant control** column, for Port 1, replace `Variant_1` with `V==1`. For Port 2, replace `Variant_2` with `V==2`.

9 Open the Block Parameters dialog box for `Variant Source1`.

10 In the **Variant control** column, replace `Variant_1` with `W==1`. For Port 2, replace `Variant_2` with `W==2`.

11 In the MATLAB Command Window, to create `Simulink.Parameter` for the variant control variables `V` and `W`, use these commands:

```
V = Simulink.Parameter;
V.Value = 1;
V.DataType='int32';
V.CoderInfo.StorageClass = 'custom';
V.CoderInfo.CustomStorageClass = 'Define';
V.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'

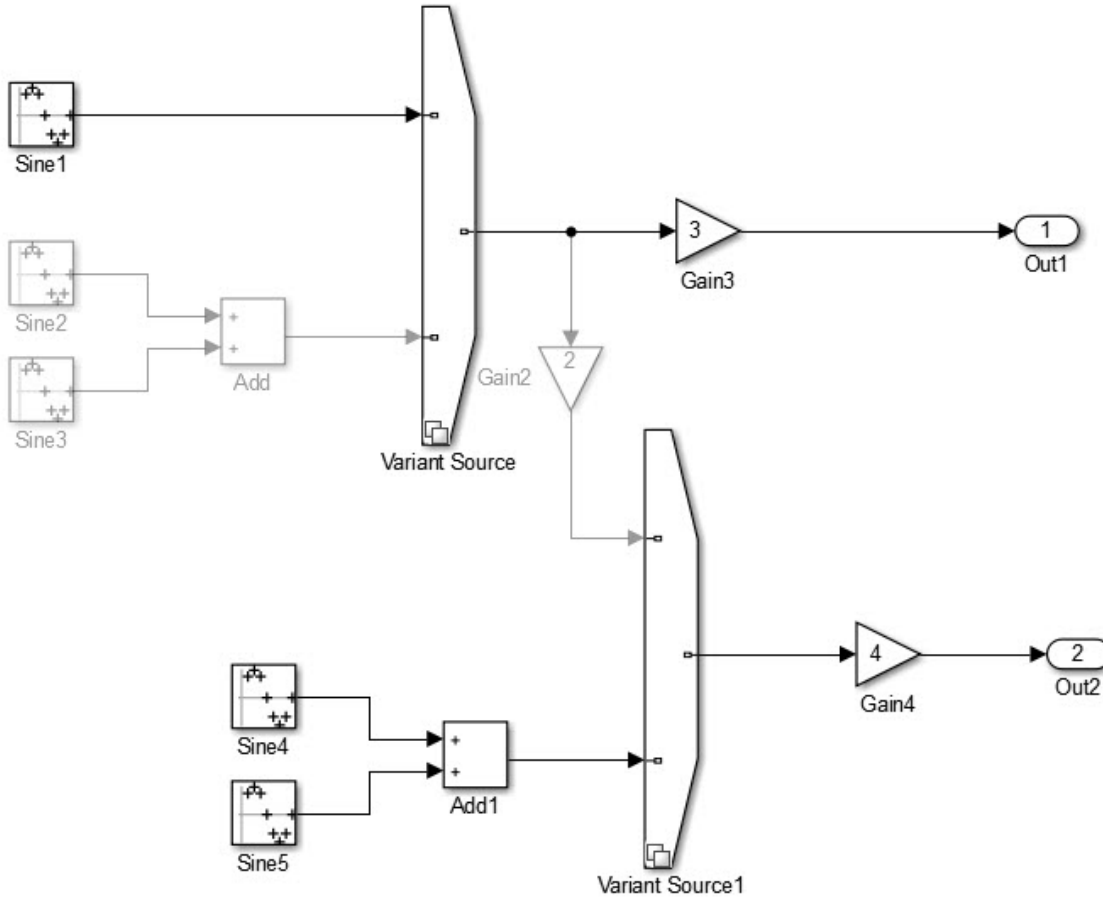
W = Simulink.Parameter;
W.Value = 2;
W.DataType='int32';
W.CoderInfo.StorageClass = 'custom';
W.CoderInfo.CustomStorageClass = 'Define';
W.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

In this example, the variant control variables are `Simulink.Parameter` objects. For code generation, if you use `Simulink.Variant` objects to specify variant controls, use `Simulink.Parameter` objects to specify their conditions. If you use scalar variant control variables to simulate the model, you can convert those variables into `Simulink.Parameter` objects. See "Convert Variant Control Variables into Simulink.Parameter Objects" (Simulink).

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes:

- `Define` with header file specified
- `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- User-defined custom storage class that defines data as a macro in a specified header file

12 Simulate the model.



Input port 1 is the active choice for `Variant Source` because the value of variant control variable `V` is `1`. Input port 2 is the active choice for `Variant Source1` because the value of variant control variable `W` is 2. The inactive choices are removed from execution, and their paths are grayed-out in the diagram.

Specify Conditions That Control Variant Choice Selection

You can generate code in which each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`. The compiler chooses the active variant at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation** > **Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
3. In the **Report** pane, select **Create code generation report**.
4. In your model, open the block parameters dialog box for `Variant Source`.
5. Select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter. During an update diagram or simulation, when you select this parameter, Simulink analyzes all variant choices. This analysis provides early validation of the code generation readiness of variant choices. During code generation, when you select this parameter, the code generator generates preprocessor conditionals that control the activation of each variant choice.
6. Clear the **Override variant conditions and use the following variant** parameter.
7. Clear the **Allow zero active variant controls** parameter.
8. Open the Block Parameters dialog box for `Variant Source 1`. Repeat steps 5 through 7.
9. Build the model. When code generation is complete, the Code Generation Report is displayed.

Review the Generated Code

1. In the code generation report, select the `inline_variants_example.c` file.
2. In the `inline_variants_example.c` file, calls to the `inline_variants_example_step` function and the `inline_variants_example_initialize` functions are conditionally compiled as shown:

```
/* Model step function */
void inline_variants_example_step(void)
{
  real_T rtb_Sine4;
  real_T rtb_VariantMerge_For_Variant_So;
```

```
  /* Sin: '<Root>/Sine1' */
#if V == 1

  rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter * 2.0 *
                  3.1415926535897931 / 10.0);

#endif                                 /* V == 1 */

  /* End of Sin: '<Root>/Sine1' */

  /* Sin: '<Root>/Sine2' incorporates:
   *  Sin: '<Root>/Sine3'
   *  Sum: '<Root>/Add'
   */
#if V == 2

  rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter_i * 2.0 *
                  3.1415926535897931 / 10.0) + sin((real_T)
    inline_variants_example_DW.counter_f * 2.0 * 3.1415926535897931 / 10.0);

#endif                                 /* V == 2 */

  /* End of Sin: '<Root>/Sine2' */

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain3'
   */
  inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

  /* Gain: '<Root>/Gain2' */
#if W == 1

  rtb_VariantMerge_For_Variant_So = 2.0 * rtb_Sine4;

#endif                                 /* W == 1 */

  /* End of Gain: '<Root>/Gain2' */

  /* Sin: '<Root>/Sine4' incorporates:
   *  Sin: '<Root>/Sine5'
   *  Sum: '<Root>/Add1'
   */
#if W == 2
```

```
  rtb_VariantMerge_For_Variant_So = sin((real_T)
    inline_variants_example_DW.counter_fe * 2.0 * 3.1415926535897931 / 10.0) *
    2.0 + sin((real_T)inline_variants_example_DW.counter_e * 2.0 *
              3.1415926535897931 / 10.0);

#endif                                 /* W == 2 */

  /* End of Sin: '<Root>/Sine4' */

/* Outport: '<Root>/Out2' incorporates:
   *  Gain: '<Root>/Gain4'
   */
  inline_variants_example_Y.Out2 = inline_variants_example_P.Gain4_Gain *
    rtb_VariantMerge_For_Variant_So;
...
}
```

The variables `rtb_Sine4` and `rtb_VariantMerge_For_Variant_So` hold the input values to the Variant Source blocks. Notice that the code for these variables is conditional. The variables `inline_variants_example_Y.Out1` and `inline_variants_example_Y.Out2` hold the output values of the Variant Source blocks. Notice that the code for these variables is not conditional.

Generate Code with Zero Active Variant Controls

You can generate code in which blocks connected to the input and the output of a Variant Source block are conditional.

1. For `Variant Source`, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.
2. For `Variant Source 1`, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.

When you select **Allow zero active variant controls** parameter, you can generate code for a model containing Variant Source and Variant Sink blocks even when you specify a value for a variant control variable that does not allow for an active variant. Choosing a value for a variant control variable that does not allow for an active variant and not selecting the **Allow zero active variant controls** parameter, produces an error.

Generate code for `inline_variants_example`. Notice in the `inline_variants_example.c` file, that the code for the variables

`inline_variants_example_Y.Out1` and `inline_variants_example_Y.Out2` is conditional.

```
/* Model step function */
void inline_variants_example_step(void)
{
 ...
 #if V == 1 || V == 2

  inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

#endif                                 /* V == 1 || V == 2 */

 ...
#if (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2

  inline_variants_example_Y.Out2 = 4.0 * rtb_VariantMerge_For_Variant_So;

#endif                      /* (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2 */

 ...
```

Global Data Guarding Limitation

For external ports and most DWork vectors, signals, and states, preprocessor conditionals (`#if` and `#endif`) surround global data variable declarations. For models in which you enable C API code for global block output signals, global block parameters, and discrete and continuous states, preprocessor conditionals do not surround global data variable declarations. For information on the C API, see "Exchange Data Between Generated and External Code Using C API" (Simulink Coder).

State Logging Limitation

There are some rare cases in which preprocessor conditionals do not surround global data structures that contain state variable declarations. For models that contain Variant Source blocks or Variant Sink blocks and also contain blocks that maintain state information, such as Unit Delay blocks, the exclusion of preprocessor conditionals surrounding state variable declarations can lead to a mismatch between simulation and code generation results.

For example, suppose that a model has a Variant Source block with four variant choices. One of these choices contains blocks with state information. If you simulate

the model with the active variant that is other than the variant choice that contains state information, there is no logged state data. In the *model*`.h` file, the generated code still initializes these global state variables to `0` because `#if` and `#endif` guards do not surround the state variable declarations. If you create a *model*`.mat` file from a *model*`.exe` file, and compare it to the simulation output, the results do not match. For this example, the simulation output is empty because there is no logged state data. The *model*`.mat` file contains multiple values of `0`.

If the active variant is the variant choice containing state information, the results do match.

Configure Dimension Variants for S-Function Blocks

To configure symbolic dimensions for S-function blocks, you can use the following C/C ++ functions. You can configure S-functions to support forward propagation, backward propagation, or forward and backward propagation of symbolic dimensions during simulation.

Many of these functions return the variable `SymbDimsId`. A `SymbDimsId` is a unique integer value. This value corresponds to each symbolic dimension specification that you create or is the result of a mathematical operation that you perform with symbolic dimensions.

Note: If you are writing an S-function with symbolic dimensions, you can not use the `%roll` directive. You must write an explicit loop.

C/C++ S-Functions	Purpose
ssSetSymbolicDimsSupport	Specify whether or not an S-function supports symbolic dimensions.
mdlSetInputPortSymbolicDimensions	Specify the symbolic dimensions of an input port and how those dimensions propagate forward.
mdlSetOutputPortSymbolicDimensions	Specify the symbolic dimensions of an output port and how those dimensions propagate backward.
ssRegisterSymbolicDimsExpr	Create a `SymbDimsId` from an expression string (`aExpr`). The expression string must form a valid syntax in C.
ssRegisterSymbolicDims	Create a `SymbDimsId` from a vector of `SymbDimsId`s.
ssRegisterSymbolicDimsString	Create a `SymbDimsId` from an identifier string (`aString`).
ssRegisterSymbolicDimsIntValue	Create a `SymbDimsId` from an integer value (`aIntValue`)

C/C++ S-Functions	Purpose
ssRegisterSymbolicDimsPlus	Create a `SymbDimsId` by adding two symbolic dimensions.
ssRegisterSymbolicDimsMinus	Create a `SymbDimsId` by subtracting two symbolic dimensions.
ssRegisterSymbolicDimsMultiply	Create a `SymbDimsId` by multiplying two symbolic dimensions.
ssRegisterSymbolicDimsDivide	Create a `SymbDimsId` by dividing two symbolic dimensions.
ssGetNumSymbolicDims	Get the number of dimensions for a `SymbDimsId`.
ssGetSymbolicDim	Get a `SymbDimsId` from a vector of `SymbDimsId`s.
ssSetInputPortSymbolicDimsId	Set the precompiled `SymbDimsId` of an input port. You can call this function from inside the `mdlInitializeSizes` function.
ssGetCompInputPortSymbolicDimsId	Get the compiled `SymbDimsId` of an input port.
ssSetCompInputPortSymbolicDimsId	Set the compiled `SymbDimsId` of an input port.
ssSetOutputPortSymbolicDimsId	Set the precompiled `SymbDimsId` of an output port. You can call this function from inside the `mdlInitializeSizes` function.
ssGetCompOutputPortSymbolicDimsId	Get the compiled `SymbDimsId` of an output port.
ssSetCompOutputPortSymbolicDimsId	Set the compiled `SymbDimsId` of an output port.
ssSetCompDWorkSymbolicDimsId	Set the compiled `SymbDimsId` of an index of a block's data type work (`DWork`) vector.

S-Function That Supports Forward Propagation of Symbolic Dimensions

This S-function subtracts the symbolic dimension B from a symbolic input dimension. It does not support backward propagation of symbolic dimensions because the compiled symbolic dimensions of the input port are not set. Symbolic dimensions are set for the output port, so forward propagation occurs.

```
static void mdlInitializeSizes(SimStruct *S)
{
     // Enable symbolic dimensions for the s-function.
     ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
   int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    // Set the compiled input symbolic dimension.
    ssSetCompInputPortSymbolicDimsId(S,  portIndex, symbDimsId);
    // Register “B” and get its symbolic dimensions id.
    const SymbDimsId symbolIdForB = ssRegisterSymbolicDimsString(S, "B");
   // Subtract “B” from the input symbolic dimension.
    const SymbDimsId outputDimsId =
        ssRegisterSymbolicDimsMinus(S, symbDimsId, symbolIdForB);
   //Set the resulting symbolic dimensions id as the output.
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, outputDimsId);
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
   int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
   // The input dimensions are not set, so this S-function only
 // supports forward propagation.
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);
}
#endif
```

S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions

This S-function transposes two symbolic dimensions. It supports forward and backward propagation of symbolic dimensions because the compiled symbolic dimension of both the input and output ports are set.

```
static void mdlInitializeSizes(SimStruct *S)
{
     // Enable symbolic dimensions for the s-function.
     ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
   int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);

    ssSetCompInputPortSymbolicDimsId(S,  portIndex, symbDimsId);

    assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

    if (SL_INHERIT ==
        ssGetCompOutputPortSymbolicDimsId(S, portIndex)) {

        const SymbDimsId idVec[] = {
            ssGetSymbolicDim(S, symbDimsId, 1),
            ssGetSymbolicDim(S, symbDimsId, 0)};
        // Register the transposed dimensions.
       // Set the output symbolic dimension to the resulting id.
  const SymbDimsId outputDimsId =
            ssRegisterSymbolicDims(S, idVec, 2U);

        ssSetCompOutputPortSymbolicDimsId(S, portIndex,
           outputDimsId);
    }
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
```

```
    int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);

    assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

    if (SL_INHERIT ==
        ssGetCompInputPortSymbolicDimsId(S, portIndex)) {

        const SymbDimsId idVec[] = {
            ssGetSymbolicDim(S, symbDimsId, 1),
            ssGetSymbolicDim(S, symbDimsId, 0)};
        const SymbDimsId inputDimsId =
            ssRegisterSymbolicDims(S, idVec, 2U);
        // Register the transposed dimensions.
       // Set the input symbolic dimension to the resulting id.
        ssSetCompInputPortSymbolicDimsId(S, portIndex, inputDimsId);
    }
}
#endif
```

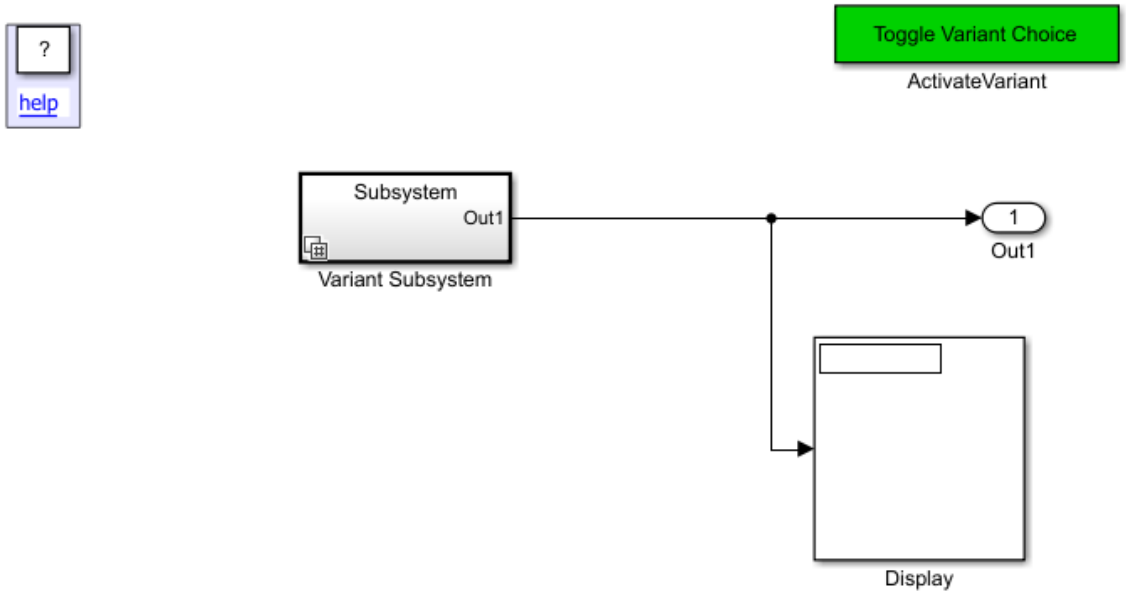
Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions

In this section...

This example shows how to use symbolic dimensions to generate code with preprocessor conditionals for a variant subsystem consisting of child subsystems of different output signal dimensions. The value of the variant control variable determines the active variant choice and the output signal dimensions. By changing the value of the variant control variable, you change the active variant and the output signal dimensions in the generated code.

Example Model

The model `slexVariantSymbolicDims` contains a Variant Subsystem consisting of the child subsystems `Subsystem` and `Subsystem1`. When the variant control variable `Var` has a value of `1`, `Subsystem` is the active variant. When `Var` has a value of `2`, `Subsystem1` is the active variant.



Simulate Model

To generate code with preprocessor conditionals, the output signal dimensions of the child subsystems must be the same during simulation. In this example, double-clicking the subsystem `Activate Variant Choice` changes the active variant and the output signal dimension. When `Var` equals `1`, the output signal dimension of each child subsystem is `5`. When `Var` equals `2`, the output signal dimension of each child subsystem is `6`.

1. Open the example model slexVariantSymbolicDims.
2. From the **Display** > **Signals & Ports** menu, select **Signal Dimensions**.
3. Open the Variant Subsystem Block Parameters dialog box. The **Analyze all choices during update diagram and generate preprocessor conditionals** parameter is selected.
4. Open `Subsystem`. In the Constant Block Parameters dialog box, the **Constant value** parameter is `P1`.
5. Open `Subsystem1`. In the Constant Block Parameters dialog box, the **Constant value** parameter is `P2`.

6. Open the base workspace. The `Simulink.Parameters` `P1` and `P2` are arrays with dimensions `'[1,A]'`. The `Simulink.Parameter` `A` has a value of `5`. `Var` has a value of `1`.
7. Simulate the model. `Subsystem` is the active variant with an output signal dimension of `5`.
8. Double-click the masked subsystem `ActivateVariant`.
9. In the base workspace, `Var` has a value of `2`. `P1` and `P2` have a dimension of `6`. `A` has a value of `6`.
10. Simulate the model. `Subsystem1` is the active variant with an output signal dimension of `6`.

In the base workspace, `A` has a **Storage class** of `ImportedDefine(Custom)`. To use a `Simulink.Parameter` object for dimension specification, it must have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

In the base workspace, `P1` and `P2` have a storage class of `ImportedExtern`. A `Simulink.Parameter` object that uses a `Simulink.Parameter` for symbolic dimension specification must have a storage class of either `ImportedExtern` or `ImportedExternPointer`.

Generate Code

1. Open the header file slexVariantSymbolicDims_variant_defines.h. The definition of `A` is conditional upon the value of `Var`.

```
/* Copyright 2016 The MathWorks, Inc. */
// To select variant choice during compile, define Var at compile time,

#ifndef Var
#define Var 1
#endif

#if Var == 1
#define A 5
```

```
#elif Var == 2
#define A 6
#else
#error "Variant control variable, Var, must be defined as 1 or 2"
#endif
```

2. Generate code.
3. Open the `slexVariantSymbolicDims.h` file. The output dimension size is `A`.

```
/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  int32_T Out1[A];                     /* '<Root>/Out1' */
} ExternalOutputs_slexVariantSymb;
```

4. Open the `slexVariantSymbolicDims.c` file. If `Var` equals `1`, `P1` has five values. If `Var` equals `2`, `P2` has six values. In the Configuration Parameters dialog box, on the **Code Generation** > **Custom Code** pane, the **Source file** parameter contains this code.

```
/* user code (top of source file) */
#if Var == 1

int32_T P1[] = { 5, 5, 5, 5, 5 };

#elif Var == 2

int32_T P2[] = { 6, 6, 6, 6, 6, 6 };

#endif
```

Preprocessor conditionals control the size of `A` and which array, `P1` or `P2`, is active in the generated code. By changing the value of `Var`, you can change the size of `A` and the active array.

Timers in Simulink Coder

Absolute and Elapsed Time Computation

In this section...

About Timers

Certain blocks require the value of either *absolute* time (that is, the time from the start of program execution to the present time) or *elapsed* time (for example, the time elapsed between two trigger events). Targets that support the real-time model (`rtModel`) data structure provide efficient time computation services to blocks that request absolute or elapsed time. Absolute and elapsed timer features include

- Timers are implemented as unsigned integers in generated code.
- In multirate models, at most one timer is allocated per rate. If no blocks executing at a given rate require a timer, a timer is not allocated to that rate. This minimizes memory allocated for timers and significantly reduces overhead involved in maintaining timers.
- Allocation of elapsed time counters for use of blocks within triggered subsystems is minimized, further reducing memory usage and overhead.
- S-function and TLC APIs let your S-functions access timers, in simulation and code generation.
- The word size of the timers is determined by a user-specified maximum counter value, **Application lifespan (days)** (Simulink). If you specify this value, timers will not overflow. For more information, see "Control Memory Allocation for Time Counters" (Simulink Coder).

See "Absolute Time Limitations" (Simulink Coder) for more information about absolute time and the restrictions that it imposes.

Timers for Periodic and Asynchronous Tasks

Timing services provided for blocks execute within *periodic* tasks (that is, tasks running at the model base rate or subrates).

The code generator also provides timer support for blocks whose execution is *asynchronous* with respect to the periodic timing source of the model. See the following topics:

- "Timers in Asynchronous Tasks" on page 17-44
- "Create a Customized Asynchronous Library" on page 17-47

Allocation of Timers

If you create or maintain an S-Function block that requires absolute or elapsed time data, it must register the requirement (see "Access Timers Programmatically" on page 15-5). In multirate models, timers are allocated on a per-rate basis. For example, consider a model structured as follows:

- There are three rates, A, B, and C, in the model.
- No blocks running at rate B require absolute or elapsed time.
- Two blocks running at rate C register a requirement for absolute time.
- One block running at rate A registers a requirement for absolute time.

In this case, two timers are generated, running at rates A and C respectively. The timing engine updates the timers as the tasks associated with rates A and C execute. Blocks executing at rates A and C obtain time data from the timers associated with rates A and C.

Integer Timers in Generated Code

In the generated code, timers for absolute and elapsed time are implemented as unsigned integers. The default size is 64 bits. This is the amount of memory allocated for a timer if you specify a value of `inf` for the **Application lifespan (days)** (Simulink) parameter. For an application with a sample rate of 1000 MHz, a 64-bit counter will not overflow for more than 500 years. See "Timers in Asynchronous Tasks" on page 17-44 and "Control Memory Allocation for Time Counters" on page 53-11 for more information.

Elapsed Time Counters in Triggered Subsystems

Some blocks, such as the Discrete-Time Integrator block, perform computations requiring the elapsed time (delta T) since the previous block execution. Blocks requiring elapsed time data must register the requirement (see “Access Timers Programmatically” on page 15-5). A triggered subsystem then allocates and maintains a single elapsed time counter if required. This timer functions at the subsystem level, not at the individual block level. The timer is generated if the triggered subsystem (or a unconditionally executed subsystem within the triggered subsystem) contains one or more blocks requiring elapsed time data.

Note: If you are using simplified initialization mode, elapsed time is reset on first execution after becoming enabled, whether or not the subsystem is configured to reset on enable. For more information, see “Underspecified initialization detection” (Simulink).

Access Timers Programmatically

In this section...

About Timer APIs

This topic describes APIs that let your S-functions take advantage of the efficiencies offered by absolute and elapsed timers. SimStruct macros are provided for use in simulation, and TLC functions are provided for inlined code generation. Note that

- To generate and use the new timers as described above, your S-functions must register the need to use an absolute or elapsed timer by calling `ssSetNeedAbsoluteTime` or `ssSetNeedElapseTime` in `mdlInitializeSampleTime`.
- Existing S-functions that read absolute time but do not register by using these macros continue to operate as expected, but generate less efficient code.

C API for S-Functions

The SimStruct macros described in this topic provide access to absolute and elapsed timers for S-functions during simulation.

In the functions below, the `SimStruct *S` argument is a pointer to the `simstruct` of the calling S-function.

- `void ssSetNeedAbsoluteTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires absolute time data, and allocates an absolute time counter for the rate at which the S-function executes (if such a counter has not already been allocated).
- `int ssGetNeedAbsoluteTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires absolute time.
- `double ssGetTaskTime(SimStruct *S, tid)`: read absolute time for a given task with task identifier `tid`. `ssGetTaskTime` operates transparently, regardless of whether or not you use the new timer features. `ssGetTaskTime` is documented in the SimStruct Functions chapter of the Simulink documentation.

- `void ssSetNeedElapseTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires elapsed time data, and allocates an elapsed time counter for the triggered subsystem in which the S-function executes (if such a counter has not already been allocated). See also "Elapsed Time Counters in Triggered Subsystems" on page 15-4.
- `int ssGetNeedElapseTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires elapsed time.
- `void ssGetElapseTime(SimStruct *S, (double *)elapseTime)`: returns, to the location pointed to by `elapseTime`, the value (as a `double`) of the elapsed time counter associated with the S-function.
- `void ssGetElapseTimeCounterDtype(SimStruct *S, (int *)dtype)`: returns the data type of the elapsed time counter associated with the S-function to the location pointed to by `dtype`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseResolution(SimStruct *S, (double *)resolution)`: returns the resolution (that is, the sample time) of the elapsed time counter associated with the S-function to the location pointed to by `resolution`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseTimeCounter(SimStruct *S, (void *)elapseTime)`: This function is provided for the use of blocks that require the elapsed time values for fixed-point computations. `ssGetElapseTimeCounter` returns, to the location pointed to by `elapseTime`, the integer value of the elapsed time counter associated with the S-function. If the counter size is 64 bits, the value is returned as an array of two 32-bit words, with the low-order word stored at the lower address.

  To determine how to access the returned counter value, obtain the data type of the counter by calling `ssGetElapseTimeCounterDtype`, as in the following code:

```
int    *y_dtype;
ssGetElapseTimeCounterDtype(S, y_dtype);

 switch(*y_dtype) {
  case SS_DOUBLE_UINT32:
      {
          uint32_T dataPtr[2];
          ssGetElapseTimeCounter(S, dataPtr);
      }
      break;
  case SS_UINT32:
```

```
      {
         uint32_T dataPtr[1];
         ssGetElapseTimeCounter(S, dataPtr);
      }
       break;
  case SS_UINT16:
     {
          uint16_T dataPtr[1];
          ssGetElapseTimeCounter(S, dataPtr);
     }
      break;
  case SS_UINT8:
     {
         uint8_T dataPtr[1];
         ssGetElapseTimeCounter(S, dataPtr);
    }
     break;
  case SS_DOUBLE:
      {
         real_T dataPtr[1];
         ssGetElapseTimeCounter(S, dataPtr);
     }
      break;
  default:
    ssSetErrorStatus(S, "Invalid data type for elaspe time
        counter");
    break;
}
```

If you want to use the actual elapsed time, issue a call to the `ssGetElapseTime` function to access the elapsed time directly. You do not need to get the counter value and then calculate the elapsed time.

```
double *y_elapseTime;
.
.
.
ssGetElapseTime(S, elapseTime)
```

TLC API for Code Generation

The following TLC functions support elapsed time counters in generated code when you inline S-functions by writing TLC scripts for them.

- `LibGetTaskTimeFromTID(block)`: Generates code to read the absolute time for the task in which `block` executes.

  `LibGetTaskTimeFromTID` is documented with other sample time functions in the TLC Function Library Reference pages of the Target Language Compiler documentation.

  Note Do not use `LibGetT` for this purpose. `LibGetT` always reads the base rate (`tid 0`) timer. If `LibGetT` is called for a block executing at a subrate, the wrong timer is read, causing serious errors.

- `LibGetElapseTime(system)`: Generates code to read the elapsed time counter for `system`. (`system` is the parent system of the calling block.) See "Generate Code for an Elapsed Time Counter" on page 15-9 for an example of code generated by this function.
- `LibGetElapseTimeCounter(system)`: Generates code to read the integer value of the elapsed time counter for `system`. (`system` is the parent system of the calling block.) This function should be used in conjunction with `LibGetElapseTimeCounterDtypeId` and `LibGetElapseTimeResolution`. (See the discussion of `ssGetElapseTimeCounter` above.)
- `LibGetElapseTimeCounterDtypeId(system)`: Generates code that returns the data type of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)
- `LibGetElapseTimeResolution(system)`: Generates code that returns the resolution of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)

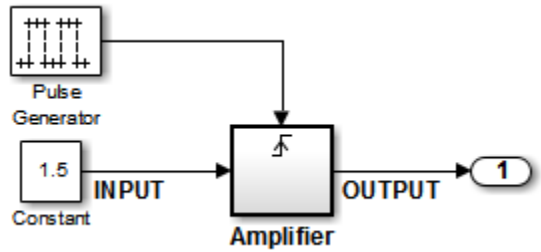
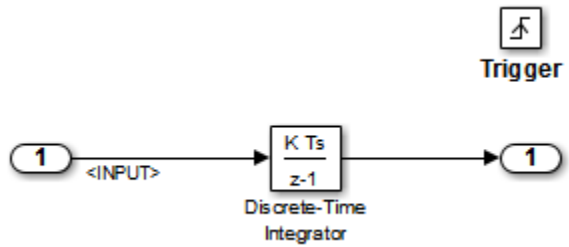
- "Absolute Time Limitations" (Simulink Coder)

Generate Code for an Elapsed Time Counter

This example shows a model that includes a triggered subsystem, `Amplifier`, consisting of a Discrete-Time Integrator block that uses an elapsed time counter. The model `ex_elapseTime` is in the folder `matlab/help/toolbox/rtw/examples`.



ex_elapseTime Model



Amplifier Subsystem

Code in the generated header file `ex_elapseTime.h` for the model uses 64 bits to implement the timer for the base rate (`clockTick0` and `clockTickH0`).

```
/*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
struct {
  time_T taskTime0;
  uint32_T clockTick0;
```

```
  uint32_T clockTickH0;
  time_T stepSize0;
  time_T tFinal;
  boolean_T stopRequestedFlag;
} Timing;
```

The code generator allocates storage for the previous-time value and elapsed-time value of the `Amplifier` subsystem (`Amplifier_PREV_T`) in the `D_Work(states)` structure in `ex_elapsedTime.h`.

```
/* Block states (auto storage) for system '<Root>' */
typedef struct {
  real_T DiscreteTimeIntegrator_DSTATE;/* '<S1>/Discrete-Time Integrator' */
  int32_T clockTickCounter;            /* '<Root>/Pulse Generator' */
  uint32_T Amplifier_ELAPS_T[2];       /* '<Root>/Amplifier' */
  uint32_T Amplifier_PREV_T[2];        /* '<Root>/Amplifier' */
 } DW_ex_elapseTime_T;
```

The elapsed time computation is performed as follows within the `ex_elapseTime_step` function:

```
 /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
  *  TriggerPort: '<S1>/Trigger'
  */
 zcEvent = rt_ZCFcn(RISING_ZERO_CROSSING,
        &ex_elapseTime_PrevZCX.Amplifier_Trig_ZCE,
        ((real_T)rtb_PulseGenerator));
 if (zcEvent != NO_ZCEVENT) {
   elapseT_H = ex_elapseTime_M->Timing.clockTickH0 -
     ex_elapseTime_DW.Amplifier_PREV_T[1];
   if (ex_elapseTime_DW.Amplifier_PREV_T[0] >
       ex_elapseTime_M->Timing.clockTick0) {
     elapseT_H--;
   }

   ex_elapseTime_DW.Amplifier_ELAPS_T[0] = ex_elapseTime_M->Timing.clockTick0 -
   ex_elapseTime_DW.Amplifier_PREV_T[0];
   ex_elapseTime_DW.Amplifier_PREV_T[0] = ex_elapseTime_M->Timing.clockTick0;
   ex_elapseTime_DW.Amplifier_ELAPS_T[1] = elapseT_H;
   ex_elapseTime_DW.Amplifier_PREV_T[1] = ex_elapseTime_M->Timing.clockTickH0;
```

As shown above, the elapsed time is maintained as a state of the triggered subsystem. The Discrete-Time Integrator block finally performs its output and update computations using the elapsed time.

```
/* DiscreteIntegrator: '<S1>/Discrete-Time Integrator' */
OUTPUT = ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE;

/* Update for DiscreteIntegrator: '<S1>/Discrete-Time Integrator' incorporates:
 *  Constant: '<Root>/Constant'
 */
ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE += 0.3 * (real_T)
  ex_elapseTime_DW.Amplifier_ELAPS_T[0] * 1.5;
```

- "Absolute and Elapsed Time Computation" (Simulink Coder)
- "Absolute Time Limitations" (Simulink Coder)

Absolute Time Limitations

Absolute time is the time that has elapsed from the beginning of program execution to the present time, as distinct from *elapsed time*, the interval between two events. See "Absolute and Elapsed Time Computation" on page 15-2 for more information.

When you design an application that is intended to run indefinitely, you must take care when logging time values, or using charts or blocks that depend on absolute time. If the value of time reaches the largest value that can be represented by the data type used by the timer to store time, the timer overflows and the logged time or block output is incorrect.

If your target uses `rtModel`, you can avoid timer overflow by specifying a value for the **Application life span** parameter. See "Integer Timers in Generated Code" on page 15-3 for more information.

The following limitations apply to absolute time:

- If you log time values by opening the Configuration Parameters dialog box and enabling **Data Import/Export > Time** parameter, your model uses absolute time.
- Every Stateflow chart that uses time is dependent on absolute time. The only way to eliminate the dependency is to change the Stateflow chart to not use time.
- The following Simulink blocks depend on absolute time:
  - Backlash
  - Chirp Signal
  - Clock
  - Derivative
  - Digital Clock
  - Discrete-Time Integrator (only when used in triggered subsystems)
  - From File
  - From Workspace
  - Pulse Generator
  - Ramp
  - Rate Limiter
  - Repeating Sequence

- Signal Generator
- Sine Wave (only when the **Sine type** parameter is set to `Time-based`)
- Step
- To File
- To Workspace (only when logging to `StructureWithTime` format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

In addition to the Simulink blocks above, blocks in other blocksets may depend on absolute time. See the documentation for the blocksets that you use.

Time-Based Scheduling in Simulink Coder

Time-Based Scheduling and Code Generation

In this section...

Sample Time Considerations

Simulink models run at one or more sample times. The Simulink product provides considerable flexibility in building multirate systems, that is, systems with more than one sample time. However, this same flexibility also allows you to construct models for which the code generator cannot generate real-time code for execution in a multitasking environment. To make multirate models operate as expected in real time (that is, to give the right answers), you sometimes must modify your model or instruct the Simulink engine to modify the model for you. In general, the modifications involve placing Rate Transition blocks between blocks that have unequal sample times. The following sections discuss issues you must address to use a multirate model in a multitasking environment. For a comprehensive discussion of sample times, including rate transitions, see "What Is Sample Time?" (Simulink), "Sample Times in Subsystems" (Simulink), "Sample Times in Systems" (Simulink), "Resolve Rate Transitions" (Simulink), and associated topics.

Tasking Modes

There are two execution modes for a fixed-step Simulink model: single-tasking and multitasking. These modes are available only for fixed-step solvers. To select an execution mode, use the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. When this parameter is selected, multitasking execution is applied for a multirate model. When this option is cleared, single-tasking execution is applied.

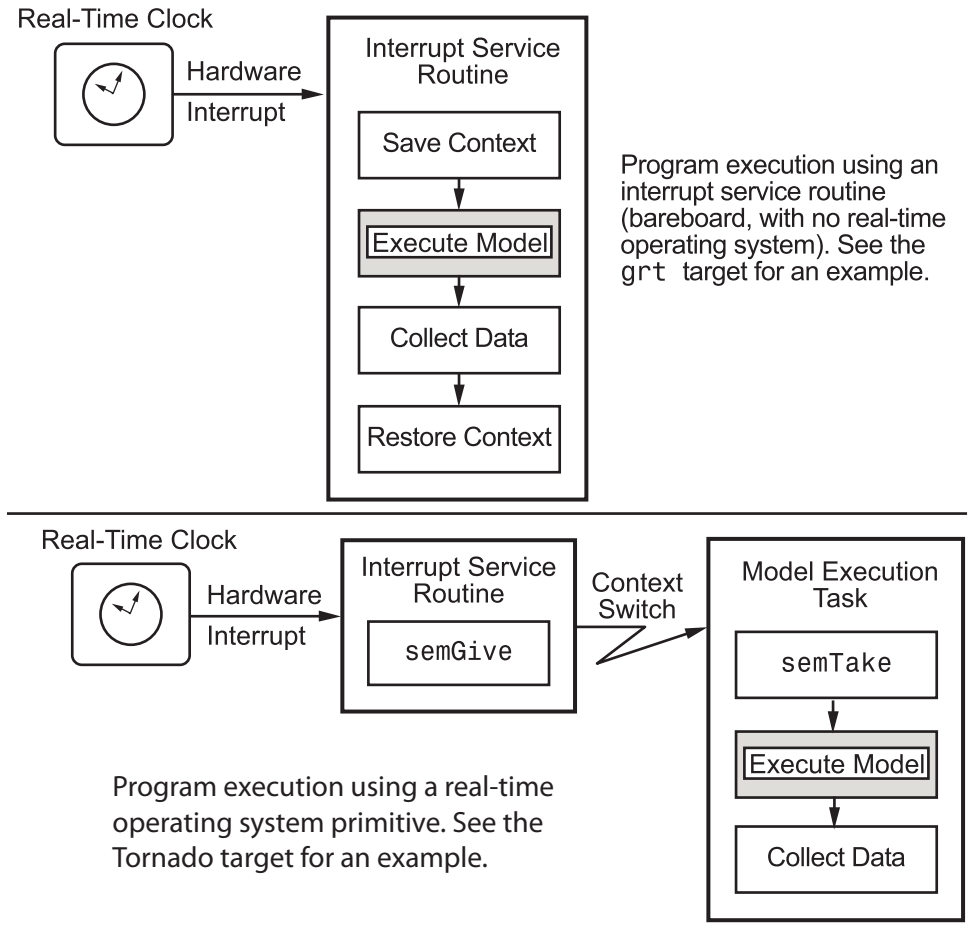
Note: A model that is multirate and uses multitasking cannot reference a multirate model that uses single-tasking.

Execution of models in a real-time system can be done with the aid of a real-time operating system, or it can be done on *bare-metal* target hardware, where the model runs in the context of an interrupt service routine (ISR).

The fact that a system (such as The Open Group UNIX or Microsoft Windows systems) is multitasking does not imply that your program can execute in real time. This is because the program might not preempt other processes when required.

In operating systems (such as PC-DOS) where only one process can exist at a given time, an interrupt service routine (ISR) must perform the steps of saving the processor context, executing the model code, collecting data, and restoring the processor context.

Other operating systems, such as POSIX-compliant ones, provide automatic context switching and task scheduling. This simplifies the operations performed by the ISR. In this case, the ISR simply enables the model execution task, which is normally blocked. The next figure illustrates this difference.



Model Execution and Rate Transitions

To generate code that executes as expected in real time, you (or the Simulink engine) might need to identify and handle sample rate transitions within the model. In multitasking mode, by default the Simulink engine flags errors during simulation if the model contains invalid rate transitions, although you can use the **Multitask rate transition** diagnostic to alter this behavior. A similar diagnostic, called **Single task rate transition**, exists for single-tasking mode.

To avoid raising rate transition errors, insert Rate Transition blocks between tasks. You can request that the Simulink engine handle rate transitions automatically by inserting hidden Rate Transition blocks. See “Automatic Rate Transition” on page 16-25 for an explanation of this option.

To understand such problems, first consider how Simulink simulations differ from real-time programs.

Execution During Simulink Model Simulation

Before the Simulink engine simulates a model, it orders the blocks based upon their topological dependencies. This includes expanding virtual subsystems into the individual blocks they contain and flattening the entire model into a single list. Once this step is complete, each block is executed in order.

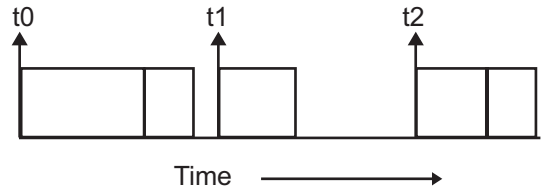
The key to this process is the ordering of blocks. A block whose output is directly dependent on its input (that is, a block with direct feedthrough) cannot execute until the block driving its input executes.

Some blocks set their outputs based on values acquired in a previous time step or from initial conditions specified as a block parameter. The output of such a block is determined by a value stored in memory, which can be updated independently of its input. During simulation, computations are performed prior to advancing the variable corresponding to time. This results in computations occurring instantaneously (that is, no computational delay).

Model Execution in Real Time

A real-time program differs from a Simulink simulation in that the program must execute the model code synchronously with real time. Every calculation results in some computational delay. This means the sample intervals cannot be shortened or lengthened (as they can be in a Simulink simulation), which leads to less efficient execution.

Consider the following timing figure.



Note the processing inefficiency in the sample interval `t1`. That interval cannot be compressed to increase execution speed because, by definition, sample times are clocked in real time.

You can circumvent this potential inefficiency by using the multitasking mode. The multitasking mode defines tasks with different priorities to execute parts of the model code that have different sample rates.

See "Multitasking and Pseudomultitasking Modes" on page 16-12 for a description of how this works. It is important to understand that section before proceeding here.

Single-Tasking Versus Multitasking Operation

Single-tasking programs require longer sample intervals, because all computations must be executed within each clock period. This can result in inefficient use of available CPU time, as shown in the previous figure.

Multitasking mode can improve the efficiency of your program if the model is large and has many blocks executing at each rate.

However, if your model is dominated by a single rate, and only a few blocks execute at a slower rate, multitasking can actually degrade performance. In such a model, the overhead incurred in task switching can be greater than the time required to execute the slower blocks. In this case, it is more efficient to execute all blocks at the dominant rate.

If you have a model that can benefit from multitasking execution, you might need to modify your model by adding Rate Transition blocks (or instruct the Simulink engine to do so) to generate expected results.

For more information about the two modes of execution and examples, see "Modeling for Single-Tasking Execution" on page 16-8 and "Modeling for Multitasking Execution" on page 16-12.

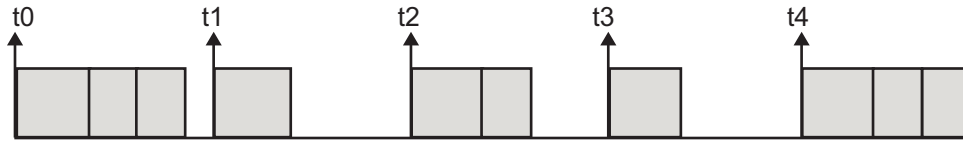
Modeling for Single-Tasking Execution

Single-Tasking Mode

You can execute model code in a strictly single-tasking manner. While this mode is less efficient with regard to execution speed, in certain situations, it can simplify your model.

In single-tasking mode, the base sample rate must define a time interval that is long enough to allow the execution of all blocks within that interval.

The next figure illustrates the inefficiency inherent in single-tasking execution.



Single-tasking system execution requires a base sample rate that is long enough to execute one step through the entire model.

Build a Program for Single-Tasking Execution

To use single-tasking execution, clear the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. If you select the checkbox, single-tasking mode is used in the following cases:

- If your model contains one sample time
- If your model contains a continuous and a discrete sample time and the fixed step size is equal to the discrete sample time

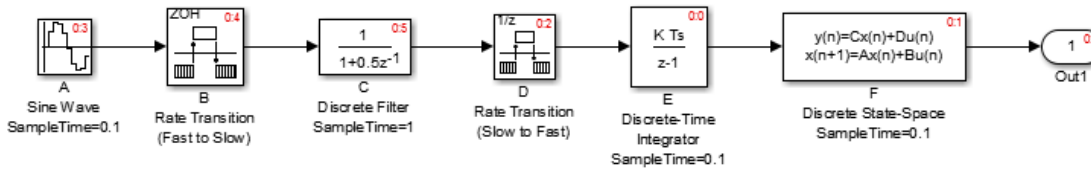
Single-Tasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see "Simulation Phases in Dynamic Systems" (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.



Note The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected/deterministic) mode, with the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options on.

This example considers the execution of the above model when the **Treat each discrete rate as a separate task** checkbox is cleared, which indicates the single-tasking mode.

In a single-tasking system, if the **Block reduction** option on the **All Parameters** tab is on, fast-to-slow Rate Transition blocks are optimized out of the model. The default case is shown (**Block reduction** on), so block B does not appear in the timing diagrams in this section. For more information, see "Block reduction" (Simulink).

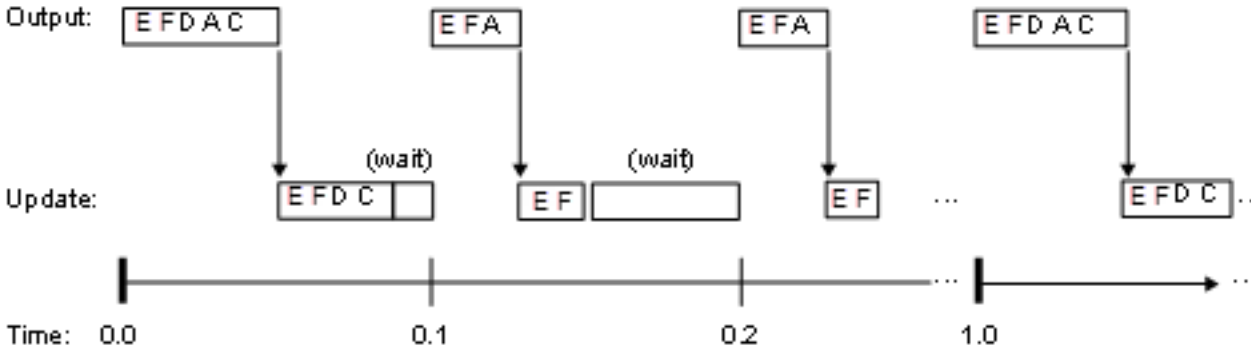
The following table shows, for each block in the model, the execution order, sample time, and whether the block has an output or update computation. Block A does not have discrete states, and accordingly does not have an update computation.

Execution Order and Sample Times (Single-Tasking)

Blocks (in Execution Order)	Sample Time (in Seconds)	Output	Update
E	0.1	Y	Y
F	0.1	Y	Y
D	1	Y	Y
A	0.1	Y	N
C	1	Y	Y

Real-Time Single-Tasking Execution

The next figure shows the scheduling of computations when the generated code is deployed in a real-time system. The generated program is shown running in real time, under control of interrupts from a 10 Hz timer.



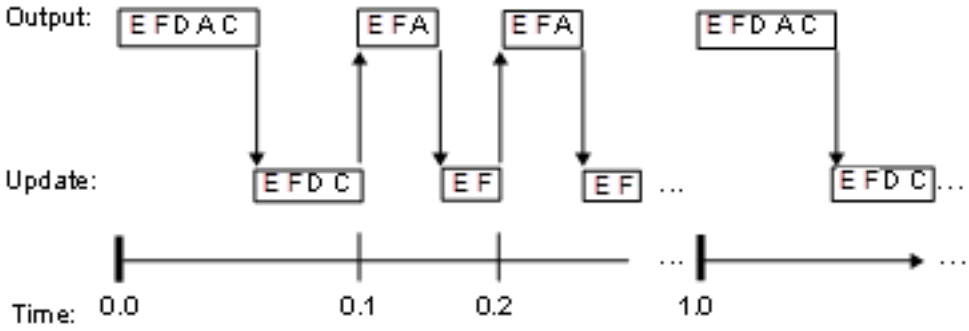
At time 0.0, 1.0, and every second thereafter, both the slow and fast blocks execute their output computations; this is followed by update computations for blocks that have states. Within a given time interval, output and update computations are sequenced in block execution order.

The fast blocks execute on every tick, at intervals of 0.1 second. Output computations are followed by update computations.

The system spends some portion of each time interval (labeled “wait”) idling. During the intervals when only the fast blocks execute, a larger portion of the interval is spent idling. This illustrates an inherent inefficiency of single-tasking mode.

Simulated Single-Tasking Execution

The next figure shows the execution of the model during the Simulink simulation loop.



Because time is simulated, the placement of ticks represents the iterations of the simulation loop. Blocks execute in exactly the same order as in the previous figure, but without the constraint of a real-time clock. Therefore there is no idle time between simulated sample periods.

Modeling for Multitasking Execution

Multitasking and Pseudomultitasking Modes

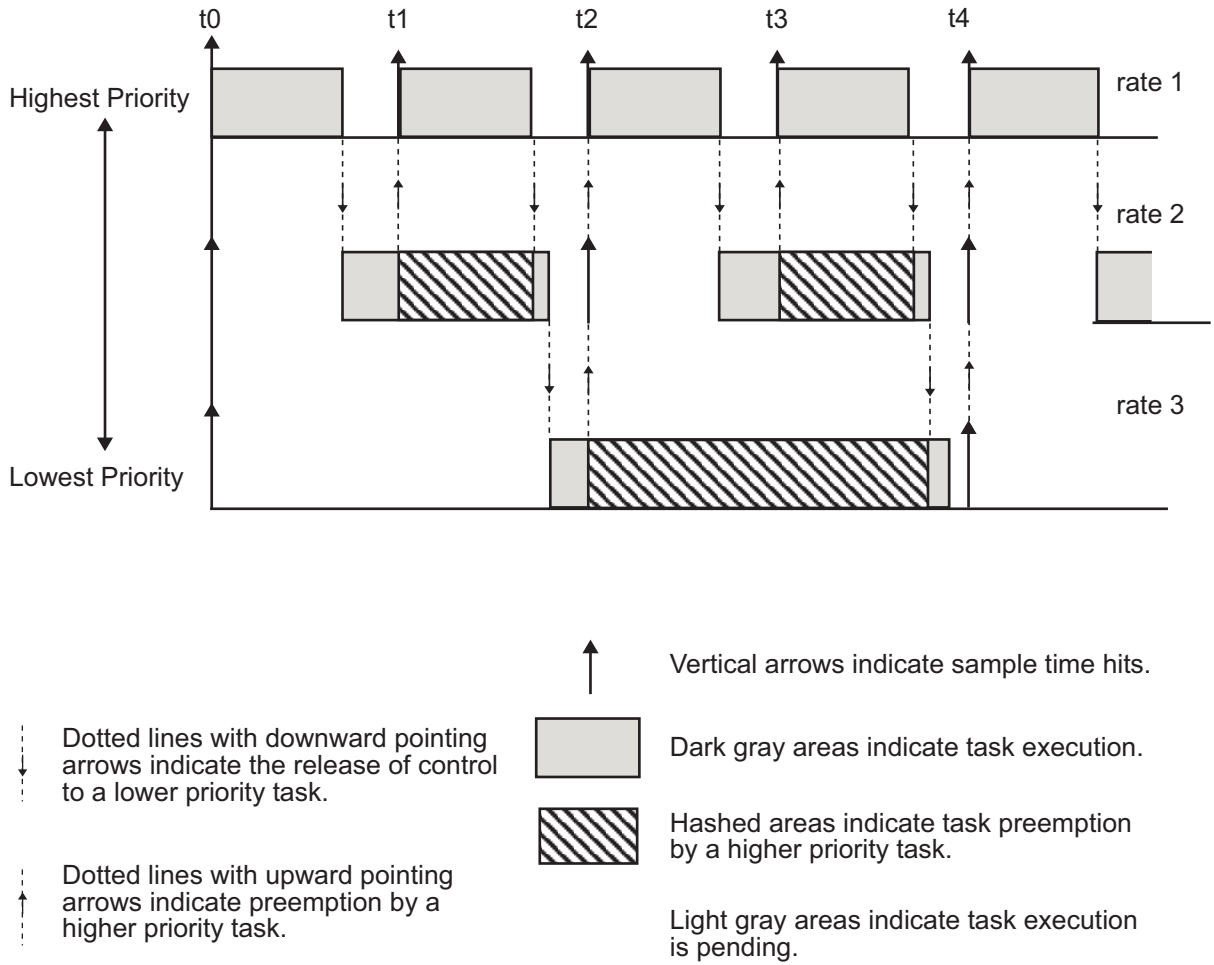
When periodic tasks execute in a multitasking mode, by default the blocks with the fastest sample rates are executed by the task with the highest priority, the next fastest blocks are executed by a task with the next higher priority, and so on. Time available in between the processing of high-priority tasks is used for processing lower priority tasks. This results in efficient program execution.

Where tasks are asynchronous rather than periodic, there may not necessarily be a relationship between sample rates and task priorities; the task with the highest priority need not have the fastest sample rate. You specify asynchronous task priorities using Async Interrupt and Task Sync blocks. You can switch the sense of what priority numbers mean by selecting or deselecting the Solver option **Higher priority value indicates higher task priority**.

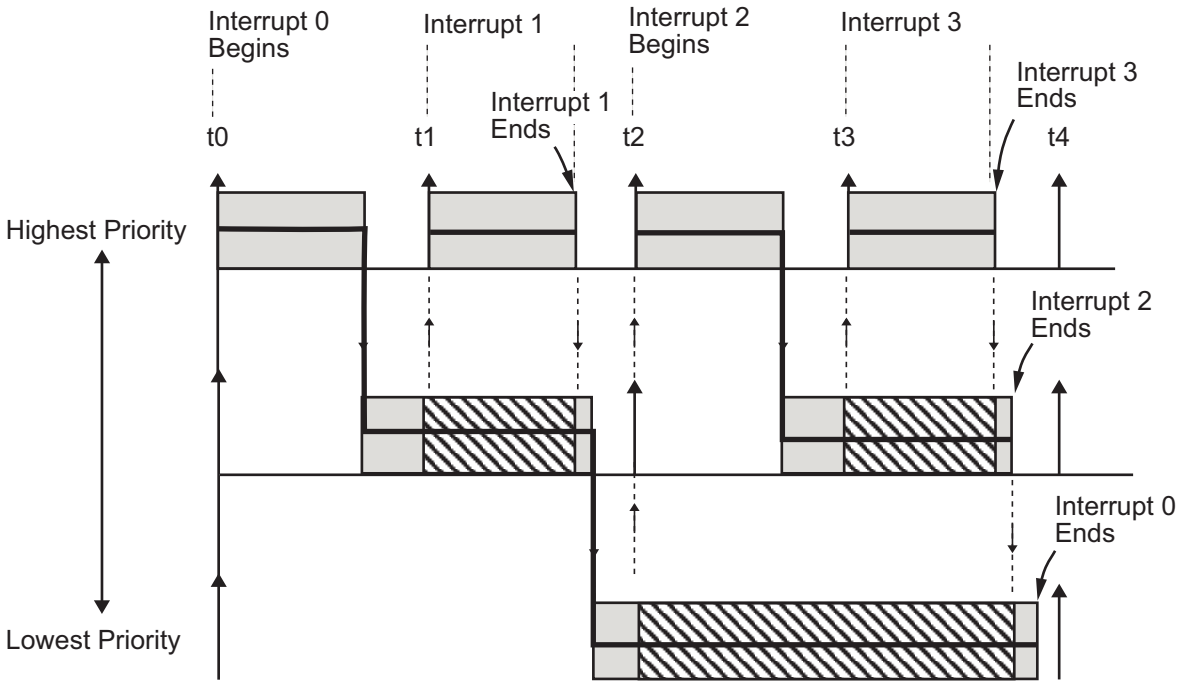
In multitasking environments (that is, under a real-time operating system), you can define separate tasks and assign them priorities. For bare-metal target hardware (that is, no real-time operating system present), you cannot create separate tasks. However, generated application modules implement what is effectively a multitasking execution scheme using overlapped interrupts, accompanied by programmatic context switching.

This means an interrupt can occur while another interrupt is currently in progress. When this happens, the current interrupt is preempted, the floating-point unit (FPU) context is saved, and the higher priority interrupt executes its higher priority (that is, faster sample rate) code. Once complete, control is returned to the preempted ISR.

The next figures illustrate how timing of tasks in multirate systems are handled by the code generator in multitasking, pseudomultitasking, and single-tasking environments.



The next figure shows how overlapped interrupts are used to implement pseudomultitasking. In this case, Interrupt 0 does not return until after Interrupts 1, 2, and 3.



Build a Program for Multitasking Execution

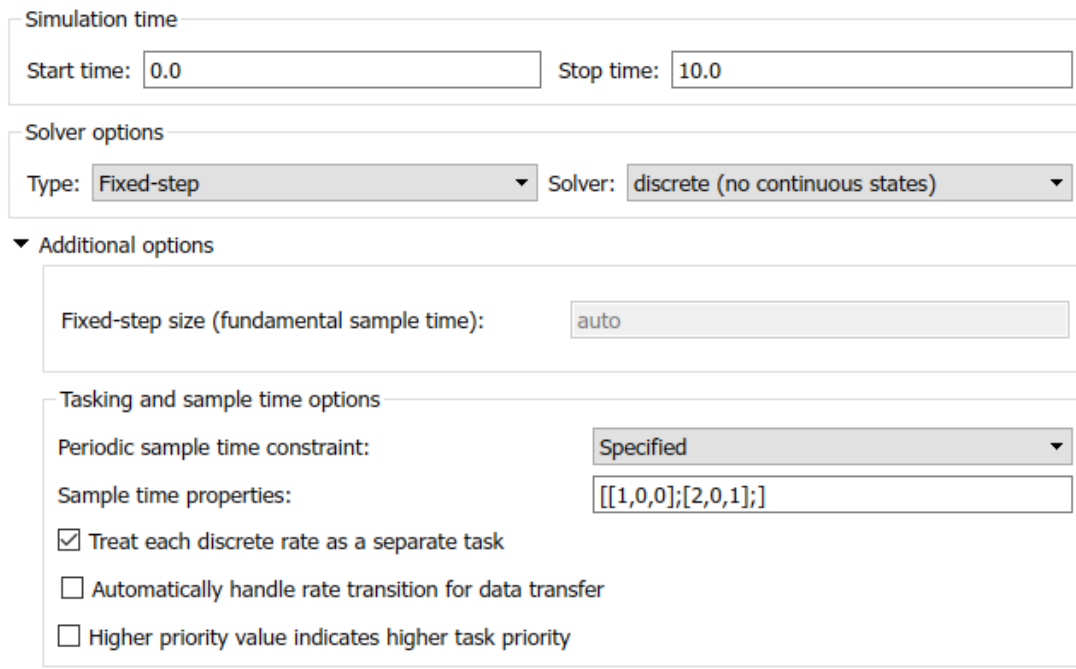
To use multitasking execution, select the **Treat each discrete rate as a separate task** check box on the **Solver** pane of the Configuration Parameters dialog box. This menu is active only if you select `Fixed-step` as the solver type. `Auto` mode results in a multitasking environment if your model has two or more different sample times. A model with a continuous and a discrete sample time runs in single-tasking mode if the fixed-step size is equal to the discrete sample time.

Execute Multitasking Models

In cases where the continuous part of a model executes at a rate that is different from the discrete part, or a model has blocks with different sample rates, the Simulink engine assigns each block a *task identifier* (`tid`) to associate the block with the task that executes at the block's sample rate.

You set sample rates and their constraints on the **Solver** pane of the Configuration Parameters dialog box. To generate code, select `Fixed-step` for the solver type. Certain restrictions apply to the sample rates that you can use:

- The sample rate of a block must be an integer multiple of the base (that is, the fastest) sample period.
- When **Periodic sample time constraint** is `unconstrained`, the base sample period is determined by the **Fixed step size** specified on the **Solvers** pane of the Configuration parameters dialog box.
- When **Periodic sample time constraint** is `Specified`, the base rate fixed-step size is the first element of the sample time matrix that you specify in the companion option **Sample time properties**. The **Solver** pane from the example model `rtwdemo_mrmtbb` shows an example.



- Continuous blocks execute by using an integration algorithm that runs at the base sample rate. The base sample period is the greatest common denominator of all rates in the model only when **Periodic sample time constraint** is set to `Unconstrained` and **Fixed step size** is `Auto`.

- The continuous and discrete parts of the model can execute at different rates only if the discrete part is executed at the same or a slower rate than the continuous part and is an integer multiple of the base sample rate.

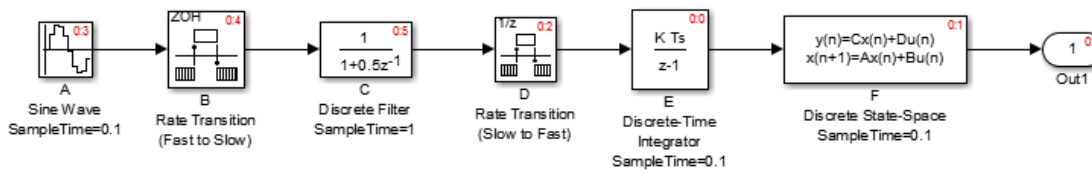
Multitasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see "Simulation Phases in Dynamic Systems" (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.



Note The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected/deterministic) mode, with the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options on.

This example considers the execution of the above model when the solver **Tasking mode** is `MultiTasking`. Block computations are executed under two tasks, prioritized by rate:

- The slower task, which gets the lower priority, is scheduled to run every second. This is called the *1 second task*.
- The faster task, which gets higher priority, is scheduled to run 10 times per second. This is called the *0.1 second task*. The 0.1 second task can preempt the 1 second task.

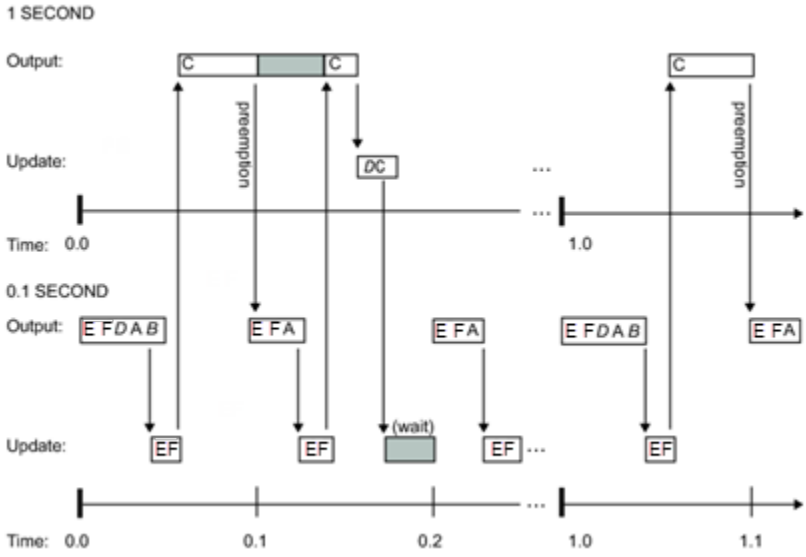
The following table shows, for each block in the model, the execution order, the task under which the block runs, and whether the block has an output or update computation. Blocks A and B do not have discrete states, and accordingly do not have an update computation.

Task Allocation of Blocks in Multitasking Execution

Blocks (in Execution Order)	Task	Output	Update
E	0.1 second task	Y	Y
F	0.1 second task	Y	Y
D	The Rate Transition block uses port-based sample times. Output runs at the output port sample time under 0.1 second task. Update runs at input port sample time under 1 second task. For more information on port-based sample times, see “Sample Times for Model Referencing” (Simulink).	Y	Y
A	0.1 second task	Y	N
B	The Rate Transition block uses port-based sample times. Output runs at the output port sample time under 0.1 second task. For more information on port-based sample times, see “Sample Times for Model Referencing” (Simulink).	Y	N
C	1 second task	Y	Y

Real-Time Multitasking Execution

The next figure shows the scheduling of computations in `MultiTasking` solver mode when the generated code is deployed in a real-time system. The generated program is shown running in real time, as two tasks under control of interrupts from a 10 Hz timer.



Simulated Multitasking Execution

The next figure shows the Simulink execution of the same model, in `MultiTasking` solver mode. In this case, the Simulink engine runs the blocks in one thread of execution, simulating multitasking. No preemption occurs.

Handle Rate Transitions

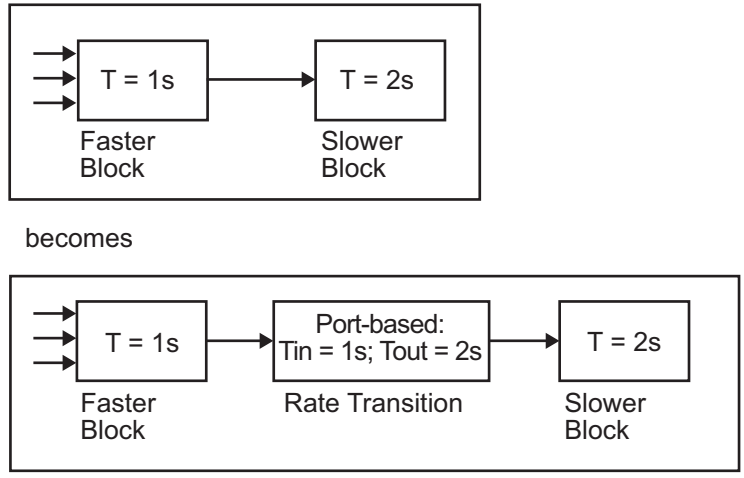
Rate Transitions

Two periodic sample rate transitions can exist within a model:

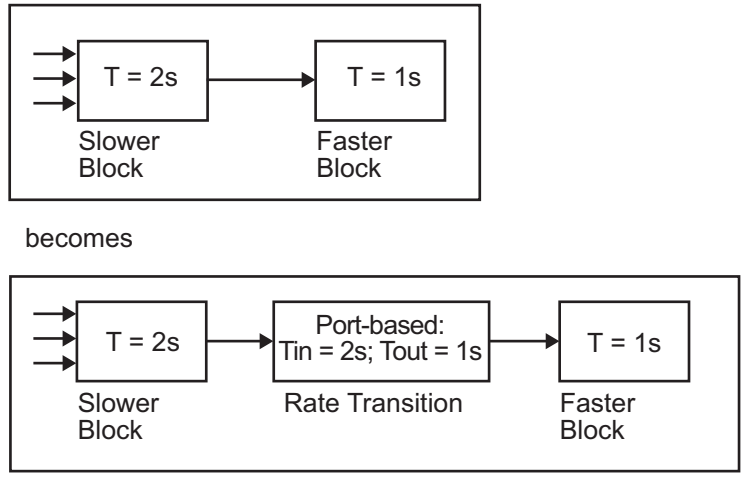
- A faster block driving a slower block
- A slower block driving a faster block

The following sections concern models with periodic sample times with zero offset only. Other considerations apply to multirate models that involve asynchronous tasks. For details on how to generate code for asynchronous multitasking, see "Asynchronous Support" (Simulink Coder).

In multitasking and pseudomultitasking systems, differing sample rates can cause blocks to be executed in the wrong order. To prevent possible errors in calculated data, you must control model execution at these transitions. When connecting faster and slower blocks, you or the Simulink engine must add Rate Transition blocks between them. Fast-to-slow transitions are illustrated in the next figure.



Slow-to-fast transitions are illustrated in the next figure.



Note: Although the Rate Transition block offers a superset of the capabilities of the Unit Delay block (for slow-to-fast transitions) and the Zero-Order Hold block (for fast-to-slow transitions), you should use the Rate Transition block instead of these blocks.

Data Transfer Problems

Rate Transition blocks deal with issues of data integrity and determinism associated with data transfer between blocks running at different rates.

- *Data integrity*: A problem of data integrity exists when the input to a block changes during the execution of that block. Data integrity problems can be caused by preemption.

  Consider the following scenario:

  - A faster block supplies the input to a slower block.
  - The slower block reads an input value V_1 from the faster block and begins computations using that value.
  - The computations are preempted by another execution of the faster block, which computes a new output value V_2.
  - A data integrity problem now arises: when the slower block resumes execution, it continues its computations, now using the “new” input value V_2.

Such a data transfer is called *unprotected*. "Faster to Slower Transitions in Real Time" on page 16-29 shows an unprotected data transfer.

In a *protected* data transfer, the output V_1 of the faster block is held until the slower block finishes executing.

- *Deterministic* versus *nondeterministic* data transfer: In a *deterministic* data transfer, the timing of the data transfer is completely predictable, as determined by the sample rates of the blocks.

  The timing of a *nondeterministic* data transfer depends on the availability of data, the sample rates of the blocks, and the time at which the receiving block begins to execute relative to the driving block.

You can use the Rate Transition block to protect data transfers in your application and make them deterministic. These characteristics are considered desirable in most applications. However, the Rate Transition block supports flexible options that allow you to compromise data integrity and determinism in favor of lower latency. The next section summarizes these options.

Data Transfer Assumptions

When processing data transfers between tasks, the code generator makes these assumptions:

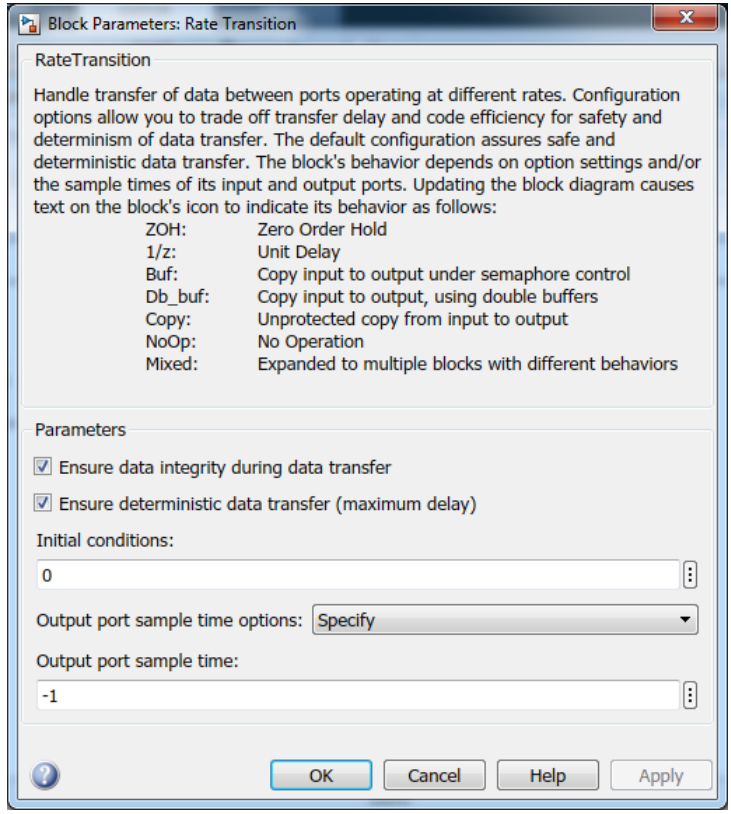
- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte-sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash or restart (especially while data is transferred between tasks).

Rate Transition Block Options

Several parameters of the Rate Transition block are relevant to its use in code generation for real-time execution, as discussed below. For a complete block description, see Rate Transition.

The Rate Transition block handles periodic (fast to slow and slow to fast) and asynchronous transitions. When inserted between two blocks of differing sample rates, the Rate Transition block automatically configures its input and output sample rates for the type of transition; you do not need to specify whether a transition is slow-to-fast or fast-to-slow (low-to-high or high-to-low priorities for asynchronous tasks).

The critical decision you must make in configuring a Rate Transition block is the choice of data transfer mechanism to be used between the two rates. Your choice is dictated by considerations of safety, memory usage, and performance. As the Rate Transition block parameter dialog box in the next figure shows, the data transfer mechanism is controlled by two options.



- **Ensure data integrity during data transfer**: When this option is on, data transferred between rates maintains its integrity (the data transfer is protected).

When this option is off, the data might not maintain its integrity (the data transfer is unprotected). By default, **Ensure data integrity during data transfer** is on.

- **Ensure deterministic data transfer (maximum delay)**: This option is supported for periodic tasks with an offset of zero and fast and slow rates that are multiples of each other. Enable this option for protected data transfers (when **Ensure data integrity during data transfer** is on). When this option is on, the Rate Transition block behaves like a Zero-Order Hold block (for fast to slow transitions) or a Unit Delay block (for slow to fast transitions). The Rate Transition block controls the timing of data transfer in a completely predictable way. When this option is off, the data transfer is nondeterministic. By default, **Ensure deterministic data transfer (maximum delay)** is on for transitions between periodic rates with an offset of zero; for asynchronous transitions, it cannot be selected.

Thus the Rate Transition block offers three modes of operation with respect to data transfer. In order of level of safety:

- **Protected/Deterministic (default):** This is the safest mode. The drawback of this mode is that it introduces deterministic latency into the system for the case of slow-to-fast periodic rate transitions. For that case, the latency introduced by the Rate Transition block is one sample period of the slower task. For the case of fast-to-slow periodic rate transitions, the Rate Transition block introduces no additional latency.
- **Protected/NonDeterministic:** In this mode, for slow-to-fast periodic rate transitions, data integrity is protected by double-buffering data transferred between rates. For fast-to-slow periodic rate transitions, a semaphore flag is used. The blocks downstream from the Rate Transition block use the latest available data from the block that drives the Rate Transition block. Maximum latency is less than or equal to one sample period of the faster task.

  The drawbacks of this mode are its nondeterministic timing. The advantage of this mode is its low latency.
- **Unprotected/NonDeterministic:** This mode is not recommended for mission-critical applications. The latency of this mode is the same as for Protected/NonDeterministic mode, but memory requirements are reduced since neither double-buffering nor semaphores are required. That is, the Rate Transition block does nothing in this mode other than to pass signals through; it simply exists to notify you that a rate transition exists (and can cause generated code to compute incorrect answers). Selecting this mode, however, generates the least amount of code.

Note In unprotected mode (**Ensure data integrity during data transfer** option off), the Rate Transition block does nothing other than allow the rate transition to exist in the model.

Rate Transition Blocks and Continuous Time

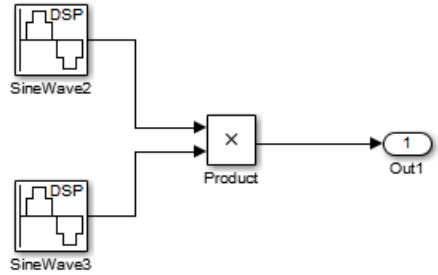
The sample time at the output port of a Rate Transition block can only be discrete or fixed in minor time step. This means that when a Rate Transition block inherits continuous sample time from its destination block, it treats the inherited sample time as Fixed in Minor Time Step. Therefore, the output function of the Rate Transition block runs only at major time steps. If the destination block sample time is continuous, Rate Transition block output sample time is the base rate sample time (if solver is fixed-step), or zero-order-hold-continuous sample time (if solver is variable-step).

Automatic Rate Transition

The Simulink engine can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- The code generator produces code for the Rate Transition blocks that were automatically inserted. This code is identical to the code generated for Rate Transition blocks that were inserted manually.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is `Whenever possible`, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer” (Simulink). To use other modes, you must insert Rate Transition blocks and set their modes manually.

For example, in this model, SineWave2 has a sample time of 2, and SineWave3 has a sample time of 3.

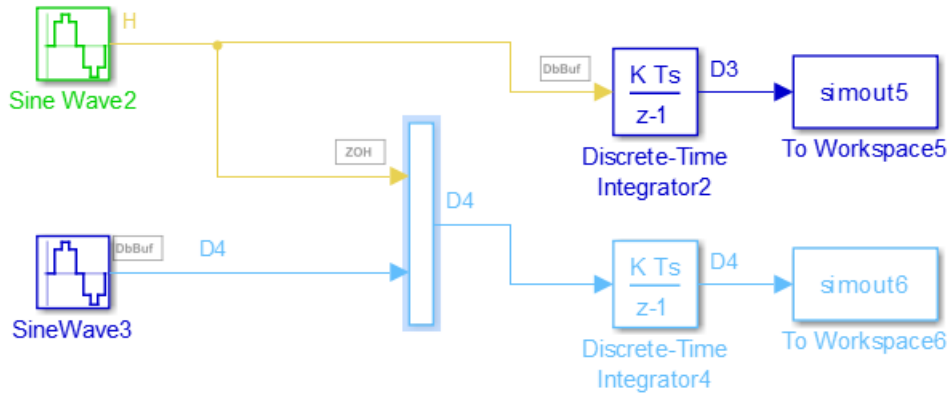


When you select **Automatically handle rate transition for data transfer**, Simulink inserts a Rate Transition block between each Sine Wave block and the Product block. The inserted blocks have the parameter values to reconcile the Sine Wave block sample times.

If the input port and output port data sample rates in a model are not multiples of each other, Simulink inserts a Rate Transition block whose sample rate is the greatest common divisor (GCD) of the two rates. If no other block in the model contains this new rate, an error occurs during simulation. In this case, you must insert a Rate Transition block manually.

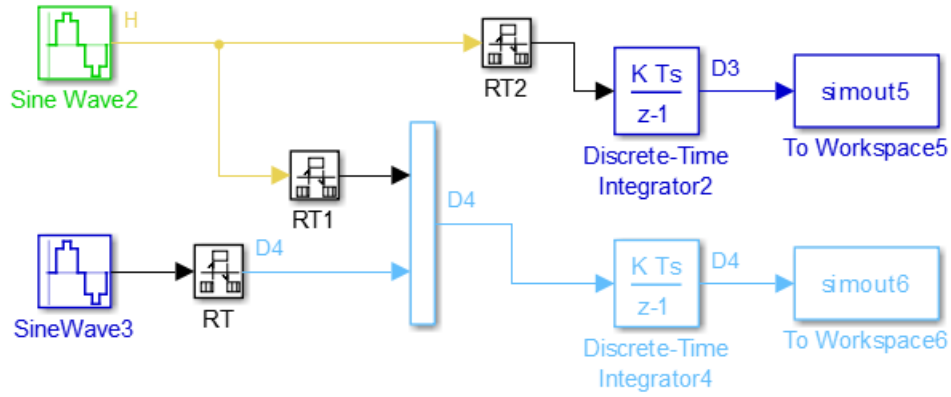
Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.



You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

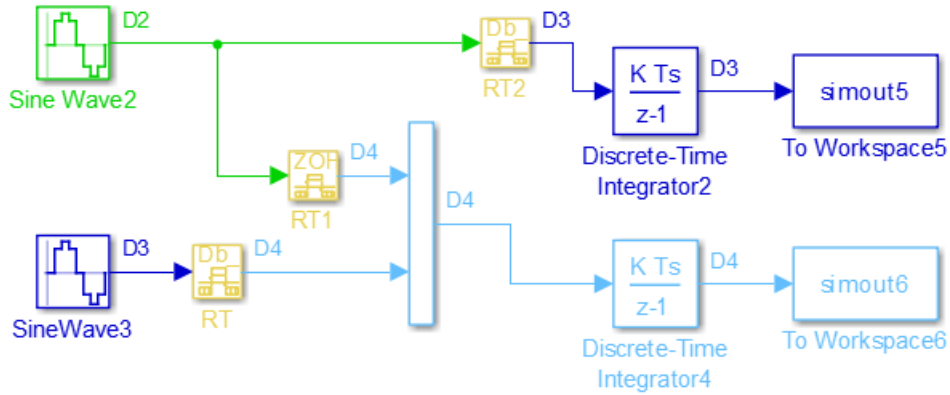


When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.
- You can set the **Initial Conditions** of these blocks.

- You can change block parameters for rate transfer.

Validate the changes to your model by updating your diagram.



Displaying inserted Rate Transition blocks is not compatible with:

- Concurrent execution environment
- Export-function models

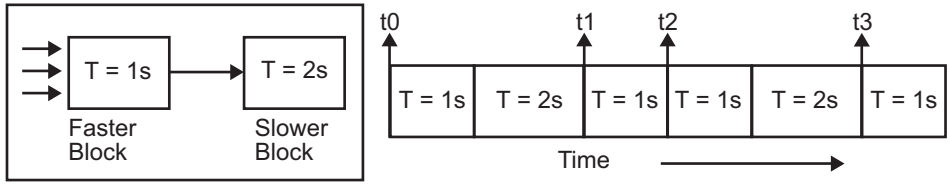
To learn more about the types of Rate Transition blocks, see Rate Transition.

Periodic Sample Rate Transitions

These sections describe cases in which Rate Transition blocks are required for periodic sample rate transitions. The discussion and timing diagrams in these sections are based on the assumption that the Rate Transition block is used in its default (protected/deterministic) mode; that is, the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options are both on. These are the settings used for automatically inserted Rate Transition blocks.

Faster to Slower Transitions in a Simulink Model

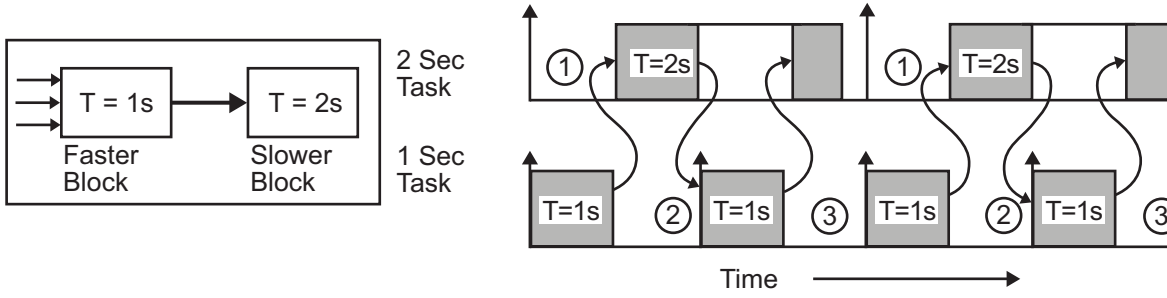
In a model where a faster block drives a slower block having direct feedthrough, the outputs of the faster block are computed first. In simulation intervals where the slower block does not execute, the simulation progresses more rapidly because there are fewer blocks to execute. The next figure illustrates this situation.



A Simulink simulation does not execute in real time, which means that it is not bound by real-time constraints. The simulation waits for, or moves ahead to, whatever tasks are required to complete simulation flow. The actual time interval between sample time steps can vary.

Faster to Slower Transitions in Real Time

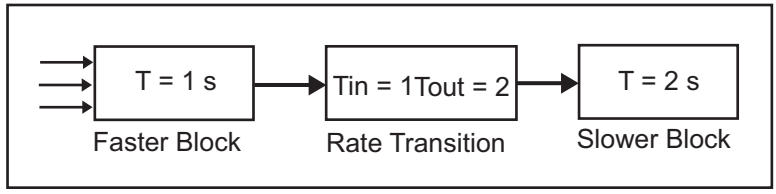
In models where a faster block drives a slower block, you must compensate for the fact that execution of the slower block might span more than one execution period of the faster block. This means that the outputs of the faster block can change before the slower block has finished computing its outputs. The next figure shows a situation in which this problem arises (T = sample time). Note that lower priority tasks are preempted by higher priority tasks before completion.



1. The faster task (T=1s) completes.
2. Higher priority preemption occurs.
3. The slower task (T=2s) resumes and its inputs have changed. This leads to unpredictable results.

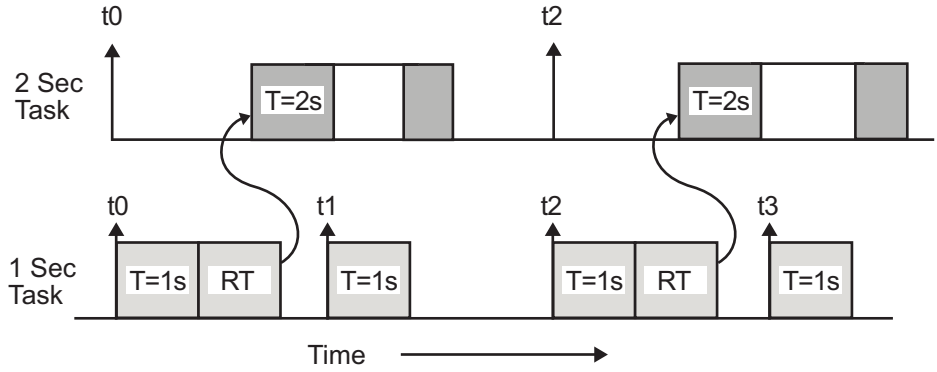
In the above figure, the faster block executes a second time before the slower block has completed execution. This can cause unpredictable results because the input data to the slow task is changing. Data might not maintain its integrity in this situation.

To avoid this situation, the Simulink engine must hold the outputs of the 1 second (faster) block until the 2 second (slower) block finishes executing. The way to accomplish this is by inserting a Rate Transition block between the 1 second and 2 second blocks. The input to the slower block does not change during its execution, maintaining data integrity.



It is assumed that the Rate Transition block is used in its default (protected/ deterministic) mode.

The Rate Transition block executes at the sample rate of the slower block, but with the priority of the faster block.

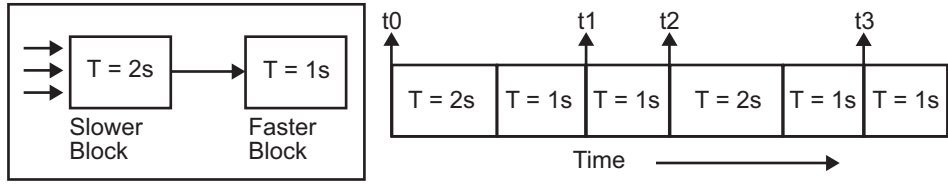


When you add a Rate Transition block, the block executes before the 2 second block (its priority is higher) and its output value is held constant while the 2 second block executes (it executes at the slower sample rate).

Slower to Faster Transitions in a Simulink Model

In a model where a slower block drives a faster block, the Simulink engine again computes the output of the driving block first. During sample intervals where only the faster block executes, the simulation progresses more rapidly.

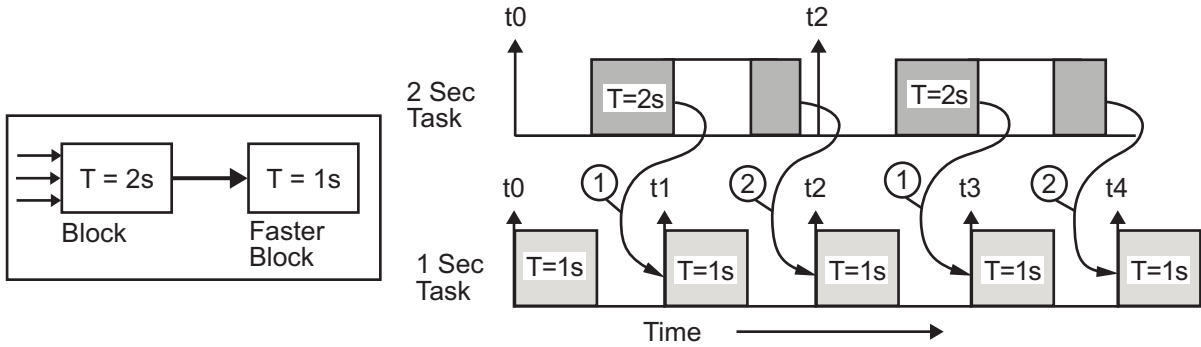
The next figure shows the execution sequence.



As you can see from the preceding figures, the Simulink engine can simulate models with multiple sample rates in an efficient manner. However, a Simulink simulation does not operate in real time.

Slower to Faster Transitions in Real Time

In models where a slower block drives a faster block, the generated code assigns the faster block a higher priority than the slower block. This means the faster block is executed before the slower block, which requires special care to avoid incorrect results.



1 The faster block executes a second time prior to the completion of the slower block.

2 The faster block executes before the slower block.

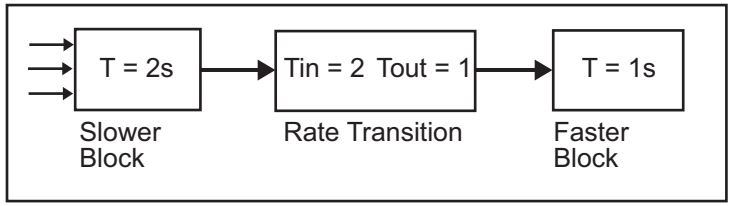
This timing diagram illustrates two problems:

- Execution of the slower block is split over more than one faster block interval. In this case the faster task executes a second time before the slower task has completed

execution. This means the inputs to the faster task can have incorrect values some of the time.

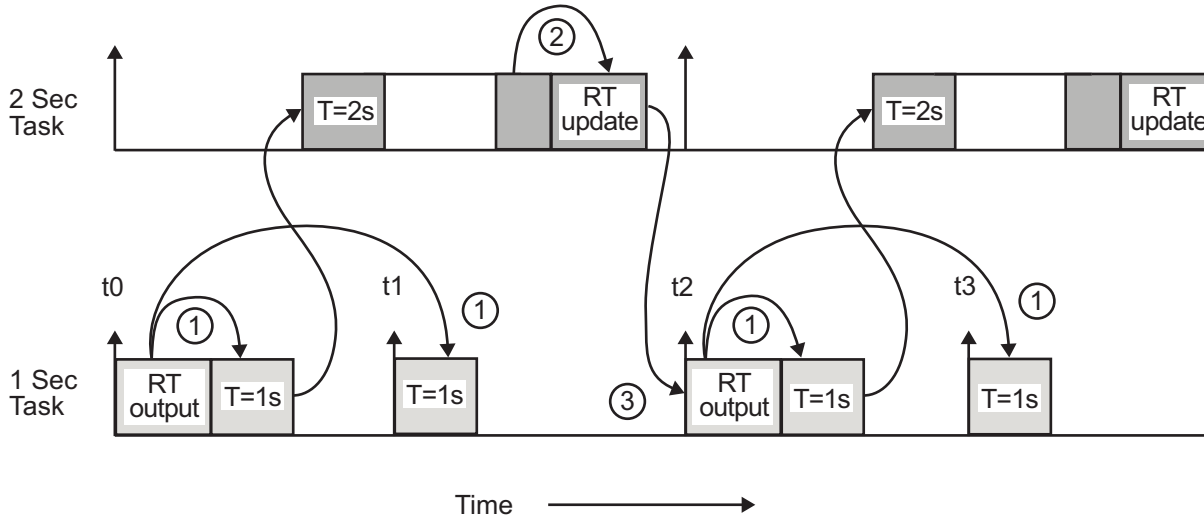
- The faster block executes before the slower block (which is backward from the way a Simulink simulation operates). In this case, the 1 second block executes first; but the inputs to the faster task have not been computed. This can cause unpredictable results.

To eliminate these problems, you must insert a Rate Transition block between the slower and faster blocks.



It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The next figure shows the timing sequence that results with the added Rate Transition block.



Three key points about transitions in this diagram (refer to circled numbers):

1. The Rate Transition block output runs in the 1 second task, but at a slower rate (2 seconds). The output of the Rate Transition block feeds the 1 second task blocks.
2. The Rate Transition update uses the output of the 2 second task to update its internal state.
3. The Rate Transition output in the 1 second task uses the state of the Rate Transition that was updated in the 2 second task.

The first problem is alleviated because the Rate Transition block is updating at a slower rate and at the priority of the slower block. The input to the Rate Transition block (which is the output of the slower block) is read after the slower block completes executing.

The second problem is alleviated because the Rate Transition block executes at a slower rate and its output does not change during the computation of the faster block it is driving. The output portion of a Rate Transition block is executed at the sample rate of the slower block, but with the priority of the faster block. Since the Rate Transition block drives the faster block and has effectively the same priority, it is executed before the faster block.

Note This use of the Rate Transition block changes the model. The output of the slower block is now delayed by one time step compared to the output without a Rate Transition block.

Configure Time-Based Scheduling

For details about solver options, see "Solver Pane" (Simulink).

Configure Start and Stop Times

The **Stop time** (Simulink) must be greater than or equal to the **Start time** (Simulink). If the stop time is zero, or if the total simulation time (`Stop` minus `Start`) is less than zero, the generated program runs for one step. If the stop time is set to `inf`, the generated program runs indefinitely.

When using the GRT or ERT targets, you can override the stop time when running a generated program from the Microsoft Windows command prompt or UNIX[3] command line. To override the stop time that was set during code generation, use the `-tf` switch.

```
model -tf n
```

The program runs for `n` seconds. If `n = inf`, the program runs indefinitely.

Certain blocks have a dependency on absolute time. If you are designing a program that is intended to run indefinitely (**Stop time** = `inf`), and your generated code does not use the `rtModel` data structure (that is, it uses `simstructs` instead), you must not use these blocks. See "Absolute Time Limitations" on page 15-12 for a list of blocks that can potentially overflow timers.

If you know how long an application that depends on absolute time needs to run, you can prevent the timers from overflowing and force the use of optimal word sizes by specifying the **Application lifespan (days)** (Simulink) parameter on the **Optimization** pane. See "Control Memory Allocation for Time Counters" on page 53-11 for details.

Configure the Solver Type

For code generation, you must configure a model to use a fixed-step solver for all targets except the S-function and RSim targets. You can configure the S-function and RSim targets with a fixed-step or variable-step solver.

3. UNIX is a registered trademark of The Open Group in the United States and other countries.

Configure the Tasking Mode

The code generator supports both single-tasking and multitasking modes for periodic sample times. See “Time-Based Scheduling and Code Generation” on page 16-2 for details.

Time-Based Scheduling Example Models

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

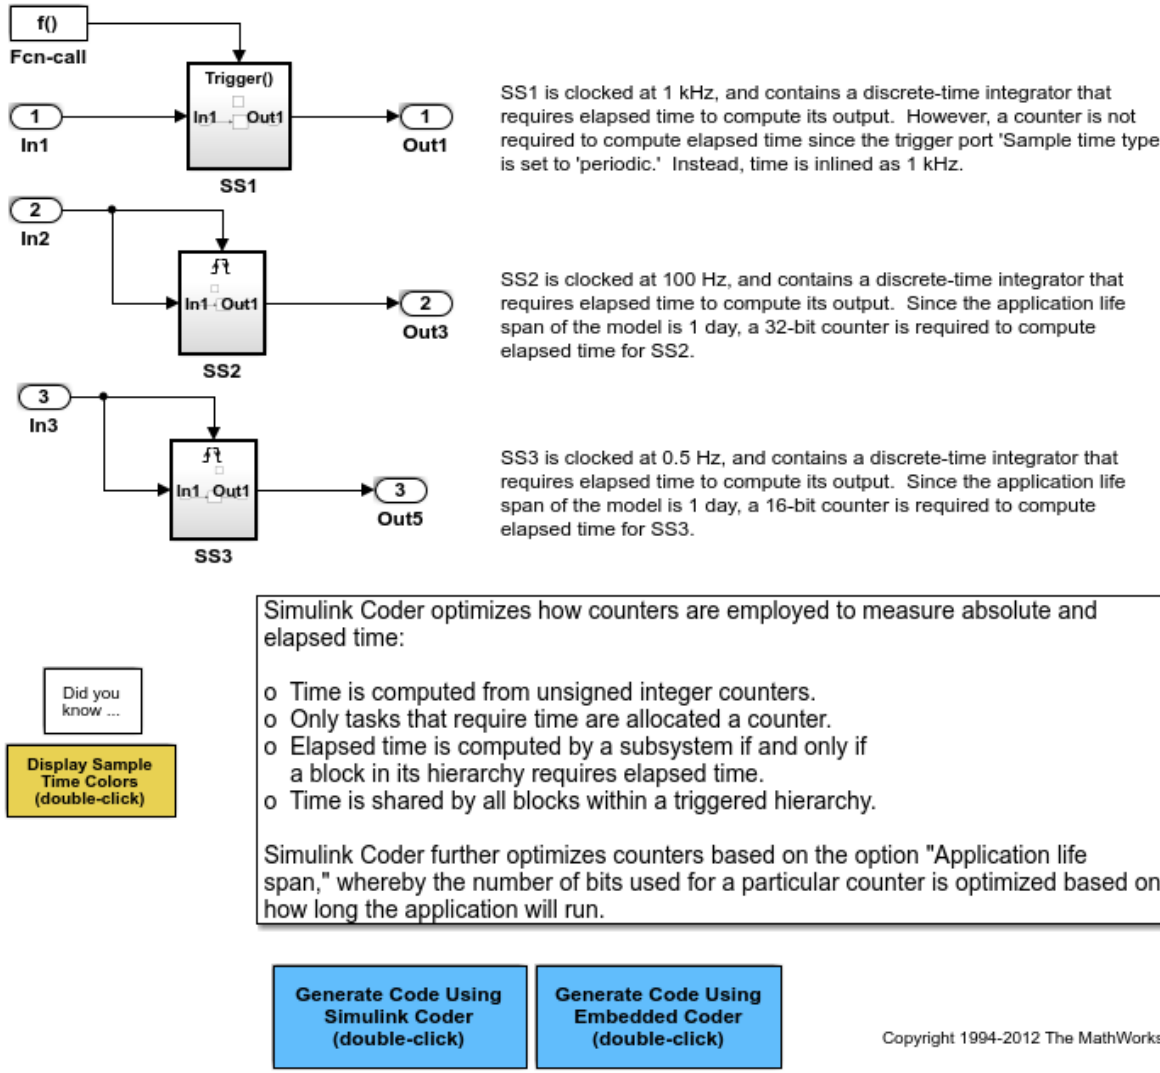
The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

Open Example Model

Open the example model `rtwdemo_abstime`.



The model consists of three subsystems `SS1`, `SS2`, and `SS3`. On the **Optimization** tab, the **Application lifespan (days)** parameter is set to the default, which is `auto`.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

Generate Code and Report

1. Create a temporary folder for the build and inspection process.

2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.

3. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review Generated Code

Open the generated source file `rtwdemo_abstime.c`.

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
    uint32_T clockTickH1;
    uint32_T clockTick2;
    uint32_T clockTickH2;
```

```
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};
```

Four 32-bit unsigned integers, `clockTick1` , `clockTickH1` , `clockTick2` , and `clockTickH2` are counters for storing the elapsed time of subsystems `SS2` and `SS3`.

Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review the Regenerated Code

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
    uint16_T clockTick2;
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};
```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for `SS2`
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for `SS3`

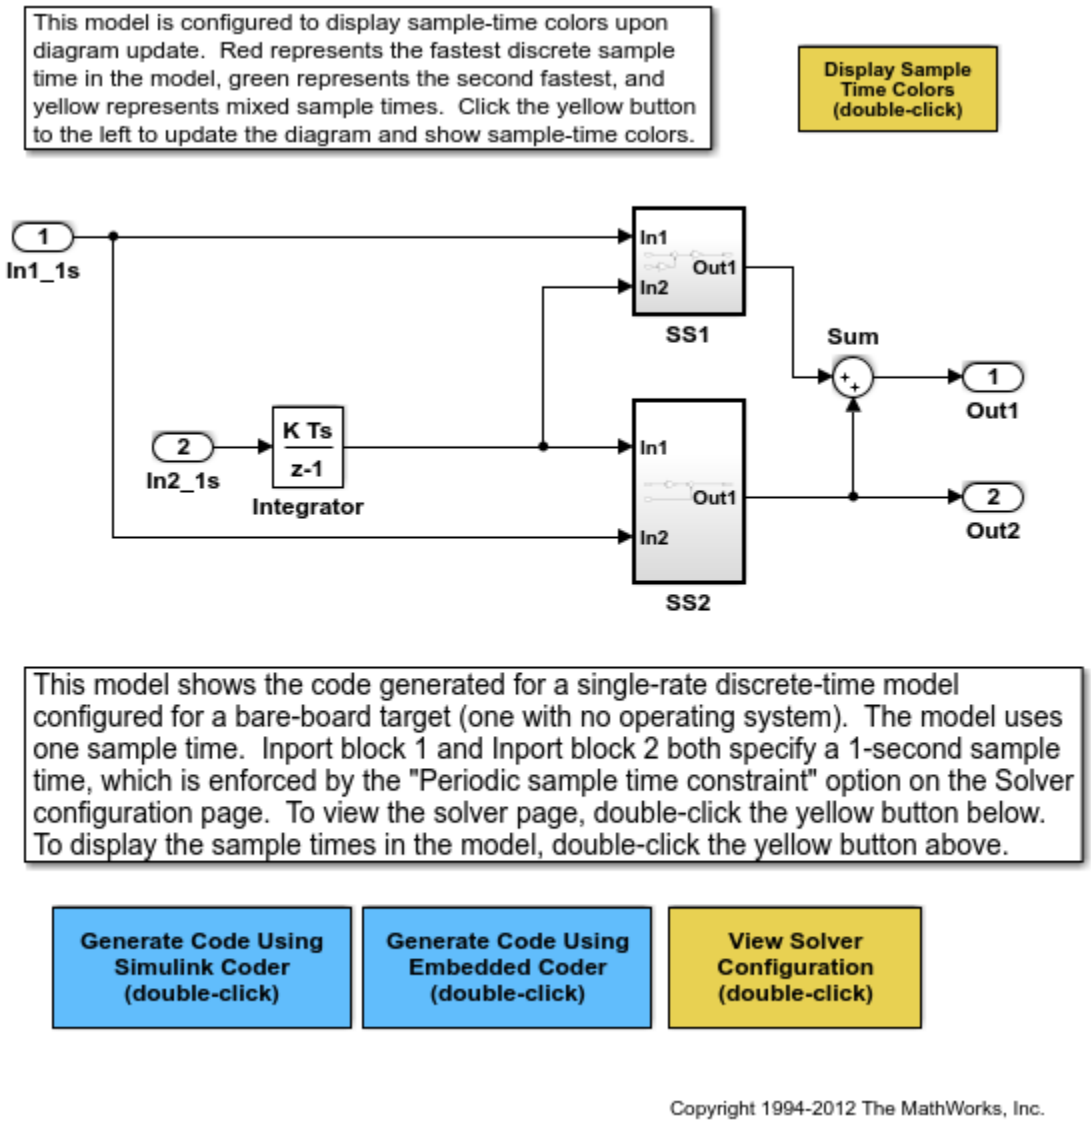
Single-Rate Modeling (Bare Board, No OS)

This model shows the code generated for a single-rate discrete-time model configured for a bare-board target (one with no operating system).

Open Example Model

Open the example model `rtwdemo_srbb`.

```
open_system('rtwdemo_srbb')
```



The model uses one sample time. Inport block 1 and Inport block 2 both specify a 1-second sample time, which is enforced by the **Periodic sample time constraint** option

on the **Solver** configuration page. To view the solver page, double-click the corresponding yellow button in the model. To display the sample times in the model, double-click the corresponding yellow button in the model.

This model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button in the model to update the diagram and show sample-time colors.

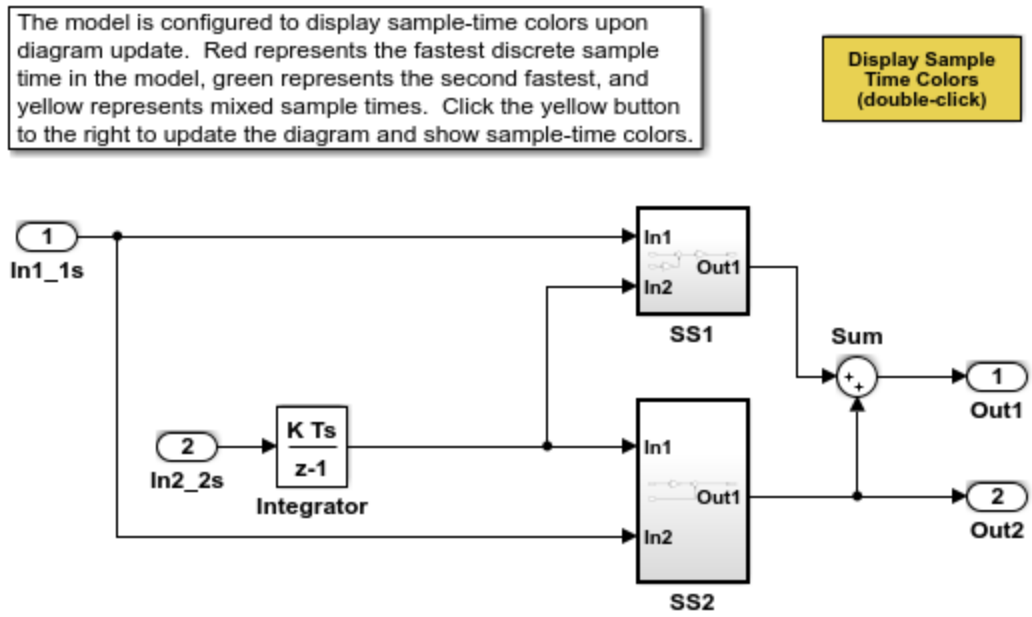
Multirate Modeling in Single-Tasking Mode (Bare Board, no OS)

This model shows the code generated for a multirate discrete-time model configured for single-tasking on a bare-board target (one with no operating system).

Open Example Model

Open the example model `rtwdemo_mrstbb`.

```
open_system('rtwdemo_mrstbb')
```



This model shows the code generated for a multirate discrete-time model configured for single-tasking on a bare-board target (one with no operating system). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for single-tasking operation. Rate transition blocks are, therefore, not necessary between blocks executing at different sample times because preemption will not occur.

Data Transfer Assumptions

Basis of operation for data transfers between tasks:

1. Data transitions occur between a single reading task and a single writing task.
2. A read or write of a byte sized variable is atomic.
3. When two tasks interact through a data transition, only one of them can preempt the other.
4. For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
5. All tasks run on a single processor. Time slicing is not allowed.
6. Processes do not crash/restart (especially while data is being transferred between tasks)

Trade Determinism and Data Integrity to Improve System Performance

This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.

Rate Transition Block Modes of Operation

Ensure data integrity and determinism (DetAndInteg) : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. Additionally, it is ensured that the relative sample time (delay) from which the data is transferred from one rate to another is always the same. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

Ensure integrity (IntegOnly) : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. However, from one transfer of data to the next, the relative sample time (delay) for which the data is transferred can vary. In this mode, the code to read/write the data is run more often than in the DetandInt mode. In the worst case, the delay is equivalent to the DetandInt mode, but the delay can be less which is important is some applications. Also, this mode support data transfers to/from asynchronous rates which the DetandInt mode cannot support. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

No data consistency operations are performed (None) : For this case, the Rate Transition block does not generated code. This mode is acceptable in some application where atomic access of scalar data types is guaranteed and when the relative temporal values of the data is not important. This mode does not introduce any delay.

Data Transfer Assumptions

Basis of operation for data transfers between tasks:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash/restart (especially while data is being transferred between tasks)

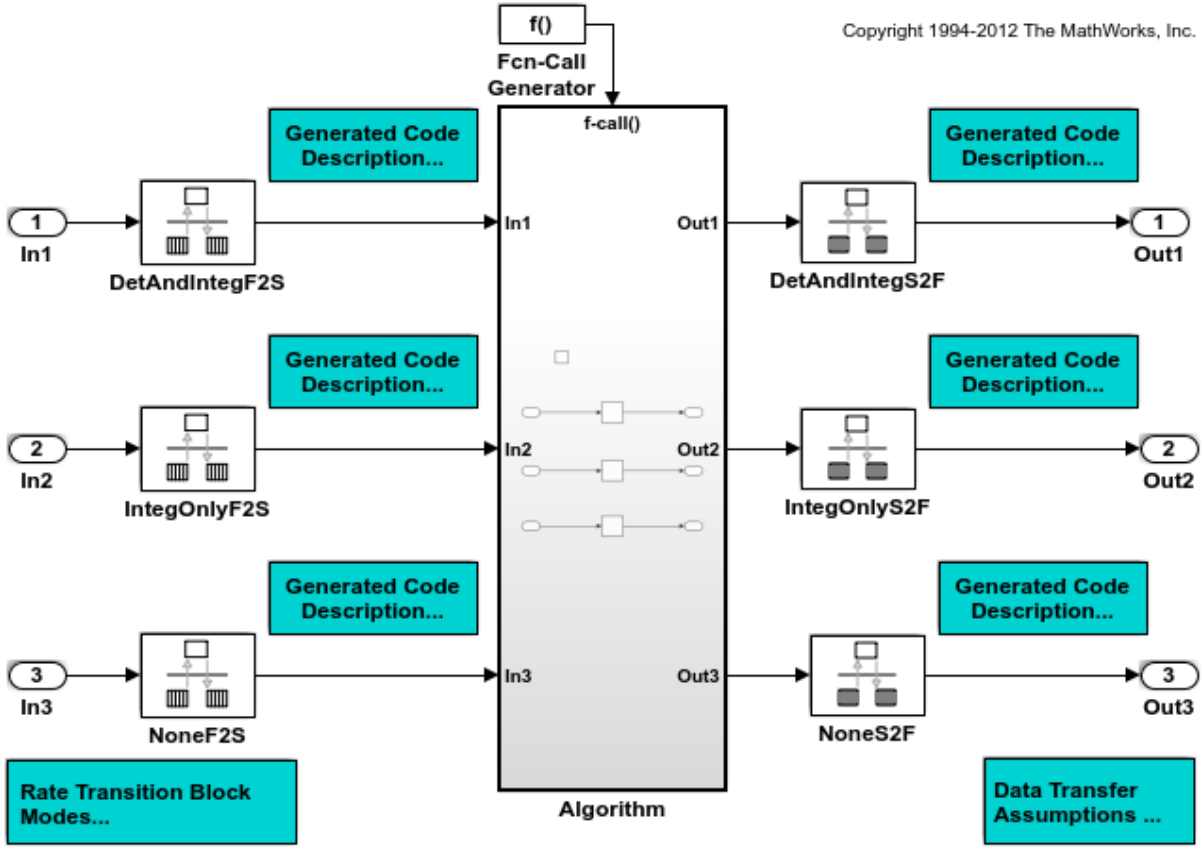
```
open_system('rtwdemo_ratetrans')
```



This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Display Sample Time Colors (double-click)

Model `rtwdemo_ratetrans` shows the differences in the operation modes of the following Rate Transition blocks.

Rate Transition block `DetAndIntegF2S`

Determinism and data integrity (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to output at slower rate but done during the faster rate context
- Data as seen by the slower rate is always the value when both the faster and slower rate last executed. Any subsequent steps by the faster rate (and associated data updates) while the slower rate is running are not seen by the slower rate.

Rate Transition block `DetAndIntegS2F`

Determinism and data integrity (slow to fast transition):

- Uses two persistent data buffers, an internal buffer and the blocks output.
- The internal buffer is copied to the output at the slower rate but done during the faster rate context.
- The internal buffer is written at the slower rate and during the slower rate context.
- The data that Fast rate sees is always delayed, i.e. data is from the previous step of the slow rate code.

Rate Transition block `IntegOnlyF2S`

Data integrity only (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to buffer during the faster rate context if a flag indicates it not in the process of being read.
- The flag is set and data is copied from the buffer to output at the slow rate, the flag is then cleared. This is an additional copy as compared to the deterministic case.
- Data as seen by the slower rate can be from a more recent step of the faster rate than from when the slower rate and faster rate both executed.

Rate Transition block `IntegOnlyS2F`

Data integrity only (slow to fast transition):

- Uses two persistent data buffers, both are internal buffers.

- One of the 2 buffers is always copied to the output at faster rate.
- One of the 2 buffers is written at the slower rate and during the slower rate context, then the active buffer is switched.
- The data as seen by the faster rate can be more recent than for the deterministic case. Specifically, when both the slower and faster rate have their hits, the faster rate will see a previous value from the slower rate. But, subsequent steps for the faster rate may see an updated value (when the slower rate updates the non-active buffer and switches the active buffer flag.

Rate Transition block `NoneF2S`

No code is generated for the Rate Transition block when determinism and data integrity is waived.

Rate Transition block `NoneS2F`

No code is generated for the Rate Transition block when determinism and data integrity is waived.

```
bdclose('rtwdemo_ratetrans');
```

Event-Based Scheduling in Simulink Coder

Asynchronous Events

Asynchronous Support

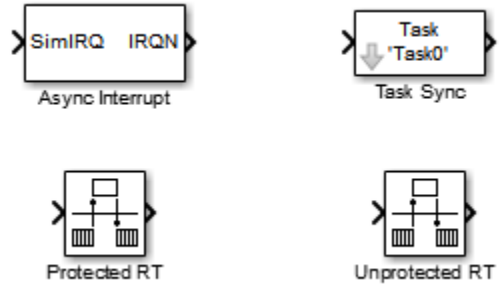
Normally, you time models from which you plan to generate code from a *periodic* interrupt source (for example, a hardware timer). Blocks in a periodically clocked single-rate model run at a timer interrupt rate (the base rate of the model). Blocks in a periodically clocked multirate model run at the base rate or at multiples of that rate.

Many systems must also support execution of blocks in response to events that are *asynchronous* with respect to the periodic timing source of the system. For example, a peripheral device might signal completion of an input operation by generating an interrupt. The system must service such interrupts, for example, by acquiring data from the interrupting device.

This chapter explains how to use blocks to model and generate code for asynchronous event handling, including servicing of hardware-generated interrupts, maintenance of timers, asynchronous read and write operations, and spawning of asynchronous tasks under a real-time operating system (RTOS). This block library demonstrates integration with an example RTOS (VxWorks). Although the blocks target an example RTOS, this chapter provides source code analysis and other information you can use to develop blocks that support asynchronous event handling for an alternative target RTOS.[4]

Block Library for Calls to an Example Real-Time Operating System

The next figure shows the blocks in the `vxlib1` block library.



4. VxWorks is a registered trademark of Wind River Systems, Inc.

The key blocks in the library are the Async Interrupt and Task Sync blocks. These blocks are targeted for an example RTOS (VxWorks). You can use them, with modification, to support your RTOS applications.

Note: You can use the blocks in the `vxlib1` (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

To implement asynchronous support for an RTOS other than the example RTOS, use the guidelines and example code are provided to help you adapt the `vxlib1` library blocks to target your RTOS. This topic is discussed in "Create a Customized Asynchronous Library" on page 17-47.

The `vxlib1` library includes blocks you can use to

- Generate interrupt-level code — Async Interrupt block
- Spawn an RTOS task that calls a function call subsystem — Task Sync block
- Enable data integrity when transferring data between blocks running as different tasks — Protected RT block
- Use an unprotected/nondeterministic mode when transferring data between blocks running as different tasks — Unprotected RT block

The use of protected and unprotected Rate Transition blocks in asynchronous contexts is discussed in "Rate Transitions and Asynchronous Blocks" on page 17-39. For general information on rate transitions, see "Time-Based Scheduling and Code Generation" on page 16-2.

Access the Block Library for RTOS Integration

To access the example RTOS (VxWorks) block library, enter the MATLAB command `vxlib1`.

Generate Code Using Library Blocks for RTOS Integration

To generate an example RTOS compatible application from a model containing `vxlib1` library blocks, use the following configuration parameter values for your model.

- Select system target file `ert.tlc` (requires an Embedded Coder license) from the browse menu for the **Code Generation** > **System target file** parameter (`SystemTargetFile`).
- Enable the **Code Generation** > **Generate code only** parameter (`GenCodeOnly`).
- Enable the **All Parameters** > **Generate an example main program** parameter (`GenerateSampleERTMain`).
- Select `VxWorksExample` from the menu for the **All Parameters** > **Target operating system** parameter (`TargetOS`).

Examples and Additional Information

Additional information relevant to the topics in this chapter can be found in

Generate Interrupt Service Routines

To generate an interrupt service routine (ISR) associated with a specific VME interrupt level for the example RTOS (VxWorks), use the Async Interrupt block. The Async Interrupt block enables the specified interrupt level and installs an ISR that calls a connected function call subsystem.

You can also use the Async Interrupt block in a simulation. It provides an input port that can be enabled and connected to a simulated interrupt source.

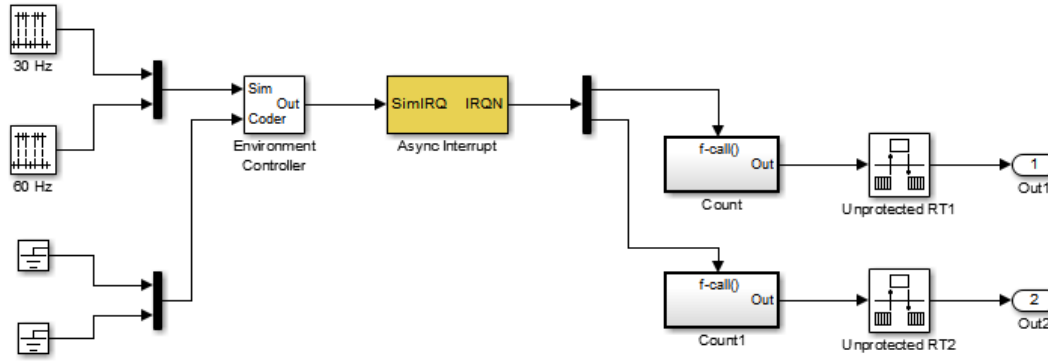
Note: The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

Connecting the Async Interrupt Block

To generate an ISR, connect an output of the Async Interrupt block to the control input of

- A function call subsystem
- The input of a Task Sync block
- The input to a Stateflow chart configured for a function call input event

The next figure shows an Async Interrupt block configured to service two interrupt sources. The outputs (signal width 2) are connected to two function call subsystems.



Requirements and Restrictions

Note the following requirements and restrictions:

- The Async Interrupt block supports VME interrupts 1 through 7.
- The Async Interrupt block uses the following system calls to the example RTOS (VxWorks):
  - `sysIntEnable`
  - `sysIntDisable`
  - `intConnect`
  - `intLock`
  - `intUnlock`
  - `tickGet`

Performance Considerations

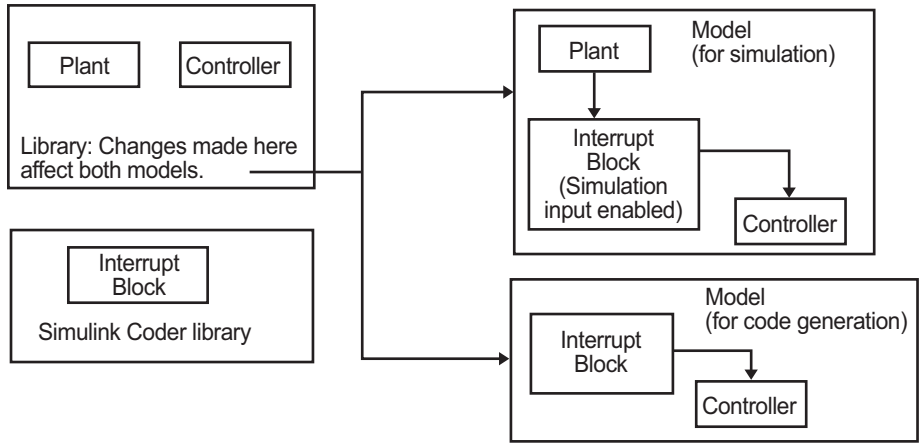
Execution of large subsystems at interrupt level can have a significant impact on interrupt response time for interrupts of equal and lower priority in the system. As a general rule, it is best to keep ISRs as short as possible. Connect only function call subsystems that contain a small number of blocks to an Async Interrupt block.

A better solution for large subsystems is to use the Task Sync block to synchronize the execution of the function call subsystem to a RTOS task. The Task Sync block is placed

between the Async Interrupt block and the function call subsystem. The Async Interrupt block then installs the Task Sync block as the ISR. The ISR releases a synchronization semaphore (performs a `semGive`) to the task, and returns immediately from interrupt level. The task is then scheduled and run by the example RTOS (VxWorks). See "Spawn and Synchronize Execution of RTOS Task" on page 17-15 for more information.

Using the Async Interrupt Block in Simulation and Code Generation

This section describes a *dual-model* approach to the development and implementation of real-time systems that include ISRs. In this approach, you develop one model that includes a plant and a controller for simulation, and another model that only includes the controller for code generation. Using a Simulink library, you can implement changes to both models simultaneously. The next figure shows how changes made to the plant or controller, both of which are in a library, are propagated to the models.

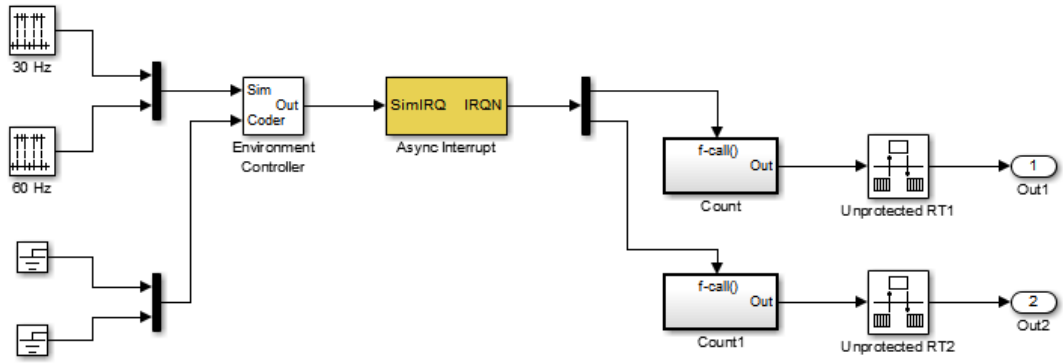


Dual-Model Use of Async Interrupt Block for Simulation and Code Generation

A *single-model* approach is also possible. In this approach, the Plant component of the model is active only in simulation. During code generation, the Plant components are effectively switched out of the system and code is generated only for the interrupt block and controller parts of the model. For an example of this approach, see the `rtwdemo_async` model.

Dual-Model Approach: Simulation

The following block diagram shows a simple model that illustrates the dual-model approach to modeling. During simulation, the Pulse Generator blocks provide simulated interrupt signals.



The simulated interrupt signals are routed through the Async Interrupt block's input port. Upon receiving a simulated interrupt, the block calls the connected subsystem.

During simulation, subsystems connected to Async Interrupt block outputs are executed in order of their priority in the example RTOS (VxWorks). In the event that two or more interrupt signals occur simultaneously, the Async Interrupt block executes the downstream systems in the order specified by their interrupt levels (level 7 gets the highest priority). The first input element maps to the first output element.

You can also use the Async Interrupt block in a simulation without enabling the simulation input. In such a case, the Async Interrupt block inherits the base rate of the model and calls the connected subsystems in order of their priorities in the RTOS. (In this case, the Async Interrupt block behaves as if all inputs received a 1 simultaneously.)

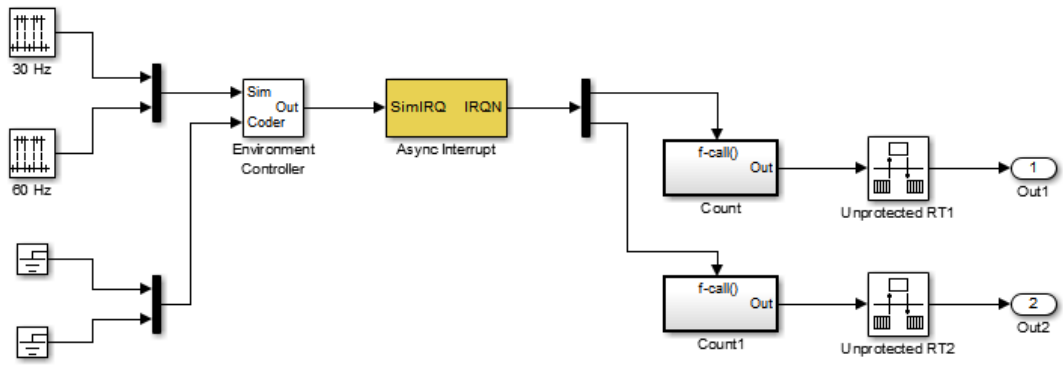
Dual-Model Approach: Code Generation

In the generated code for the sample model,

- Ground blocks provide input signals to the Environment Controller block

- The Async Interrupt block does not use its simulation input

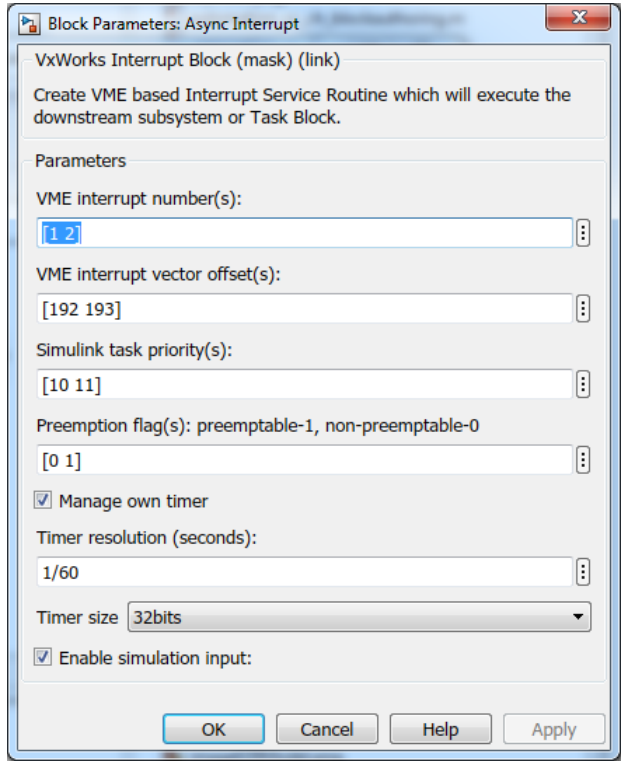
The Ground blocks drive control input of the Environment Controller block, so code is not generated for that signal path. The code generator does not produce code for blocks that drive the simulation control input to the Environment Controller block because that path is not selected during code generation. However, the sample times of driving blocks for the simulation input to the Environment Controller block contribute to the sample times supported in the generated code. To avoid including unnecessary sample times in the generated code, use the sample times of the blocks driving the simulation input in the model where generated code is intended.



Standalone functions are installed as ISRs and the interrupt vector table is as follows:

Offset	
192	`&isr_num1_vec192()`
193	`&isr_num2_vec193()`

Consider the code generated from this model, assuming that the Async Interrupt block parameters are configured as shown in the next figure.



Initialization Code

In the generated code, the Async Interrupt block installs the code in the Subsystem blocks as interrupt service routines. The interrupt vectors for `IRQ1` and `IRQ2` are stored at locations `192` and `193` relative to the base of the interrupt vector table, as specified by the **VME interrupt vector offset(s)** parameter.

Installing an ISR requires two RTOS (VxWorks) calls, `int_connect` and `sysInt_Enable`. The Async Interrupt block inserts these calls in the *`model`*`_initialize` function, as shown in the following code excerpt.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Connect and enable ISR function: isr_num1_vec192 */
    if( intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
      printf("intConnect failed for ISR 1.\n");
    }
    sysIntEnable(1);
```

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if( intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK)
{
  printf("intConnect failed for ISR 2.\n");
}
sysIntEnable(2);
```

The hardware that generates the interrupt is not configured by the Async Interrupt block. Typically, the interrupt source is a VME I/O board, which generates interrupts for specific events (for example, end of A/D conversion). The VME interrupt level and vector are set up in registers or by using jumpers on the board. You can use the `mdlStart` routine of a user-written device driver (S-function) to set up the registers and enable interrupt generation on the board. You must match the interrupt level and vector specified in the Async Interrupt block dialog to the level and vector set up on the I/O board.

Generated ISR Code

The actual ISR generated for `IRQ1` in the RTOS (VxWorks) is listed below.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */

void isr_num1_vec192(void)
{
  int_T lock;
  FP_CONTEXT context;

   /* Use tickGet() as a portable tick counter example.
      A much higher resolution can be achieved with a
      hardware counter */
   Async_Code_M->Timing.clockTick2 = tickGet();

   /* disable interrupts (system is configured as non-ive) */
   lock = intLock();

   /* save floating point context */
   fppSave(&context);

   /* Call the system: <Root>/Subsystem A */
   Count(0, 0);

   /* restore floating point context */
   fppRestore(&context);
```

```
   /* re-enable interrupts */
   intUnlock(lock);
}
```

There are several features of the ISR that should be noted:

- Because of the setting of the **Preemption Flag(s)** parameter, this ISR is locked; that is, it cannot be preempted by a higher priority interrupt. The ISR is locked and unlocked in the example RTOS (VxWorks) by the `int_lock` and `int_unlock` functions.
- The connected subsystem, `Count`, is called from within the ISR.
- The `Count` function executes algorithmic (model) code. Therefore, the floating-point context is saved and restored across the call to `Count`.
- The ISR maintains its own absolute time counter, which is distinct from other periodic base rate or subrate counters in the system. Timing data is maintained for the use of any blocks executed within the ISR that require absolute or elapsed time.

  See “Timers in Asynchronous Tasks” on page 17-44 for details.

Model Termination Code

The model's termination function disables the interrupts in the RTOS (VxWorks):

```
/* Model terminate function */
void Async_Code_terminate(void)
{
   /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
   /* Disable interrupt for ISR system: isr_num1_vec192 */
   sysIntDisable(1);

   /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
   /* Disable interrupt for ISR system: isr_num2_vec193 */
   sysIntDisable(2);
}
```

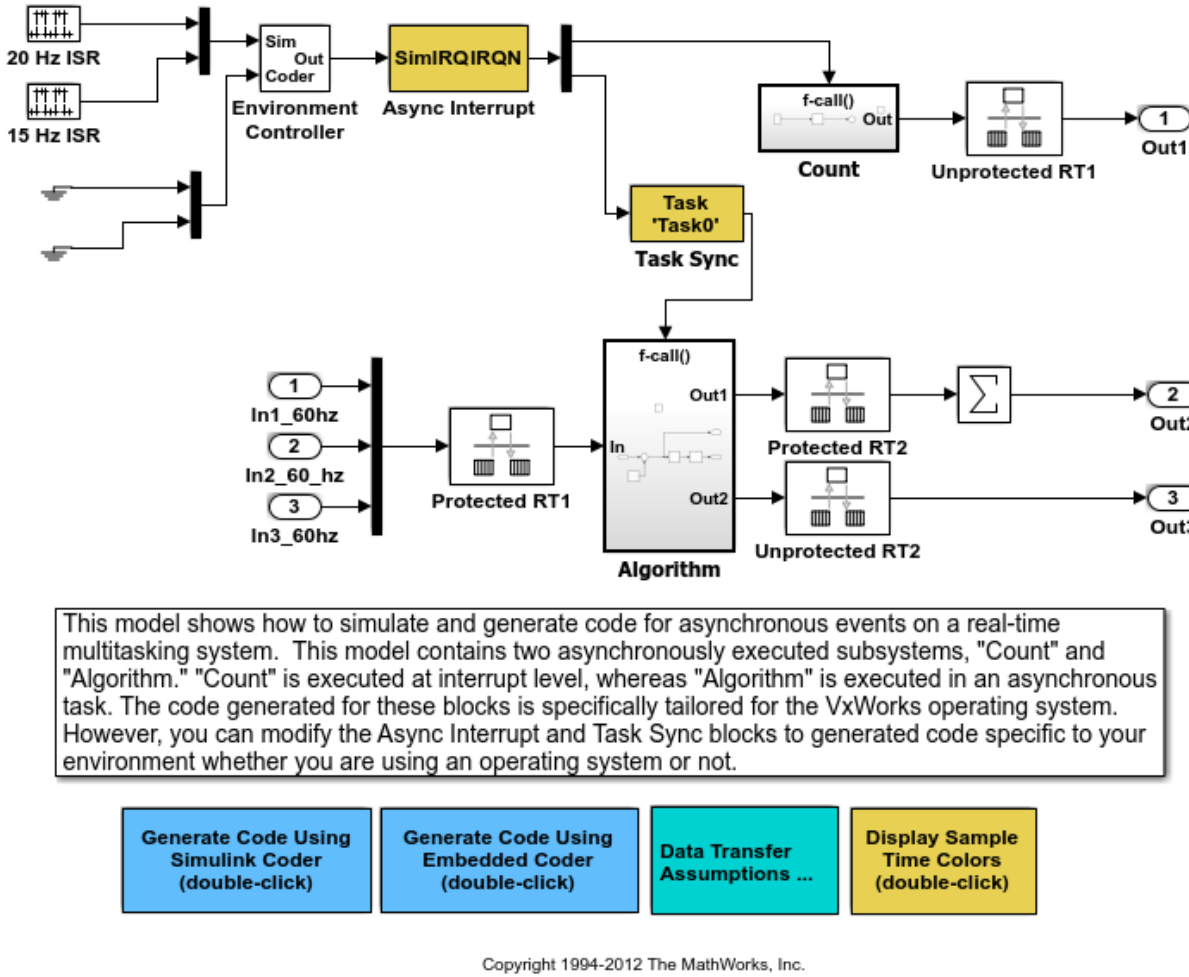
Spawn and Synchronize Execution of RTOS Task

This example shows how to simulate and generate code for asynchronous events on a multitasking real-time operating system (VxWorks®). The model shows different techniques for handling asynchronous events depending on the size of the triggered subsystems.

About the Example Model

Open the example model `rtwdemo_async`.



The model simulates an interrupt source and includes an Async Interrupt block, a Task Sync block, function-call subsystems `Count` and `Algorithm`, and Rate Transition blocks. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to subsystem `Count` and the Task Sync block. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with an Inport block that connects to one of the preceding model elements

The Async Interrupt and Task Sync blocks enable the subsystems to execute asynchronously.

`Count` represents a simple interrupt service routine (ISR) that executes at interrupt level. It is best to keep ISRs as simple as possible. This subsystem includes only a Discrete-Time Integrator block.

`Algorithm` includes more substance. It includes multiple blocks and produces two output values. Execution of larger subsystems at interrupt level can significantly impact response time for interrupts of equal and lower priority in the system. A better solution for larger subsystems is to use the Task Sync block to represent the ISR for the function-call subsystem.

The Async Interrupt block generates calls to ISRs. Place the block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event

For each specified interrupt level, the block generates a Versa Module Eurocard (VME) ISR that executes the connected subsystem, Task Sync block, or chart.

In the example model, the Async Interrupt block is configured for VME interrupts 1 and 2, by using interrupt vector offsets 192 and 193. Interrupt 1 connects directly to subsystem `Count`. Interrupt 2 connects to a Task Sync block, which serves as the ISR for `Algorithm`. Place a Task Sync block in one of the following locations:

- Between an Async Interrupt block and a function-call subsystem or Stateflow® chart.
- At the output port of a Stateflow® chart that has an event, `Output to Simulink`, that you configure as a function call.

In the example model, the Task Sync block is between the Async Interrupt block and function-call subsystem `Algorithm`. The Task Sync block is configured with the task name `Task()`, a priority of 50, a stack size of 8192, and data transfers of the task

synchronized with the caller task. The spawned task uses a semaphore to synchronize task execution. The Async Interrupt block triggers a release of the task semaphore.

Four Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, Protected Rate Transition blocks protect data transfers (prevent them from being preempted and corrupted). In the other two instances, Unprotected Rate Transition blocks introduce no special behavior. Their presence informs Simulink® of a rate transition.

The code generated for the Async Interrupt and Task Sync blocks is tailored for the example RTOS (VxWorks®). However, you can modify the blocks to generate code specific to your run-time environment.

Data Transfer Assumptions

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-size variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not stop and restart, especially while data is being transferred between tasks.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are reddish-blue. Asynchronous interrupts and tasks are purple. The Rate Transition Blocks, which are a hybrid rate (their input and output sample times can differ), are yellow.

Generate Code and Report

Generate code and a code generation report for the model. Generated code for the Async Interrupt and Task Sync blocks is for the example RTOS (VxWorks®). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

2. Build the model.

```
### Starting build procedure for model: rtwdemo_async
Warning:  Simulink Coder: The tornado.tlc target will be removed in a future release.

### Wrapping unrecognized make command (angle brackets added)
###    <make>
### in default batch file
### Successful completion of code generation for model: rtwdemo_async
```

Review Initialization Code

Open the generated source file `rtwdemo_async.c`. The initialization code:

1. Creates and initializes the synchronization semaphore `Task0_semaphore`.

```
*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID = semBCreate(SEM_Q_PRIORITY,
  SEM_EMPTY);
if (rtwdemo_async_DW.SFunction_PWORK.SemID == NULL) {
  printf("semBCreate call failed for block Task0.\n");
}
```

2. Spawns task `task0` and assigns the task priority 50.

```
rtwdemo_async_DW.SFunction_IWORK.TaskID = taskSpawn("Task0",
  50.0,
  VX_FP_TASK,
  8192.0,
  (FUNCPTR)Task0,
  0, 0, 0, 0, 0, 0, 0,0, 0, 0);
if (rtwdemo_async_DW.SFunction_IWORK.TaskID == ERROR) {
  printf("taskSpawn call failed for block Task0.\n");
}

/* End of Start for S-Function (vxtask1): '<S5>/S-Function' */

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
  printf("intConnect failed for ISR 1.\n");
}

sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
```

```
/* Connect and enable ISR function: isr_num2_vec193 */
if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
  printf("intConnect failed for ISR 2.\n");
}

sysIntEnable(2);
```

3. Connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```
{
  int32_T i;
  for (i = 0; i < 60; i++) {
    /* InitializeConditions for RateTransition: '<Root>/Protected RT1' */
    rtwdemo_async_DW.ProtectedRT1_Buffer[i] = 0.0;

```

The order of these operations is important. Before the code generator enables the interrupt that activates the task, it must spawn the task.

Review Task and Task Synchronization Code

In the generated source file `rtwdemo_async.c`, review the task and task synchronization code.

The code generator produces the code for function `Task0` from the Task Sync block. That function includes a small amount of interrupt-level code and runs as an RTOS task.

The task waits in an infinite `for` loop until the system releases a synchronization semaphore. If the system releases the semaphore, the function updates its task timer and calls the code generated for the `Algorithm` subsystem.

In the example model, the **Synchronize the data transfer of this task with the caller task** parameter for the Task Sync block is set. This parameter setting updates the timer associated with the Task Sync block (`rtM->Timing.clockTick2`) with the value of the timer that the Async Interrupt block (`rtM->Timing.clockTick3`) maintains. As a result, code for blocks within the `Algorithm` subsystem use timer values that are based on the time of the most recent interrupt, rather than the most recent activation of `Task0`.

```
{
  /* Wait for semaphore to be released by system: rtwdemo_async/Task Sync */
  for (;;) {
    if (semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID,NO_WAIT) !=
        ERROR) {
      logMsg("Rate for Task Task0() too fast.\n",0,0,0,0,0,0);

#if STOPONOVERRUN

      logMsg("Aborting real-time simulation.\n",0,0,0,0,0,0);
      semGive(stopSem);
      return(ERROR);

#endif

    } else {
      semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID, WAIT_FOREVER);
    }

    /* Use the upstream clock tick counter for this Task. */
    rtwdemo_async_M->Timing.clockTick4 = rtwdemo_async_M->Timing.clockTick3;

    /* Call the system: '<Root>/Algorithm' */
```

```
{
  {
    int32_T tmp;
    int32_T i;

    /* RateTransition: '<Root>/Protected RT1' */
    tmp = rtwdemo_async_DW.ProtectedRT1_ActiveBufIdx * 60;
    for (i = 0; i < 60; i++) {
      rtwdemo_async_B.ProtectedRT1[i] =
        rtwdemo_async_DW.ProtectedRT1_Buffer[i + tmp];
    }

    /* End of RateTransition: '<Root>/Protected RT1' */

          rtwdemo_async_DW.ProtectedRT2_Buffer[i +
            (rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx == 0) * 60] =
            rtwdemo_async_B.Sum[i];
        }

        rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx = (int8_T)
          (rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx == 0);

        /* End of Update for RateTransition: '<Root>/Protected RT2' */
      }
    }
  }
}
```

The code generator produces code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. ISR `isr_num2_vec192`:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem that connects to the referenced model Inport block, which receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```
void isr_num1_vec192(void)
{
  int_T lock;
  FP_CONTEXT context;

  /* Use tickGet()  as a portable tick
     counter example. A much higher resolution can
     be achieved with a hardware counter */
  rtwdemo_async_M->Timing.clockTick2 = tickGet();

  /* disable interrupts (system is configured as non-preemptive) */
  lock = intLock();

  /* save floating point context */
  fppSave(&context);

  /* Call the system: '<Root>/Count' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

    /* Output and update for function-call system: '<Root>/Count' */
    rtwdemo_async_DW.Count_ELAPS_T = rtwdemo_async_M->Timing.clockTick2 -
      rtwdemo_async_DW.Count_PREV_T;
    rtwdemo_async_DW.Count_PREV_T = rtwdemo_async_M->Timing.clockTick2;

    /* Outport: '<Root>/Out1' incorporates:
     *  DiscreteIntegrator: '<S2>/Integrator'
     */
    rtwdemo_async_Y.Out1 = rtwdemo_async_DW.Integrator_DSTATE_l;

    /* Update for DiscreteIntegrator: '<S2>/Integrator' */
    rtwdemo_async_DW.Integrator_DSTATE_l += 0.016666666666666666 * (real_T)
      rtwdemo_async_DW.Count_ELAPS_T;

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
```

```
  }

  /* restore floating point context */
  fppRestore(&context);

  /* re-enable interrupts */
  intUnlock(lock);
}

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
```

ISR `isr_num2_vec293` maintains a timer that stores the tick count at the time that the interrupt occurs. After updating the timer, the ISR releases the semaphore that activates `Task0`.

```
void isr_num2_vec193(void)
{
  /* Use tickGet()  as a portable tick
     counter example. A much higher resolution can
     be achieved with a hardware counter */
  rtwdemo_async_M->Timing.clockTick3 = tickGet();

  /* Call the system: '<S4>/Subsystem' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

    /* Output and update for function-call system: '<S4>/Subsystem' */

    /* S-Function (vxtask1): '<S5>/S-Function' */

    /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
    /* Release semaphore for system task: Task0 */
    semGive(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID);

    /* End of Outputs for S-Function (vxtask1): '<S5>/S-Function' */

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
  }
}

/* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
```

Review Task Termination Code

The Task Sync block generates the following termination code.

```
static void rtwdemo_async_terminate(void)
{
  /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num1_vec192 */
  sysIntDisable(1);

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num2_vec193 */
  sysIntDisable(2);

  /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

  /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' incorporates:
   *  Terminate for SubSystem: '<S4>/Subsystem'
   */

  /* Termination for function-call system: '<S4>/Subsystem' */

  /* Terminate for S-Function (vxtask1): '<S5>/S-Function' */

  /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
  /* Destroy task: Task0 */
  taskDelete(rtwdemo_async_DW.SFunction_IWORK.TaskID);

  /* End of Terminate for S-Function (vxtask1): '<S5>/S-Function' */

  /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}
```

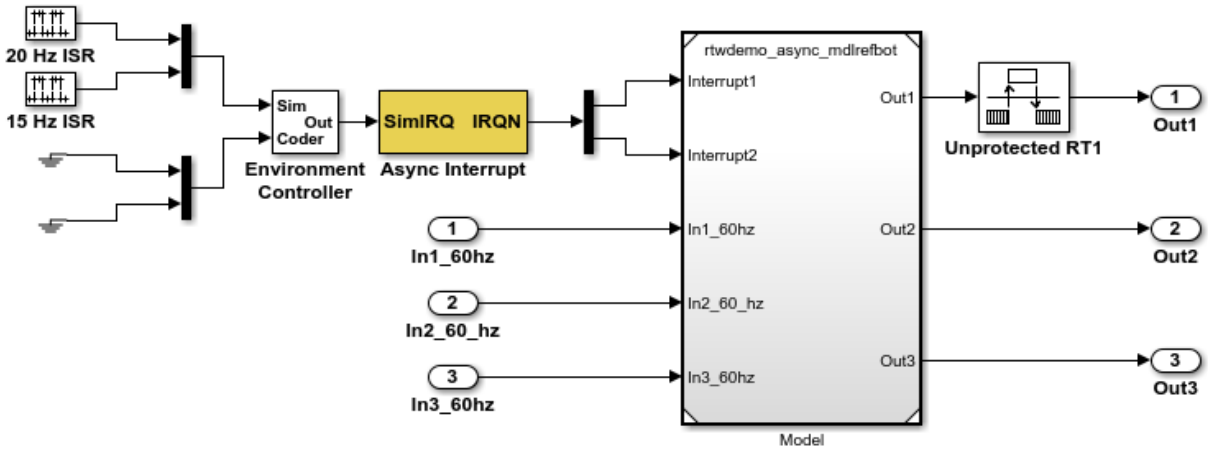
Pass Asynchronous Events in RTOS as Input To a Referenced Model

This example shows how to simulate and generate code for a model that triggers asynchronous events in an example RTOS (VxWorks®) that get passed as input to a referenced model.

Open Example Model

Open the example model `rtwdemo_async_mdlreftop`.

```
Warning: Undefined function 'LibraryBrowserCustomizer' for
input arguments of type 'DAStudio.CustomizationManager'.
```



This model shows how to simulate and generate code for asynchronous events on a real-time multitasking system. The two asynchronous events, "Interrupt1" and "Interrupt2", are executed in the referenced model via two different function-call input ports. The code generated for these blocks is specifically tailored for the VxWorks operating system. However, you can modify the Async Interrupt block to generate code specific to your environment whether or not you are using an operating system.

The model simulates an interrupt source and includes an Async Interrupt block and referenced model. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to Inport blocks 1 and 2 of the referenced model. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with a Inport block that connects to one of the preceding model elements

In this example model, the Async Interrupt block passes asynchronous events (function-call trigger signals), `Interrupt1` and `Interrupt2`, to the referenced model through Inport blocks 1 and 2.

The code generated for the Async Interrupt block is tailored for the example real-time operating system (VxWorks). However, you can modify the block to generate code specific to your run-time environment.

Open the referenced model.

The referenced model includes the two Inport blocks that receive the interrupts, each connected to an Asynchronous Task Specification block, function-call subsystems `Count` and `Algorithm`, and Rate Transition blocks. The Asynchronous Task Specification block, in combination with a root-level Inport block, allows a reference model to receive asynchronous function-call input. To use the block:

1. Connect the Asynchronous Task Specification block to the output port of a root-level Inport block that outputs a function-call trigger.
2. Select the **Output function call** parameter of the Inport block to specify that it accepts function-call signals.
3. On the Asynchronous Task Specification parameters dialog box, set the task priority for the asynchronous task associated with an Inport block. Specify an integer or []. If you specify an integer, it must match the priority of the interrupt initiated by the Async Interrupt block in the parent model. If you specify [], the priorities do not have to match.

The Asynchronous Task Specification block for the higher priority interrupt, `interrupt1`, connects to function-call subsystem `Count`. `Count` represents a simple interrupt service routine (ISR). The second Asynchronous Task Specification block

connects to the subsystem `Algorithm`, which includes more substance. It includes multiple blocks and produces two output values. Both subsystems execute at interrupt level.

For each interrupt level specified for the Async Interrupt block in the parent model, the block generates a VME ISR that executes the connected subsystem, Task Sync block, or chart.

In the example top model, the Async Interrupt block is configured for VME interrupts 1 and 2, using interrupt vector offsets 192 and 193. Interrupt 1 is wired to trigger subsystem `Count`. Interrupt 2 is wired to trigger subsystem `Algorithm`.

The Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, the blocks protect data transfers (prevent them from being preempted and corrupted). In the other instance, no special behavior occurs.

Data Transfer Assumptions

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-sized variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash and restart, especially while data is being transferred between tasks.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are magenta. Asynchronous interrupts are purple. The Rate Transition Blocks, which are hybrid (input and output sample times can differ), appear yellow.

Generate Code and Report

Generate code and a code generation report for the model. Async Interrupt block and Task Sync block generated code is for the example RTOS (VxWorks). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

2. Build the model.

```
Warning:  Simulink Coder: The tornado.tlc target will be removed in a future release.

### Wrapping unrecognized make command (angle brackets added)
###    <make>
### in default batch file
### Successfully updated the model reference RTW target for model: rtwdemo_async_mdlref
### Starting build procedure for model: rtwdemo_async_mdlreftop
Warning:  Simulink Coder: The tornado.tlc target will be removed in a future release.

### Wrapping unrecognized make command (angle brackets added)
###    <make>
### in default batch file
### Successful completion of code generation for model: rtwdemo_async_mdlreftop
```

Review Initialization Code

Open the generated source file `rtwdemo_async_mdlreftop.c`. The initialization code connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```
static void rtwdemo_async_mdlreftop_initialize(void)
{
  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Connect and enable ISR function: isr_num1_vec192 */
  if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
    printf("intConnect failed for ISR 1.\n");
  }

  sysIntEnable(1);

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Connect and enable ISR function: isr_num2_vec193 */
  if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
    printf("intConnect failed for ISR 2.\n");
  }

  sysIntEnable(2);

  /* SystemInitialize for ModelReference: '<Root>/Model' */
  rtwdemo_async_mdlrefbot_Init(&rtwdemo_async_mdlreftop_Y.Out1);

  /* Enable for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
```

```
  /* Enable for ModelReference: '<Root>/Model' incorporates:
   *  Enable for Inport: '<Root>/In1_60hz'
   *  Enable for Inport: '<Root>/In2_60_hz'
   *  Enable for Inport: '<Root>/In3_60hz'
   */
  rtwdemo_async_mdlrefbot_Interrupt1_Enable();
  rtwdemo_async_mdlrefbot_Interrupt2_Enable();

  /* End of Enable for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}
```

Review ISR Code

In the generated source file `rtwdemo_async_mdlreftop.c`, review the code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. Each ISR:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem connected to the referenced model Inport block that receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```
void isr_num1_vec192(void)
{
  int_T lock;
  FP_CONTEXT context;

  /* disable interrupts (system is configured as non-preemptive) */
  lock = intLock();

  /* save floating point context */
  fppSave(&context);

  /* Call the system: '<Root>/Model' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

    /* ModelReference: '<Root>/Model' incorporates:
     *  Inport: '<Root>/In1_60hz'
     *  Inport: '<Root>/In2_60_hz'
```

```
     *  Inport: '<Root>/In3_60hz'
     */
    rtwdemo_async_mdlrefbot_Interrupt1(&rtwdemo_async_mdlreftop_Y.Out1);

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
  }

  /* restore floating point context */
  fppRestore(&context);

  /* re-enable interrupts */
  intUnlock(lock);
}

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{
  FP_CONTEXT context;

  /* save floating point context */
  fppSave(&context);

  /* Call the system: '<Root>/Model' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

    /* ModelReference: '<Root>/Model' incorporates:
     *  Inport: '<Root>/In1_60hz'
     *  Inport: '<Root>/In2_60_hz'
     *  Inport: '<Root>/In3_60hz'
     */
    rtwdemo_async_mdlrefbot_Interrupt2();

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
  }

  /* restore floating point context */
  fppRestore(&context);
}
```

Review Task Termination Code

The Task Sync block generates the following termination code.

```
static void rtwdemo_async_mdlreftop_terminate(void)
{
  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num1_vec192 */
  sysIntDisable(1);

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num2_vec193 */
  sysIntDisable(2);
}
```

Rate Transitions and Asynchronous Blocks

Because an asynchronous function call subsystem can preempt or be preempted by other model code, an inconsistency arises when more than one signal element is connected to an asynchronous block. The issue is that signals passed to and from the function call subsystem can be in the process of being written to or read from when the preemption occurs. Thus, some old and some new data is used. This situation can also occur with scalar signals in some cases. For example, if a signal is a double (8 bytes), the read or write operation might require two machine instructions. The following sections describe these issues.

In this section...

Note: The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

About Rate Transitions and Asynchronous Blocks

The Simulink Rate Transition block is designed to deal with preemption problems that occur in data transfer between blocks running at different rates. These issues are discussed in "Time-Based Scheduling and Code Generation" (Simulink Coder).

You can handle rate transition issues automatically by selecting the **Automatically handle data transfers between tasks** option on the **Solver** pane of the Configuration Parameters dialog box. This saves you from having to manually insert Rate Transition blocks to avoid invalid rate transitions, including invalid *asynchronous-to-periodic* and *asynchronous-to-asynchronous* rate transitions, in multirate models. For asynchronous tasks, the Simulink engine configures inserted blocks for data integrity but not determinism during data transfers.

For asynchronous rate transitions, the Rate Transition block provides data integrity, but cannot provide determinism. Therefore, when you insert Rate Transition blocks

explicitly, you must clear the **Ensure data determinism** check box in the Block Parameters dialog box.

When you insert a Rate Transition block between two blocks to maintain data integrity and priorities are assigned to the tasks associated with the blocks, the code generator assumes that the higher priority task can preempt the lower priority task and the lower priority task cannot preempt the higher priority task. If the priority associated with task for either block is not assigned or the priorities of the tasks for both blocks are the same, the code generator assumes that either task can preempt the other task.

Priorities of periodic tasks are assigned by the Simulink engine, in accordance with the options specified in the **Solver options** section of the **Solver** pane of the Configuration Parameters dialog box. When the **Periodic sample time constraint** option field of **Solver options** is set to `Unconstrained`, the model base rate priority is set to `40`. Priorities for subrates then increment or decrement by `1` from the base rate priority, depending on the setting of the **Higher priority value indicates higher task priority option**.

You can assign priorities manually by using the **Periodic sample time properties** field. The Simulink engine does not assign a priority to asynchronous blocks. For example, the priority of a function call subsystem that connects back to an Async Interrupt block is assigned by the Async Interrupt block.

The **Simulink task priority** field of the Async Interrupt block specifies a priority level (required) for every interrupt number entered in the **VME interrupt number(s)** field. The priority array sets the priorities of the subsystems connected to each interrupt.

For the Task Sync block, if the example RTOS (VxWorks) is the target, the **Higher priority value indicates higher task priority** option should be deselected. The **Simulink task priority** field specifies the block priority relative to connected blocks (in addition to assigning an RTOS priority to the generated task code).

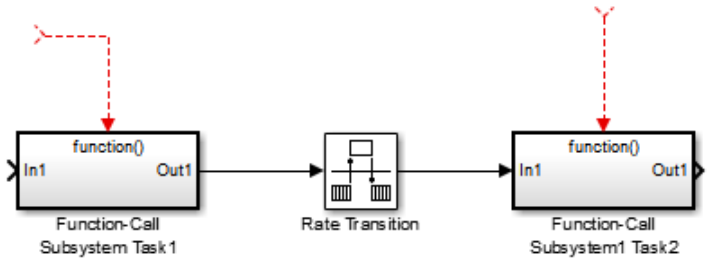
The `vxlib1` library provides two types of rate transition blocks as a convenience. These are simply preconfigured instances of the built-in Simulink Rate Transition block:

- Protected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** on and **Ensure deterministic data transfer** off.
- Unprotected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** option off.

Handle Rate Transitions for Asynchronous Tasks

For rate transitions that involve asynchronous tasks, you can maintain data integrity. However, you cannot achieve determinism. You have the option of using the Rate Transition block or target-specific rate transition blocks.

Consider the following model, which includes a Rate Transition block.



You can use the Rate Transition block in either of the following modes:

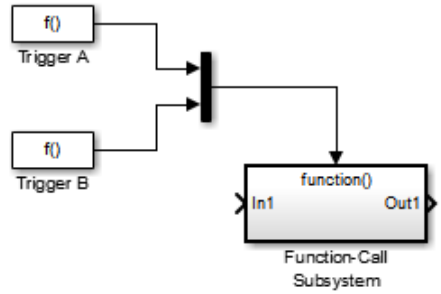
- Maintain data integrity, no determinism
- Unprotected

Alternatively, you can use target-specific rate transition blocks. The following blocks are available for the example RTOS (VxWorks):

- Protected Rate Transition block (reader)
- Protected Rate Transition block (writer)
- Unprotected Rate Transition block

Handle Multiple Asynchronous Interrupts

Consider the following model, in which two functions trigger the same subsystem.



The two tasks must have equal priorities. When priorities are the same, the outcome depends on whether they are firing periodically or asynchronously, and also on a diagnostic setting. The following table and notes describe these outcomes:

Supported Sample Time and Priority for Function Call Subsystem with Multiple Triggers

	Async Priority = 1	Async Priority = 2	Async Priority Unspecified	Periodic Priority = 1	Periodic Priority = 2
Async Priority = 1	Supported (1)				
Async Priority = 2		Supported (1)			
Async Priority Unspecified			Supported (2)		
Periodic Priority = 1				Supported	
Periodic Priority = 2					Supported

1. Control these outcomes using the **Tasks with equal priority** option in the **Diagnostics** pane of the Configuration Parameters dialog box; set this diagnostic to `none` if tasks of equal priority cannot preempt each other in the target system.
2. For this case, the following warning message is issued unconditionally:

```
The function call subsystem <name> has multiple asynchronous
triggers that do not specify priority. Data integrity will
not be maintained if these triggers can preempt one another.
```

Empty cells in the above table represent multiple triggers with differing priorities, which are unsupported.

The code generator provides absolute time management for a function call subsystem connected to multiple interrupts in the case where timer settings for `TriggerA` and `TriggerB` (time source, resolution) are the same.

Assume that all of the following conditions are true for the model shown above:

- A function call subsystem is triggered by two asynchronous triggers (TriggerA and TriggerB) having identical priority settings.
- Each trigger sets the source of time and timer attributes by calling the functions `ssSetTimeSource` and `ssSetAsyncTimerAttributes`.
- The triggered subsystem contains a block that needs elapsed or absolute time (for example, a Discrete Time Integrator).

The asynchronous function call subsystem has one global variable, `clockTick#` (where `#` is the task ID associated with the subsystem). This variable stores absolute time for the asynchronous task. There are two ways timing can be handled:

- If the time source is set to `SS_TIMESOURCE_BASERATE`, the code generator produces timer code in the function call subsystem, updating the clock tick variable from the base rate clock tick. Data integrity is maintained if the same priority is assigned to TriggerA and TriggerB.
- If the time source is `SS_TIMESOURCE_SELF`, generated code for both TriggerA and TriggerB updates the same clock tick variable from the hardware clock.

The word size of the clock tick variable can be set directly or be established according to the **Application lifespan (days)** (Simulink) setting and the timer resolution set by the TriggerA and TriggerB S-functions (which must be the same). See “Timers in Asynchronous Tasks” on page 17-44 and “Control Memory Allocation for Time Counters” on page 53-11 for more information.

Timers in Asynchronous Tasks

An ISR can set a source for absolute time. This is done with the function `ssSetTimeSource`. The function `ssSetTimeSource` cannot be called before `ssSetOutputPortWidth` is called. If this occurs, the program will come to a halt and generate an error message. `ssSetTimeSource` has the following three options:

- `SS_TIMESOURCE_SELF`: Each generated ISR maintains its own absolute time counter, which is distinct from a periodic base rate or subrate counters in the system. The counter value and the timer resolution value (specified in the **Timer resolution (seconds)** parameter of the Async Interrupt block) are used by downstream blocks to determine absolute time values required by block computations.
- `SS_TIMESOURCE_CALLER`: The ISR reads time from a counter maintained by its caller. Time resolution is thus the same as its caller's resolution.
- `SS_TIMESOURCE_BASERATE`: The ISR can read absolute time from the model's periodic base rate. Time resolution is thus the same as its base rate resolution.

Note: The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

By default, the counter is implemented as a 32-bit unsigned integer member of the `Timing` substructure of the real-time model structure. For a target that supports the `rtModel` data structure, when the time data type is not set by using `ssSetAsyncTimeDataType`, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter. As an example (from ERT target code),

```
/* Real-time Model Data Structure */
struct _RT_MODEL_elapseTime_exp_Tag {
   const char *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
```

```
    uint32_T clockTick2;
  } Timing;
};
```

The example omits unused fields in the `Timing` data structure (a feature of ERT target code not found in GRT). For a target that supports the `rtModel` data structure, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter.

By default, the `vxlib1` library blocks for the example RTOS (VxWorks) set the timer source to `SS_TIMESOURCE_SELF` and update their counters by using the system call `tickGet`. `tickGet` returns a timer value maintained by the RTOS kernel. The maximum word size for the timer is `UINT32`. The following example shows a generated call to `tickGet`.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{

 /* Use tickGet() as a portable tick counter example. A much
    higher resolution can be achieved with a hardware counter */
 rtM->Timing.clockTick2 = tickGet();
. . .
```

The `tickGet` call is supplied only as an example. It can (and in many instances should) be replaced by a timing source that has better resolution. If you are implementing a custom asynchronous block for an RTOS other than the example RTOS (VxWorks), you should either generate an equivalent call to the target RTOS, or generate code to read a timer register on the target hardware.

The default **Timer resolution (seconds)** parameter of your Async Interrupt block implementation should be changed to match the resolution of your target's timing source.

The counter is updated at interrupt level. Its value represents the tick value of the timing source at the most recent execution of the ISR. The rate of this timing source is unrelated to sample rates in the model. In fact, typically it is faster than the model's base rate. Select the timer source and set its rate and resolution based on the expected rate of interrupts to be serviced by the Async Interrupt block.

For an example of timer code generation, see “Async Interrupt Block Implementation” on page 17-48.

Create a Customized Asynchronous Library

This topic describes how to implement asynchronous blocks for use with your target RTOS, using the Async Interrupt and Task Sync blocks as a starting point. Rate Transition blocks are target-independent, so you do not need to develop customized rate transition blocks. The following sections provide implementation details.

In this section...

Note: The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

About Implementing Asynchronous Blocks

You can customize the asynchronous library blocks by modifying the block implementation. These files are

- The block's underlying S-function MEX-file
- The TLC files that control code generation of the block

In addition, you need to modify the block masks to remove references specific to the example RTOS (VxWorks) and to incorporate parameters required by your target RTOS.

Custom block implementation is an advanced topic, requiring familiarity with the Simulink MEX S-function format and API, and with the Target Language Compiler (TLC). These topics are covered in the following documents:

- Simulink topics "What Is an S-Function?" (Simulink), "Use S-Functions in Models" (Simulink), "How S-Functions Work" (Simulink), and "Implementing S-Functions" (Simulink) describe MEX S-functions and the S-function API in general.

- The “Inlining S-Functions” (Simulink Coder), “Inline C MEX S-Functions” (Simulink Coder), and “S-Functions and Code Generation” (Simulink Coder) describe how to create a TLC block implementation for use in code generation.

The following sections discuss the C/C++ and TLC implementations of the asynchronous library blocks, including required `SimStruct` macros and functions in the TLC asynchronous support library (`asynclib.tlc`).

Async Interrupt Block Implementation

The source files for the Async Interrupt block are located in *`matlabroot`*`/rtw/c/tornado/devices` (open):

- `vxinterrupt1.c`: C MEX-file source code, for use in configuration and simulation
- `vxinterrupt1.tlc`: TLC implementation, for use in code generation
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “asynclib.tlc Support Library” on page 17-53.

C MEX Block Implementation

Most of the code in `vxinterrupt1.c` performs ordinary functions that are not related to asynchronous support (for example, obtaining and validating parameters from the block mask, marking parameters nontunable, and passing parameter data to the *`model`*`.rtw` file).

The `mdlInitializeSizes` function uses special `SimStruct` macros and `SS_OPTIONS` settings that are required for asynchronous blocks, as described below.

Note that the following macros cannot be called before `ssSetOutputPortWidth` is called:

- `ssSetTimeSource`
- `ssSetAsyncTimerAttributes`
- `ssSetAsyncTimerResolutionEl`
- `ssSetAsyncTimerDataType`
- `ssSetAsyncTimerDataTypeEl`
- `ssSetAsyncTaskPriorities`
- `ssSetAsyncTaskPrioritiesEl`

If one of the above macros is called before `ssSetOutputPortWidth`, the following error message appears:

```
SL_SfcnMustSpecifyPortWidthBfCallSomeMacro {
S-function '%s' in '%<BLOCKFULLPATH>'
must set output port %d width using
ssSetOutputPortWidth before calling macro %s
 }
```

ssSetAsyncTimerAttributes

`ssSetAsyncTimerAttributes` declares that the block requires a timer, and sets the resolution of the timer as specified in the **Timer resolution (seconds)** parameter.

The function prototype is

```
ssSetAsyncTimerAttributes(SimStruct *S, double res)
```

where

- S is a Simstruct pointer.
- `res` is the **Timer resolution (seconds)** parameter value.

The following code excerpt shows the call to ssSetAsyncTimerAttributes.

```
/* Setup Async Timer attributes */
ssSetAsyncTimerAttributes(S,mxGetPr(TICK_RES)[0]);
```

ssSetAsyncTaskPriorities

`ssSetAsyncTaskPriorities` sets the Simulink task priority for blocks executing at each interrupt level, as specified in the block's **Simulink task priority** field.

The function prototype is

```
ssSetAsyncTaskPriorities(SimStruct *S, int numISRs,
                         int *priorityArray)
```

where

- `S` is a `SimStruct` pointer.
- `numISRs` is the number of interrupts specified in the **VME interrupt number(s)** parameter.
- `priorityarray` is an integer array containing the interrupt numbers specified in the **VME interrupt number(s)** parameter.

The following code excerpt shows the call to `ssSetAsyncTaskPriorities`:

```
/* Setup Async Task Priorities */
    priorityArray = malloc(numISRs*sizeof(int_T));
    for (i=0; i<numISRs; i++) {
        priorityArray[i] = (int_T)(mxGetPr(ISR_PRIORITIES)[i]);
    }
    ssSetAsyncTaskPriorities(S, numISRs, priorityArray);
    free(priorityArray);
    priorityArray = NULL;
}
```

SS_OPTION Settings

The code excerpt below shows the `SS_OPTION` settings for `vxinterrupt1.c`. `SS_OPTION_ASYNCHRONOUS_INTERRUPT` should be used when a function call subsystem is attached to an interrupt. For more information, see the documentation for `SS_OPTION` and `SS_OPTION_ASYNCHRONOUS` in *`matlabroot`*`/simulink/include/simstruc.h`.

```
ssSetOptions( S, (SS_OPTION_EXCEPTION_FREE_CODE |
             SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
             SS_OPTION_ASYNCHRONOUS_INTERRUPT |
```

TLC Implementation

This section discusses each function of `vxinterrupt1.tlc`, with an emphasis on target-specific features that you will need to change to generate code for your target RTOS.

Generate #include Directives

`vxinterrupt1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

BlockInstanceSetup Function

For each connected output of the Async Interrupt block, `BlockInstanceSetup` defines a function name for the corresponding ISR in the generated code. The functions names are of the form

`isr_`*`num`*`_vec_`*`offset`*

where *num* is the ISR number defined in the **VME interrupt number(s)** block parameter, and *offset* is an interrupt table offset defined in the **VME interrupt vector offset(s)** block parameter.

In a custom implementation, this naming convention is optional.

The function names are cached for use by the `Outputs` function, which generates the actual ISR code.

Outputs Function

`Outputs` iterates over the connected outputs of the Async Interrupt block. An ISR is generated for each such output.

The ISR code is cached in the `"Functions"` section of the generated code. Before generating the ISR, `Outputs` does the following:

- Generates a call to the downstream block (cached in a temporary buffer).
- Determines whether the ISR should be locked or not (as specified in the **Preemption Flag(s)** block parameter).
- Determines whether the block connected to the Async Interrupt block is a Task Sync block. (This information is obtained by using the `asynclib` calls `LibGetFcnCallBlock` and `LibGetBlockAttribute`.) If so,
  - The preemption flag for the ISR must be set to `1`. An error results otherwise.
  - The RTOS (VxWorks) calls to save and restore floating-point context are generated, unless the user has configured the model for integer-only code generation.

When generating the ISR code, `Outputs` calls the `asynclib` function `LibNeedAsyncCounter` to determine whether a timer is required by the connected subsystem. If so, and if the time source is set to be `SS_TIMESOURCE_SELF` by `ssSetTimeSource`, `LibSetAsyncCounter` is called to generate an RTOS (VxWorks) `tickGet` function call and update the counter. In your implementation, you should generate either an equivalent call to the target RTOS, or generate code to read the a timer register on the target hardware.

Start Function

The `Start` function generates the required RTOS (VxWorks) calls (`int_connect` and `sysInt_Enable`) to connect and enable each ISR. You should replace this with calls to your target RTOS.

Terminate Function

The `Terminate` function generates the call `sysIntDisable` to disable each ISR. You should replace this with calls to your target RTOS.

Task Sync Block Implementation

The source files for the Task Sync block are located in *`matlabroot`*`/rtw/c/tornado/devices` (open). They are

- `vxtask1.cpp`: MEX-file source code, for use in configuration and simulation.
- `vxtask1.tlc`: TLC implementation, for use in code generation.
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in "asynclib.tlc Support Library" on page 17-53.

C MEX Block Implementation

Like the Async Interrupt block, the Task Sync block sets up a timer, in this case with a fixed resolution. The priority of the task associated with the block is obtained from the **Simulink task priority** parameter. The `SS_OPTION` settings are the same as those used for the Async Interrupt block.

```
ssSetAsyncTimerAttributes(S, 0.01);

priority  = (int_T) (*(mxGetPr(PRIORITY)));
ssSetAsyncTaskPriorities(S,1,&priority);

ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE |
                 SS_OPTION_ASYNCHRONOUS |
                 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
}
```

TLC Implementation

Generate #include Directives

`vxtask1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

BlockInstanceSetup Function

The `BlockInstanceSetup` function derives the task name, block name, and other identifiers used later in code generation. It also checks for and warns about unconnected block conditions, and generates a storage declaration for a semaphore (`stopSem`) that is used in case of interrupt overflow conditions.

Start Function

The `Start` function generates the required RTOS (VxWorks) calls to define storage for the semaphore that is used in management of the task spawned by the Task Sync block. Depending on the value of the `CodeFormat` TLC variable of the target, either a static storage declaration or a dynamic memory allocation call is generated. This function also creates a semaphore (`semBCreate`) and spawns an RTOS task (`taskSpawn`). You should replace these with calls to your target RTOS.

Outputs Function

The `Outputs` function generates an example RTOS (VxWorks) task that waits for a semaphore. When it obtains the semaphore, it updates the block's tick timer and calls the downstream subsystem code, as described in "Spawn and Synchronize Execution of RTOS Task" on page 17-15. `Outputs` also generates code (called from interrupt level) that grants the semaphore.

Terminate Function

The `Terminate` function generates the example RTOS (VxWorks) call `taskDelete` to end execution of the task spawned by the block. You should replace this with calls to your target RTOS.

Note also that if the target RTOS has dynamically allocated memory associated with the task, the `Terminate` function should deallocate the memory.

asynclib.tlc Support Library

`asynclib.tlc` is a library of TLC functions that support the implementation of asynchronous blocks. Some functions are specifically designed for use in asynchronous blocks. For example, `LibSetAsyncCounter` generates a call to update a timer for an asynchronous block. Other functions are utilities that return information required by asynchronous blocks (for example, information about connected function call subsystems).

The following table summarizes the public calls in the library. For details, see the library source code and the `vxinterrupt1.tlc` and `vxtask1.tlc` files, which call the library functions.

Summary of asynclib.tlc Library Functions

Function	Description
`LibBlockExecuteFcnCall`	For use by inlined S-functions with function call outputs. Generates code to execute a function call subsystem.
`LibGetBlockAttribute`	Returns a field value from a block record.
`LibGetFcnCallBlock`	Given an S-Function block and call index, returns the block record for the downstream function call subsystem block.
`LibGetCallerClockTickCounter`	Provides access to the time counter of an upstream asynchronous task.
`LibGetCallerClockTickCounter-HighWord`	Provides access to the high word of the time counter of an upstream asynchronous task.
`LibManageAsyncCounter`	Determines whether an asynchronous task needs a counter and manages its own timer.
`LibNeedAsyncCounter`	If the calling block requires an asynchronous counter, returns `TLC_TRUE`, otherwise returns `TLC_FALSE`.
`LibSetAsyncClockTicks`	Returns code that sets `clockTick` counters that are to be maintained by the asynchronous task.
`LibSetAsyncCounter`	Generates code to set the tick value of the block's asynchronous counter.
`LibSetAsyncCounterHighWord`	Generates code to set the tick value of the high word of the block's asynchronous counter

Import Asynchronous Event Data for Simulation

Capabilities

You can import asynchronous event data into a function-call subsystem via an Inport block. For standalone fixed-step simulations, you can specify:

- The time points at which each asynchronous event occurs
- The number of asynchronous events at each time point

Input Data Format

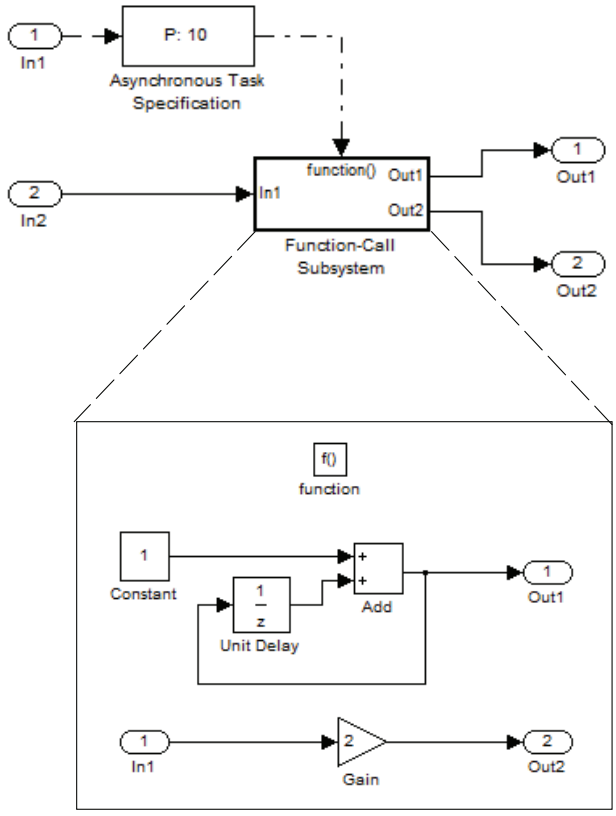
You can enter your asynchronous data at the MATLAB command line or on the **Data Import/Export** pane of the Configuration Parameters dialog box. In either case, a number of restrictions apply to the data format.

- The expression for the parameter **Data Import/Export > Input** must be a comma-separated list of tables.
- The table corresponding to the input port outputting asynchronous events must be a column vector containing time values for the asynchronous events.
  - The time vector of the asynchronous events must be of double data type and monotonically increasing.
  - All time data must be integer multiples of the model step size.
  - To specify multiple function calls at a given time step, you must repeat the time value accordingly. In other words, if you wish to specify three asynchronous events at $t = 1$ and two events at $t = 9$, then you must list `1` three times and `9` twice in your time vector. (`t = [1 1 1 9 9]'`)
- The table corresponding to normal data input port can be of any other supported format.

See “Load Data to Root-Level Input Ports” (Simulink) for more information.

Example

In this model, a function-call subsystem is used to track the total number of asynchronous events and to multiply a set of inputs by 2.



1. To input data via the Configuration Parameters dialog box,

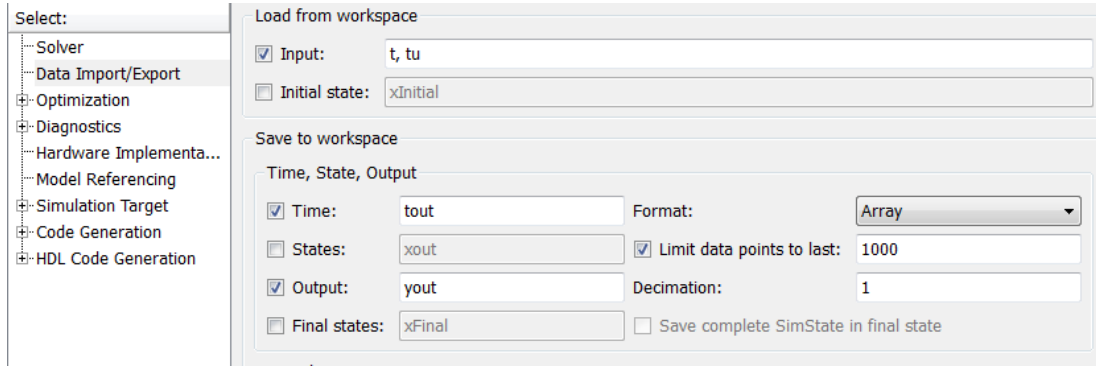
   a. Select **Simulation > Configuration Parameters > Data Import/Export**.

   b. Select the **Input** parameter.

   c. For this example, enter the following command in the MATLAB window:

   ```
   >> t = [1 1 5 9 9 9]', u = [[0:10]' [0:10]']
   ```

   Alternatively, you can enter the data as *t, tu* in the Data Import/Export pane:



Here, *t* is a column vector containing the times of asynchronous events for Inport block In1 while *tu* is a table of input values versus time for Inport block In2.

2. By default, the **Time** and **Output** options are selected and the output variables are named *tout* and *yout*.
3. Simulate the model.
4. Display the output by entering `[tout yout]` at the MATLAB command line and obtain:

```
ans =

     0     0    -1
     1     2     2
     2     2     2
     3     2     2
     4     2     2
     5     3    10
     6     3    10
     7     3    10
     8     3    10
     9     6    18
    10     6    18
```

Here the first column contains the simulation times.

The second column represents the output of Out1 — the total number of asynchronous events. Since the function-call subsystem is triggered twice at $t = 1$,

the output is 2. It is not called again until $t = 5$, and so does not increase to 3 until then. Finally, it is called three times at 9, so it increases to 6.

The third column contains the output of Out2 obtained by multiplying the input value at each asynchronous event time by 2. At any other time, the output is held at its previous value

Asynchronous Support Limitations

In this section...

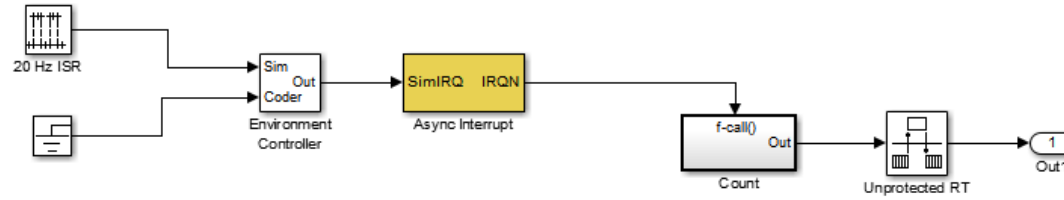
Asynchronous Task Priority

The Simulink product does not simulate asynchronous task behavior. Although you can specify a task priority for an asynchronous task represented in a model with the Task Sync block, the priority setting is for code generation purposes only and is not honored during simulation.

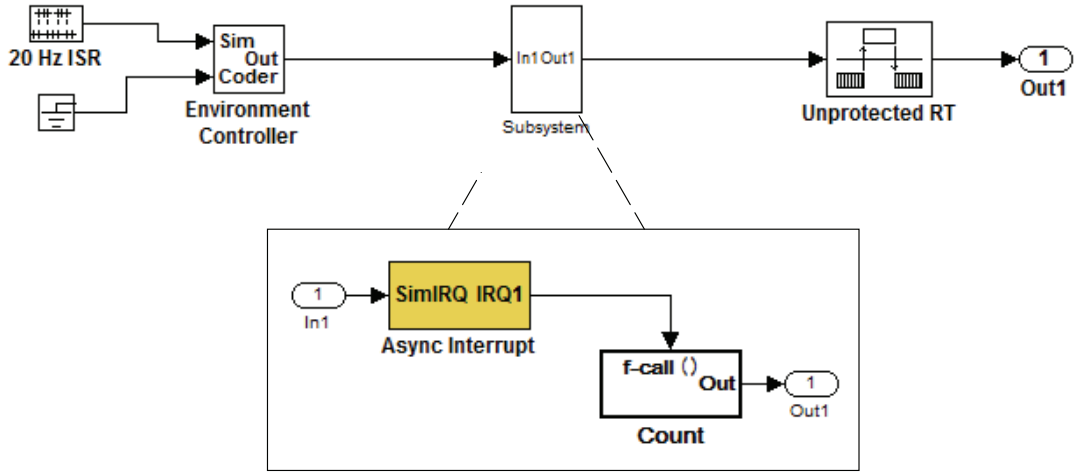
Convert an Asynchronous Subsystem into a Model Reference

You can use the Asynchronous Task Specification block to specify an asynchronous function-call input to a model reference. However, you must convert the Async Interrupt and Function-Call blocks into a subsystem and then convert the subsystem into a model reference.

Following is an example with step-by-step instructions for conversion.



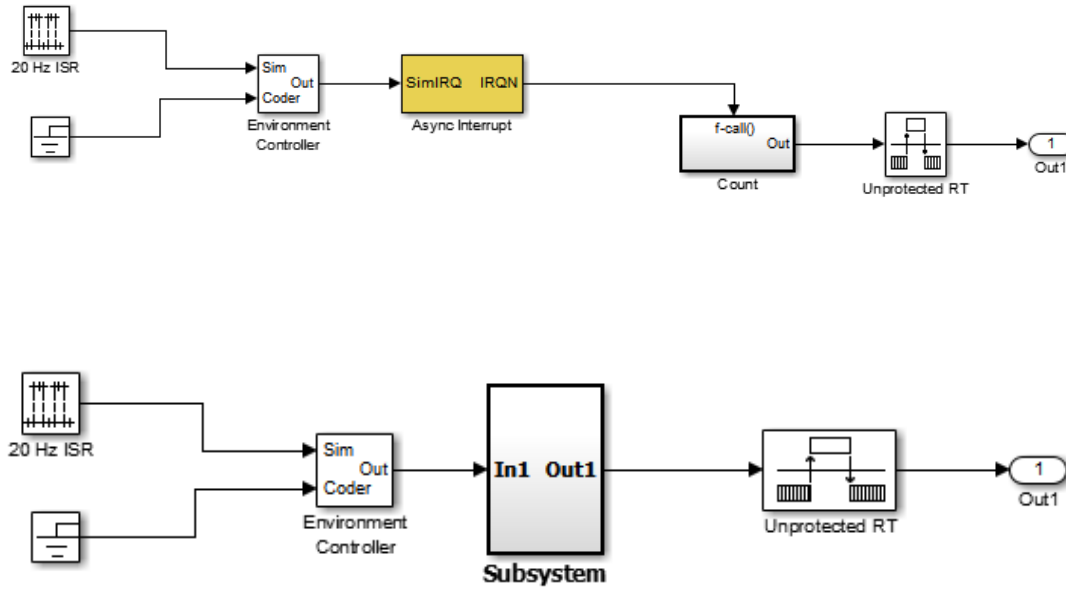
1 Convert the Async Interrupt and Count blocks into a subsystem. Select both blocks and right-click Count. From the menu, select **Subsystem & Model Reference > Create Subsystem from Selection**.



2 To prepare for converting the new subsystem to a Model block, set the following configuration parameters in the top model. Open the Configuration Parameters dialog box.

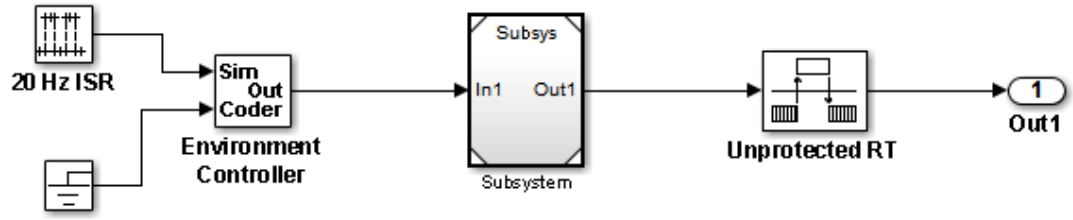
- Under Diagnostics, navigate to the Sample Time pane. Then set **Multitask rate transition** to `error` and **Multitask conditionally executed subsystem** to `error`.
- Under Diagnostics, navigate to the Connectivity pane. Set **Bus signal treated as vector**, and **Invalid function-call connection** to `error`. Also set **Context-dependent inputs** to `Enable All`.
- Under Diagnostics, navigate to the Data Validity pane and set the **Multitask data store** option to `error`.
- On the **All Parameters** tab, set **Underspecified initialization detection** to `Simplified`.
- If your model is large or complex, run the Model Advisor checks in the folder "Migrating to Simplified Initialization Mode Overview" (Simulink) and make the suggested changes.

3 Convert the subsystem to an atomic subsystem. Select **Edit > Subsystem Parameters > Treat as atomic unit**.

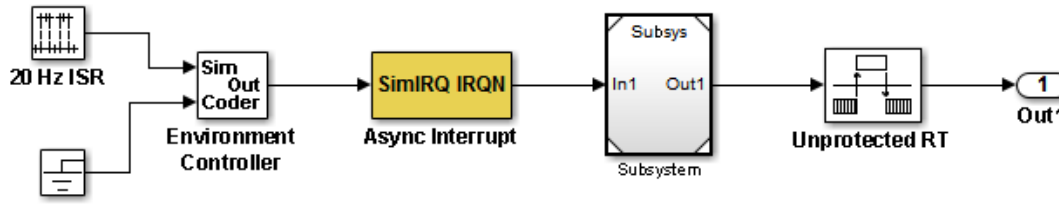


4 Convert the subsystem to a Model block. Right-click the subsystem and select **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**. A window opens with a model reference block inside of it.

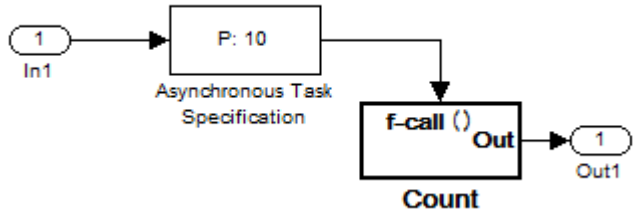
5 Replace the subsystem in the top model with the new model reference block.



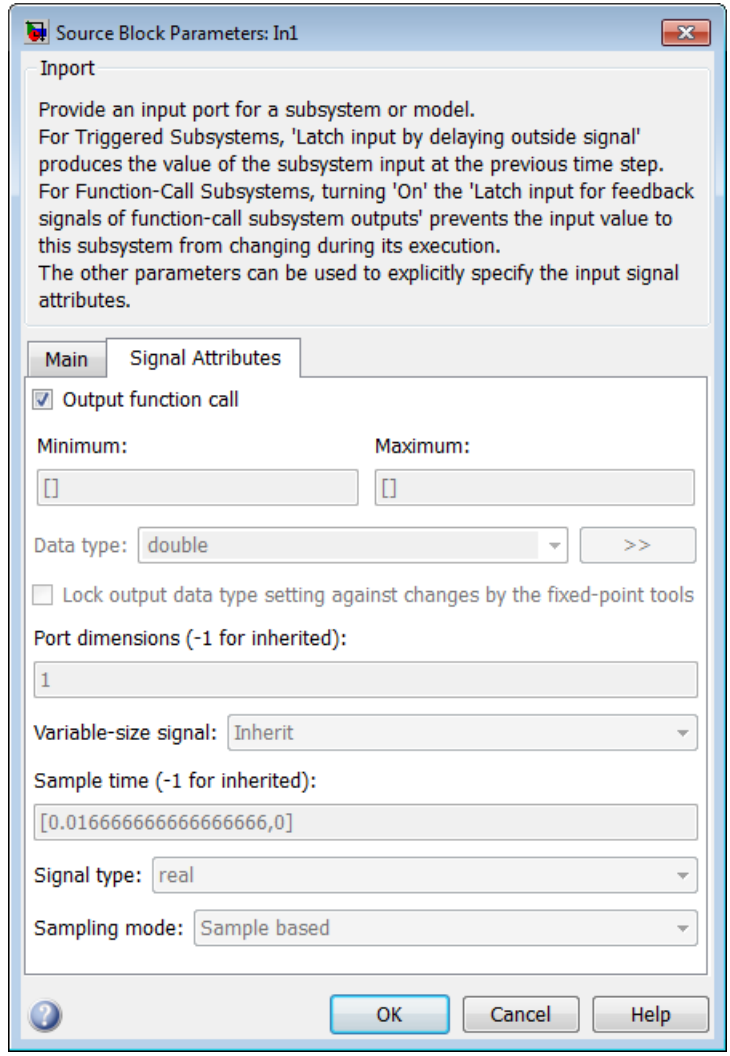
6 Move the Async Interrupt block from the model reference to the top model, before the model reference block.



7 Insert an Asynchronous Task Specification block in the model reference. Set the priority of the Asynchronous Task Specification block. (For more information on setting the priority, see Asynchronous Task Specification (Simulink Coder).)



8 In the model reference, double-click the input port to open its Source Block Parameters dialog box. Click the **Signal Attributes** tab and select the **Output function call** option. Click **OK**.



9 Save your model and then perform **Simulation > Update Diagram** to verify your settings.

Scheduling Considerations in Embedded Coder

Use Discrete and Continuous Time

In this section...

Support for Discrete and Continuous Time Blocks

The ERT target supports code generation for discrete and continuous time blocks. If the **Support: continuous time** option is selected on the **Code Generation > Interface** pane, you can use these blocks in your models, without restriction.

Note that use of certain blocks is not recommended for production code generation for embedded systems. The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, execute the following command and see the "Code Generation Support" column of the table that appears:

```
showblockdatatypetable
```

Support for Continuous Solvers

The ERT target supports continuous solvers. In the **Solver** options dialog, you can select an available solver in the **Solver** menu. (Note that the solver **Type** must be `fixed-step` for use with the ERT target.)

Note Custom targets must be modified to support continuous time. The required modifications are described in "Customize System Target Files" (Simulink Coder).

Support for Stop Time

The ERT target supports the stop time for a model. When generating host-based executables, the stop time value is honored if one of the following is true:

- **External mode** is selected on the **Code Generation > Interface** pane

- **MAT-file logging** is selected on the **All Parameters** tab
- **Classic call interface** is selected on the **All Parameters** tab

Otherwise, the executable runs indefinitely.

Note: The ERT target provides both generated and static examples of the `ert_main.c` file. The `ert_main.c` file controls the overall model code execution by calling the *`model`*`_step` function and optionally checking the `ErrorStatus`/`StopRequested` flags to terminate execution. For a custom target, if you provide your own custom static `main.c`, you should consider including support for checking these flags.

Optimize Multirate Multitasking Execution for RTOS Run-Time Environments

Using the `rtmStepTask` macro, run-time environments that employ task management mechanisms of an real-time operating system (RTOS)—for example, VxWorks—can improve performance of generated code by eliminating redundant scheduling calls during the execution of tasks in a multirate, multitasking model, The following sections describe implementation details.

Use rtmStepTask

The `rtmStepTask` macro is defined in `model.h` and its syntax is as follows:

```
boolean task_ready = rtmStepTask(rtm, idx);
```

The arguments are:

- `rtm`: pointer to the real-time model structure (`rtM`)
- `idx`: task identifier (`tid`) of the task whose scheduling counter is to be tested

`rtmStepTask` returns `TRUE` if the task's scheduling counter equals zero, indicating that the task should be scheduled for execution on the current time step. Otherwise, it returns `FALSE`.

If your target supports the **Generate an example main program** parameter, you can generate calls to `rtmStepTask` using the TLC function `RTMTaskRunsThisBaseStep`.

Schedule Code for Real-time Model without an RTOS

To understand the optimization that is available for an RTOS target, consider how the ERT target schedules tasks for bareboard targets (where RTOS is not present). The ERT target maintains *scheduling counters* and *event flags* for each subrate task. The scheduling counters are implemented within the real-time model (rtM) data structure as arrays, indexed on task identifier (`tid`).

The scheduling counters are updated by the base-rate task. The counters are clock rate dividers that count up the sample period associated with each subrate task. When a given subrate counter reaches a value that indicates it has a hit, the sample period for

that rate has elapsed and the counter is reset to zero. When this occurs, the subrate task must be scheduled for execution.

The event flags indicate whether or not a given task is scheduled for execution. For a multirate, multitasking model, the event flags are maintained by code in the main program for the model. For each task, the code maintains a task counter. When the counter reaches 0, indicating that the task's sample period has elapsed, the event flag for that task is set.

On each time step, the counters and event flags are updated and the base-rate task executes. Then, the scheduling flags are checked in `tid` order, and tasks whose event flag is set is executed. Therefore, tasks are executed in order of priority.

For bareboard targets that cannot rely on an external RTOS, the event flags are mandatory to allow overlapping task preemption. However, an RTOS target uses the operating system itself to manage overlapping task preemption, making the maintenance of the event flags redundant.

Schedule Code for Multirate Multitasking on an RTOS

The following task scheduling code, from `ertmainlib.tlc`, is designed for multirate multitasking operation on an example RTOS (VxWorks) target. The example uses the TLC function `RTMTaskRunsThisBaseStep` to generate calls to the `rtmStepTask` macro. A loop iterates over each subrate task, and `rtmStepTask` is called for each task. If `rtmStepTask` returns `TRUE`, the RTOS `semGive` function is called, and the RTOS schedules the task to run.

```
%assign ifarg = RTMTaskRunsThisBaseStep("i")
for (i = 1; i < %<FcnNumST>; i++) {
   if (%<ifarg>) {
     semGive(taskSemList[i]);
     if (semTake(taskSemList[i],NO_WAIT) != ERROR) {
       logMsg("Rate for SubRate task %d is too fast.\n",i,0,0,0,0,0);
       semGive(taskSemList[i]);
     }
   }
}
```

Suppress Redundant Scheduling Calls

Redundant scheduling calls are still generated by default for backward compatibility. To change this setting and suppress them, add the following TLC variable definition to your system target file before the `%include "codegenentry.tlc"` statement:

```
%assign SuppressSetEventsForThisBaseRateFcn = 1
```

Data, Function, and File Definition

Data Representation in Simulink Coder

Access Signal, State, and Parameter Data During Execution

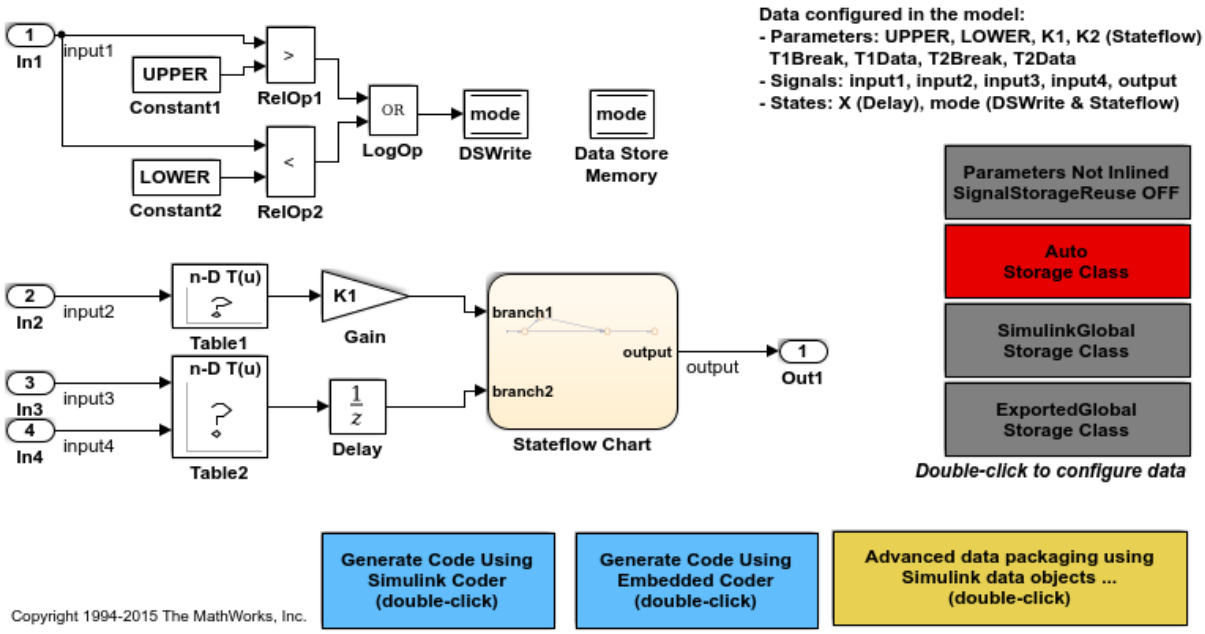
As you iteratively develop a model, you capture output signal and state data that model execution generates. You also tune parameter values during execution to observe the effect on the outputs. You can then base your design decisions upon analysis of these outputs. To access this signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

By default, optimization settings make the generated code more efficient by eliminating unnecessary signal storage and inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for this data, you can disable the optimizations or specify code generation settings for individual data items.

Explore Example Model

Open the example model rtwdemo_basicsc.

```
rtwdemo_basicsc
```



The model loads numeric MATLAB variables, such as `K1`, into the base workspace.

In the model, open the block dialog box for the Gain block labeled `Gain`. The block uses the variable `K1` to set the value of the **Gain** parameter.

Disable Optimizations

In the model, clear the model configuration parameter **Signal storage reuse**. When you clear this optimization and other optimizations such as **Eliminate superfluous local variables (expression folding)**, the generated code allocates memory for signal lines. Clearing **Signal storage reuse** disables most of the other optimizations.

```
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','off')
```

Set the optimization **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to `Tunable`. When set to `Tunable`, this configuration parameter causes the generated code to allocate memory for block parameters and workspace variables.

```
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc.h`. This header file defines a structure type that contains signal data. The structure contains fields that each represent a signal line in the model. For example, the output signal of the Gain block labeled `Gain` appears as the field `Gain`.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (auto storage) */',...
    'B_rtwdemo_basicsc_T;',1,1)
```

```
/* Block signals (auto storage) */
typedef struct {
  real32_T Table1;                     /* '<Root>/Table1' */
  real32_T Gain;                       /* '<Root>/Gain' */
  real32_T Delay;                      /* '<Root>/Delay' */
```

```
  real32_T Table2;                     /* '<Root>/Table2' */
  boolean_T RelOp1;                    /* '<Root>/RelOp1' */
  boolean_T RelOp2;                    /* '<Root>/RelOp2' */
  boolean_T LogOp;                     /* '<Root>/LogOp' */
} B_rtwdemo_basicsc_T;
```

The file defines a structure type that contains block parameter data. The MATLAB variable `K1` appears as a field of the structure. The other fields of the structure represent other block parameters and workspace variables from the model, including initial conditions for signals.

```
rtwdemodbtype(file,'/* Parameters (auto storage) */',...
    '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (auto storage) */
struct P_rtwdemo_basicsc_T_ {
  real_T K2;                           /* Variable: K2
                                        * Referenced by: '<Root>/Stateflow Chart'
                                        */
  real32_T LOWER;                      /* Variable: LOWER
                                        * Referenced by: '<Root>/Constant2'
                                        */
  real32_T T1Break[11];                /* Variable: T1Break
                                        * Referenced by: '<Root>/Table1'
                                        */
  real32_T T1Data[11];                 /* Variable: T1Data
                                        * Referenced by: '<Root>/Table1'
                                        */
  real32_T T2Break[3];                 /* Variable: T2Break
                                        * Referenced by: '<Root>/Table2'
                                        */
  real32_T T2Data[9];                  /* Variable: T2Data
                                        * Referenced by: '<Root>/Table2'
                                        */
  real32_T UPPER;                      /* Variable: UPPER
                                        * Referenced by: '<Root>/Constant1'
                                        */
  int8_T K1;                           /* Variable: K1
                                        * Referenced by: '<Root>/Gain'
                                        */
  real32_T Delay_InitialCondition;     /* Computed Parameter: Delay_InitialCondition
                                        * Referenced by: '<Root>/Delay'
                                        */
  uint32_T Table2_maxIndex[2];         /* Computed Parameter: Table2_maxIndex
```

```
                                        * Referenced by: '<Root>/Table2'
                                        */
  boolean_T DataStoreMemory_InitialValue;/* Computed Parameter: DataStoreMemory_Initial
                                          * Referenced by: '<Root>/Data Store Memory'
                                          */
};
```

View the file `rtwdemo_basicsc_data.c`. This source file allocates global memory for a parameter structure and initializes the field values based on the parameter values in the model.

View the source file `rtwdemo_basicsc.c`. The code allocates global memory for a structure variable that contains signal data.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Block signals (auto storage) */',...
    'B_rtwdemo_basicsc_T rtwdemo_basicsc_B;',1,1)
```

```
/* Block signals (auto storage) */
B_rtwdemo_basicsc_T rtwdemo_basicsc_B;
```

The code algorithm in the model `step` function calculates the signal values. It then assigns these values to the fields of the signal structure. To perform the calculations, the algorithm uses the parameter values from the fields of the parameter structure.

Exclude Data Items from Optimizations

When you want to select code generation optimizations such as **Signal storage reuse**, you can preserve individual data items from the optimizations. The generated code then allocates addressable memory for the items.

Select the optimizations that you previously cleared.

```
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','on')
set_param('rtwdemo_basicsc','LocalBlockOutputs','on')
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Inlined')
```

Right-click the output of the Gain block labeled `Gain` and select **Properties**. In the Signal Properties dialog box, select **Test point**.

```
portHandle = get_param('rtwdemo_basicsc/Gain','PortHandles');
portHandle = portHandle.Outport;
set_param(portHandle,'TestPoint','on')
```

Convert the MATLAB variable `K1` to a `Simulink.Parameter` object. With parameter objects, you can create addressable parameters to tune during execution of the generated code.

```
K1 = Simulink.Parameter(K1);
```

Apply a storage class other than `Auto` to the parameter object `K1`. For example, use the storage class `SimulinkGlobal` to represent the parameter object as a field of the global parameter structure.

```
K1.StorageClass = 'SimulinkGlobal';
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc.h`. The structure that contains signal data now defines only one field, `Gain`, which represents the test-pointed output of the Gain block.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (auto storage) */',...
    'B_rtwdemo_basicsc_T;',1,1)
```

```
/* Block signals (auto storage) */
typedef struct {
  real32_T Gain;                       /* '<Root>/Gain' */
} B_rtwdemo_basicsc_T;
```

The structure that contains block parameter data defines one field, `K1`, which represents the parameter object `K1`.

```
rtwdemodbtype(file,'/* Parameters (auto storage) */',...
    '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (auto storage) */
struct P_rtwdemo_basicsc_T_ {
  int8_T K1;                           /* Variable: K1
                                        * Referenced by: '<Root>/Gain'
                                        */
};
```

Access Data Through Generated Interfaces

You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For example, use the C API to log signal data and tune parameters during execution.

Copy this custom source code into a file named `myHandCode.c` in your current folder.

```
#include "myHandHdr.h"

#define paramIdx 0 /* Index of the target parameter,
determined by inspecting the array of structures generated by the C API. */
#define sigIdx 0 /* Index of the target signal,
determined by inspecting the array of structures generated by the C API. */

void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
    /* Take action with the parameter value only at
       the beginning of simulation and at the 5-second mark. */
    if (*tPtr == 0 || *tPtr == 5) {

        /* Local variables to store information extracted from
           the model mapping information (mmi). */
        void** dataAddrMap;
        const rtwCAPI_DataTypeMap *dataTypeMap;
        const rtwCAPI_ModelParameters *params;
        int_T addrIdx;
        uint16_T dTypeIdx;
        uint8_T slDataType;

        /* Use built-in C API macros to extract information. */
        dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
        dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
        params = rtwCAPI_GetModelParameters(mmi);
        addrIdx = rtwCAPI_GetModelParameterAddrIdx(params,paramIdx);
        dTypeIdx =  rtwCAPI_GetModelParameterDataTypeIdx(params,paramIdx);
        slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

        /* Handle data types 'double' and 'int8'. */
        switch (slDataType) {

            case SS_DOUBLE: {
                real_T* dataAddress;
```

```
                dataAddress = dataAddrMap[addrIdx];
                /* At the 5-second mark, increment the parameter value by 1. */
                if (*tPtr == 5) {
                    (*dataAddress)++;
                }
                printf("Parameter value is %f\n", *dataAddress);
                break;
            }

            case SS_INT8: {
                int8_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                if (*tPtr == 5) {
                    (*dataAddress)++;
                }
                printf("Parameter value is %i\n", *dataAddress);
                break;
            }
        }
    }
}

void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
    /* Take action with the signal value only when
       the simulation time is an integer value. */
    if (*tPtr-(int_T)*tPtr == 0) {

        /* Local variables to store information extracted from
           the model mapping information (mmi). */
        void** dataAddrMap;
        const rtwCAPI_DataTypeMap *dataTypeMap;
        const rtwCAPI_Signals *sigs;
        int_T addrIdx;
        uint16_T dTypeIdx;
        uint8_T slDataType;

        /* Use built-in C API macros to extract information. */
        dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
        dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
        sigs = rtwCAPI_GetSignals(mmi);
        addrIdx = rtwCAPI_GetSignalAddrIdx(sigs,sigIdx);
        dTypeIdx =  rtwCAPI_GetSignalDataTypeIdx(sigs,sigIdx);
        slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);
```

```
        /* Handle data types 'double' and 'single'. */
        switch (slDataType) {

            case SS_DOUBLE: {
                real_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                printf("Signal value is %f\n", *dataAddress);
                break;
            }

            case SS_SINGLE: {
                real32_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                printf("Signal value is %f\n", *dataAddress);
                break;
            }
        }
    }
}
```

Copy this custom header code into a file named `myHandHdr.h` in your current folder.

```
#include <stdio.h>
#include <string.h>
#include <math.h>
/* Include rtw_modelmap.h for definitions of C API macros. */
#include "rtw_modelmap.h"
#include "builtin_typeid_types.h"
#include "rtwtypes.h"
void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

In the model, set **Configuration Parameters > Code Generation > Custom Code > Insert custom C code in generated > Header file** to `#include "myHandHdr.h"`. In the same pane in the Configuration Parameters dialog box, set **Additional Build Information > Source files** to `myHandCode.c`.

```
set_param('rtwdemo_basicsc','CustomHeaderCode','#include "myHandHdr.h"')
set_param('rtwdemo_basicsc','CustomSource','myHandCode.c')
```

Select **Configuration Parameters > All Parameters > MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

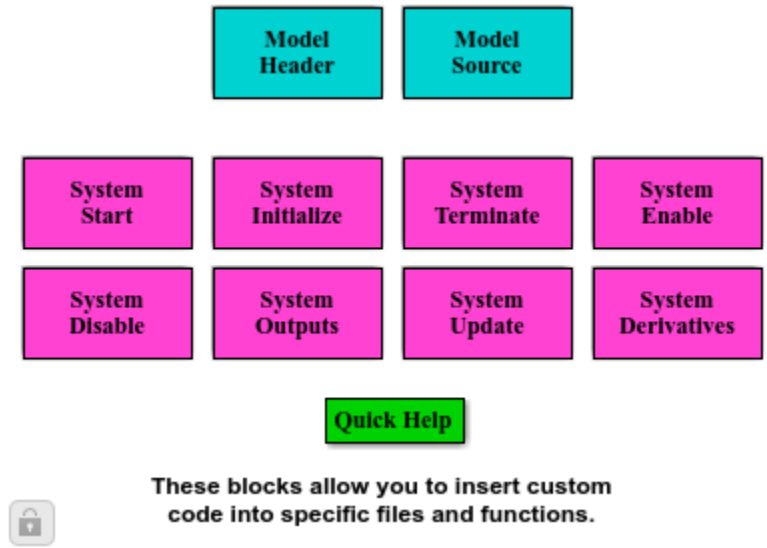
```
set_param('rtwdemo_basicsc','MatFileLogging','on')
```

Select all of the options under **Configuration Parameters > Code Generation > Interface > Generate C API for**.

```
set_param('rtwdemo_basicsc','RTWCAPIParams','on')
set_param('rtwdemo_basicsc','RTWCAPISignals','on')
set_param('rtwdemo_basicsc','RTWCAPIStates','on')
set_param('rtwdemo_basicsc','RTWCAPIRootIO','on')
```

Load the Custom Code block library.

```
custcode
```



Add a System Outputs block to the model.

```
add_block('custcode/System Outputs','rtwdemo_basicsc/System Outputs')
```

In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this custom code:

```
{
rtwdemo_basicsc_U.input2++;
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

In the block dialog box, set **System Outputs Function Exit Code** to this custom code:

```
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['{\nrtwdemo_basicsc_U.input2++;'...
    '\nrtwCAPI_ModelMappingInfo *MMI = '...
    '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
    '\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n}']);
temp.Bottom = sprintf(['{\nrtwCAPI_ModelMappingInfo *MMI = '...
    '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
    '\nlogFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n}']);
set_param('rtwdemo_basicsc/System Outputs','RTWdata',temp)
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the interface file `rtwdemo_basicsc_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc_capi.c');
rtwdemodbtype(file,'/* Block output signal information */',...
    '/* Individual block tuning',1,0)
```

```
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 0, 0, TARGET_STRING("rtwdemo_basicsc/Gain"),
    TARGET_STRING(""), 0, 0, 0, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

In the file `rtwdemo_basicsc.c`, view the code algorithm in the model `step` function. The algorithm first executes the custom code that you specified in the System Outputs block.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* user code (Output function Body) */',...
    '/* Logic: ''<Root>/LogOp'' incorporates:',1,0)
```

```
  /* user code (Output function Body) */

  /* System '<Root>' */
  {
    rtwdemo_basicsc_U.input2++;
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
  }
```

This custom code first perturbs the input signal `input2` by incrementing the value of the signal each time the `step` function executes. The code then uses the built-in macro `rtmGetDataMapInfo` to extract model mapping information from the model data structure `rtwdemo_basicsc_M`. The pointer `MMI` points to the extracted mapping information, which allows the custom functions `tuneFcn` and `logFcn` to access the information contained in the arrays of structures that the C API file `rtwdemo_basicsc_capi.c` defines.

View the custom function `tuneFcn` in the file `myHandCode.c`. This function uses the C API (through the model mapping information `mmi`) and a pointer to the simulation time to print the value of the parameter `K1` at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a `switch case` block, the function can access the parameter data whether the data type is `int8` or `double`.

View the code algorithm in the model `step` function again. Near the end of the function, the algorithm executes the custom code that you specified in the System Outputs block. This code calls the custom function `logFcn`.

```
rtwdemodbtype(file,'/* user code (Output function Trailer) */',...
    '/* Matfile logging */',1,0)
```

```
  /* user code (Output function Trailer) */

  /* System '<Root>' */
  {
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
  }
```

View the custom function `logFcn` in the file `myHandCode.c`. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is `single` or `double`.

At the command prompt, run the generated executable `rtwdemo_bascisc.exe`.

```
system('rtwdemo_basicsc')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Data Exchange Interfaces” (Simulink Coder).

Default Data Structures in the Generated Code

The generated code creates variables to represent model data such as signals, block parameters, and states. The code generation settings that you choose for a model determine the default scope of each datum. If the code generator applies a global scope to a datum, by default the datum appears as a field of a global data structure rather than a separate global variable. For example, the generated code creates default structures to contain block output signals, tunable parameters, and constant-valued nontunable parameters that the code generator cannot inline.

The table shows the most common global data structures in the generated code. The default name of each structure variable is *model_structname*. *model* is the name of the model. *structname* is the structure name in the table.

Global data structures generated for a standalone model

Structure Name	Data Represented in the Structure
`U`	Data from root Inport blocks
`Y`	Data from root Outport blocks
`B`	Block output signals
`ConstB`	Block outputs that have constant values
`P`	Block parameters
`DefaultP`	Default parameters in the system
`ConstP`	Constant parameters
`DW`	Discrete block states
`X`	Continuous block states
`XDot`	Derivatives of continuous states at each time step
`XDis`	Status of enabled subsystems
`ZCV`	Zero-crossing signals
`PrevZCX`	Previous zero-crossing signal states
`Obj`	Used by ERT C++ code generation to refer to referenced model objects

The table shows the most common global data structures generated for atomic subsystems and referenced models. The default name of each structure variable is *model_structname* for referenced models and *model_subsystem_structname* for subsystems.

Global data structures generated for subsystems and referenced models

Structure Name	Data Represented in the Structure
`B`	Block output signals
`ConstB`	Block outputs that have constant values
`P`	Block parameters
`DW`	Discrete block states
`MdlRefDW`	Discrete block states in referenced model
`X`	Continuous states in model reference
`XDis`	Status of enabled subsystems
`ZCV`	Zero-crossing signals
`RTM`	RT_Model structure

If you have an Embedded Coder license, you can control the names of these global structure variables. For more information, see "Global variables" (Simulink Coder) and "System-generated identifiers" (Simulink Coder).

You can exclude data from appearing in these structures by using:

- Storage classes. For example, you can use storage classes to represent signals, tunable parameters, and states as individual global variables. For more information, see "Control Signals and States in Code by Applying Storage Classes" (Simulink Coder) and "Block Parameter Representation in the Generated Code" (Simulink Coder).
- Configuration parameters, such as those on the **Optimization > Signals and Parameters** pane in the Configuration Parameters dialog box. You can adjust these configuration parameters to control the default representation of data. For more information, see "Optimization Pane: Signals and Parameters" (Simulink).

Use the Real-Time Model Data Structure

The code generator uses the real-time model (RT_MODEL) data structure. This structure is also referred to as the `rtModel` data structure. You can access `rtModel` data by using a set of macros analogous to the `ssSetxxx` and `ssGetxxx` macros that S-functions use to access `SimStruct` data, including noninlined S-functions compiled by the code generator.

You need to use the set of macros `rtmGetxxx` and `rtmSetxxx` to access the real-time model data structure. The `rtModel` is an optimized data structure that replaces `SimStruct` as the top level data structure for a model. The `rtmGetxxx` and `rtmSetxxx` macros are used in the generated code as well as from the `main.c` or `main.cpp` module. If you are customizing `main.c` or `main.cpp` (either a static file or a generated file), you need to use `rtmGetxxx` and `rtmSetxxx` instead of the `ssSetxxx` and `ssGetxxx` macros.

Usage of `rtmGetxxx` and `rtmSetxxx` macros is the same as for the `ssSetxxx` and `ssGetxxx` versions, except that you replace `SimStruct S` by real-time model data structure `rtM`. The following table lists `rtmGetxxx` and `rtmSetxxx` macros that are used in `grt_main.c` and `grt_main.cpp`.

Macros for Accessing the Real-Time Model Data Structure

rtm Macro Syntax	Description
`rtmGetdX(rtm)`	Get the derivatives of block continuous states
`rtmGetOffsetTimePtr(RT_MDL rtM)`	Return the pointer to vector that stores sample time offsets of the model associated with rtM
`rtmGetNumSampleTimes(RT_MDL rtM)`	Get the number of sample times that a block has
`rtmGetPerTaskSampleHitsPtr(RT_MDL)`	Return a pointer to `NumSampleTime` × `NumSampleTime` matrix
`rtmGetRTWExtModeInfo(RT_MDL rtM)`	Return an external mode information data structure of the model (used internally for external mode)
`rtmGetRTWLogInfo(RT_MDL)`	Return a data structure used by code generator logging (internal use only)
`rtmGetRTWRTModelMethodsInfo(RT_MDL)`	Return a data structure of real-time model methods information (internal use only)
`rtmGetRTWSolverInfo(RT_MDL)`	Return data structure containing solver information of the model (internal use only)

rtm Macro Syntax	Description
`rtmGetSampleHitPtr(RT_MDL)`	Return a pointer to Sample Hit flag vector
`rtmGetSampleTime(RT_MDL rtM, int TID)`	Get task sample time
`rtmGetSampleTimePtr(RT_MDL rtM)`	Get pointer to a task sample time
`rtmGetSampleTimeTaskIDPtr(RT_MDL rtM)`	Get pointer to a task ID
`rtmGetSimTimeStep(RT_MDL)`	Return simulation step type ID (`MINOR_TIME_STEP`, `MAJOR_TIME_STEP`)
`rtmGetStepSize(RT_MDL)`	Return the fundamental step size of the model
`rtmGetT(RT_MDL,t)`	Get the current simulation time
`rtmSetT(RT_MDL,t)`	Set the time of the next sample hit
`rtmGetTaskTime(RT_MDL,tid)`	Get the current time for the current task
`rtmGetTFinal(RT_MDL)`	Get the simulation stop time
`rtmSetTFinal(RT_MDL,finalT)`	Set the simulation stop time
`rtmGetTimingData(RT_MDL)`	Return a data structure used by timing engine of the model (internal use only)
`rtmGetTPtr(RT_MDL)`	Return a pointer to the current time
`rtmGetTStart(RT_MDL)`	Get the simulation start time
`rtmIsContinuousTask(rtm)`	Determine whether a task is continuous
`rtmIsMajorTimeStep(rtm)`	Determine whether the simulation is in a major step
`rtmIsSampleHit(RT_MDL,tid)`	Determine whether the sample time is hit
`rtmGetErrorStatus(rtm)`	Get the current error status
`rtmSetErrorStatus(rtm,val)`	Set the current error status
`rtmGetErrorStatusPointer(rtm)`	Return a pointer to the current error status
`rtmGetStopRequested(rtm)`	Return whether a stop is requested
`rtmGetBlockIO(rtm)`	Get the block I/O data structure
`rtmSetBlockIO(rtm,val)`	Set the block I/O data structure
`rtmGetContStates(rtm)`	Get the continuous states data structure
`rtmSetContStates(rtm,val)`	Set the continuous states data structure

rtm Macro Syntax	Description
`rtmGetDefaultParam(rtm)`	Get the default parameters data structure
`rtmSetDefaultParam(rtm,val)`	Set the default parameters data structure
`rtmGetPrevZCSigState(rtm)`	Get the previous zero-crossing signal state data structure
`rtmSetPrevZCSigState(rtm,val)`	Set the previous zero-crossing signal state data structure
`rtmGetRootDWork(rtm)`	Get the DWork data structure
`rtmSetRootDWork(rtm,val)`	Set the DWork data structure
`rtmGetU(rtm)`	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmSetU(rtm,val)`	Set the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmGetY(rtm)`	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
`rtmSetY(rtm,val)`	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

For additional details on usage, see "SimStruct Macros and Functions Listed by Usage" (Simulink).

Use Enumerated Data in Generated Code

In this section...

Enumerated Data Types

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code. The following is a MATLAB class definition for an enumerated data type named `BasicColors`, which is used in the examples in this section.

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
end
```

For basic information about enumerated data types and their use in Simulink models, see “Use Enumerated Data in Simulink Models” (Simulink). For information about enumerated data types in Stateflow charts, see “Define Enumerated Data in a Chart” (Stateflow).

Specify Integer Data Type for Enumeration

When you specify a data type for your enumeration, you can:

- Control the size of enumerated data types in the generated code by specifying a superclass.

- Reduce RAM/ROM usage.
- Improve code portability.
- Improve integration with legacy code.

You can specify any of these integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `Simulink.IntEnumType`. Specify values in the range of the signed integer for your hardware platform.

Use a Class Definition in a MATLAB File

To specify an integer data type size, derive your enumeration class from the integer data type.

```
classdef Colors < int8
   enumeration
     Red(0)
     Green(1)
     Blue(2)
   end
end
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red      ((Colors)0)
#define Green ((Colors)1)
#define Blue     ((Colors)2)
```

Use the Function `Simulink.defineIntEnumType`

To specify an integer data type size, specify the name-value pair `StorageType` as the integer data type.

```
Simulink.defineIntEnumType('Colors',{'Red','Green','Blue'},...
[0;1;2],'StorageType','int8')
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red      ((Colors)0)
#define Green ((Colors)1)
#define Blue     ((Colors)2)
```

Customize Enumerated Data Type

When you generate code from a model that uses enumerated data, you can implement these static methods to customize the behavior of the type during simulation and in generated code:

- `getDefaultValue` — Specifies the default value of the enumerated data type.
- `getDescription` — Specifies a description of the enumerated data type.
- `getHeaderFile` — Specifies a header file where the type is defined for generated code.
- `getDataScope` — Specifies whether generated code exports or imports the enumerated data type definition to or from a separate header file.
- `addClassNameToEnumNames` — Specifies whether the class name becomes a prefix in generated code.

The first of these methods, `getDefaultValue`, is relevant to both simulation and code generation, and is described in "Specify a Default Enumerated Value" (Simulink). The other methods are relevant only to code generation. To customize the behavior of an enumerated type, include a version of the method in the `methods(Static)` section of the enumeration class definition. If you do not want to customize the type, omit the `methods(Static)` section. The table summarizes the methods and the data to supply for each one.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value
`getDefaultValue`	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A character vector containing the name of an enumeration member in the class (see "Instantiate Enumerations" (Simulink)).

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value
`getDescription`	Specifies a description of the enumeration class.	`''`	A character vector containing the description of the type.
`getHeaderFile`	Specifies the name of a header file. The method `getDataScope` determines the significance of the file.	`''`	A character vector containing the name of the header file that defines the enumerated type. By default, the generated `#include` directive uses the preprocessor delimiter `"` instead of `<` and `>`. To generate the directive `#include <myTypes.h>`, specify the custom return value as `'<myTypes.h>'`.
`getDataScope`	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method `getHeaderFile` to specify the generated or included header file that defines the type.	`'Auto'`	One of: `'Auto'`, `'Exported'`, or `'Imported'`.
`addClassNameToEnumName`	Specifies whether to prefix the class name in generated code.	`false`	`true` or `false`.

Specify a Description

To specify a description for an enumerated data type, include this method in the `methods(Static)` section of the enumeration class:

```
function retVal = getDescription()
% GETDESCRIPTION  Optional description of the data type.
  retVal = 'description';
end
```

Substitute a MATLAB character vector for *`description`*. The generated code that defines the enumerated type includes the specified description.

Import Type Definition in Generated Code

To prevent generated code from defining an enumerated data type, which allows you to provide the definition in an external file, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getHeaderFile()
  % GETHEADERFILE Specifies the file that defines this type in generated code.
  % The method getDataScope determines the significance of the specified file.
  retVal = 'imported_enum_type.h';
end

function retVal = getDataScope()
  % GETDATASCOPE Specifies whether generated code imports or exports this type.
  % Return one of:
  % 'Auto':     define type in model_types.h, or import if header file specified
  % 'Exported': define type in a generated header file
  % 'Imported': import type definition from specified header file
  % If you do not define this method, DataScope is 'Auto' by default.
  retVal = 'Imported';
end
```

Instead of defining the type in *`model`*`_types.h`, which is the default behavior, generated code imports the definition from the specified header file using a `#include` statement like:

```
#include "imported_enum_type.h"
```

Generating code does not create the imported header file. You must provide the header file, using the file name specified by the method `getHeaderFile`, that defines the enumerated data type.

To create a Simulink enumeration that corresponds to your existing C-code enumeration, use the `Simulink.importExternalCTypes` function.

Export Type Definition in Generated Code

To generate a separate header file that defines an enumerated data type, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getDataScope()
  % GETDATASCOPE Specifies whether generated code imports or exports this type.
  % Return one of:
  % 'Auto':     define type in model_types.h, or import if header file specified
  % 'Exported': define type in a generated header file
  % 'Imported': import type definition from specified header file
  % If you do not define this method, DataScope is 'Auto' by default.
  retVal = 'Exported';
end

function retVal = getHeaderFile()
  % GETHEADERFILE Specifies the file that defines this type in generated code.
  % The method getDataScope determines the significance of the specified file.
  retVal = 'exported_enum_type.h';
end
```

Generated code exports the enumerated type definition to the generated header file `exported_enum_type.h`.

Add Prefixes To Class Names

By default, enumerated values in generated code have the same names that they have in the enumeration class definition. Alternatively, your code can prefix every enumerated value in an enumeration class with the name of the class. You can use this technique to prevent identifier conflicts or to improve the readability of the code. To specify class name prefixing, include this method in the `methods(Static)` section of an enumeration class:

```
function retVal = addClassNameToEnumNames()
  % ADDCLASSNAMETOENUMNAMES Specifies whether to add the class name
  % as a prefix to enumeration member names in generated code.
  % Return true or false.
  % If you do not define this method, no prefix is added.
  retVal = true;
end
```

Specify the return value as `true` to enable class name prefixing or as `false` to suppress prefixing. If you specify `true`, each enumerated value in the class appears in generated code as *`EnumTypeName_EnumName`*. For the example enumeration class `BasicColors` in "Enumerated Data Types" on page 19-22, the data type definition in generated code might look like this:

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_
```

```
typedef enum {
  BasicColors_Red = 0,            /* Default value */
  BasicColors_Yellow = 1,
  BasicColors_Blue = 2,
} BasicColors;

#endif
```

The enumeration class name `BasicColors` appears as a prefix for each of the enumerated names.

Control Enumerated Type Implementation in Generated Code

Suppose that you define an enumerated type `BasicColors`. You can specify that the generated code implement the type definition using:

- An `enum` block. The native integer type of your hardware is the underlying integer type for the enumeration members.
- A `typedef` statement and a series of `#define` macros. The `typedef` statement bases the enumerated type name on a specific integer data type, such as `int8`. The macros associate the enumeration members with the underlying integer values.

Implement Enumerated Type Using `enum` Block

To implement the type definition using an `enum` block:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from the type `Simulink.IntEnumType`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Do not specify the property `StorageType`.

When you generate code, the type definition appears in an `enum` block.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
  Red = 0,            /* Default value */
  Yellow,
  Blue,
} BasicColors;
```

```
#endif
```

Implement Enumerated Type Using a Specific Integer Type

To implement the type definition using a `typedef` statement and `#define` macros:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from a specific integer type such as `int8`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Specify the property `StorageType` using a specific integer type such as `int8`.

When you generate code, the type definition appears as a `typedef` statement and a series of `#define` macros.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef int8_T BasicColors;

#define Red ((BasicColors)0)            /* Default value */
#define Yellow ((BasicColors)1)
#define Blue ((BasicColors)2)

#endif
```

By default, the generated file *`model`*`_types.h` contains enumerated type definitions.

Type Casting for Enumerations

Safe Casting

A Simulink Data Type Conversion block accepts a signal of integer type. The block converts the input to one of the underlying values of an enumerated type.

If the input value does not match any of the underlying values of the enumerated type values, Simulink inserts a safe cast to replace the input value with the enumerated type default value.

Enable and Disable Safe Casting

You can enable or disable safe casting for enumerations during code generation for a Simulink Data Type Conversion block or a Stateflow block.

To control safe casting, enable or disable the **Saturate on integer overflow** block parameter. The parameter works as follows:

- **Enabled:** Simulink replaces a nonmatching input value with the default value of the enumerated values during simulation. The software generates a safe cast function during code generation.
- **Disabled:** For a nonmatching input value, Simulink generates an error during simulation. The software omits the safe cast function during code generation. In this case, the code is more efficient. However, the code may be more vulnerable to run-time errors.

Safe Cast Function in Generated Code

This example shows how the safe cast function `int32_T ET08_safe_cast_to_BasicColors` for the enumeration `BasicColors` appears in generated code when generated for 32-bit hardware.

```
static int32_T ET08_safe_cast_to_BasicColors(int32_T input)
{
 int32_T output;
 /* Initialize output value to default value for BasicColors (Red) */
 output = 0;
 if ((input >= 0) && (input <= 2)) {
 /* Set output value to input value if it is a member of BasicColors */
  output = input;
 }
 return output;
}
```

Through this function, the enumerated type's default value is used if the input value does not match one of underlying values of the enumerated type's values.

If the block's **Saturate on integer overflow** parameter is disabled, this function does not appear in generated code.

Enumerated Type Limitations

- Generated code does not support logging enumerated data.

Data Stores in Generated Code

In this section...

About Data Stores

A data store contains data that is accessible in a model hierarchy at or below the level in which the data store is defined. Data stores can allow subsystems and referenced models to share data without having to use I/O ports to pass the data from level to level. See "Data Stores with Data Store Memory Blocks" (Simulink) for information about data stores in Simulink. This section provides additional information about data store code generation.

Generate Code for Data Store Memory Blocks

To control the code generated for a Data Store Memory block, apply a storage class to the data store. You can associate a Data Store Memory block with a signal object that you store in a workspace or data dictionary, and control code generation for the block by applying the storage class to the object:

1. Instantiate the desired signal object.
2. Set the object's `CoderInfo.StorageClass` property to indicate the desired storage class.
3. Open the block dialog box for the Data Store Memory block that you want to associate with the signal object.
4. Enter the name of the signal object in the **Data store name** field.
5. Select **Data store name must resolve to Simulink signal object**.
6. *Do not* set the storage class field to a value other than `Auto` (the default).
7. Click **OK** or **Apply**.

Note When a Data Store Memory block is associated with a signal object, the mapping between the **Data store name** and the signal object name must be one-

to-one. If two or more identically named entities map to the same signal object, the name conflict is flagged as an error at code generation time. See "Resolve Conflicts in Configuration of Signal Objects" on page 19-131 for more information.

Storage Classes for Data Store Memory Blocks

You can control how Data Store Memory blocks in your model are stored and represented in the generated code by assigning storage classes and type qualifiers. You do this in almost exactly the same way you assign storage classes and type qualifiers for block states.

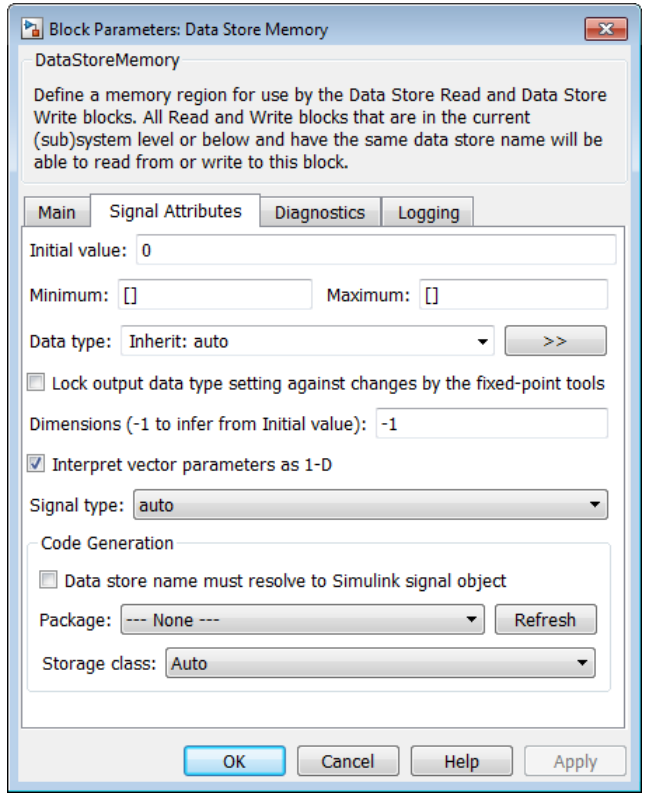
Data Store Memory blocks, like block states, have `Auto` storage class by default, and their memory is stored within the `DWork` vector. The symbolic name of the storage location is based on the data store name.

You can generate code from multiple Data Store Memory blocks that have the same data store name, subject to the following restriction: *at most one* of the identically named blocks can have a storage class other than `Auto`. An error is reported if this condition is not met.

For blocks with `Auto` storage class, the code generator produces a unique symbolic name for each block to avoid name clashes. For Data Store Memory blocks with storage classes other than `Auto`, the generated code uses the data store name as the symbol.

In the following model, a Data Store Write block writes to memory declared by the Data Store Memory block `myData`:

To control the storage declaration for a Data Store Memory block, use the **Code Generation > Signal object class** and **Code Generation > Storage class** drop-down lists of the Data Store Memory block dialog box. Set **Signal object class** to `Simulink.Signal` (the default), and choose a storage class from the **Storage class** drop-down list. The next figure shows the Data Store Memory block dialog box for the preceding model.



Data Store Memory blocks are nonvirtual because code is generated for their initialization in `.c` and `.cpp` files and their declarations in header files. The following table shows how the code generated for the Data Store Memory block in the preceding model differs for different settings of **Code Generation** > **Storage class**. The table gives the variable declarations and `MdlOutputs` code generated for the `myData` block.

Storage Class	Declaration	Code

`Auto` or `SimulinkGlobal`	In *`model`*`.h`
	
	`typedef struct`
	`D_Work_tag`
	`{`
	`  real_T myData;`
	`}`
	`D_Work;`
		`model``_DWork.myData =`
		`  rtb_SineWave;`

Storage Class	Declaration	Code

	In *model*.c or *model*.cpp
	`/* Block states (auto storage) */`
	`D_Work model_DWork;`	

`ExportedGlobal`	In *model*.c or *model*.cpp
	`/* Exported block states */`
	`real_T myData;`
	In *model*.h
	`extern real_T myData;`
		`myData = rtb_SineWave;`

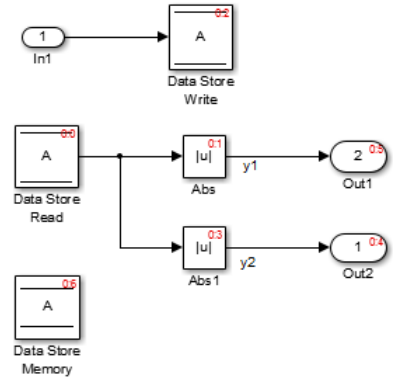
`ImportedExtern`	In *model*_private.h `extern real_T myData;`	`myData = rtb_SineWave;`
`ImportedExternPointer`	In *model*_private.h `extern real_T *myData;`	`(*myData) = rtb_SineWave;`

For information about applying storage classes, see "Control Signals and States in Code by Applying Storage Classes" (Simulink Coder).

Data Store Buffering in Generated Code

A Data Store Read block is a nonvirtual block that copies the value of the data store to its output buffer when it executes. Since the value is buffered, downstream blocks connected to the output of the data store read utilize the same value, even if a Data Store Write block updates the data store in between execution of two of the downstream blocks.

The next figure shows a model that uses blocks whose priorities have been modified to achieve a particular order of execution:



```
/* local block i/o variables */
real_T rtb_DataStoreRead;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A;
```

Buffer the value of A

```
/* Abs: '<Root>/Abs1' incorporates:
 *  DataStoreRead: '<Root>/Data Store Read'
 */
y1 = fabs(A);
```

Use A (whose value equals the buffered value at this point

```
/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 *  Inport: '<Root>/In1'
 */
A = u1;
```

Update the value of A

```
/* Abs: '<Root>/Abs' */
y2 = fabs(rtb_DataStoreRead);
```

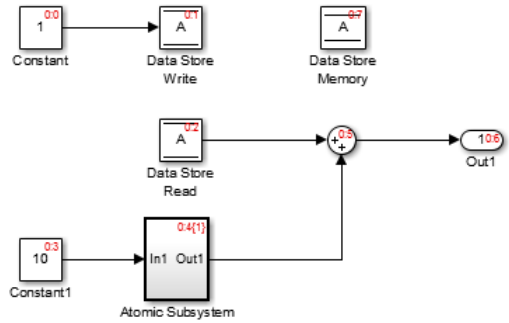
Consistently use the same buffered value as before the update to A

The following execution order applies:

1. The block Data Store Read buffers the current value of the data store A at its output.
2. The block Abs1 uses the buffered output of Data Store Read.
3. The block Data Store Write updates the data store.
4. The block Abs uses the buffered output of Data Store Read.

Because the output of Data Store Read is a buffer, both Abs and Abs1 use the same value: the value of the data store at the time that Data Store Read executes.

The next figure shows another example:



```
real_T rtb_DataStoreRead;

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 *  Constant: '<Root>/Constant'
 */
A = DoBufferDSMRead2_P.Constant_Value;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A;
```

Buffer the value of A

```
/* Outputs for atomic SubSystem: '<Root>/Atomic Subsystem' */
DoBufferDSMRead_AtomicSubsystem();
```

We don't do a global analysis to detect if this function writes to A

```
/* end of Outputs for SubSystem: '<Root>/Atomic Subsystem' */

/* Outport: '<Root>/Out1' incorporates:
 *  Sum: '<Root>/Sum'
 */
DoBufferDSMRead2_Y.Out1 = rtb_DataStoreRead + DoBufferDSMRead2_B.Abs;
```

Use the buffered value of A

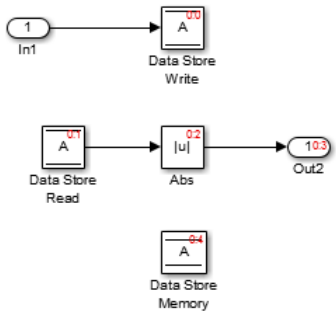
In this example, the following execution order applies:

1. The block Data Store Read buffers the current value of the data store A at its output.
2. Atomic Subsystem executes.
3. The Sum block adds the output of Atomic Subsystem to the output of Data Store Read.

Simulink assumes that Atomic Subsystem might update the data store, so Simulink buffers the data store. Atomic Subsystem executes after Data Store Read buffers its

output, and the buffer provides a way for the Sum block to use the value of the data store as it was when Data Store Read executed.

In some cases, the code generator determines that it can optimize away the output buffer for a Data Store Read block, and the generated code refers to the data store directly, rather than a buffered value of it. The next figure shows an example:



```
/* Model step function */
void DONTbufferDSMRead_step(void)
{
  /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
   *  Inport: '<Root>/In1'
   */
  A = u1;

  /* Abs: '<Root>/Abs' incorporates:
   *  DataStoreRead: '<Root>/Data Store Read'
   */
  y2 = fabs(A);
}
```

In the generated code, the argument of the `fabs()` function is the data store `A` rather than a buffered value.

Structures in Generated Code Using Data Stores

If you use more than one data store to provide global access to multiple signals in generated code, you can combine the signals into a single structure variable by using one data store. This combination of signal data can help you integrate the code generated from a model with other existing code that requires the data in a structure format.

This example shows how to store several model signals in a structure in generated code using a single data store. To store multiple signals in a data store, you configure the data store to accept a composite signal, such as a nonvirtual bus signal or an array of nonvirtual bus signals.

Explore Example Model

1. Open the example model ex_bus_struct_in_code.

   The model contains three subsystems that perform calculations on the inputs from the top level of the model. In each subsystem, a Data Store Memory block stores an intermediate calculated signal.

2. Generate code with the model. In the code generation report, view the file `ex_bus_struct_in_code.c`. The code defines a global variable for each data store.

   ```
   real_T BioBTURate;
   real_T CoalBTURate;
   real_T GasBTURate;
   ```

Suppose that you want to integrate code generated from the example model with other existing code. Suppose also that the existing code requires access to all of the data from the three data stores in a single structure variable. You can use a data store to assemble all of the target data in a structure in generated code.

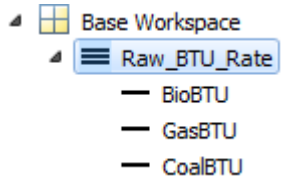
Configure Data Store

Configure a data store to contain multiple signals by creating a bus type to use as the data type of the data store. Define the bus type using the same hierarchy of elements as the structure that you want to appear in generated code.

1. Open the Bus Editor tool.

   ```
   buseditor
   ```

2 Define a new bus type `Raw_BTU_Rate` with one element for each of the three target signals. Name the elements `BioBTU`, `GasBTU`, and `CoalBTU`.



3 At the top level of the example model, add a Data Store Memory block.

4 In the block dialog box, set **Data store name** to `Raw_BTU_Data`. Click **Apply**.

5 On the **Signal Attributes** tab, set **Data type** to `Bus: Raw_BTU_Rate`.

6 Under **Code Generation**, set **Storage class** to `ExportedGlobal`.

Write to Data Store Elements

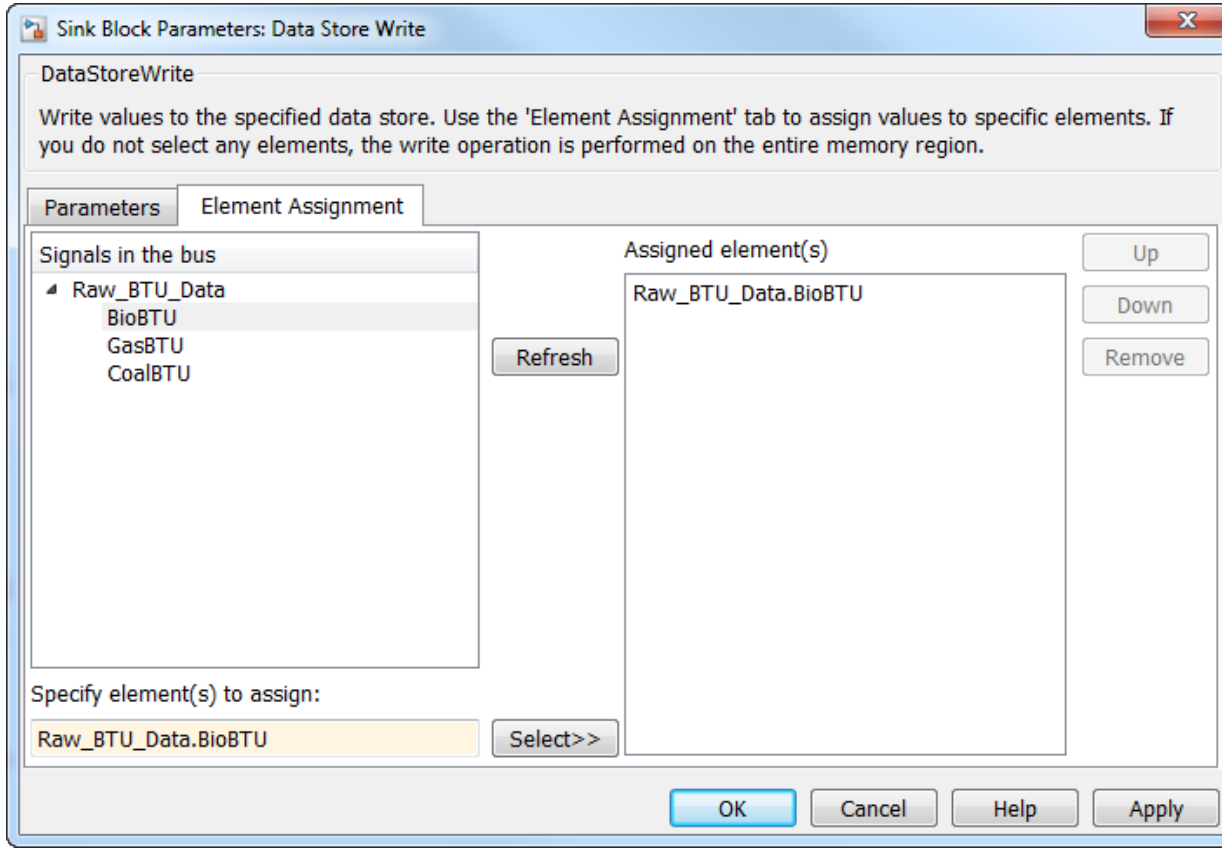
To write to a specific element of a data store, use a Data Store Write block. On the **Element Assignment** tab in the dialog box, you can specify to write to a single element, a collection of elements, or the entire contents of a data store.

1 Open the **Biomass Calc** subsystem.

2 Delete the Data Store Memory block `BioBTURate`.

3 In the block dialog box for the Data Store Write block, set **Data store name** to `Raw_BTU_Data`.

4 On the **Element Assignment** tab, under **Signals in the bus**, expand the contents of the data store `Raw_BTU_Data`. Click the element `BioBTU`, and then click **Select**. Click **OK**.



5 Modify the **Gas Calc** and **Coal Calc** subsystems similarly.

- Delete the Data Store Memory block in each subsystem.
- In each Data Store Write block dialog box, set **Data store name** to `Raw_BTU_Data`.
- In the **Gas Calc** subsystem, use the Data Store Write block to write to the data store element `GasBTU`. In the **Coal Calc** subsystem, write to the element `CoalBTU`.

Generate Code with Data Store Structure

1. Generate code for the example model.
2. In the code generation report, view the file `ex_bus_struct_in_code_types.h`. The code defines a structure that corresponds to the bus type `Raw_BTU_Rate`.

```
typedef struct {
  real_T BioBTU;
  real_T GasBTU;
  real_T CoalBTU;
} Raw_BTU_Rate;
```

3. View the file `ex_bus_struct_in_code.c`. The code represents the data store with a global variable `Raw_BTU_Data` of the structure type `Raw_BTU_Rate`. In the model step function, the code assigns the data from the calculated signals to the fields of the global variable `Raw_BTU_Data`.

Specify Single-Precision Data Type for Embedded Application

When you want code that uses only single precision, such as when you are targeting a single-precision processor, you can use model configuration parameters and block parameters to prevent the introduction of `double` in the model.

To design and validate a single-precision model, see "Validate a Floating-Point Embedded Model" (Simulink). If you have Fixed-Point Designer, you can use the Single Precision Converter app (see "Single-Precision Design for Simulink" (Fixed-Point Designer)).

Use `single` Data Type as Default for Underspecified Types

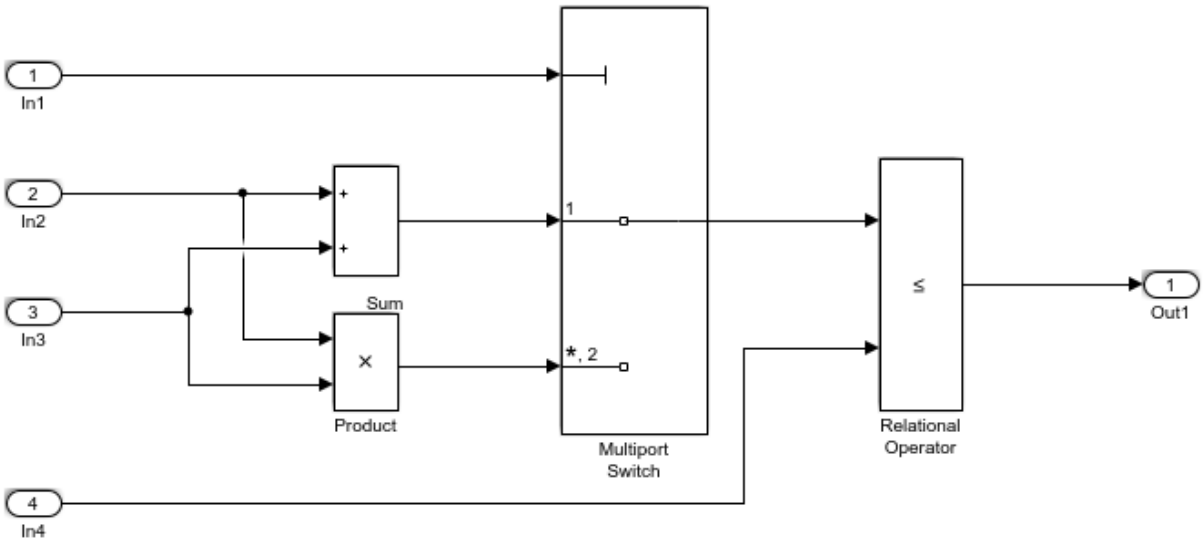
This example shows how to avoid introducing a double-precision data type in code generated for a single-precision hardware target.

If you specify an inherited data type for signals, but data type propagation rules cannot determine data types for the signals, the signal data types default to `double`. You can use a model configuration parameter to specify the default data type as `single`.

Explore Example Model

Open the example model rtwdemo_underspecified_datatype.

```
model = 'rtwdemo_underspecified_datatype';
open_system(model);
```



The root inports `In2`, `In3`, and `In4` specify `Inherit: Auto` for the **Data type** block parameter. The downstream blocks also use inherited data types.

Generate Code with `double` as Default Data Type

The model starts with the configuration parameter **System target file** set to `ert.tlc`, which requires Embedded Coder. Set **System target file** to `grt.tlc` instead.

```
set_param(model,'SystemTargetFile','grt.tlc')
```

Generate code from the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the `double` data type to define the variables `In2`, `In3`, and `In4` because the Inport data types are underspecified in the model.

```
cfile = fullfile('rtwdemo_underspecified_datatype_grt_rtw',...
    'rtwdemo_underspecified_datatype.h');
rtwdemodbtype(cfile,...
    '/* External inputs (root inport signals with auto storage) */',...
    '/* External outputs (root outports fed by signals with auto storage) */', 1, 0);
```

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  int8_T In1;                          /* '<Root>/In1' */
  real_T In2;                          /* '<Root>/In2' */
  real_T In3;                          /* '<Root>/In3' */
  real_T In4;                          /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

Generate Code with `single` as Default Data Type

Open the Configuration Parameters dialog box. On the **Optimization** pane, select `single` in the **Default for underspecified data type** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'DefaultUnderspecifiedDataType', 'single');
```

Generate code from the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the `single` data type to define the variables `In2`, `In3`, and `In4`.

```
rtwdemodbtype(cfile,...
    '/* External inputs (root inport signals with auto storage) */',...
    '/* External outputs (root outports fed by signals with auto storage) */', 1, 0);
```

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
```

```
  int8_T In1;                          /* '<Root>/In1' */
  real32_T In2;                        /* '<Root>/In2' */
  real32_T In3;                        /* '<Root>/In3' */
  real32_T In4;                        /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

Block Parameter Representation in the Generated Code

Blocks have numeric parameters that determine how they calculate output values. For example, a Gain block has a **Gain** parameter. A Discrete Transfer Fcn has multiple parameters that represent the coefficients.

When you generate code from a model, block parameters can appear in the code as inlined numbers, formal parameters of functions, or global variables. Control parameter representation so that you can tune parameter values during algorithm execution, integrate the generated code with your handwritten code, and improve execution of the generated code.

For information about setting block parameter values in a model, see "Set Block Parameter Values" (Simulink).

Default Parameter Representation

You can control whether, by default, block parameters appear in the generated code as:

- Tunable fields of a global structure that contains parameter data. For example, if the value of the **Gain** parameter of a Gain block is `5.2`, the generated code algorithm can appear as `input = myModel_P.myGainBlock_Gain * output;` where the field `myModel_P.myGainBlock_Gain` is initialized to `5.2`.

  Use this configuration to enable you to change parameter data during execution for experimentation and rapid prototyping.
- Inlined numeric constants whose values you cannot change during execution. For example, the generated code algorithm can appear as `input = 5.2 * output;`.

  Use this configuration to optimize the generated code for production. See "Inline Numeric Values of Block Parameters" on page 53-43.

Configure Parameters as Tunable by Default

When you set **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** (see "Default parameter behavior" (Simulink)) to `Tunable` (the default when you use a GRT-based system target file such as `grt.tlc`), the generated code allocates memory to represent block parameters. Therefore, you can tune the block parameter values during code execution.

If you use numeric expressions, such as `3.57` or `5/2`, to specify block parameter values in the model, each block parameter appears in the generated code as a tunable field of the global parameters structure (for example, *`model`*`_P`). The code generator initializes each field by using the corresponding block parameter value from the model.

Workspace variables are variables that you use to specify block parameter values in a model. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary.

When you set **Default parameter behavior** to `Tunable`, workspace variables that use the storage class `Auto` appear in the generated code as tunable fields of the global parameters structure. If you use such a variable to specify multiple block parameter values, the variable appears as a single field of the global parameters structure. The code does not create multiple fields to represent the block parameters. Therefore, tuning the field value during code execution changes the mathematical behavior of the model in the same way as tuning the value of the MATLAB variable or parameter object during simulation.

For more information about the default global structures in the generated code that store signal, state, and parameter data, see "Default Data Structures in the Generated Code" on page 19-16.

To configure block parameter tunability for rapid prototyping, see "Configure Block Parameter Tunability for Rapid Prototyping" on page 19-56.

Configure Parameters as Inlined by Default

When you set **Default parameter behavior** to `Inlined` (the default when you use an ERT-based system target file such as `ert.tlc`), the generated code algorithm inlines the numeric values of block parameters. Therefore, you cannot tune the block parameters during code execution. Workspace variables that use the storage class `Auto`, such as numeric MATLAB variables, also appear in the generated code as inlined constants.

However, the code cannot represent some parameters, such as arrays, as inlined constants. These parameters appear as fields of a global structure that contains constant-valued, nontunable parameters. The structure uses the `const` type qualifier.

The code generator pools equivalent parameter values into a single field of the `const` structure instead of creating multiple fields. For example, if two Gain blocks use the nonscalar value `[2 5 7]` for the value of the **Gain** parameter, the code generator creates

a single structure field to store that value, and shares the field between the lines of code for each block. This pooling reduces the memory consumption of the structure and facilitates code reuse (see "Shared Constant Parameters for Code Reuse" on page 3-24).

If you have an Embedded Coder license, you can generate scalar inlined parameters as macros instead of literal numbers to improve code readability. See "Generate scalar inlined parameters as" (Simulink Coder).

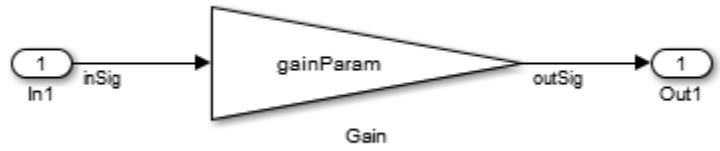
Override Default Parameter Behavior by Creating Global Variables in the Generated Code

You can control the code generated for a block parameter by applying a *storage class* or custom storage class to a `Simulink.Parameter` object. Use the parameter object to set the value of one or more block parameters in a model. By using this technique, you override the setting of **Default parameter behavior** for individual block parameters. For example, you can use this technique to import or export the corresponding generated variable to or from the generated code.

Choose from these built-in storage classes:

- `Auto`: The default storage class. Control the parameter tunability in the generated code by setting the model configuration parameter **Default parameter behavior**.
- `SimulinkGlobal`: Store the parameter object as a field of the generated global parameters structure, *`model`*`_P`, as if you set **Default parameter behavior** to `Tunable`. You can tune the parameter during code execution.
- `ExportedGlobal`: Export the declaration and definition of the parameter from the generated code as an individual global variable. You can tune the variable value during execution and use it in your custom code.
- `ImportedExtern`: Import the definition of the parameter from your custom code.
- `ImportedExternPointer`: Import a pointer to the parameter from your custom code.

For each of the storage classes, the table shows the declaration and the code generated for the workspace variable, `gainParam`, in the example model, `param_examp`. The numeric value of `gainParam` is `15.23`.



Storage Class	Declaration	Definition	Algorithmic Code
`Auto` (with **Default parameter behavior** set to `Inlined`)	None, because the parameter is inlined	None, because the parameter is inlined	`outSig = 15.23 * inSig;`

`SimulinkGl`	In *`model`*`.h`
	`struct P_param_examp_T_ {`
	`  real_T gainParam;`
	`};`
	`extern P_param_examp_T param_exa`
		In *`model`*`_data.c`
		`P_param_examp_T param_examp_P =`
		`  15.23`
		`};`
			`outSig =`
			` param_examp_P.gainParam *`
			` inSig;`

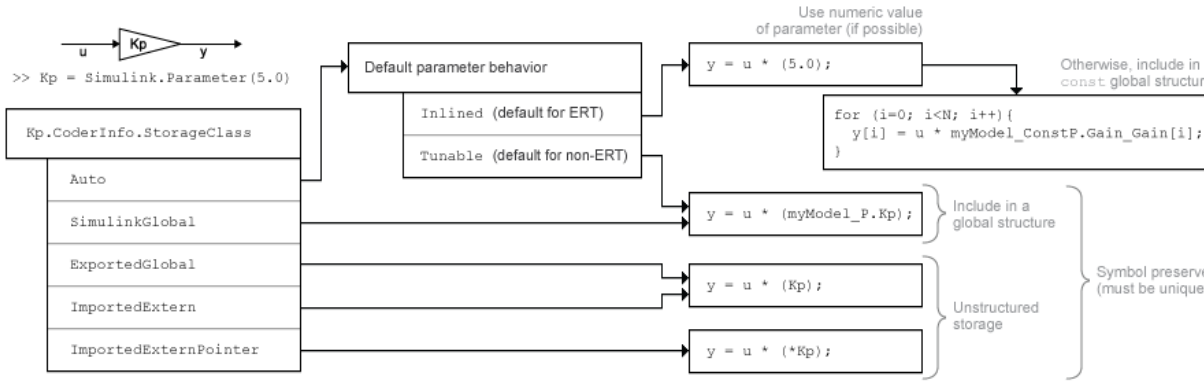
`ExportedGl`	In *`model`*`.h` `extern real_T gainParam;`	In *`model`*`.c` `real_T gainParam = 15.23;`	`outSig =` ` gainParam * inSig;`
`ImportedEx`	In *`model`*`_private.h` `extern real_T gainParam;`	None, because the parameter is imported	`outSig =` `  gainParam * inSig;`
`ImportedEx`	In *`model`*`_private.h` `extern real_T *gainParam;`	None, because the parameter is imported	`outSig =` `  *gainParam * inSig;`

For an example of how to use a storage class to control the code generated for a block parameter, see “Create Tunable Calibration Parameter in the Generated Code” on page 19-60.

If you have an Embedded Coder license, you can use and create custom storage classes for greater control over parameter representation. See “Introduction to Custom Storage Classes” on page 23-2.

Parameter Object Configuration Quick Reference Diagram

This diagram shows the code generation and storage class options that control the representation of parameter objects in the generated code.



Preservation of Expressions

You can specify block parameter values as expressions that use `Simulink.Parameter` objects or workspace variables. For example, you can use the expression `5 * gainParam`. See "Use MATLAB Functions and Custom Functions" (Simulink).

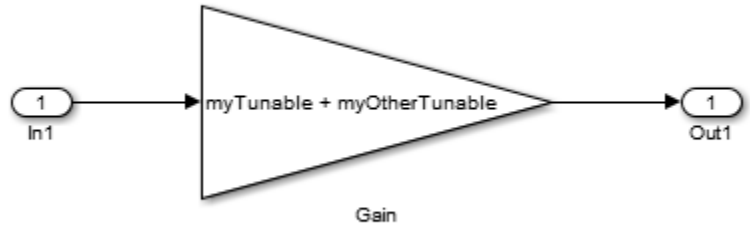
A *tunable workspace variable* is a `Simulink.Parameter` object or workspace variable that appears tunable in the generated code. For example, an object or variable is tunable if you apply a storage class other than `Auto` or if you set **Default parameter behavior** to `Tunable`.

An expression that contains one or more tunable workspace variables, model arguments, or tunable mask parameters is called a *tunable expression*. The expression is tunable because the code generator attempts to preserve the expression in the code. Because the code generator preserves the expression, you can change the values of the parameter data during code execution.

Expression with Tunable Parameter Objects

This example shows how the code generator preserves an expression that you use to set the value of a block parameter.

Consider the model `ex_tunable_expressions`.



The variables `myTunable` and `myOtherTunable` are `Simulink.Parameter` objects that use these property values.

Parameter Object Name	`StorageClass` Property	`Value` Property
`myTunable`	`ExportedGlobal`	`0.75`
`myOtherTunable`	`ExportedGlobal`	`2.0`

The generated code represents the tunable parameter objects `myTunable` and `myOtherTunable` as individual global variables. The algorithm preserves the expression `myTunable + myOtherTunable`.

```
ex_tunable_expressions_Y.Out1 = (myTunable + myOtherTunable) *
ex_tunable_expressions_U.In1;
```

Loss of Parameter Tunability

A block parameter, MATLAB variable, or `Simulink.Parameter` object is tunable if it appears in the generated code as data stored in memory, such as a global variable. For example, when you apply the storage class `ExportedGlobal` to a parameter object, the parameter object appears tunable in the generated code. When you set **Default parameter behavior** to `Tunable`, MATLAB variables and parameter objects appear tunable in the generated code. By definition, model arguments also appear tunable.

Under certain conditions, the code generator cannot maintain tunability of a parameter, variable, object, or expression. In this case, the code generator inlines the numeric value, preventing you from changing the value during code execution.

To detect these conditions in your model, set the model configuration parameter **Detect loss of tunability** (see "Detect loss of tunability" (Simulink)) to `warning` or `error`.

Tunable Expression Limitations

The code generator reduces certain expressions to an inlined numeric value in the generated code. For example, in "Expression with Tunable Parameter Objects" on page 19-51, you used the expression `myTunable + myOtherTunable` to set the value of a block parameter. If you instead use the expression `myTunable ^ myOtherTunable`, the code generator:

1. Evaluates the numeric value of the expression by using the values of the parameter objects. In this case, the expression value is $\text{myTunable}^{\text{myOtherTunable}} = 0.75^{2.0} = 0.5625$.
2. Inlines the expression value in the generated code algorithm. In this case, the calculation appears in the code as `ex_tunable_expressions_Y.Out1 = 0.5625 * ex_tunable_expressions_U.In1;`.

The code generator removes the tunability of `myTunable` and `myOtherTunable`.

To avoid loss of tunability due to unsupported expressions, observe these guidelines:

- Expressions involving complex (`i`) workspace variables or parameter objects are not supported.
- Certain operators and functions cause the code generator to reduce expressions and remove tunability. To determine whether an operator or function causes loss of tunability, use the information in this table.

Category	Operators or Functions
1	`+ - .* ./ < > <= >= == ~= & |`
2	`* /`
3	`abs`, `acos`, `asin`, `atan`, `atan2`, `boolean`, `ceil`, `cos`, `cosh`, `exp`, `floor`, `log`, `log10`, `sign`, `sin`, `sinh`, `sqrt`, `tan`, `tanh`, `single`, `int8`, `int16`, `int32`, `uint8`, `uint16`, `uint32`
4	`: .^ ^ [] {} . \ .\ ' .' , ;`

  - Use operators from category 1 without loss of tunability.
  - Use operators from category 2 in expressions as long as at least one operand is a scalar. For example, scalar/scalar and scalar/matrix operand combinations are supported, but matrix/matrix combinations are not supported.

    - You can use tunable workspace variables as arguments for the functions in category 3. If you use other functions, the code generator removes the tunability of the arguments.
    - The operators in category 4 are not supported.
- The Fcn and If blocks do not support tunable expressions for code generation or in referenced models.
- You can specify any data type for the `Simulink.Parameter` objects or workspace variables that makeup expressions. As long as the data type of these variables and objects and the data type of the corresponding block parameters are the same or `double`, the code generator can preserve tunability.

Linear Block Parameter Tunability

These blocks have a `Realization` parameter that affects the tunability of their numeric parameters:

- Transfer Fcn
- State-Space
- Discrete State-Space

To set the `Realization` parameter, you must use the command prompt:

```
set_param(gcb,'Realization','auto')
```

For the `Realization` parameter, you can choose these options:

- `general`: The block's numeric parameters appear tunable in the generated code.
- `sparse`: The generated code represents the block's parameters as transformed values that increase efficiency. The parameters are not tunable.
- `auto`: The default. If one or more of the block's parameters are tunable (for example, because you use a tunable parameter object to set a parameter value), then the block uses the `general` realization. Otherwise, the block uses the `sparse` realization.

  To tune the parameter values of one of these blocks during an external mode simulation, the block must use the `general` realization.

Configure Block Parameter Tunability for Rapid Prototyping

As you iteratively develop a model, to experiment with block parameter values (for example, the **Gain** parameter of a Gain block), you can *tune* the values during simulation or execution of the generated code. You can then observe the effect on signal values, and base your design decisions on analysis of these outputs. To access parameter data, you can configure the generated code to store the data in addressable global memory.

Optimization settings can make the generated code more efficient by inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for parameters, you can disable the optimizations for all block parameters. Regardless of the settings that you use for the optimizations, you can also specify code generation settings for individual block parameters.

Goal	Considerations and More Information
Configure parameters as tunable by default	To prevent block parameter inlining in the generated code, and instead store parameter values in global memory, set the model configuration parameter **Default parameter behavior** to `Tunable`. Each block parameter appears in the generated code as a field of a global structure. For more information about **Default parameter behavior**, see "Default parameter behavior" (Simulink). For an example, see "Access Signal, State, and Parameter Data During Execution" (Simulink Coder).
Create separate global variables	When you set **Default parameter behavior** to `Tunable`, block parameters appear in the generated code as fields of a structure whose name you cannot explicitly specify. To instead store parameter data in separate global variables whose names, file placement, and other characteristics you can control, apply storage classes to `Simulink.Parameter` objects. See "Create Tunable Calibration Parameter in the Generated Code" on page 19-60.
Tune parameters during external mode simulation	When you generate code and an external executable from a model, you can simulate the model in external mode to communicate with the running executable. You can tune parameters and monitor signals during the simulation. However, in this simulation mode, tunability limitations that apply to code generation also apply to the simulation. For information about the code generation limitations, see "Loss of Parameter Tunability" on page 19-52.

Goal	Considerations and More Information
	For information about external mode, see "Set Up and Use Host/ Target Communication Channel" (Simulink Coder).
Tune parameters with Simulink Real-Time	If you have Simulink Real-Time, you can tune parameters and monitor signals during execution of your real-time application. Make parameters observable by using storage classes and the model configuration parameter **Default parameter behavior**. See "Tunable Block Parameters and MATLAB Variables" (Simulink Real-Time).

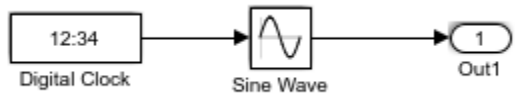
Tune Phase Parameter of Sine Wave Block During Code Execution

Under certain conditions, you cannot configure the **Phase** parameter of a Sine Wave block to appear in the generated code as a tunable global variable (for more information, see the block reference page). This example shows how to generate code so that you can tune the phase during execution.

Create the model `ex_phase_tunable`:

```
open_system('ex_phase_tunable')
```



Set **Default parameter behavior** to `Tunable` so that the parameters of the Sine Wave block appear in the generated code as tunable fields of the global parameter structure.

```
set_param('ex_phase_tunable','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('ex_phase_tunable')
```

```
### Starting build procedure for model: ex_phase_tunable
### Successful completion of code generation for model: ex_phase_tunable
```

In the code generation report, view the file `ex_phase_tunable.c`. The code algorithm in the model `step` function calculates the Sine Wave block output. The parameters of the block, including **Phase**, appear in the code as tunable structure fields.

```
file = fullfile('ex_phase_tunable_grt_rtw','ex_phase_tunable.c');
rtwdemodbtype(file,'/* Outport: ''<Root>/Out1'' incorporates:',...
    'ex_phase_tunable_P.SineWave_Bias;',1,1)
```

```
  /* Outport: '<Root>/Out1' incorporates:
   *  DigitalClock: '<Root>/Digital Clock'
   *  Sin: '<Root>/Sine Wave'
   */
  ex_phase_tunable_Y.Out1 = sin(ex_phase_tunable_P.SineWave_Freq *
    (((ex_phase_tunable_M->Timing.clockTick1+
```

```
   ex_phase_tunable_M->Timing.clockTickH1* 4294967296.0)) * 1.0) +
ex_phase_tunable_P.SineWave_Phase) * ex_phase_tunable_P.SineWave_Amp +
ex_phase_tunable_P.SineWave_Bias;
```

During code execution, you can assign new values to the structure field that corresponds to the **Phase** parameter.

Create Tunable Calibration Parameter in the Generated Code

A *calibration parameter* is a value stored in global memory that an algorithm reads for use in calculations but does not write to. Calibration parameters are *tunable* because you can change the stored value during algorithm execution. You create calibration parameters so that you can:

- Determine an optimal parameter value by tuning the parameter and monitoring signal values during execution.
- Efficiently adapt an algorithm to different execution conditions by overwriting the parameter value stored in memory. For example, you can use the same control algorithm for multiple vehicles of different masses by storing different parameter values in each vehicle's engine control unit.

In Simulink, create a `Simulink.Parameter` object to represent a calibration parameter. You use the parameter object to set block parameter values, such as the **Gain** parameter of a Gain block. To control the representation of the parameter object in the generated code, you apply a storage class or custom storage class to the object.

To make block parameters accessible in the generated code by default, for example for rapid prototyping, set **Default parameter behavior** (see "Default parameter behavior" (Simulink)) to `Tunable`. See "Configure Block Parameter Tunability for Rapid Prototyping" on page 19-56.

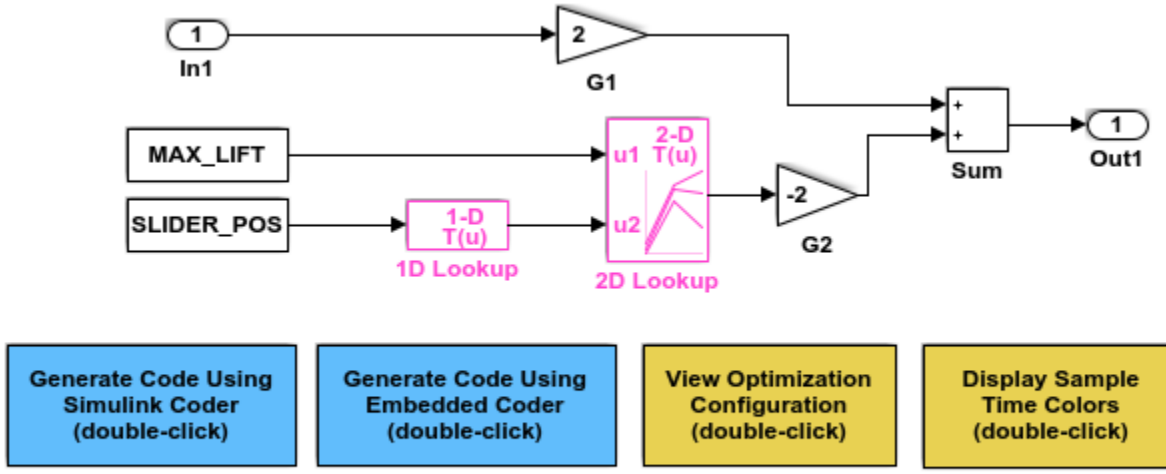
Represent Block Parameter as Tunable Global Variable

This example shows how to create tunable parameter data by representing a block parameter as a global variable in the generated code.

Configure Block Parameter by Using Parameter Object

Open the example model rtwdemo_paraminline.

```
rtwdemo_paraminline
```



In the G1 block dialog box, change **Gain** from `2` to `myGainParam`. Click **Apply**.

Click the action button next to the **Gain** parameter value. Select **Create Variable**.

In the Create New Data block dialog box, set **Value** to `Simulink.Parameter(2)`. Click **Create**. A `Simulink.Parameter` object `myGainParam` stores the parameter value, `2`, in the base workspace.

In the myGainParam dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. This storage class causes the parameter object to appear in the generated code as a tunable global variable.

Alternatively, to create the parameter object and configure the model, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G1','Gain','myGainParam')
myGainParam = Simulink.Parameter(2);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated file `rtwdemo_paraminline.h` contains an `extern` declaration of the global variable `myGainParam`. You can include (`#include`) this header file so that your code can read and write the value of the variable during execution.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.h');
rtwdemodbtype(file,'extern real_T myGainParam;','extern real_T myGainParam;',1,1)

extern real_T myGainParam;             /* Variable: myGainParam
```

The file `rtwdemo_paraminline.c` allocates memory for and initializes `myGainParam`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,'/* Exported block parameters */','real_T myGainParam = 2.0;',1,1)

/* Exported block parameters */
real_T myGainParam = 2.0;              /* Variable: myGainParam
```

The generated code algorithm in the model `step` function uses `myGainParam` for calculations.

```
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)

/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/G1'
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = myGainParam * rtwdemo_paraminline_U.In1 + 150.0;
}
```

Configure Accessibility of Signal Data

When you tune the value of a parameter during algorithm execution, you monitor or capture output signal values to analyze the effect of the tuning. To represent signals in

the generated code as accessible data, you can use techniques such as test points and storage classes. See “Signal Representation in Generated Code” on page 19-112.

Programmatic Interfaces for Tuning Parameters

You can configure the generated code to include:

- A C application programming interface (API) for tuning parameters independent of external mode. The generated code includes extra code so that you can write your own code to access parameter values. See “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).
- A Target Language Compiler API for tuning parameters independently of external mode. See “Parameter Functions” (Simulink Coder).

Set Tunable Parameter Minimum and Maximum Values

It is a best practice to specify minimum and maximum values for tunable parameters.

You can specify these minimum and maximum values:

- In the block dialog box that uses the parameter object. Use this technique to store the minimum and maximum information in the model.
- By using the properties of a Simulink.Parameter object that you use to set the parameter value. Use this technique to store the minimum and maximum information outside the model.

For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).

Considerations for Other Modeling Goals

Goal	Considerations and More Information
Apply storage type qualifiers such as `const` and `volatile`	The storage type qualifier `const` can protect the integrity of parameter data and enable compilers to optimize machine code. If necessary, you can also use `volatile` to prevent compilers from eliminating storage for parameter data. If you have Embedded Coder, to generate storage type qualifiers, use custom storage classes. See “Type Qualifiers” on page 13-15.

Goal	Considerations and More Information
Generate ASAP2 description	You can generate an `a2l` file that uses the ASAP2 standard to describe your calibration parameters. For more information, see "Define ASAP2 Information for Parameters and Signals" on page 44-3.
Generate AUTOSAR (`arxml`) description	If you have an Embedded Coder license, you can generate an `arxml` file that describes calibration parameters used by models that you configure for the AUTOSAR standard. See "Model AUTOSAR Calibration Parameters and Lookup Tables".
Store lookup table data for calibration	To store lookup table data for calibration according to the ASAP2 or AUTOSAR standards (for example, STD_AXIS, COM_AXIS, or CURVE), you can use `Simulink.LookupTable` and `Simulink.Breakpoint` objects in lookup table blocks. However, some limitations apply. See Simulink.LookupTable. To work around the limitations of `Simulink.LookupTable` and `Simulink.Breakpoint` objects, use `Simulink.Parameter` and `AUTOSAR.Parameter` objects instead. See "Define ASAP2 Information for Parameters and Signals" on page 44-3 and "Configure STD_AXIS and COM_AXIS Lookup Tables for AUTOSAR Measurement and Calibration".
Use pragmas to store parameter data in specific memory locations	If you have an Embedded Coder license, to generate code that includes custom pragmas, use custom storage classes and memory sections. See "Control Data and Function Placement in Memory by Inserting Pragmas" on page 27-2.

Specify Instance-Specific Parameter Values for Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

When you generate code from a model hierarchy that uses model arguments, the arguments appear in the code as formal parameters of the referenced model entry-point functions, such as the output (`step`) function. The generated code then passes the instance-specific parameter values, which you specify in each Model block, to the corresponding function calls.

Whether you use or don't use model arguments, you can use storage classes to configure block parameters to appear in the generated code as tunable global variables. You can also use storage classes to generate tunable model argument values, which the generated code stores in memory and passes to the function calls. You can then change the values during execution.

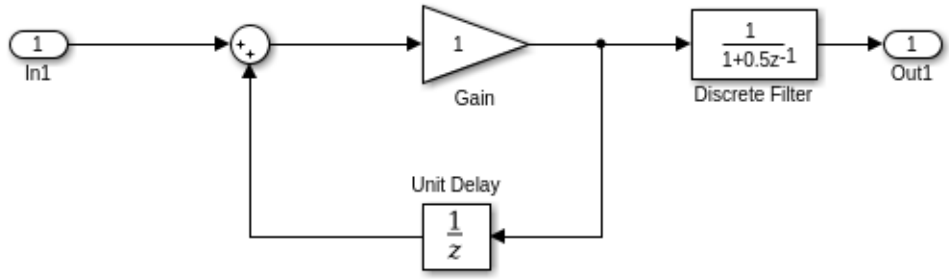
Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments

Configure a referenced model to accept parameter data through formal parameters of the generated model entry-point function. This technique enables you to specify a different parameter value for each instance (Model block) of the referenced model.

Configure Referenced Model to Use Model Arguments

Create the model `ex_arg_code_ref`. This model represents a reusable algorithm.

```
open_system('ex_arg_code_ref')
```



In the Inport block dialog box, on the **Signal Attributes** tab, set **Data type** to `single`. Due to data type inheritance, the other signals in the model use the same data type.

```
set_param('ex_arg_code_ref/In1','OutDataTypeStr','single')
```

In the Model Explorer **Model Hierarchy** pane, expand the node **ex_arg_code_ref** and select **Model Workspace**.

Select **Add > Simulink Parameter** twice. Two `Simulink.Parameter` objects appear in the **Contents** pane.

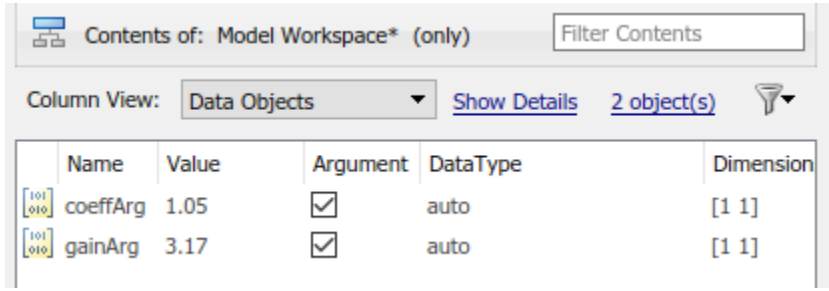
Rename the objects as `gainArg` and `coeffArg`.

Set the `Value` property of the objects. For example, set them to `3.17` and `1.05`, respectively.

```
modelWorkspace = get_param('ex_arg_code_ref','ModelWorkspace');
assignin(modelWorkspace,'gainArg',Simulink.Parameter(3.17));
assignin(modelWorkspace,'coeffArg',Simulink.Parameter(1.05));
```

In the **Contents** pane, for `coeffArg` and `gainArg`, select the check box in the **Argument** column.

```
set_param('ex_arg_code_ref','ParameterArgumentNames','coeffArg,gainArg')
```



In the `ex_arg_code_ref` model, in the Gain block dialog box, set **Gain** to `gainArg`.

```
set_param('ex_arg_code_ref/Gain','Gain','gainArg')
```

In the Discrete Filter block dialog box, set **Numerator** to `coeffArg`.

```
set_param('ex_arg_code_ref/Discrete Filter','Numerator','coeffArg')
```

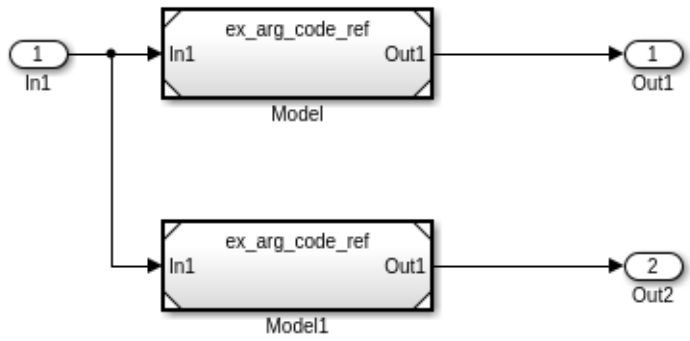
Save the `ex_arg_code_ref` model.

```
save_system('ex_arg_code_ref')
```

Specify Instance-Specific Parameter Values in Model Blocks

Create the model `ex_arg_code_ref`. This model uses multiple instances (Model blocks) of the reusable algorithm.

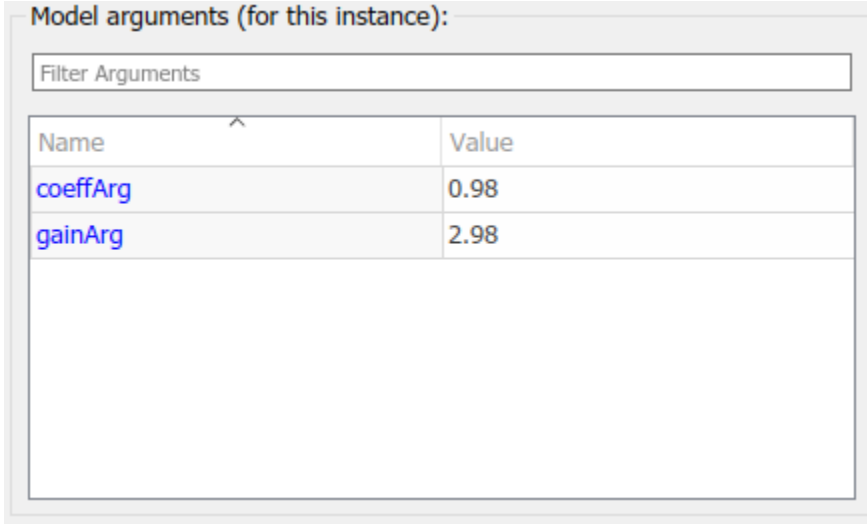
```
open_system('ex_arg_code')
```



Open the upper Model block dialog box.

Under **Model arguments**, set **coeffArg** and **gainArg** to `0.98` and `2.98`.

```
set_param('ex_arg_code/Model','ParameterArgumentValues',...
    struct('coeffArg','0.98','gainArg','2.98'))
```



In the other Model block dialog box, set **coeffArg** and **gainArg** to `1.11` and `3.34`.

```
set_param('ex_arg_code/Model1','ParameterArgumentValues',...
    struct('coeffArg','1.11','gainArg','3.34'))
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_ref.c` defines the referenced model entry-point function, `ex_arg_code_ref`. The function has two formal parameters, `rtp_coeffArg` and `rtp_gainArg`, that correspond to the model arguments, `coeffArg` and `gainArg`. The formal parameters use the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
/* Output and update for referenced model: 'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1, real32_T *rty_Out1,
```

```
                    DW_ex_arg_code_ref_f_T *localDW, real32_T rtp_coeffArg,
                    real32_T rtp_gainArg)
```

The file `ex_arg_code.c` contains the definition of the top model entry-point function, `ex_arg_code`. This function calls the referenced model entry-point function, `ex_arg_code_ref`, and uses the model argument values that you specified (such as `1.11` and `3.34`) as the values of `rtp_coeffArg` and `rtp_gainArg`.

```
/* ModelReference: '<Root>/Model' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                &(ex_arg_code_DW.Model_DWORK1.rtdw), 0.98F, 2.98F);

/* ModelReference: '<Root>/Model1' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_DWORK1.rtdw), 1.11F, 3.34F);
```

The formal parameters use the data type `real32_T` (`single`) because:

1. The block parameters in `ex_arg_code_ref` determine their data types through internal rules. For example, in the Gain block dialog box, on the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default). In this case, the internal rule chooses the same data type as the input and output signals, `single`.
2. The model arguments in the model workspace use context-sensitive data typing because the value of the `DataType` property is set to `auto` (the default). With this setting, the model arguments use the same data type as the block parameters, `single`.
3. The formal parameters in the generated code use the same data type as the model arguments, `single`.

Generate Tunable Argument Values

You can configure the instance-specific values in the Model blocks to appear in the generated code as tunable global variables. This technique enables you to store the parameter values for each instance in memory and to tune the values during code execution.

View the contents of the `ex_arg_code_ref` model workspace in Model Explorer.

Copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace to the base workspace.

Rename `gainArg` as `gainForInst1`. Rename `coeffArg` as `coeffForInst1`.

```
gainForInst1 = getVariable(modelWorkspace,'gainArg');
gainForInst1 = copy(gainForInst1);
coeffForInst1 = getVariable(modelWorkspace,'coeffArg');
coeffForInst1 = copy(coeffForInst1);
```

Copy `gainForInst1` and `coeffForInst1` as `gainForInst2` and `coeffForInst2`.

```
gainForInst2 = copy(gainForInst1);
coeffForInst2 = copy(coeffForInst1);
```

Set the instance-specific parameter values by using the `Value` property of the parameter objects in the base workspace.

```
gainForInst1.Value = 2.98;
coeffForInst1.Value = 0.98;

gainForInst2.Value = 3.34;
coeffForInst2.Value = 1.11;
```

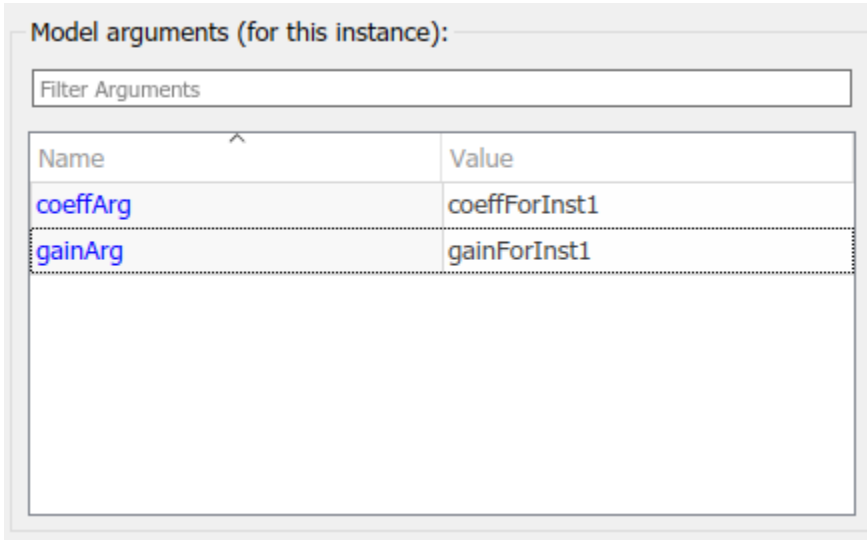
For the new parameter objects, set `StorageClass` to `ExportedGlobal`. This setting causes the parameter objects to appear in the generated code as tunable global variables.

```
gainForInst1.StorageClass = 'ExportedGlobal';
coeffForInst1.StorageClass = 'ExportedGlobal';
gainForInst2.StorageClass = 'ExportedGlobal';
coeffForInst2.StorageClass = 'ExportedGlobal';
```

In the top model, `ex_arg_code`, open the upper Model block dialog box.

Set **coeffArg** to `coeffForInst1` and **gainArg** to `gainForInst1`.

```
set_param('ex_arg_code/Model','ParameterArgumentValues',...
    struct('coeffArg','coeffForInst1','gainArg','gainForInst1'))
```



In the other Model block dialog box, set **coeffArg** to `coeffForInst2` and **gainArg** to `gainForInst2`.

```
set_param('ex_arg_code/Model1','ParameterArgumentValues',...
    struct('coeffArg','coeffForInst2','gainArg','gainForInst2'))
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code.c` defines the global variables that correspond to the parameter objects in the base workspace.

```
/* Exported block parameters */
real32_T coeffForInst1 = 0.98F;        /* Variable: coeffForInst1
                                        * Referenced by: '<Root>/Model'
                                        */
real32_T coeffForInst2 = 1.11F;        /* Variable: coeffForInst2
                                        * Referenced by: '<Root>/Model1'
                                        */
real32_T gainForInst1 = 2.98F;         /* Variable: gainForInst1
                                        * Referenced by: '<Root>/Model'
                                        */
real32_T gainForInst2 = 3.34F;         /* Variable: gainForInst2
                                        * Referenced by: '<Root>/Model1'
```

```
                                                                */
```

In each call to `ex_arg_code_ref`, the top model algorithm uses the global variables to set the values of the formal parameters.

```
/* ModelReference: '<Root>/Model' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                &(ex_arg_code_DW.Model_DWORK1.rtdw), coeffForInst1,
                gainForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_DWORK1.rtdw), coeffForInst2,
                gainForInst2);
```

The global variables in the generated code use the data type `real32_T` (`single`) because:

1. The parameter objects in the base workspace use context-sensitive data typing because the `DataType` property is set to `auto` (the default). With this setting, the parameter objects in the base workspace use the same data type as the model arguments, `single`.
2. The global variables in the generated code use the same data type as the parameter objects in the base workspace.

Group Multiple Model Arguments into Single Structure

Use the Model Explorer to copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace into the base workspace.

```
temp = getVariable(modelWorkspace,'gainArg');
gainArg = copy(temp);
temp = getVariable(modelWorkspace,'coeffArg');
coeffArg = copy(temp);
```

At the command prompt, combine these two parameter objects into a structure, `structArg`.

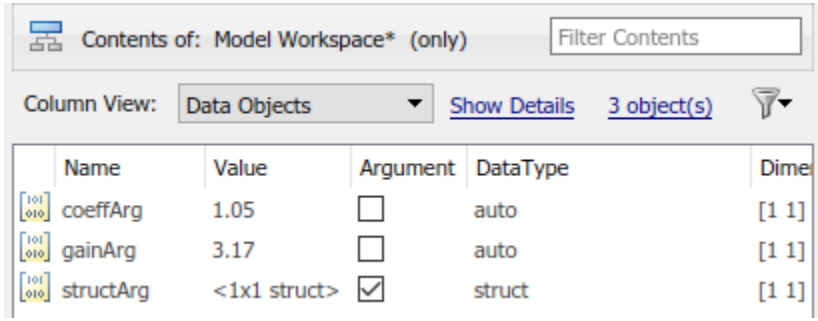
```
structArg = Simulink.Parameter(struct('gain',gainArg.Value,...
    'coeff',coeffArg.Value));
```

Use the Model Explorer to move `structArg` into the model workspace.

```
assignin(modelWorkspace,'structArg',copy(structArg));
clear structArg gainArg coeffArg
```

In the **Contents** pane, configure `structArg` as the only model argument.

```
set_param('ex_arg_code_ref','ParameterArgumentNames','structArg')
```



In the `ex_arg_code_ref` model, set the **Gain** parameter of the Gain block to `structArg.gain`.

```
set_param('ex_arg_code_ref/Gain','Gain','structArg.gain')
```

In the Discrete Filter block dialog box, set **Numerator** to `structArg.coeff`.

```
set_param('ex_arg_code_ref/Discrete Filter',...
    'Numerator','structArg.coeff')
```

At the command prompt, combine the four parameter objects in the base workspace into two structures. Each structure stores the parameter values for one instance of `ex_arg_code_ref`.

```
structForInst1 = Simulink.Parameter(struct('gain',gainForInst1.Value,...
    'coeff',coeffForInst1.Value));

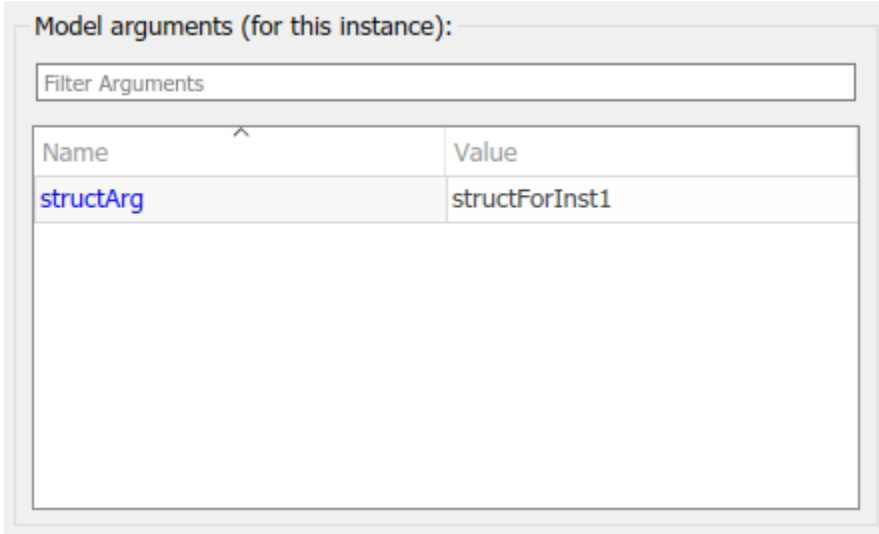
structForInst2 = Simulink.Parameter(struct('gain',gainForInst2.Value,...
    'coeff',coeffForInst2.Value));
```

Apply the storage class `ExportedGlobal` to the parameter objects.

```
structForInst1.StorageClass = 'ExportedGlobal';
structForInst2.StorageClass = 'ExportedGlobal';
```

In the top model, in the upper Model block dialog box, set **structArg** to `structForInst1`.

```
set_param('ex_arg_code/Model','ParameterArgumentValues',...
    struct('structArg','structForInst1'))
```



In the other Model block dialog box, set **structArg** to `structForInst2`.

```
set_param('ex_arg_code/Model1','ParameterArgumentValues',...
    struct('structArg','structForInst2'))
```

Use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

Rename the bus object as `myParamStructType` by copying it.

```
myParamStructType = copy(slBus1);
```

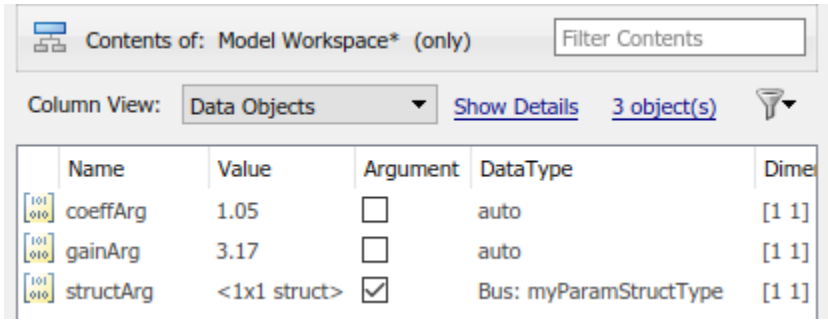
Set the data type of the parameter objects in the base workspace by using the bus object.

```
structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';
```

Use the Model Explorer to view the contents of the `ex_arg_code_ref` model workspace.

For the parameter object `structArg`, set `DataType` to `Bus: myParamStructType`.

```
temp = getVariable(modelWorkspace,'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace,'structArg',copy(temp));
```



Save the `ex_arg_code_ref` model.

```
save_system('ex_arg_code_ref')
```

When you use structures to group parameter values, you cannot take advantage of context-sensitive data typing to control the data types of the fields of the structures (for example, the fields of `structForInst1`). However, you can use the properties of the bus object to control the field data types.

Set the data type of the elements in the bus object to `single`. The corresponding fields in the structures (such as `structForInst1` and `structArg`) use the same data type.

```
myParamStructType.Elements(1).DataType = 'single';
myParamStructType.Elements(2).DataType = 'single';
```

Generate code from the top model, `ex_arg_code`.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_types.h` defines the structure type `myParamStructType`, which corresponds to the `Simulink.Bus` object.

```
typedef struct {
  real32_T gain;
  real32_T coeff;
} myParamStructType;
```

In the file `ex_arg_code_ref.c`, the referenced model entry-point function has a formal parameter, `rtp_structArg`, that correspond to the model argument `structArg`.

```
/* Output and update for referenced model: 'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1, real32_T *rty_Out1,
                     DW_ex_arg_code_ref_f_T *localDW, const myParamStructType
                     *rtp_structArg)
```

The file `ex_arg_code.c` defines the global structure variables that correspond to the parameter objects in the base workspace.

```
/* Exported block parameters */
myParamStructType structForInst1 = {
  2.98F,
  0.98F
} ;                                    /* Variable: structForInst1
                                        * Referenced by: '<Root>/Model'
                                        */

myParamStructType structForInst2 = {
  3.34F,
  1.11F
} ;                                    /* Variable: structForInst2
                                        * Referenced by: '<Root>/Model1'
                                        */
```

The top model algorithm in the file `ex_arg_code.c` passes the addresses of the structure variables to the referenced model entry-point function.

```
  /* ModelReference: '<Root>/Model' incorporates:
   *  Inport: '<Root>/In1'
   *  Outport: '<Root>/Out1'
   */
  ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                  &(ex_arg_code_DW.Model_DWORK1.rtdw), &structForInst1);

  /* ModelReference: '<Root>/Model1' incorporates:
   *  Inport: '<Root>/In1'
   *  Outport: '<Root>/Out2'
   */
```

```
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_DWORK1.rtdw), &structForInst2);
```

Control Data Types of Model Arguments and Argument Values

When you use model arguments, you can apply a data type to:

- The block parameters that use the arguments (for certain blocks, such as those in the Discrete library).
- The arguments in the referenced model workspace.
- The argument values that you specify in Model blocks.

To generate efficient code by eliminating unnecessary typecasts and C shifts, consider using inherited and context-sensitive data typing to match the data types.

- In the model workspace, use a MATLAB variable whose data type is `double` or a parameter object whose `DataType` property is set to `auto`. In this case, the variable or object uses the same data type as the block parameter.
- When you set the argument values in Model blocks, take advantage of context-sensitive data typing. To set an argument value, use an untyped value.

  - A literal number such as `15.23`. Do not use a typed expression such as `single(15.23)`.
  - A MATLAB variable whose data type is `double`.
  - A `Simulink.Parameter` object whose `DataType` property is set to `auto`.

  In these cases, the number, variable, or object uses the same data type as the model argument in the referenced model workspace. If you also configure the model argument to use context-sensitive data typing, you can control the data types of the block parameter, the argument, and the argument value by specifying the type only for the block parameter.

For basic information about controlling parameter data types, see “Parameter Data Types in the Generated Code” on page 19-79.

Use Model Argument in Different Data Type Contexts

If you use a model argument to set multiple block parameter values, and the data types of the block parameters differ, you cannot use context-sensitive data typing (`double` or `auto`) for the argument in the model workspace. You must explicitly specify a data type

for the argument. For example, if the argument in the model workspace is a parameter object (such as `Simulink.Parameter`), set the `DataType` property to a value other than `auto`. For more information about this situation, see “Reuse Parameter Data in Different Data Type Contexts” on page 19-93.

In this case, you can continue to take advantage of context-sensitive data typing to control the data type of the argument values that you specify in Model blocks. Each argument value uses the data type that you specify for the corresponding argument in the model workspace.

Parameter Data Types in the Generated Code

The data type of a block parameter (such as the **Gain** parameter of a Gain block), numeric MATLAB variable, or `Simulink.Parameter` object determines the data type that the corresponding entity in the generated code uses (for example, a global variable or an argument of a function). To generate more efficient code, you can match parameter data types with signal data types or store parameters in smaller data types.

For basic information about setting block parameter data types in a model, see "Control Block Parameter Data Types" (Simulink).

Significance of Parameter Data Types

The data type that a block parameter, MATLAB variable, or parameter object uses determines the data type that the generated code uses to store the parameter value in memory. For example:

- If you set the model configuration parameter **Default parameter behavior** (see "Default parameter behavior" (Simulink)) to `Tunable`, the **Gain** parameter of a Gain block appears in the generated code as a field of a global structure that stores parameter data. If you apply the data type `single` to the block parameter in the model, the structure field uses the corresponding data type (`real32_T`).
- If you apply the storage class `ExportedGlobal` to a `Simulink.Parameter` object, the object appears in the generated code as a separate global variable. If you set the `DataType` property of the object to `int8`, the global variable in the code uses the corresponding data type (`int8_T`).
- If you configure a `Simulink.Parameter` object in a model workspace as a model argument, the object appears in the generated code as a formal parameter of a model entry-point function, such as the `step` function. The `DataType` property of the object determines the data type of the formal parameter.

Other than determining the data type that the generated code uses to store parameter values in memory, the data type of a parameter, variable, or object can also:

- Cause the block to cast the value of the parameter prior to code generation. The cast can result in overflow, underflow, or quantization.
- Cause the generated code to include extra code, for example saturation code.

Parameter Data Type Mismatch

When the data types of block parameters, workspace variables, and signals differ, blocks can use typecasts to reconcile the data type mismatches. These typecasts can cause the generated code algorithm, including the model `step` function, to include explicit casts to reconcile mismatches in storage data type and C bit shifts to reconcile mismatches in fixed-point scaling.

Parameter data type mismatches can occur when:

- The data type that you specify for a MATLAB variable or parameter object (`Simulink.Parameter`) differs from the data type of a block parameter. The block parameter typecasts the value of the variable or object.
- The data type that you specify for an initial value differs from the data type of the initialized signal or state.
- The data type that you specify for a block parameter differs from the data type of the signal or signals that the parameter operates on. Some blocks typecast the parameter to perform the operation. For example, the Gain block performs this typecast.

If you configure a variable or object to use bias or fractional fixed-point slope, the block parameter cannot perform the typecast. In this case, you must match the data type of the variable or parameter object with the data type of the block parameter. Use one of these techniques:

- Use context-sensitive data typing for the variable or parameter object. For a MATLAB variable, use a `double` number to set the value of the variable. For a parameter object, set the `DataType` property to `auto`.
- Use a `Simulink.AliasType` or `Simulink.NumericType` object to set the data type of the block parameter and the data type of a parameter object.

  Use this technique when you cannot rely on context-sensitive data typing, for example, when you use the field of a structure to set the value of the block parameter.
- Manually specify the same data type for the block parameter and the variable or parameter object.

  Use this technique to reduce the dependence of the model on inherited and context-sensitive data types and on external variables and objects.

For blocks that access parameter data through pointer or reference in the generated code, if you specify a different data type of the workspace variable and block parameter, the

generated code implicitly casts the data type of the variable to the data type of the block parameter. Note, that an implicit cast requires a data copy which could significantly increase RAM consumption and slow down code execution speed for large data sets. For example, Lookup Table blocks often access large vectors or matrices through pointer or reference in the generated code.

For information about matching parameter data types when you use model arguments, see “Control Data Types of Model Arguments and Argument Values” on page 19-77.

Detect Downcast and Loss of Precision due to Data Type Mismatches

You can configure diagnostic configuration parameters to detect unintentional data type mismatches that result in quantization and loss of parameter precision. See “Model Configuration Parameters: Data Validity Diagnostics” (Simulink).

Considerations for Other Modeling Patterns

When you use specific modeling patterns and constructs such as fixed-point data types, parameter structures, and lookup table objects, use different techniques to control parameter data types.

Tunable Parameters and Best-Precision Fixed-Point Scaling

To apply best-precision fixed-point scaling to a tunable block parameter or parameter object, you can use the Fixed-Point Tool to autoscale an entire system or use the Data Type Assistant to configure individual parameters or objects. See “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” (Simulink).

If a tunable parameter uses best-precision fixed-point scaling, Simulink chooses a data type based on the minimum and maximum values that you specify for the parameter. You can specify these values in the block dialog box that uses the parameter or in the properties of a Simulink.Parameter object.

If you do not specify a minimum or maximum, Simulink chooses a data type based on the value of the parameter. The chosen scaling might restrict the range of possible tuning values. Therefore, it is a best practice to specify minimum and maximum values for each tunable parameter.

A tunable parameter can use best-precision scaling even if you do not specify it in the parameter data type. For example, the Gain block can choose a best-precision scaling if the **Parameter data type** in the block dialog box is set to `Inherit: Inherit via internal rule`. This setting is the default for the block.

Control Data Types of Structure Fields

When you use a structure as the value of a block parameter (for example to initialize a bus signal), or when you organize multiple block parameter values into a single structure, you can create a `Simulink.Bus` object to use as the data type of a `Simulink.Parameter` object. You can then control the data types of individual fields in the structure. See "Control Field Data Types and Characteristics by Creating Parameter Object" (Simulink) and "Control Data Types of Initial Condition Structure Fields" (Simulink).

Control Data Types of Lookup Table Objects

When you use Simulink.LookupTable and Simulink.Breakpoint objects to store table and breakpoint data for a lookup table block, to control the data types of the table and breakpoint data, use one of these techniques:

- Set the `Value` property of the embedded `Simulink.lookuptable.Table` and `Simulink.lookuptable.Breakpoint` objects by using untyped expressions such as `[1 2 3]`, which returns a `double` vector. To control the data type, set the `DataType` property to a value other than `auto`.

  Use this technique to separate the value of the table or breakpoint data from the data type, which can improve readability and understanding of your design. You can then use a `Simulink.NumericType` or `Simulink.AliasType` object to:

  - Customize the name of the data type in the generated code.
  - Match the data type of the table or breakpoint data with the data type of a signal in the model.
- Set the `Value` property of the embedded objects by using typed expressions such as `single([1 2 3])`. To use a fixed-point data type, set the `Value` property with an `fi` object.

  Set the `DataType` property of the embedded objects to the default value, `auto`. The table and breakpoint data then acquire the data type that you use to set the `Value` property.

Use this technique to store the data type information in the `Value` property, which can simplify the way you interact with the `Simulink.LookupTable` and `Simulink.Breakpoint` objects. You can leave the `DataType` property at the default value.

When you later change the breakpoint or table data in the `Value` property, preserve the data type information by using a typed expression. Alternatively, if you use a command at the command prompt or a script to change the data, to avoid using a typed expression, use subscripted assignment, `(:)`.

```
myLUTObject.Table.Value(:) = [4 5 6];
```

When you change the data stored in the `Value` property, if you do not use a typed expression or subscripted assignment, you lose the data type information.

When blocks in a subsystem use `Simulink.LookupTable` or `Simulink.Breakpoint` objects, you cannot set data type override (see "Control Fixed-Point Instrumentation and Data Type Override" (Simulink)) only on the subsystem. Instead, set data type override on the entire model.

Generate Efficient Code by Specifying Data Types for Block Parameters

To generate more efficient code, match the data types of block parameters (such as the **Gain** parameter of a Gain block) with signal data types. Alternatively, you can store parameters in smaller data types.

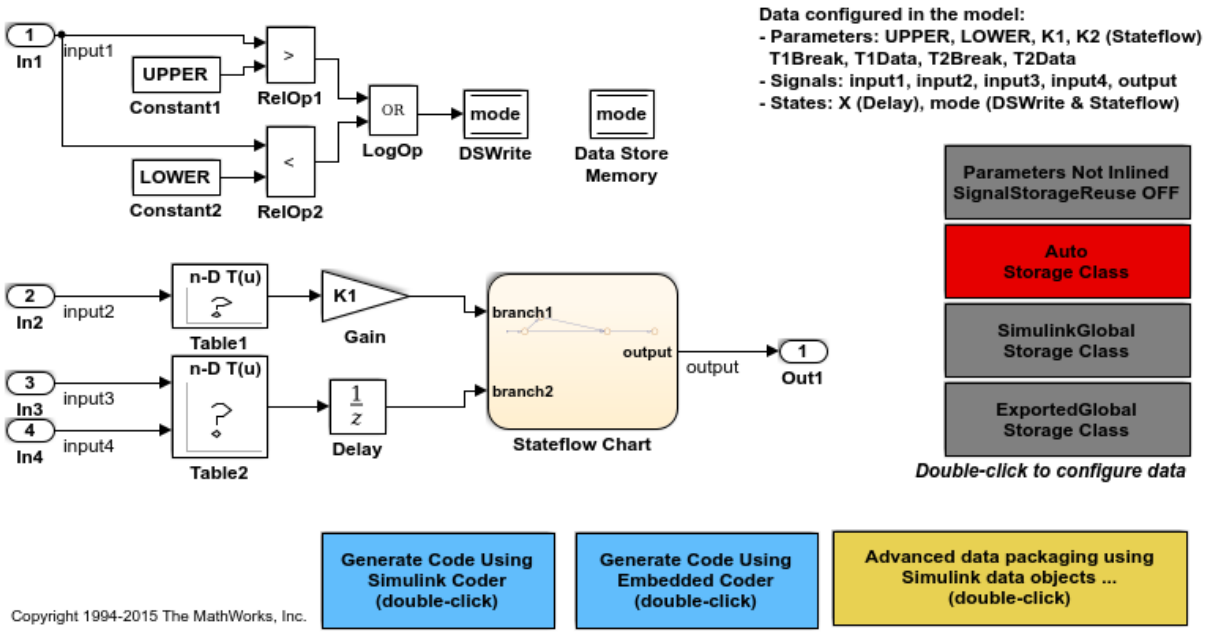
Eliminate Unnecessary Typecasts and Shifts by Matching Data Types

These examples show how to generate efficient code by configuring a block parameter to use the same data type as a signal that the block operates on.

Store Data Type Information in Model

Open the example model `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```



Open the `Gain` block dialog box. The input signal of this block uses the data type `single`.

View the **Parameter Attributes** tab. **Parameter data type** is set to `Inherit: Same as input`. The **Gain** parameter of this block uses the same data type as the input signal.

At the command prompt, convert the numeric variable `K1` to a `Simulink.Parameter` object.

```
K1 = Simulink.Parameter(2);
```

Configure `K1` to appear in the generated code as a global variable by applying the storage class `ExportedGlobal`.

```
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

On the **Main** tab, click the action button next to the value of the **Gain** parameter. Select **Open Variable**. The value of the **Data type** property is `auto`, which means the parameter object acquires its data type from the block parameters that use the object.

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable `K1` by using the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)
```

```
/* Exported block parameters */
real32_T K1 = 2.0F;                    /* Variable: K1
```

The generated code algorithm in the model `step` function uses `K1` directly without typecasting.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X = K1',...
```

```
' rtCP_Table1_bpO1Data, rtCP_Table1_tableData,',1,1)

rtwdemo_basicsc_DW.X = K1 * look1_iflf_binlx(rtwdemo_basicsc_U.input2,
  rtCP_Table1_bpO1Data, rtCP_Table1_tableData, 10U);
```

In the **Gain** block dialog box, on the **Parameter Attributes** tab, you can optionally set **Parameter data type** to `Inherit: Inherit via internal rule` (the default). In this case, the block parameter chooses the same data type as the input signal (`single`). However, when you use `Inherit: Inherit via internal rule`, under other circumstances (for example, when you use fixed-point data types) the block parameter might choose a different data type.

Store Data Type Information in Parameter Object

When you use a `Simulink.Parameter` object to export or import parameter data from the generated code to your custom code, for example by applying the storage class `ImportedExtern`, you can specify data type information in the parameter object. To match the data type of the parameter object with a signal data type, create a `Simulink.NumericType` or `Simulink.AliasType` object. You can strictly control the data type that the parameter object uses in the generated code, eliminating the risk that Simulink chooses a different data type when you make changes to the model.

At the command prompt, create a `Simulink.NumericType` object that represents the data type `single`.

```
myType = Simulink.NumericType;
myType.DataTypeMode = 'Single';
```

Use this data type object as the data type of the parameter object.

```
K1.DataType = 'myType';
```

Use the data type object to set the output data type of the Inport block named `In2`. Due to data type propagation, the input signal of the Gain block also uses this data type.

```
set_param('rtwdemo_basicsc/In2','OutDataTypeStr','myType')
```

In the Gain block dialog box, on the **Parameter Attributes** tab, set **Parameter data type** to `Inherit: Inherit from 'Gain'`.

```
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr','Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The global variable `K1` continues to use the data type `real32_T`.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)

/* Exported block parameters */
real32_T K1 = 2.0F;                    /* Variable: K1
```

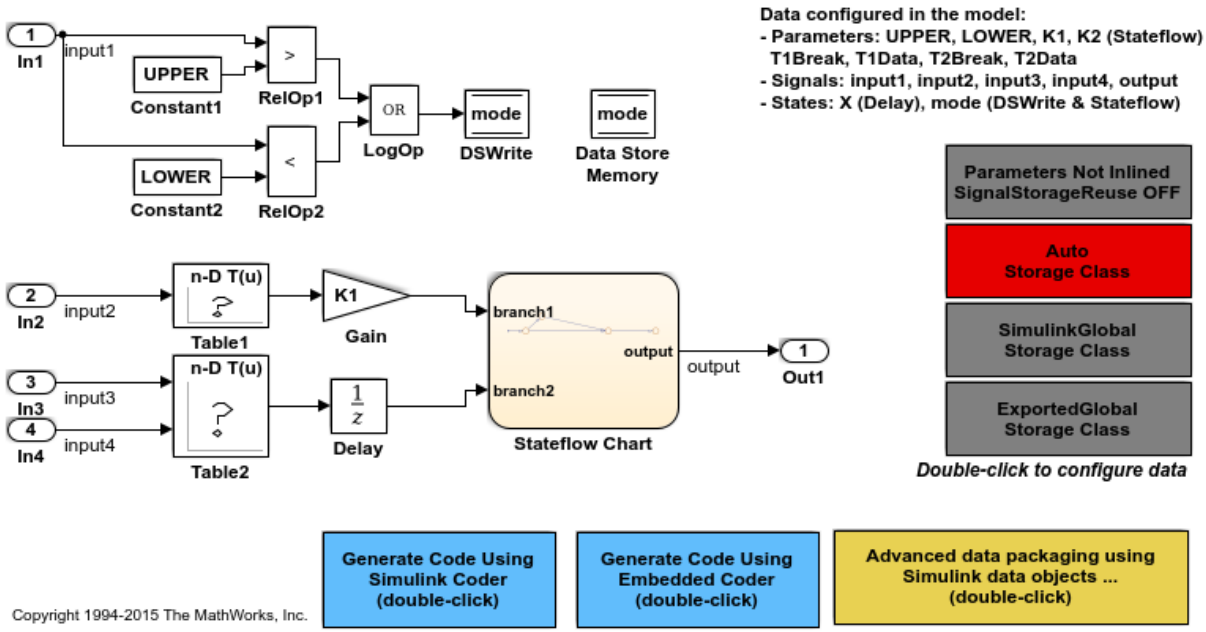
Reduce Memory Consumption by Storing Parameter Value in Small Data Type

When you use a parameter object (for example, `Simulink.Parameter`) to set block parameter values, you can configure the object to appear in the generated code as a tunable global variable. By default, the parameter object and the corresponding global variable typically uses the same data type as the signal or signals on which the block operates. For example, if the input signal of a Gain block uses the data type `int16`, the parameter object typically use the same data type. To reduce the amount of memory that this variable consumes, specify that the variable use a smaller integer data type such as `int8`.

Store Parameter Value in Integer Data Type

Open the example model `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```



In the model, select **Display > Signals and Ports > Port Data Types**. Many of the signals in the model use the data type `single`.

Open the Gain block dialog box. The block uses the MATLAB variable `K1`, which is in the base workspace, to set the value of the **Gain** parameter. The value of the variable is `2`.

At the command prompt, convert `K1` into a `Simulink.Parameter` object. Configure the object to appear in the generated code as a global variable by applying the storage class `ExportedGlobal`.

```
K1 = Simulink.Parameter(2);
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

Configure the parameter object to use the data type `int8`.

```
K1.DataType = 'int8';
```

In the Gain block dialog box, on the **Parameter Attributes** tab, set **Parameter data type** to `Inherit: Inherit from 'Gain'`. With this setting, the **Gain** parameter of the block inherits the `int8` data type from the parameter object.

```
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr',...
    'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable `K1` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T K1 = 2;',1,1)
```

```
/* Exported block parameters */
int8_T K1 = 2;                         /* Variable: K1
```

The code algorithm in the model `step` function uses `K1` to calculate the output of the Gain block. The algorithm casts `K1` to the data type `real32_T` (`single`) because the signals involved in the calculation use the data type `real32_T`.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X =','1OU);',1,1)
```

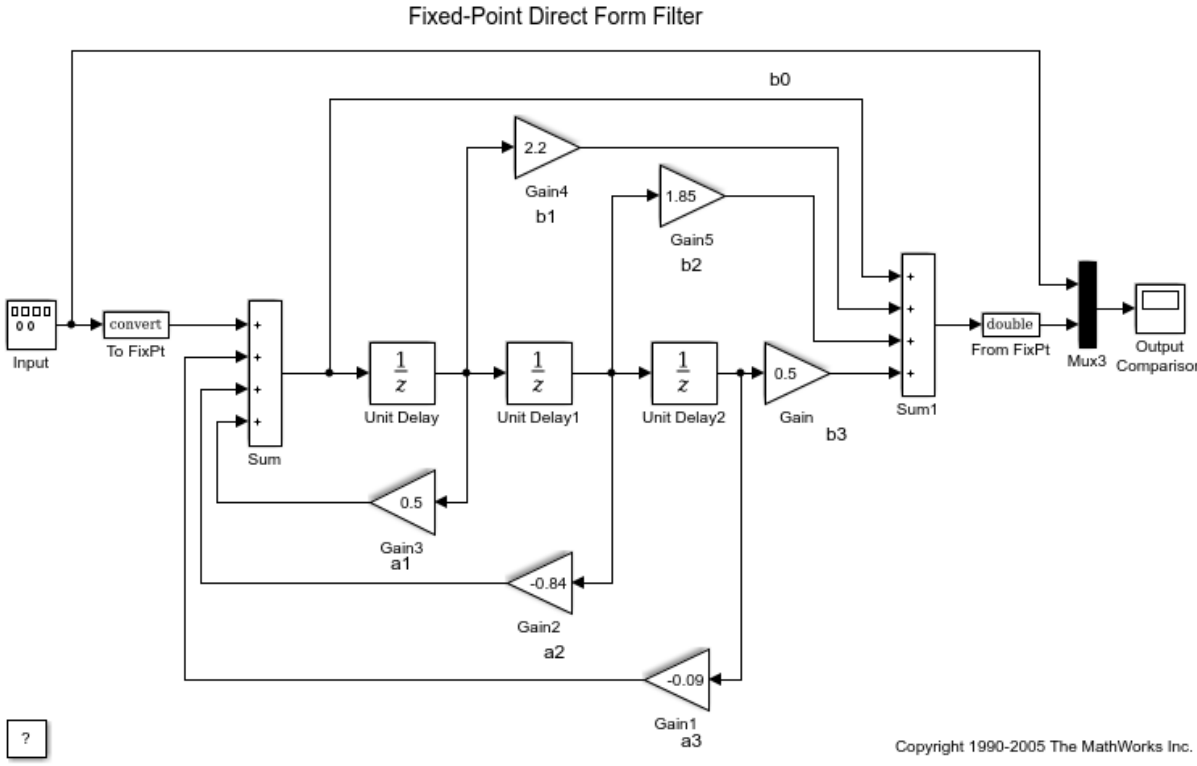
```
    rtwdemo_basicsc_DW.X = (real32_T)K1 * look1_iflf_binlx
      (rtwdemo_basicsc_U.input2, rtCP_Table1_bpOlData, rtCP_Table1_tableData,
       1OU);
```

Store Fixed-Point Parameter Value in Smaller Integer Data Type

Suppose you configure the signals in your model to use fixed-point data types. You want a gain parameter to appear in the generated code as a tunable global variable. You know the range of real-world values that you expect the parameter to assume (for example, between 0 and 4). If you can meet your application requirements despite reduced precision, you can reduce memory consumption by configuring the parameter to use a different data type than the input and output signals of the block.

Open the example model `fxpdemo_direct_form2`.

```
fxpdemo_direct_form2
```



Update the model diagram. Signals in this model use signed fixed-point data types with a word length of 16 and binary-point-only scaling.

Open the Gain5 block dialog box. The **Gain** parameter is set to `1.85`. Suppose you want to configure this parameter.

Set **Gain** to `myGainParam` and click **Apply**.

Click the action button next to the parameter value. Select **Create Variable**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.85)` and click **Create**. The `Simulink.Parameter` object `myGainParam` appears in the base workspace.

In the `myGainParam` property dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. With this setting, `myGainParam` appears in the generated code as a global variable.

In the block dialog box, on the **Parameter Attributes** tab, set **Parameter minimum** to `0` and **Parameter maximum** to `4`.

Set **Parameter data type** to `fixdt(0,8)` and click **Apply**.

Click the **Show Data Type Assistant** button. The Data Type Assistant shows that the expression `fixdt(0,8)` specifies an unsigned fixed-point data type with a word length of 8 and best-precision scaling. When you simulate or generate code, the block parameter chooses a fraction length (scaling) that enables the data type to represent values between the parameter minimum and maximum (0 and 4) with the best possible precision.

In the Data Type Assistant, set **Scaling** to `Binary point`. Click **Calculate Best-Precision Scaling**, **Fixed-point details**, and **Refresh Details**. The information under **Fixed-point details** shows that a fraction length of 5 can represent the parameter values with a precision of 0.03125.

Set **Scaling** back to `Best precision` and click **OK**. In this example, when you simulate or generate code, the block parameter chooses a fraction length of 5.

You can use these commands at the command prompt to create the object and configure the block:

```
myGainParam = Simulink.Parameter(1.85);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
set_param('fxpdemo_direct_form2/Gain5','Gain','myGainParam')
set_param('fxpdemo_direct_form2/Gain5','ParamMin','0','ParamMax','4')
set_param('fxpdemo_direct_form2/Gain5','ParamDataTypeStr','fixdt(0,8)')
```

Configure the model to produce a code generation report. To reduce clutter in the Command Window, clear the configuration parameter **Verbose build**.

```
set_param('fxpdemo_direct_form2','GenerateReport','on',...
    'LaunchReport','on','RTWVerbose','off')
```

Generate code from the model.

```
rtwbuild('fxpdemo_direct_form2')
```

```
### Starting build procedure for model: fxpdemo_direct_form2
```

```
Code generation utilizes device specific information (e.g., microprocessor word sizes)

### Successful completion of build procedure for model: fxpdemo_direct_form2
```

The generated file `fxpdemo_direct_form2.c` defines the global variable `myGainParam` by using the data type `uint8_T`, which corresponds to the specified word length, 8. The code initializes the variable by using an integer value that, given the fraction length of 5, represents the real-world parameter value 1.85.

```
file = fullfile('fxpdemo_direct_form2_grt_rtw','fxpdemo_direct_form2.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T myGainParam = 59U;',1,1)
```

```
/* Exported block parameters */
uint8_T myGainParam = 59U;             /* Variable: myGainParam
```

The code algorithm uses `myGainParam` to calculate the output of the Gain5 block. The algorithm uses a C shift to scale the result of the calculation.

```
rtwdemodbtype(file,'/* Gain: ''<Root>/Gain5'' */',...
'/* Gain: ''<Root>/Gain'' incorporates:',1,0)
```

```
  /* Gain: '<Root>/Gain5' */
  fxpdemo_direct_form2_B.Gain5 = (int16_T)(myGainParam *
    fxpdemo_direct_form2_B.UnitDelay1 >> 5);
```

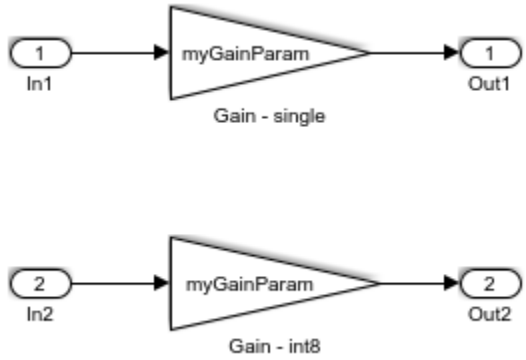
Reuse Parameter Data in Different Data Type Contexts

When you use a `Simulink.Parameter` object or a numeric MATLAB variable to set two or more block parameter values, if the block parameters have different data types, you must explicitly specify the data type of the object or variable. For example, you cannot leave the data type of the parameter object at the default value, `auto`.

Create and Configure Example Model

Create the model `ex_paramdt_contexts`.

```
ex_paramdt_contexts
```



Set these block parameter values:

- `In1` block: **Data type**: `single`
- `In2` block: **Data type**: `int8`

In the block labeled `Gain - single`, set these parameter values:

- **Gain**: `myGainParam`
- **Output data type**: `Inherit: Same as input`
- **Parameter data type**: `Inherit: Same as input`

In the block labeled `Gain - int8`, set these parameter values:

- **Gain**: `myGainParam`
- **Output data type**: `Inherit: Same as input`

- **Parameter data type**: `Inherit: Same as input`

You can use these commands to set the parameter values:

```
set_param('ex_paramdt_contexts/In1','OutDataTypeStr','single')
set_param('ex_paramdt_contexts/In2','OutDataTypeStr','int8')
set_param('ex_paramdt_contexts/Gain - single','Gain','myGainParam',...
    'OutDataTypeStr','Inherit: Same as input',...
    'ParamDataTypeStr','Inherit: Same as input')
set_param('ex_paramdt_contexts/Gain - int8','Gain','myGainParam',...
    'OutDataTypeStr','Inherit: Same as input',...
    'ParamDataTypeStr','Inherit: Same as input')
```

Create a `Simulink.Parameter` object named `myGainParam` in the base workspace. Configure the object to appear in the generated code as a global variable by applying the storage class `ExportedGlobal`. Configure the object to use the data type `int8`.

```
myGainParam = Simulink.Parameter(3);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
myGainParam.DataType = 'int8';
```

In this model, you use the parameter object `myGainParam` to set two block parameter values. The block parameters inherit different data types from the input signals (`single` or `int8`). To use `myGainParam` in these different data type contexts, explicitly specify the data type of the parameter object by setting the `DataType` property to `int8`.

Match Parameter Object Data Type with Signal Data Type

Optionally, use a `Simulink.NumericType` or `Simulink.AliasType` object to set the parameter object data type and one of the signal data types. This technique eliminates unnecessary typecasts and shifts in the generated code due to a mismatch between the parameter object data type and the signal data type.

Create a `Simulink.NumericType` object to represent the data type `int8`.

```
sharedType_int8 = fixdt('int8');
```

Use this data type object to set:

- The data type of the parameter object. Set the `DataType` property to `sharedType_int8`.
- The data type of the `int8` signal. Use the **Data type** parameter in the Inport block dialog box.

```
myGainParam.DataType = 'sharedType_int8';
set_param('ex_paramdt_contexts/In2','OutDataTypeStr','sharedType_int8')
```

The parameter object and the signal use the data type `int8`. To change this data type, adjust the properties of the data type object `sharedType_int8`.

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_paramdt_contexts')
```

```
### Starting build procedure for model: ex_paramdt_contexts
### Successful completion of build procedure for model: ex_paramdt_contexts
```

The generated file `ex_paramdt_contexts.c` defines the global variable `myGainParam` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('ex_paramdt_contexts_grt_rtw','ex_paramdt_contexts.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T myGainParam = 3;',1,1)
```

```
/* Exported block parameters */
int8_T myGainParam = 3;                /* Variable: myGainParam
```

The generated code algorithm in the model `step` function uses `myGainParam` to calculate the outputs of the two Gain blocks. In the case of the Gain block whose input signal uses the data type `single`, the code algorithm casts `myGainParam` to the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
rtwdemodbtype(file,'/* Model step function */',...
    '/* Model initialize function */',1,0)
```

```
/* Model step function */
void ex_paramdt_contexts_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain - single'
   *  Inport: '<Root>/In1'
   */
  ex_paramdt_contexts_Y.Out1 = (real32_T)myGainParam * ex_paramdt_contexts_U.In1;

  /* Outport: '<Root>/Out2' incorporates:
   *  Gain: '<Root>/Gain - int8'
```

```
   *  Inport: '<Root>/In2'
   */
  ex_paramdt_contexts_Y.Out2 = (int8_T)(myGainParam * ex_paramdt_contexts_U.In2);
}
```

- “Block Parameter Representation in the Generated Code” on page 19-47

Organize Block Parameter Values into Structures in the Generated Code

In C code, you use structures to store data in contiguous locations in memory. With structures, you can organize data in the code by using meaningful names. Each structure acts as a namespace, so you can reuse a name to represent multiple data items. Similar to arrays, structures enable you to write code that efficiently transfers and operates on large amounts of data by using pointers.

When you configure the generated code to store block parameter values in memory, for example by applying storage classes to `Simulink.Parameter` objects or by creating model arguments, you can organize the parameter data into structures in the generated code.

- Create a parameter structure in Simulink. Use each field of the structure to set a block parameter value. Optionally, use a `Simulink.Bus` object as the data type of the structure. The generated code creates a structure type definition and a structure variable. Use this technique to finely control the data types and order of the fields.
- If you have an Embedded Coder license, apply a custom storage class, such as the built-in custom storage class `Struct`, to multiple `Simulink.Parameter` objects. Use this technique to avoid the effort of creating the structure in Simulink and to organize both signal and parameter data into a single structure. See "Organize Parameter Data into a Structure by Using the `Struct` Custom Storage Class" on page 23-8.

  When you use this technique, to create a nested structure instead of a flat structure, you must create your own custom storage class by writing TLC code. Consider creating a parameter structure in Simulink instead.

Creating Tunable Parameter Structures

When you create a structure in Simulink, you can configure the generated code to define and initialize a corresponding structure variable or to reuse a structure variable from your existing C code. Use this technique to share a structure of parameter data with your existing code or to generate parameter data whose values you can change (tune) during code execution.

1. Store the structure in a Simulink.Parameter object.
2. Apply a storage class other than `Auto` to the parameter object.

3 Use the fields of the structure to set block parameter values in your model.

The numeric fields of the structure are tunable in the generated code. However, if any field contains a nontunable entity, such as a multidimensional array, none of the structure fields are tunable.

You cannot declare individual substructures or fields within a parameter structure as tunable. You cannot use a `Simulink.Parameter` object as the value of a structure field. Instead, you must store the entire structure in the parameter object.

The fields of parameter structures do not support context-sensitive data typing. However, to match the data type of a field with the data type of another data item in a model, you can use a bus object and a data type object.

1 Use a `Simulink.Bus` object as the data type of the structure.
2 Use a `Simulink.AliasType` or `Simulink.NumericType` object as the data type of the element in the bus object and as the data type of the target data item.

Control Name and File Placement of Structure Type Definition

When you generate code from a model that uses a tunable parameter structure, by default the code generator creates a `struct` type definition that has a generated name such as `struct_z98c0D2qc4btL`. You can control this type name to improve code readability and integrate the generated code with your own code. Create a `Simulink.Bus` object and use it as the data type of the `Simulink.Parameter` object that stores the structure.

To control the file placement of the generated `struct` type definition, use the `HeaderFile` and `DataScope` properties of the bus object. Use this technique to:

- Export the type definition to a header file that you can include in your custom code.
- Import the type definition from your custom code.

  To generate a bus object that represents a `struct` type defined by your code, use the `Simulink.importExternalCTypes` function.

Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

C Construct

```
typedef struct {
  double G1;
  double G2;
} myStructType;

myStructType myStruct = {
  2.0,
  -2.0
} ;
```

Procedure

At the command prompt, create a structure named `myStruct` with two fields.

```
myStruct.G1 = 2;
myStruct.G2 = -2;
```

Store the structure in a `Simulink.Parameter` object.

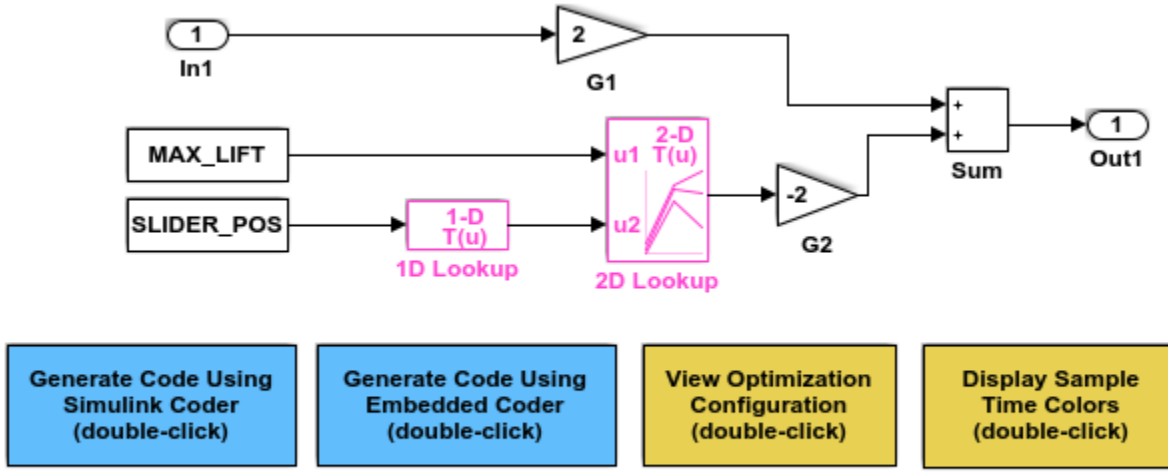
```
myStruct = Simulink.Parameter(myStruct);
```

Apply the storage class `ExportedGlobal` so that the structure appears in the generated code as a global variable.

```
myStruct.CoderInfo.StorageClass = 'ExportedGlobal';
```

Open the example model `rtwdemo_paraminline`.

```
rtwdemo_paraminline
```



In the G1 block dialog box, set **Gain** to `myStruct.G1`.

```
set_param('rtwdemo_paraminline/G1','Gain','myStruct.G1')
```

In the G2 block dialog box, set **Gain** to `myStruct.G2`.

```
set_param('rtwdemo_paraminline/G2','Gain','myStruct.G2')
```

Results

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated header file `rtwdemo_paraminline_types.h` defines a structure type with a randomized name.

```
file = fullfile('rtwdemo_paraminline_grt_rtw',...
    'rtwdemo_paraminline_types.h');
```

```
rtwdemodbtype(file,'typedef struct {','} struct_6h72eH5WFuEIyQr5YrdGuB;',...
    1,1)
```

```
typedef struct {
  real_T G1;
  real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,'struct_6h72eH5WFuEIyQr5YrdGuB myStruct',...
    '/* Variable: myStruct',1,1)
```

```
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
  2.0,
  -2.0
} ;                                    /* Variable: myStruct
```

Specify Name of Structure Type

Optionally, specify a name to use for the structure type definition (`struct`).

Create a `Simulink.Bus` object that represents the structure type.

```
Simulink.Bus.createObject(myStruct.Value);
```

The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

```
myStructType = slBus1.copy;
```

Use the bus object as the data type of the parameter object.

```
myStruct.DataType = 'Bus: myStructType';
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
rtwdemodbtype(file,'myStructType myStruct = {','/* Variable: myStruct',...
    1,1)
```

```
myStructType myStruct = {
  2.0,
  -2.0
} ;                                     /* Variable: myStruct
```

Structure Padding

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the default data structures (see "Default Data Structures in the Generated Code" (Simulink Coder)), `Simulink.Bus` objects, and parameter structures that you use in a model.

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see "Provide Data Alignment Specifications for Compilers" on page 51-135.

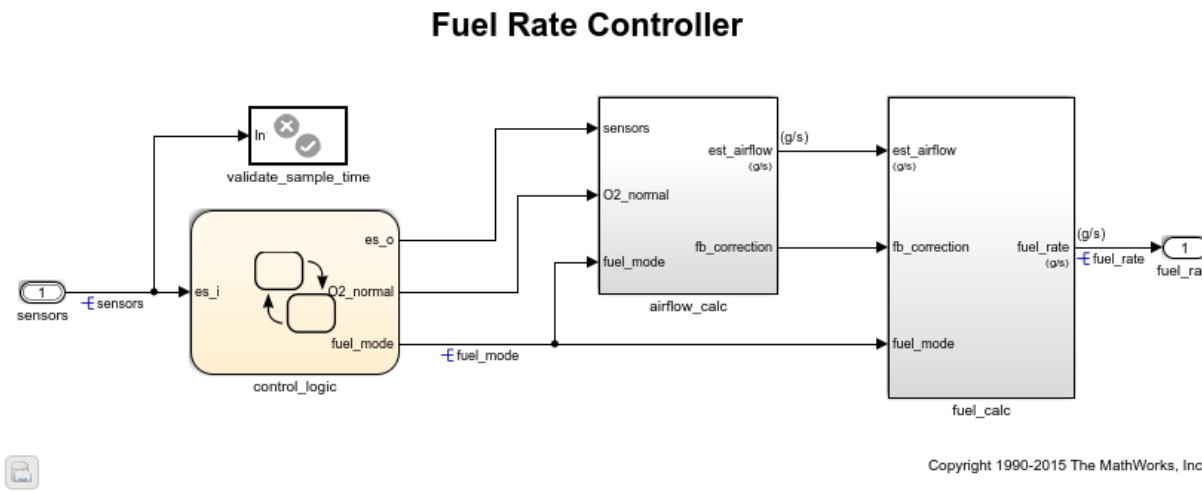
Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open this example model:

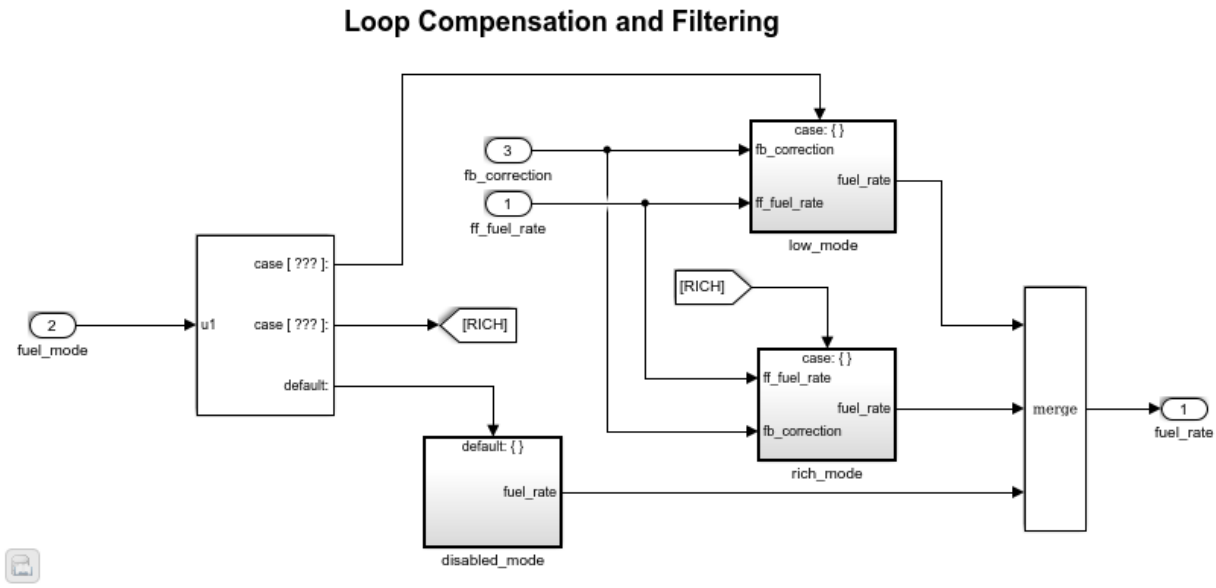
```
open_system('sldemo_fuelsys_dd_controller')
```



This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

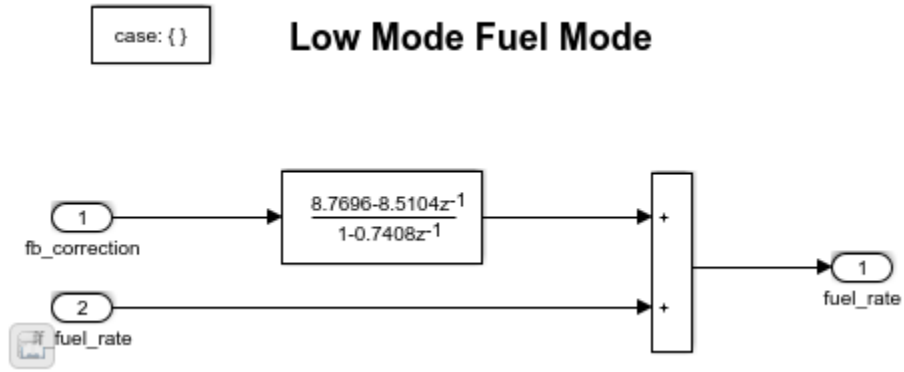
```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation'])
```



This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation/low_mode'])
```



The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/low_mode/Discrete Filter'];
```

```
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock,'Numerator'));
params.richNumerator = eval(get_param(richBlock,'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock,'Numerator','params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock,'Numerator','params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index `2`.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.sldd`.

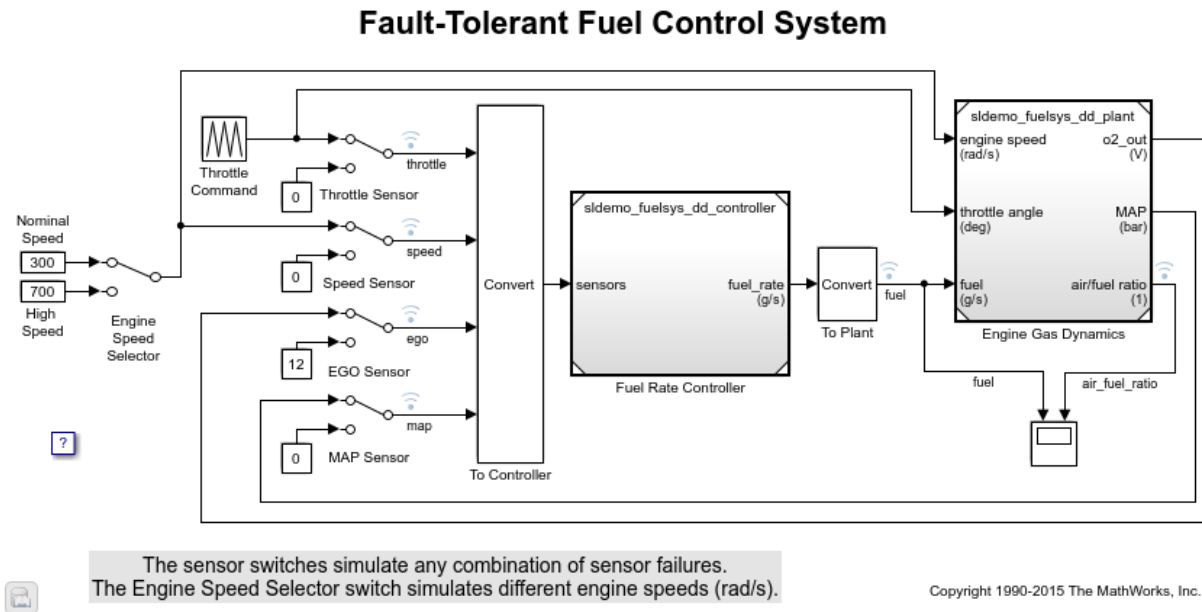
```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
addEntry(sectObj,'params',params)
addEntry(sectObj,'paramsType',paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see "Enumerations in Data Dictionary" (Simulink).

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```



Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to `Storage Class`.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj,'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,params);

tempEntryObj = getEntry(sectObj,'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: sldemo_fuelsys_dd_controller
```

```
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
  Weak = 1,                            /* Default value */
  Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_paramsType_',...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
  real32_T lowNumerator[2];
  real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
```

```
rtwdemodbtype(file,'FilterCoeffs Ctrl = Aggressive;',...
    '/* Block signals (auto storage) */',1,0)

FilterCoeffs Ctrl = Aggressive;        /* Variable: Ctrl
                                        * Referenced by:
                                        *   '<S12>/Discrete Filter'
                                        *   '<S13>/Discrete Filter'
                                        */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file,'/* Exported block parameters */',...
    '/* Variable: params',1,1)

/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
  }, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
  } } ;                                /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

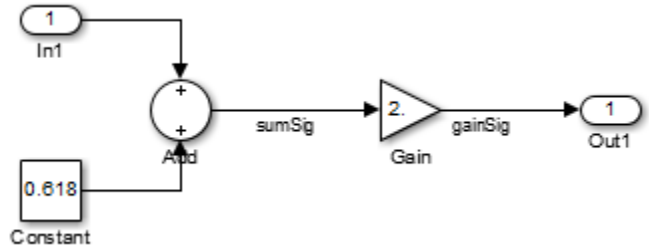
Signal Representation in Generated Code

In this section...

The code generator offers a number of options that let you control how signals in your model are stored and represented in the generated code.

- Control whether signal storage is declared in global memory space or locally in functions (that is, in stack variables).
- Control the allocation of stack space when using local storage.
- Declare signals as *test points* to store them in unique memory locations
- Reduce memory usage by instructing the code generator to store signals in reusable buffers.
- Control whether or not signals declared in generated code are interfaceable (visible) to externally written code. You can also specify that signals are to be stored in locations declared by externally written code.
- Preserve the symbolic names of signals in generated code by using signal labels.

The discussion in the following sections refers to code generated from `signal_examp`, the model shown in the next figure.



signal_examp Model

Signal Storage Concepts

This section discusses structures and concepts you must understand to choose the best signal storage options for your application:

- The global block I/O data structure *`model`*`_B`
- The concept of signal *storage classes* as used by the code generator

Global Block I/O Structure

By default, the code generator attempts to optimize memory usage by sharing signal memory and using local variables.

However, under a number of circumstances you should place signals in global memory. For example,

- You might want a signal to be stored in a structure that is visible to externally written code.
- The number and/or size of signals in your model might exceed the stack space available for local variables.

In such cases, it is possible to override the default behavior and store selected signals in a model-specific *global block I/O data structure*. The global block I/O structure is called *`model`*`_B` (in earlier versions this was called `rtB`).

The following code shows how *`model`*`_B` is defined and declared in code generated (with signal storage optimizations off) from the `signal_examp` model shown in the signal_examp Model figure.

```
(in signal_examp.h)
/* Block signals (auto storage) */
extern B_signal_examp_T signal_examp_B;

(in signal_examp.c)
/* Block signals (auto storage) */
B_signal_examp_T signal_examp_B;
```

Field names for signals stored in *model*_B are generated according to the rules described in "Symbolic Naming Conventions for Signals" on page 19-118.

In certain cases, the code generator places signals in the block I/O structure, even when you specify the storage class for the signal object as Auto or if you enable the option to reuse the signal. This override occurs when the values of these signals need to be persistent across time step. In such cases, the only way to represent these signals locally in generated code is to change the semantics of your Simulink model.

Signal Storage Class

The *storage class* property of a signal specifies how the product declares and stores the signal. In some cases this specification is qualified by more options.

In the context of the code generator, the term "storage class" is not synonymous with the term *storage class specifier*, as used in the C language.

Default Storage Class

Auto is the default storage class and is the storage class you should use for signals that you do not need to interface to external code. Signals with Auto storage class can be stored in local and/or shared variables or in a global data structure. The form of storage depends on the **Signal storage reuse**, **Reuse local block outputs**, and **Enable local block outputs** options, and on available stack space. See "Signals with Auto Storage Class" on page 19-115 for a full description of code generation options for signals with Auto storage class.

Explicitly Assigned Storage Classes

Signals with storage classes other than Auto are stored either as members of an appropriate global data structure, such as *model*_B or *model*_U, or in unstructured global variables, independent of the global data structures. These storage classes are for signals that you want to monitor and/or interface to external code.

The **Signal storage reuse**, **Enable local block outputs**, **Reuse local block outputs**, and **Eliminate superfluous local variables (expression folding)** optimizations do not apply to signals with storage classes other than `Auto`.

Use the Signal Properties dialog box to assign these storage classes to signals:

- `SimulinkGlobal`: The signal is stored as a field of a global data structure such as the block I/O structure. Signals with `SimulinkGlobal` storage class must have unique signal names. See "Control Signals and States in Code by Applying Storage Classes" on page 19-123 for more information.
- `ExportedGlobal`: The signal is stored in a global variable, independent of the global data structures. *`model`*`.h` exports the variable. Signals with `ExportedGlobal` storage class must have unique signal names. See "Control Signals and States in Code by Applying Storage Classes" on page 19-123 for more information.
- `ImportedExtern`: *`model`*`_private.h` declares the signal as an `extern` variable. Your code must supply the variable definition. Signals with `ImportedExtern` storage class must have unique signal names. See "Control Signals and States in Code by Applying Storage Classes" on page 19-123 for more information.
- `ImportedExternPointer`: *`model`*`_private.h` declares the signal as an `extern` pointer. Your code must define a valid pointer variable. Signals with `ImportedExtern` storage class must have unique signal names. See "Control Signals and States in Code by Applying Storage Classes" on page 19-123 for more information.

Signals with Auto Storage Class

Options are available for signals with `Auto` storage class:

- **Signal storage reuse**
- **Enable local block outputs**
- **Reuse local block outputs**
- **Eliminate superfluous local variables (expression folding)**

Use these options to control signal memory reuse and choose local or global (*`model`*`_B`) storage for signals. These options are on the **All Parameters** tab of the Configuration Parameters dialog box.

These options interact. When the **Signal storage reuse** option is selected,

- The **Reuse local block outputs** option is enabled and selected, and signal memory is reused whenever possible, reducing stack size where signals are being buffered in local variables.
- The **Enable local block outputs** option is enabled and selected. This parameter lets you choose whether reusable signal variables are declared as local variables in functions or as members of *`model`*`_B`.
- The **Eliminate superfluous local variables (expression folding)** is enabled and selected, and block computations collapse into single expressions.

The following code examples illustrate the effects of the **Signal storage reuse**, **Enable local block outputs**, and **Reuse local block outputs** options. The examples were generated from the `signal_examp` model (see figure signal_examp Model). For clarity in showing the individual Gain and Sum block computation, expression folding is off in this example.

This code example shows signal storage optimization, with **Signal storage reuse**, **Enable local block outputs**, and **Reuse local block outputs** selected. The local variable `rtb_gainSig` holds the outputs of the Sum and Gain blocks.

```
/* Model step function */
void signal_examp_step(void)
{
  real_T rtb_gainSig;

  /* Sum: '<Root>/Sum' incorporates:
   *  Constant: '<Root>/Constant'
   *  Inport: '<Root>/In1'
   */
  rtb_gainSig = signal_examp_U.In1 + signal_examp_P.Constant_Value;

  /* Gain: '<Root>/Gain' */
  rtb_gainSig *= signal_examp_P.Gain_Gain;

  /* Outport: '<Root>/Out1' */
  signal_examp_Y.Out1 = rtb_gainSig;
}
```

This example shows the code with **Signal storage reuse** cleared. The global variable `signal_example_B.sumSig` holds the output of the Sum block.

```
/* Model step function */
void signal_examp_step(void)
{
  /* Sum: '<Root>/Sum' incorporates:
   *  Constant: '<Root>/Constant'
   *  Inport: '<Root>/In1'
   */
```

```
  signal_examp_B.sumSig = signal_examp_P.Constant_Value + signal_examp_U.In1;

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   */
  signal_examp_Y.Out1 = signal_examp_P.Gain_Gain * signal_examp_B.sumSig;
}
```

In large models, disabling **Signal storage reuse** can significantly increase RAM and ROM usage. Therefore, this approach is not recommended for code deployment; however it can be useful in rapid prototyping environments.

The following table summarizes the possible combinations of the **Signal storage reuse** / **Reuse block outputs** and **Enable local block outputs** options.

	Signal storage reuse and Reuse local block outputs ON	Signal storage reuse OFF (Reuse local block outputs disabled)
Enable local block outputs ON	Reuse signals in local memory (fully optimized)	N/A
Enable local block outputs OFF	Reuse signals in *model*_B structure	Individual signal storage in *model*_B structure

Signals with Test Points

A *test point* is a signal that is stored in a unique location that other signals cannot share or reuse. See "Test Points" (Simulink) for information about including test points in your model.

When you generate code for models that include test points, the build process allocates a separate memory buffer for each test point. Test points are stored as members of an appropriate global data structure such as *model*_B or *model*_U.

Declaring a signal as a test point disables the following options for that signal. This can lead to increased code and data size. You do not lose the benefits of optimized storage for other signals in your model.

- **Signal storage reuse**
- **Enable local block outputs**
- **Reuse local block outputs**

- **Eliminate superfluous local variables (expression folding)**

For an example of storage declarations and code generated for a test point, see "Summary of Signal Storage Class Options" on page 19-119.

If you have an Embedded Coder license, you can specify that the build process ignore test points in the model, allowing optimal buffer allocation, using the "Ignore test point signals" (Simulink Coder) parameter. Ignoring test points facilitates transitioning from prototyping to deployment and avoids accidental degradation of generated code due to workflow artifacts. For more information, see "Ignore test point signals" (Simulink Coder).

Symbolic Naming Conventions for Signals

When signals have a storage class other than `Auto`, the code generator preserves symbolic information about the signals or their originating blocks in the generated code.

For labeled signals, field names in *`model`*`_B` derive from the signal names. In the following example, the field names *`model`*`_B.sumSig` and *`model`*`_B.gainSig` are derived from the corresponding labeled signals in the `signal_examp` model (shown in figure signal_examp Model).

```
/* Block signals (auto storage) */
typedef struct _BlockIO_signal_examp {
    real_T sumSig;                       /* '<Root>/Add' */
    real_T gainSig;                      /* '<Root>/Gain' */
} BlockIO_signal_examp;
```

When you clear the **Signal storage reuse** optimization, `sumSig` is not part of *`model`*`_B`, and a local variable is used for it instead. For unlabeled signals, *`model`*`_B` field names are derived from the name of the source block or subsystem.

The components of a generated signal label are

- The root model name, followed by
- The name of the generating signal object, followed by
- Unique *name-mangling* text (if required)

The number of characters that a signal label can have is limited by the **Maximum identifier length** parameter specified on the **Symbols** pane of the Configuration

Parameters dialog box. See "Construction of Generated Identifiers" (Simulink Coder) for more detail.

When a signal has `Auto` storage class, the build process controls generation of variable or field names without regard to signal labels.

Summary of Signal Storage Class Options

The next table shows, for each signal storage class option, the variable declaration and the code generated for Sum (`sumSig`) and Gain (`gainSig`) block outputs of the model shown in figure signal_examp Model.

Storage Class	Declaration	Code

`Auto`
 	
(with **Signal storage reuse** optimizations on)
	In *`model`*`.c` or *`model`*`.cpp`
	
	`real_T rtb_sumSig;`
		`rtb_sumSig = signal_examp_U.In1 +`
		`  signal_examp_P.Constant_Value;`
		`rtb_sumSig *=`
		`  signal_examp_P.Gain_Gain;`
		`signal_examp_Y.Out1 = rtb_sumSig;`

Test point (for `sumSig` only)	In *`model`*`.h`
	
	`typedef struct`
	`_BlockIO_signal_examp`
	`{`
	`  real_T sumSig;`
	`}`
	`BlockIO_signal_examp;`
	
	In *`model`*`.c` or *`model`*`.cpp`
	
	`BlockIO_signal_examp`
	`signal_examp_B;`
	`real_T rtb_gainSig;`
		`signal_examp_B.sumSig =`
		`  signal_examp_U.In1 +`
		`  signal_examp_P.Constant_Value;`
		`rtb_gainSig =`
		`  signal_examp_B.sumSig *`
		`  signal_examp_P.Gain_Gain;`
		`signal_examp_Y.Out1 = rtb_gainSig;`

`ExportedGlobal` (for `sumSig` only)	In *`model`*`.h`
	
	`extern real_T sumSig;`
	
	In *`model`*`.c` or *`model`*`.cpp`
	
	`real_T sumSig;`
	`real_T rtb_gainSig;`
		`sumSig = signal_examp_U.In1 +`
		`signal_examp_P.Constant_Value;`
		`rtb_gainSig = sumSig *`
		`  signal_examp_P.Gain_Gain;`
		`signal_examp_Y.Out1 = rtb_gainSig;`

`ImportedExtern`	In *`model`*`_private.h`
	
	`extern real_T sumSig;`
	
	In *`model`*`.c` or *`model`*`.cpp`
	
	`real_T rtb_gainSig;`
		`sumSig = signal_examp_U.In1 +`
		`signal_examp_P.Constant_Value;`
		`rtb_gainSig = sumSig *`
		`  signal_examp_P.Gain_Gain;`
		`signal_examp_Y.Out1 = rtb_gainSig;`

Storage Class	Declaration	Code

`ImportedExternPointer`	In *`model`*`_private.h`
	`extern real_T *sumSig;`
	In *`model`*`.c` or *`model`*`.cpp`
	`real_T rtb_gainSig;`
		`(*sumSig) = signal_examp_U.In1 + signal_examp_P.Constant_Value;`
		`rtb_gainSig = (*sumSig) * signal_examp_P.Gain_Gain;`
		`signal_examp_Y.Out1 = rtb_gainSig;`

Interfaces for Monitoring Signals

The code generator includes

- Support for developing a Target Language Compiler API for monitoring signals and states independent of external mode. See "Input Signal Functions" (Simulink Coder) and "Output Signal Functions" (Simulink Coder).
- A C application program interface (API) for monitoring signals and states independent of external mode. See "Exchange Data Between Generated and External Code Using C API" (Simulink Coder) for information.
- An interface for exporting ASAP2 files, which you customize to use signal objects. For details, see "Export ASAP2 File for Data Measurement and Calibration" (Simulink Coder).

Share Data Between Code Generated from Simulink, Stateflow, and MATLAB

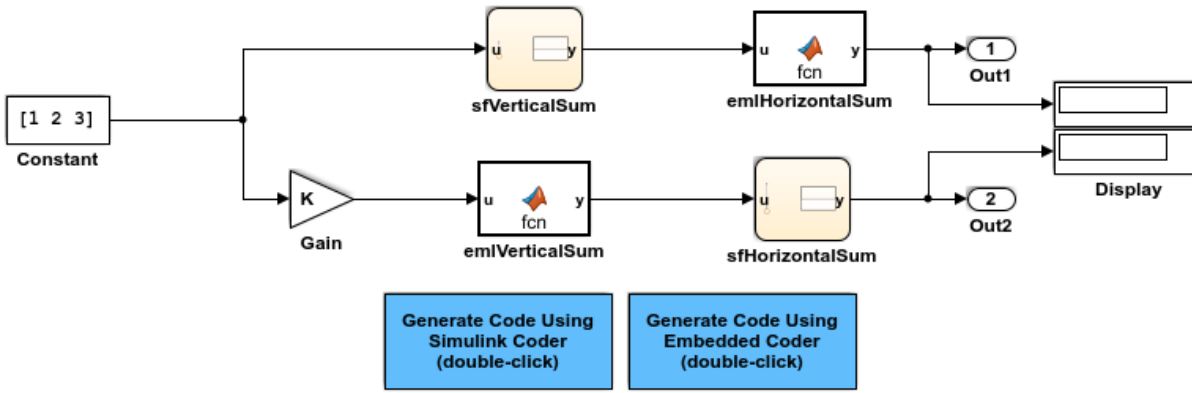
Stateflow and MATLAB Coder can fully define their data definitions, or they can inherit them from Simulink. Data definition capabilities include:

- Inheriting input/output data types and sizes from Simulink.
- Parameterized data types and sizes. That is, data type and size may be specified as a function of another data's type and size, e.g., `type(y)=type(u)` and `size(y)=size(u)`.
- Inferred output size and type from Simulink via signal attribute back propagation.
- Parameter scoped data, which allows referencing Simulink parameters in Stateflow and MATLAB.

Open Example Model

Open the example model `rtwdemo_dynamicio`.

```
open_system('rtwdemo_dynamicio')
```



Instructions

1. Compile the model (**Simulation > Update Diagram**) and note the displayed signal types and sizes.
2. Change the data type and/or size of the Constant block and recompile the model. Note that the attributes of the signals automatically adapt to the Constant block specification.
3. Generate and inspect code using the blue buttons in the model. Note that `K` is shared by the Gain and sfVerticalSum block.

Notes

- The data type and size of all Stateflow and MATLAB data is inherited from Simulink.
- The Gain block and the Stateflow chart sfVerticalSum share the Simulink parameter `K`, which is defined in the MATLAB workspace as a Simulink.Parameter with `SimulinkGlobal` storage class (i.e., `rtP.K` in the generated code).

Control Signals and States in Code by Applying Storage Classes

Signals and block states appear in the generated code as variables. For basic information about signal representation in the generated code, see "Signal Representation in Generated Code" on page 19-112. For basic information about state representation, see "Discrete Block State Naming in Generated Code" (Simulink Coder) and "Continuous Block State Naming in Generated Code" (Simulink Coder).

In a model, you can assign each signal and state a *storage class* to determine the variable scope in the generated code. You can use storage classes to monitor signal and state data during execution and interface signals and states to externally written code.

To specify storage classes for signals and states, you can use *signal objects*, which you store in a workspace or data dictionary. Signal objects are objects of the class `Simulink.Signal`. If you create your own data class package, signal objects are also objects of the subclass of `Simulink.Signal` that your package defines. For basic information about data objects, see "Data Objects" (Simulink).

You can apply storage classes directly to signal lines and block states by using the Signal Properties dialog box or the **State Attributes** tab of a block dialog box. This technique does not require you to store a signal object in a workspace.

You can interface test points and other signals that are stored as members of *`model`*`_B`, or of another global data structure such as *`model`*`_U`, to your code. To do this, your code must know the address of the global data structure where the data is stored, and other information. This information is not automatically exported. The code generator provides C/C++ and Target Language Compiler APIs that give your code access to *`model`*`_B` and other data structures. See "Interfaces for Monitoring Signals" on page 19-120 for more information.

If you have an Embedded Coder license, you can use and create custom storage classes to represent more complex data such as structures and macros. You can also use custom storage classes to export data declarations to specific generated files. For more information, see "Introduction to Custom Storage Classes" on page 23-2 and "Simulink Package Custom Storage Classes" on page 23-5.

In this section...

In this section...

Storage Classes for Signals and States

To control the code generated for signals and states, use storage class. For example, you can import or export the corresponding variable to or from the code.

You can choose from these built-in storage classes:

- `Auto`, which is the default storage class. The code generator determines signal or state storage based on optimization settings such as configuration parameters.
- `SimulinkGlobal`. The generated code contains a structured global variable for signals and another structured global variable for states that use this storage class. Each signal or state appears as a field of the appropriate structure.
- `ExportedGlobal`. Export the signal or state as a unique global variable in the generated code. The code contains an `extern` declaration for the variable.
- `ImportedExtern`. Import the signal or state as a unique global variable in the generated code. Your code must provide the variable definition.
- `ImportedExternPointer`. Import the signal or state as a unique global pointer variable in the generated code. Your code must provide the pointer variable definition.

Storage Classes for Signal Lines

To control the code generated for signals that use `Auto` storage class, on the **All Parameters** tab of the Configuration Parameters dialog box, adjust these options:

- **Signal storage reuse**
- **Reuse block outputs**
- **Enable local block outputs**

- **Eliminate superfluous local variables (expression folding)**

These configuration parameters determine, for example, whether a signal appears in the code as a local variable or whether expression folding eliminates the signal altogether.

To customize the code generation for an individual signal, specify a storage class other than `Auto`. For each of the storage classes, the table shows the variable declaration and the code generated for the Inport signal, `inSig`, of the example model `signal_examp`.

Storage Class	Declaration and Definition	Code

`Auto` (with storage optimizations on)	In `signal_examp.h`
	`typedef struct {`
	`  real_T inSig;`
	`} ExtU_signal_examp_T;`
	`extern ExtU_signal_examp_T signal_examp_U;`
		`Gain1Sig =`
		`  signal_examp_P.Gain_Gain *`
		`  signal_examp_U.inSig;`

`SimulinkGlobal`	In `signal_examp.h`
	`typedef struct {`
	`  real_T inSig;`
	`} ExtU_signal_examp_T;`
	`extern ExtU_signal_examp_T signal_examp_U;`
		`Gain1Sig =`
		`  signal_examp_P.Gain_Gain *`
		`  signal_examp_U.inSig;`

`ExportedGlobal`	In `signal_examp.c`
	`real_T inSig;`
	In `signal_examp.h`
	`extern real_T inSig;`
		`Gain1Sig = inSig *`
		`  signal_examp_P.Gain_Gain;`

`ImportedExtern`	In `signal_examp_private.h` `extern real_T inSig;`	`Gain1Sig = inSig *` `  signal_examp_P.Gain_Gain;`
`ImportedExternPointer`	In `signal_examp_private.h`	`Gain1Sig = (*inSig) *` `  signal_examp_P.Gain_Gain;`

Storage Class	Declaration and Definition	Code
	`extern real_T *inSig;`	

Storage Classes for Block States

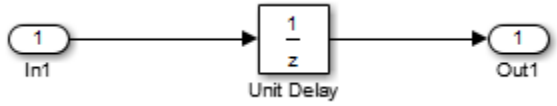
Use the `Auto` storage class for states that you do not need to interface to external code. States with `Auto` storage class are typically stored as fields of the `DWork` structure in the generated code.

You can assign a symbolic name to states that use the `Auto` storage class. If you do not supply a state name, the code generator produces one, as described in "Discrete Block State Naming in Generated Code" on page 19-160.

States with `SimulinkGlobal` storage class are stored as fields of the `DWork` structure.

Block states with storage classes other than `Auto` or `SimulinkGlobal` are stored in unstructured global variables, independent of the `Dwork` vector. Use these storage classes for states that you want to interface to external code.

For each of the storage classes, the table shows the variable declaration and initialization code generated for the Unit Delay block state in the example model `state_examp`. The block state name is specified as `udx`. The initial value is `0`.



Storage Class	Declaration and Definition	Initialization Code

`Auto`	In `state_examp.h`
	
	`typedef struct`
	`{`
	`  real_T udx;`
	`  }`
	`DW_state_examp_T;`
		`state_examp_DW.udx = 0.0;`

`SimulinkGlobal`	In `state_examp.h`
	
	`typedef struct`
	`{`
	`  real_T udx;`
	`  }`
	`DW_state_examp_T;`
		`state_examp_DW.udx = 0.0;`

Storage Class	Declaration and Definition	Initialization Code

`ExportedGlobal`	In `state_examp.c`
	`real_T udx;`
	In `state_examp.h`
	`extern real_T udx;`
		`udx = 0.0;`

`ImportedExtern`	In `state_examp_private.h` `extern real_T udx;`	`udx = 0.0;`
`ImportedExternPointer`	In `state_examp_private.h` `extern real_T *udx;`	`*udx = state_examp_U.In1;`

Use Model Data Editor to Configure Data Interface

Use the Model Data Editor to apply storage classes to Inport and Outport blocks, signal lines, and Data Store Memory blocks. Use this technique to apply the storage classes without locating the blocks and signals in the model and to configure the data interface of the model by using a single list.

To open the Model Data Editor, select **View** > **Model Data**. For information about using the Model Data Editor, see "Configure Data Properties by Using a Table" (Simulink). For an example that shows how to apply storage classes to Inport and Outport blocks, see "Design Data Interface by Configuring Inport and Outport Blocks" on page 19-134.

- For an Inport block, the Model Data Editor applies the storage class to the output signal of the block, not to the block itself.
- You can use the Model Data Editor to apply a storage class directly to a root-level Outport block or to the input signal that drives the block.

  - To store the storage class specification in the Outport block, use the **Inports/Outports** tab in the Model Data Editor. When you use this technique, the specification remains after you delete the input signal that drives the block. Use this technique to configure the model interface before you develop the internal algorithm.
  - To store the specification in the input signal that drives the block, use the **Signals** tab in the Model Data Editor or use the Signal Properties dialog box. Use this technique to use the custom storage class `Reusable` (Embedded Coder). To use

this custom storage class, you associate the signal line with a `Simulink.Signal` object in a workspace or data dictionary instead of storing the specification in the signal line.

Signal Objects for Code Generation

To specify code generation options for a signal or state in a model by using a data object:

1. Create a signal data object, which is an object of the class `Simulink.Signal` or of a subclass of `Simulink.Signal`.
2. Specify code generation options by modifying the `CoderInfo` property of the signal object.
3. Associate the signal object with a signal or state in a model diagram. For example, in a Signal Properties dialog box, or on the **State Attributes** tab of a block dialog box, specify the object name as the name of the target signal or state.
4. Generate code and build your target executable.

Signal objects have a property `CoderInfo` that contains an object of the class `Simulink.CoderInfo`. You can use the properties of the `Simulink.CoderInfo` object to specify code generation options for the target model signal or state.

For basic information about signal objects, including how to create them, see "Data Objects" (Simulink).

Create and Configure Signal Object for Code Generation

To control the code generation of a signal by creating a signal object, you can use Model Explorer.

1. In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the signal object. For example, select`Base Workspace`.
2. Click Add Signal  .

   A `Simulink.Signal` object named `Sig` appears in the base workspace.
3. In the **Contents** pane, change the name of the signal object to a meaningful name. For example, name the object `mySignal` or `myState`.
4. Select the signal object in the **Contents** pane. In the **Dialog** pane, in the **Storage class** drop-down list, select a storage class such as `ExportedGlobal`. Click **Apply**.

5 Open the Signal Properties dialog box for a signal in a model, or open the **State Attributes** tab of a block dialog box. Specify **Signal name** or **State name** as `mySignal` or `myState` and click **Apply**.

6 Select the check box next to **Signal name must resolve to Simulink signal object** or **State name must resolve to Simulink signal object**. Click **OK**.

7 Generate code.

Programmatically Create and Configure Signal Object for Code Generation

At the command prompt, you can control the code generation of a signal by creating a signal object.

1 Create a `Simulink.Signal` object named `mySignal` or `myState` in the base workspace.

```
mySignal = Simulink.Signal;
```

2 Specify a storage class for the object. For example, specify the storage class `ExportedGlobal`.

```
mySignal.StorageClass = 'ExportedGlobal';
```

The `StorageClass` property is a property of the `Simulink.CoderInfo` object that resides in the `CoderInfo` property of the signal object. However, you can use the preceding syntax to access the storage class property. You can also explicitly access the property by using the syntax `mySignal.CoderInfo.StorageClass`.

3 Open the Signal Properties dialog box for a signal in a model, or open the **State Attributes** tab of a block dialog box. Specify **Signal name** or **State name** as `mySignal` or `myState` and click **Apply**.

4 Select the check box next to **Signal name must resolve to Simulink signal object** or **State name must resolve to Simulink signal object**. Click **OK**.

5 Generate code.

Apply Storage Classes Directly to Signal Lines, Block States, and Outport Blocks

Through dialog boxes, you can apply storage classes directly to signal lines and block states. You do not need a data object that you store in a workspace or data dictionary.

However, if you specify a storage class for a signal or state with this technique, you cannot use a signal object in a workspace to specify other characteristics of the signal or state, such as data type.

To apply a storage class directly to a signal line, use the Signal Properties dialog box. For a block state, use the **State Attributes** tab in the block dialog box.

1. Open the **Code Generation** tab in a Signal Properties dialog box, or the **State Attributes** tab in a block dialog box.
2. Specify a name in the **Signal name** box or the **State name** box. Click **Apply**.
3. In the **Storage class** drop-down list , select a storage class.

To apply a storage class directly to an Outport block, use the Model Data Editor. You can also use the Model Data Editor to apply custom storage classes to signals through a list that you can sort, group, and filter. See "Use Model Data Editor to Configure Data Interface" on page 19-127.

Programmatically Apply Storage Classes Directly to Signals, States, and Outport Blocks

To programmatically apply storage classes to signal lines and block states, use the function `set_param`. You can apply a storage class without creating a `Simulink.Signal` object in a workspace or data dictionary. The storage class specification is saved in the model file.

However, you can use this technique to specify only a storage class for the object. You must specify other signal or state characteristics, such as data type, in the source block dialog box. You cannot use a signal object in a workspace to specify these other characteristics.

This example shows how to programmatically apply a storage class to a signal line.

1. Open the example model `rtwdemo_secondOrderSystem`.

   ```
   rtwdemo_secondOrderSystem
   ```

2. Get a handle to the output of the block named Force: f(t).

   ```
   portHandles = get_param('rtwdemo_secondOrderSystem/Force: f(t)','PortHandles');
   outportHandle = portHandles.Outport;
   ```

3. Set the name of the corresponding signal to `ForceSignal`.

   ```
   set_param(outportHandle,'Name','ForceSignal')
   ```

4. Set the storage class of the signal to `ExportedGlobal`.

   ```
   set_param(outportHandle,'StorageClass','ExportedGlobal')
   ```

5. Generate code from the model. The code declares and defines a global variable `ForceSignal` to represent the signal.

To apply a storage class directly to an Outport block, using the function `set_param`, specify the block parameter `SignalName` to name the signal that the block represents. Use the parameter `StorageClass` to specify a storage class.

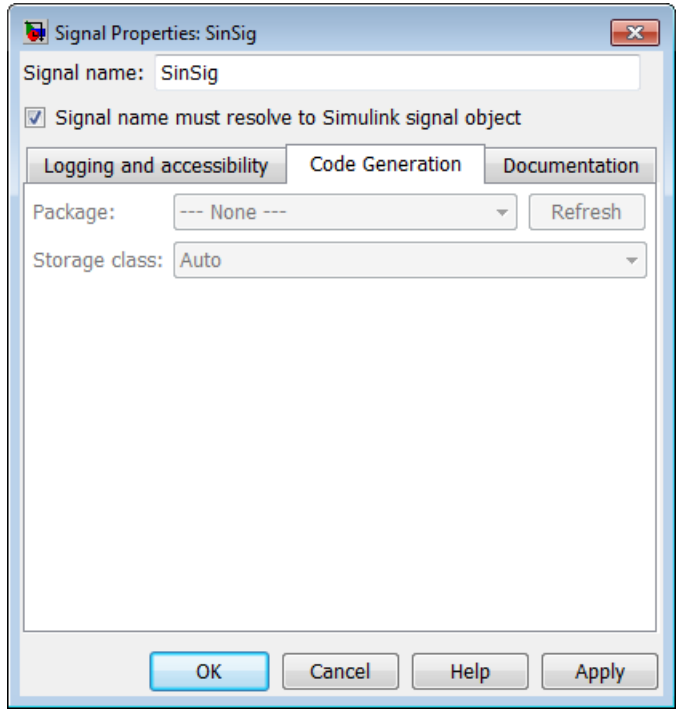
To apply a storage class to a block state, using the function `set_param`, specify the block parameter `StateIdentifier` to name the state. Use the parameter `StateStorageClass` to specify a storage class.

To apply a storage class to a data store that you define by using a Data Store Memory block, use the block parameter `StateStorageClass`. You do not need to specify a state name because the data store already has a name.

To programmatically apply a custom storage class to a signal, state, Outport block, or data store, use embedded signal objects. Custom storage classes do not affect the generated code unless you use a system target file based on `ert.tlc`, which requires Embedded Coder. You can also use this technique to set storage classes. See "Programmatically Apply Custom Storage Classes Directly to Signals, States, and Outport Blocks Using Embedded Signal Objects" on page 23-63.

Resolve Conflicts in Configuration of Signal Objects

If a signal is defined in the Signal Properties dialog box and a signal object of the same name is defined by using the command line or in the Model Explorer, the potential exists for ambiguity when the Simulink engine attempts to resolve the symbol representing the signal name. One way to resolve the ambiguity is to specify that a signal resolve to a Simulink data object. Select the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. You cannot specify the **Storage class** property on the **Code Generation** tab in the Signal Properties dialog box.



As the preceding figure shows, the **Storage class** menu is disabled because it is up to the `SinSig` `Simulink.Signal` object to specify its own storage class.

The signal and signal objects `SinSig` both have `SimulinkGlobal` storage class. Therefore, `SinSig` resolves to the signal object `SinSig`.

Note The rules for compatibility between block states/signal objects are identical to those given for signals/signal objects.

Design Data Interface by Configuring Inport and Outport Blocks

The data interface of a model is the means by which the model exchanges data (for example, signal values) with other, external models or systems. Customize the data interface of a model to:

- Enable integration of the generated code with your own code.
- Improve traceability and readability of the code.

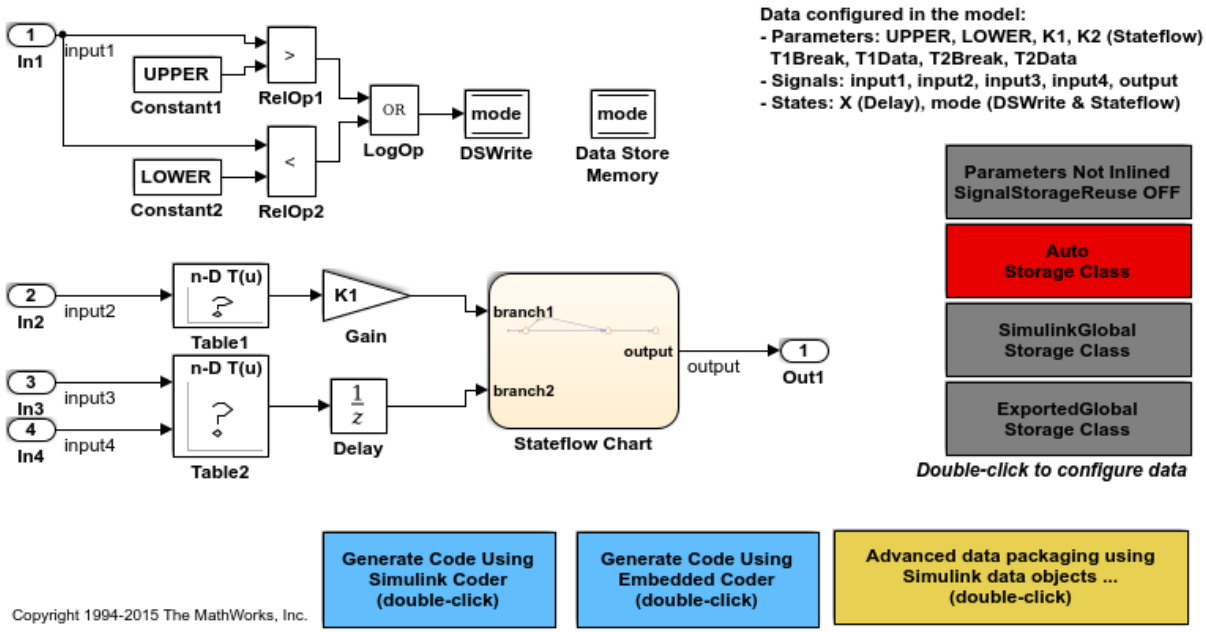
At the top level of a model, Inport and Outport blocks represent the input and output signals of the model. To customize the data interface in the generated code, configure these blocks. Early in the design process, when a model can contain unconnected Inport and Outport blocks, use this technique to specify the interface before developing the internal algorithm.

When you apply storage classes to Inport and Outport blocks, each block appears in the generated code as a field of a global structure or as a separate global variable that the generated algorithm references directly. If you have Embedded Coder, you can use function prototype control instead of storage classes to pass data into and out of the model `step` function as formal parameters. See “Control Generation of Function Prototypes”.

Design Data Interface

Open the example model rtwdemo_basicsc.

```
open_system('rtwdemo_basicsc')
```



In the model, select **View > Model Data**.

In the Model Data Editor, select the **Inports/Outports** tab. Each row in the table represents an Inport or Outport block.

Name the output signal of the Outport block labeled `Out1`. Set **Signal Name** to `output_sig`.

For each of the Inport blocks, set **Data Type** to `single` or to a different data type. Due to the data type inheritance settings that the other blocks in the model use by default, downstream signals use the same or a similar data type.

Optionally, configure other design attributes such as **Min** and **Max** (minimum and maximum values).

Set the **Change View** drop-down list to `Code`.

For the Outport block and all of the Inport blocks, set **Storage Class** to `ExportedGlobal`. To configure all of the blocks at once, select all of the rows in the table.

To configure the blocks and signals, you can use these commands at the command prompt.

```
temp = Simulink.Signal;
temp.StorageClass = 'ExportedGlobal';

portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'SignalObject',temp);

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'SignalObject',temp);

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'SignalObject',temp);

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'SignalObject',temp);

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
    'SignalObject',temp)
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc');

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

View the generated file `rtwdemo_basicsc.c`. Because you applied the storage class `ExportedGlobal` to the Inport and Outport blocks, the code creates separate global variables that represent the inputs and the output.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T output_sig;',1,1)

/* Exported block signals */
real32_T input1;                       /* '<Root>/In1' */
real32_T input2;                       /* '<Root>/In2' */
real32_T input3;                       /* '<Root>/In3' */
real32_T input4;                       /* '<Root>/In4' */
```

```
real32_T output_sig;                   /* '<Root>/Out1' */
```

The generated algorithm in the model `step` function directly references these global variables to calculate and store the output signal value, `output_sig`.

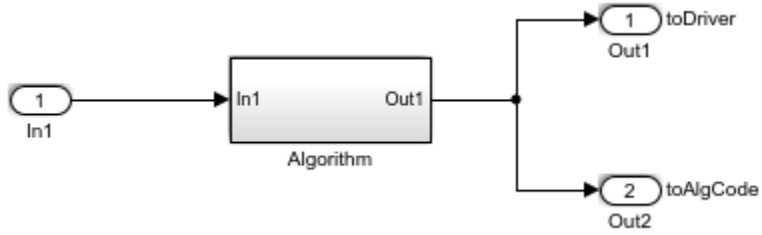
While you use the Model Data Editor to configure the interface of a system, consider using the interface display to view the system inputs and outputs (Inport and Outport blocks) at a high level. See "Configure Data Interface for Component" (Simulink).

Route Signal Data to Multiple Outputs

You can route a single signal to multiple Outport blocks and apply a different storage class to each Outport. For example, use this technique to send signal data to a custom function (such as a device driver) and to a global variable that your custom algorithmic code can use:

1. Branch the target signal line to each Outport block.
2. For more efficient code, set the storage class of the target signal line to `Auto` (the default). Optimizations can then eliminate the signal line from the generated code.
3. Use the Model Data Editor to apply the custom storage class `GetSet` to one Outport block and `ExportToFile` to the other Outport block. Apply a signal name to each block.

```
open_system('ex_route_sig')
```



Limitations

You cannot apply a storage class to an Outport block if the input to the block has a variable size. Instead, apply the storage class to the signal line.

Group Signals into Structures in the Generated Code Using Buses

Buses in a model represent multiple signals as a single signal line. You can use nonvirtual buses to create signal structures in the generated code.

You can generate flat and nested structures. See “Structures of Signals” on page 13-87.

For basic information about buses in models, see “Buses” (Simulink).

Import or Export Structure Variable and Definition

This example shows how to export the definition of a bus type and the declaration of a nonvirtual bus signal in generated code. You can control the bus type definition and the bus signal declaration in the generated code independently of each other.

Explore Example Model

1. Open the model rtwdemo_slbus.

   The model creates a `Simulink.Bus` object `BusObject` in the base workspace.
2. Update the model diagram to display thick lines for composite signals, including buses.

   The bus signal `S1` uses the bus type that `BusObject` defines.

Control Scope of Bus Type

To control code generated for a bus type that a `Simulink.Bus` object defines, adjust the code generation settings for the object.

The generated code represents nonvirtual bus types with `struct` definitions. The `struct` definitions contain fields corresponding to the elements of the bus.

1. At the command prompt, specify the `DataScope` property of `BusObject` as `'Exported'`.

   ```
   BusObject.DataScope = 'Exported';
   ```
2. Specify the `HeaderFile` property of the object as `'myBusTypeHdr.h'`.

   ```
   BusObject.HeaderFile = 'myBusTypeHdr.h';
   ```

Control Scope of Bus Signal

You can use a `Simulink.Signal` object to control code generated for signals in a model, including composite signals such as buses. To control code generated for a nonvirtual bus signal, apply a storage class to the bus.

1. View the model in the Simulink Editor.
2. In the signal properties dialog box for the bus signal `S1`, select the option **Signal name must resolve to Simulink.Signal object**.
3. At the command prompt, create a `Simulink.Signal` object to represent the bus signal `S1`. Specify the data type of the object as `BusObject`.

   ```
   S1 = Simulink.Signal;
   S1.DataType = 'Bus: BusObject';
   ```

4. Specify the storage class of the object as `ExportedGlobal`.

   ```
   S1.StorageClass = 'ExportedGlobal';
   ```

For more information about applying storage classes to signals, see "Control Signals and States in Code by Applying Storage Classes" on page 19-123.

Generate and Inspect Code

1. In the Simulink Editor, double-click the blue box labeled **Generate Code Using Simulink Coder**.
2. In the code generation report, view the generated file `myBusTypeHdr.h`. The code in the header file represents the bus type `BusObject` with a `struct` definition.

   ```
   typedef struct {
     real_T temperature;
     real_T heat;
     real_T pressure[20];
   } BusObject;
   ```

3. View the file `rtwdemo_slbus.c`. The code exports the declaration of the signal `S1` and uses the structure type `BusObject` in the declaration.

   ```
   /* Exported block signals */
   BusObject S1;
   ```

Generate Code That Reuses `struct` Types from Existing C Code

If your existing C code exchanges data through structures, you can generate code that packages and accesses signal data according to the existing `struct` type definitions. This technique enables you to match interfaces between the bodies of code and to compile the code into a single application. For an example, see "Exchange Structured and Enumerated Data Between Generated and External Code" on page 21-28.

Arrays of Structures

You can further package multiple consistent bus signals into an array of buses. The array of buses appears in the generated code as an array of structures. To create arrays of buses, see "Combine Buses into an Array of Buses" (Simulink).

Structure Padding

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the default data structures (see "Default Data Structures in the Generated Code" (Simulink Coder)), `Simulink.Bus` objects, and parameter structures that you use in a model.

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see "Provide Data Alignment Specifications for Compilers" on page 51-135.

Generate Efficient Code for Bus Signals

In this section...

In a model, you use bus signals to package multiple signals together into a single signal line. You can create virtual or nonvirtual bus signals. The representation in the generated code depends on:

- For a virtual bus, the generated code appears as if the bus did not exist.
- Generated code for a nonvirtual bus represents the bus data with a structure. When you want to trace the correspondence between the model and the code, the use of a structure in the generated code can be helpful. To generate structures using nonvirtual bus signals, see "Group Signals into Structures in the Generated Code Using Buses" on page 19-139.

For general information about buses, see and "Virtual and Nonvirtual Buses" (Simulink).

To generate efficient code from models that contain bus signals, eliminate unnecessary data copies by following best practices as you construct the model.

Code Efficiency for Bus Signals

When you use buses in a model for which you intend to generate code:

- Setting bus diagnostic configuration parameters can make model development easier.
- The bus implementation techniques, and the choice of a nonvirtual or virtual bus, can influence the speed, size, and clarity of the generated code.
- Some useful bus implementation techniques are not immediately obvious.

When you work with buses, these guidelines help you to improve the results. The guidelines describe techniques to:

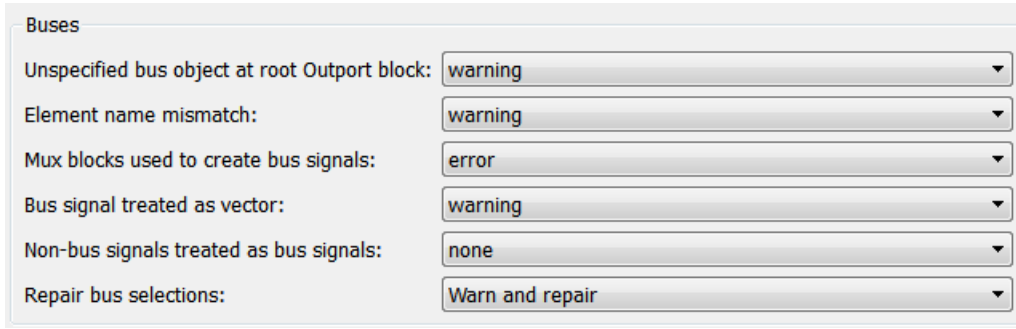
- Simplify the layout of the model.
- Increase the efficiency of generated code.
- Define data structures for function (subsystem) interfaces.

- Define data structures that match existing data structures in external C code.

There are some trade-offs among speed, size, and clarity. For example, the code for nonvirtual buses is easier to read because the buses appear in the code as structures, but the code for virtual buses is faster because virtual buses do not require copying signal data. Apply some of the guidelines based on where you are in the application development process.

Set Bus Diagnostics

Simulink provides diagnostics that you can use to optimize bus usage. Set the following values on the **Configuration Parameters** > **Diagnostics** > **Connectivity** pane.



Optimize Virtual and Nonvirtual Buses

Virtual buses are graphical conveniences that do not affect generated code. As a result, the code generation engine is able to fully optimize the signals in the bus. Use virtual buses rather than nonvirtual buses wherever possible. You can convert between virtual and nonvirtual buses by using Signal Conversion blocks. In some cases, Simulink automatically converts a virtual bus to a nonvirtual bus when required. For example, a Stateflow chart converts an input virtual bus to a nonvirtual bus.

To bundle function-call signals, you must use a virtual bus.

You must use nonvirtual buses for:

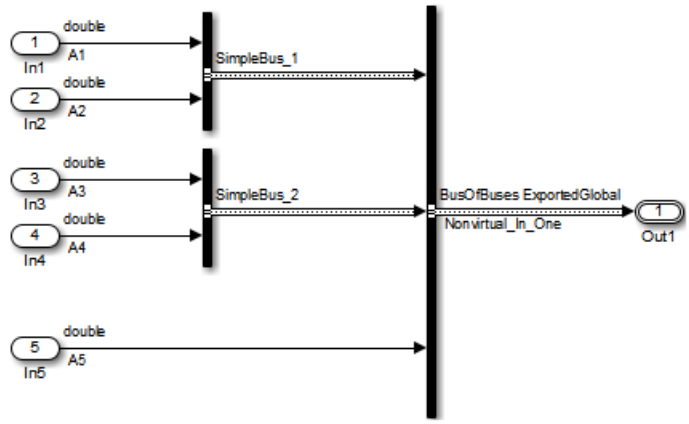
- Nonauto storage classes
- Generating a specific structure from the bus
- Root-level Inport or Outport blocks when the bus has mixed data types

Avoid Nonlocal Nested Buses in Nonvirtual Buses

Buses can contain subordinate buses. To generate efficient code, set the storage classes of subordinate buses to `Auto`. Setting the storage class to `Auto` eliminates:

- Allocation of redundant memory for the subordinate bus signal and for the parent bus signal
- Additional copy operations (copying data to the subordinate bus, and then copying from the subordinate bus to the final bus)

This model contains nonvirtual bus signals. The subordinate bus signals `Sub_Bus_1` and `Sub_Bus_2` use the storage class `Auto`.



The generated code algorithm efficiently assigns the input signal data to the bus signals.

```
void ex_nonvirtual_buses_step(void)
{
  Nonvirtual_In_One.SimpleBus_1.A1 = A1;
  Nonvirtual_In_One.SimpleBus_1.A2 = A2;
  Nonvirtual_In_One.SimpleBus_2.A3 = A3;
  Nonvirtual_In_One.SimpleBus_2.A4 = A4;
  Nonvirtual_In_One.A5 = A5;
}
```

Maximize Signal Storage Optimization

The value of the "Maximum stack size (bytes)" (Simulink) parameter, on the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box constrains the use of stack space used by local block output variables. The command-line equivalent for this parameter is `MaxStackSize`. If the accumulated size of variables in local memory exceeds `MaxStackSize`, the product places subsequent local variables in global memory space.

If it is important that you maximize potential for signal storage optimization, then set `MaxStackSize` to accommodate the size and number of signals in your model. This minimizes overflow into global memory space and maximizes use of local memory. Local variables offer more optimization potential through mechanisms such as expression folding and buffer reuse. See "Customize Stack Space Allocation" (Simulink Coder) for more information.

Control Signal and State Initialization in the Generated Code

To initialize signals and discrete states with custom values for simulation and code generation, you can use signal objects and block parameters. Data initialization increases application reliability and is a requirement of safety critical applications. Initializing signals for both simulation and code generation can expedite transitions between phases of Model-Based Design.

For basic information about specifying initial values for signals and discrete states in a model, see “Initialize Signals and Discrete States” (Simulink).

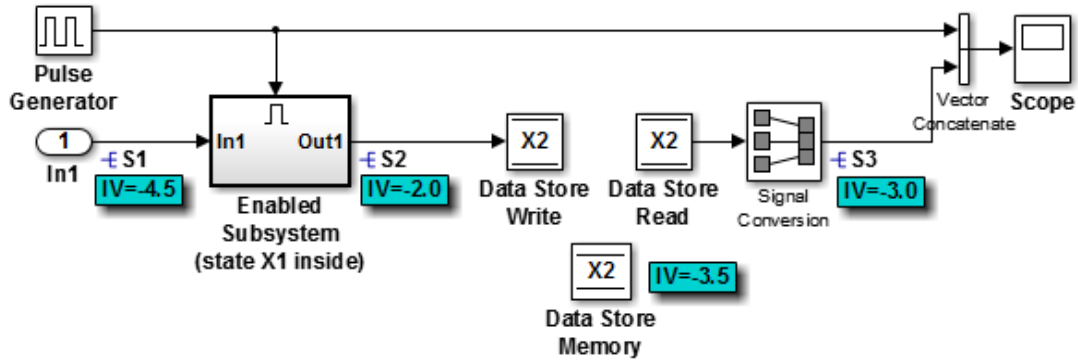
Signal and State Initialization in the Generated Code

The initialization behavior for code generation is the same as that for model simulation with the following exceptions:

- RSim executables can use the **Data Import/Export** pane of the Configuration Parameters dialog box to load input values from MAT-files. GRT and ERT executables cannot load input values from MAT-files.
- The initial value for a block output signal or root level input or output signal can be overwritten by an external (calling) program.
- Setting the initial value for persistent signals is relevant if the value is used or viewed by an external application.

When you generate code, initialization statements are placed in *`model`*`.c` or *`model`*`.cpp` in the model's initialize code.

For example, consider the model rtwdemo_sigobj_iv.



If you create and initialize signal objects in the base workspace, the code generator places initialization code for the signals in the file `rtwdemo_sigobj_iv.c` under the `rtwdemo_sigobj_iv_initialize` function, as shown below.

```
 /* Model initialize function */

     void rtwdemo_sigobj_iv_initialize(void)

     {
        .
        .
        .
 /* exported global signals */
 S3 = -3.0;

 S2 = -2.0;
        .
        .
        .
/* exported global states */
X1 = 0.0;
X2 = 0.0;

/* external inputs */
S1 = -4.5;
        .
        .
        .
```

The following code shows the initialization code for the enabled subsystem's Unit Delay block state `X1` and output signal `S2`.

```
void MdlStart(void) {
          .
          .
          .
 /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
  X1 = aa1;

 /* Start for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */

  /* virtual outports code */

  /* (Virtual) Outport Block: '<S2>/Out1' */

  S2 = aa2;

}
```

For an enabled subsystem, the initial value is also used as a reset value if the subsystem's Outport block parameter **Output when disabled** is set to `reset`. The following code from `rtwdemo_sigobj_iv.c` shows the assignment statement for `S3` as it appears in the model output function `rtwdemo_sigobj_iv_output`.

```
/* Model output function */

static void rtwdemo_sigobj_iv_output(void)
```

```
{
        .
        .
        .
 /* Disable for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */

    /* (Virtual) Outport Block: '<S2>/Out1' */

    S2 = aa2;
```

Generate Tunable Initial Conditions

You can represent initial conditions for signals and states by creating tunable global variables in the generated code. These variables allow you to restart an application by using initial conditions that are stored in memory.

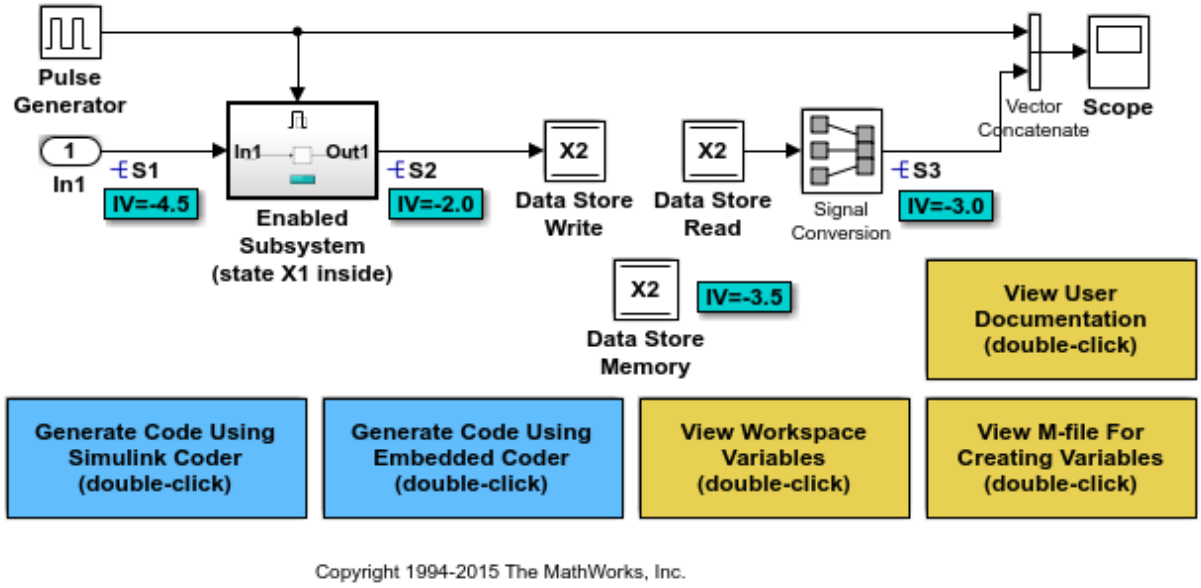
If you set **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to `Tunable`, initial conditions appear as tunable fields of the global parameters structure.

Whether you set **Default parameter behavior** to `Tunable` or `Inlined`, you can use a tunable parameter to specify the `InitialValue` property of a signal object or the **Initial condition** parameter of a block. For basic information about tunable parameters, see "Block Parameter Representation in the Generated Code" (Simulink Coder).

This example shows how to use tunable parameters to specify initial conditions for signals and states.

Explore Example Model

Open the example model rtwdemo_sigobj_iv. The signal `S2` uses a `Simulink.Signal` object in the base workspace.



Double-click the `Simulink.Signal` object `S2` to view its properties. The **Initial value** property is set to `aa2`. The object uses the variable `aa2` to specify an initial condition for the signal `S2`. The **Storage class** property is set to `ExportedGlobal`. To use a `Simulink.Signal` object to initialize a signal, the signal object must use a storage class other than `Auto` or `SimulinkGlobal`.

On the **Optimization > Signals and Parameters** pane in the Configuration Parameters dialog box, click **Configure**. The variable `aa2` is a tunable parameter that uses the storage class `ExportedGlobal`.

In the model, open the Enabled Subsystem. In the Outport block dialog box, the parameter **Output when disabled** is set to `reset`. When the subsystem becomes disabled, the output signal `S2` resets to the initial value `aa2`.

Open the Unit Delay block dialog box. On the **State Attributes** tab, the **State name** box is set to `X1`.

Open the Enable block dialog box. The parameter **States when enabling** is set to `reset`. When the subsystem transitions from a disabled state to an enabled state, it resets internal block states, such as `X1`, to their initial values.

In the base workspace, double-click the `Simulink.Signal` object `X1` to view its properties. The **Initial value** property is set to `aa1`.

Double-click the `Simulink.Parameter` object `aa1` to view its properties. The **Storage class** property is set to `ExportedGlobal`. You can generate tunable initial conditions for block states by using tunable parameters such as `aa1` and `Simulink.Signal` objects such as `X1`.

Generate and Inspect Code

Generate code with the example model.

```
### Starting build procedure for model: rtwdemo_sigobj_iv
### Successful completion of build procedure for model: rtwdemo_sigobj_iv
```

In the code generation report, view the file `rtwdemo_sigobj_iv.c`. The code uses global variables to represent the block state `X1` and the signal `S2`.

```
/* Exported block states */
real_T X1;                             /* '<S2>/Unit Delay' */

/* Exported block signals */
real_T S1;                             /* '<Root>/In1' */
real_T S3;                             /* '<Root>/Signal Conversion' */
real_T S2;                             /* '<S2>/Unit Delay' */
```

The code uses global variables to represent the tunable parameters `aa1` and `aa2`.

```
/* Exported block parameters */
real_T aa1 = -2.5;                     /* Variable: aa1

real_T aa2 = -2.0;                     /* Variable: aa2
```

The model initialization function uses the tunable parameter `aa1` to initialize the state `X1`. The function also uses the tunable parameter `aa2` to initialize the signal `S2`.

```
  /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside
  /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
  X1 = aa1;

  /* SystemInitialize for Outport: '<S2>/Out1' */
  S2 = aa2;
```

In the model step function, when the Enabled Subsystem transitions from a disabled state to an enabled state, the Unit Delay block state `X1` resets to its initial value.

```
if (rtb_PulseGenerator > 0) {
  if (!rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
    /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
    X1 = aa1;
    rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = true;
  }
```

If the Enabled Subsystem becomes disabled during code execution, the algorithm uses the tunable initial condition `aa2` to set the value of the signal `S2`.

```
} else {

  if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
    /* Disable for Outport: '<S2>/Out1' */
    S2 = aa2;
    rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
  }
}
```

Generate Tunable Initial Condition Structure for Bus Signal

When you use a MATLAB® structure to specify initialization values for the signal elements in a bus, you can create a tunable global structure in the generated code.

If you set **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to `Tunable`, the initial condition appears as a tunable substructure of the global parameters structure.

Whether you set **Default parameter behavior** to `Tunable` or `Inlined`, you can specify the initial condition by using a tunable `Simulink.Parameter` object whose value is a structure. If you apply a storage class other than `Auto` to the parameter object, the structure is tunable in the generated code.

To generate efficient code by avoiding data type mismatches between the structure and the bus signal, use either:

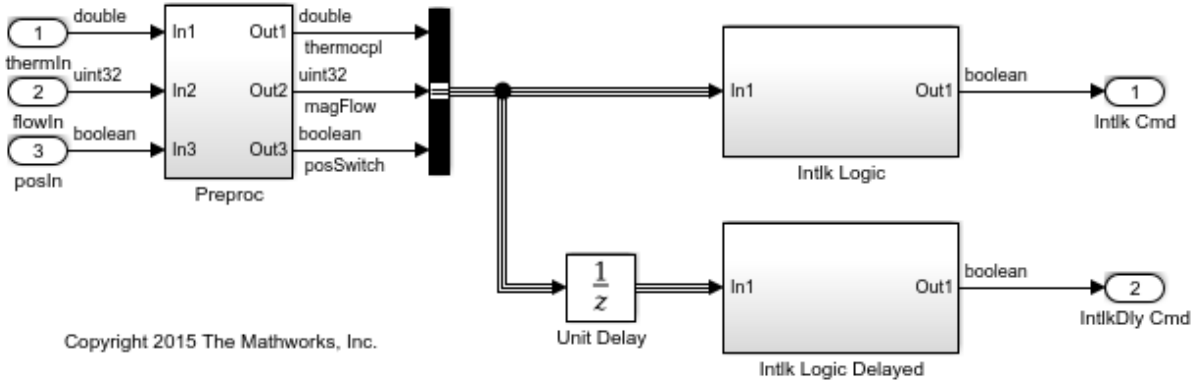
- Typed expressions to specify the values of the structure fields. Match the data type of each field with the data type of the corresponding signal element.
- A `Simulink.Bus` object to control the data types of the structure fields and the signal elements.

For basic information about using structures to initialize bus signals, and to decide how to control field data types, see "Specify Initial Conditions for Bus Signals" (Simulink).

Generate Tunable Initial Condition Structure

This example shows how to use a tunable structure parameter to initialize a virtual bus signal.

Open the example model rtwdemo_tunable_init_struct.



In the Inport block dialog boxes, open the **Signal Attributes** tab. Each Inport uses a different output data type.

Open the Bus Creator block dialog box. The block output is a virtual bus.

In the Configuration Parameters dialog box, open the **Optimization > Signals and Parameters** pane. The configuration parameter **Default parameter behavior** is set to `Tunable`. By default, block parameters, including initial conditions, appear in the generated code as tunable fields of the global parameters structure.

Open the Unit Delay block dialog box. Set **Initial condition** to a structure that specifies an initial condition for each of the three signal elements. To generate efficient code,

match the data types of the structure fields with the data types of the corresponding signal elements.

```
set_param('rtwdemo_tunable_init_struct/Unit Delay','InitialCondition',...
'struct(''thermocpl'',15.23,''magFlow'',uint32(79),''posSwitch'',false)')
```

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_tunable_init_struct
### Successful completion of build procedure for model: rtwdemo_tunable_init_struct
```

In the code generation report, view the file `rtwdemo_tunable_init_struct_types.h`. The code defines a structure type whose fields use the data types that you specified in the `struct` expression.

```
#ifndef DEFINED_TYPEDEF_FOR_struct_mqGi1jsItEOG7cf1bNqMu_
#define DEFINED_TYPEDEF_FOR_struct_mqGi1jsItEOG7cf1bNqMu_

typedef struct {
  real_T thermocpl;
  uint32_T magFlow;
  boolean_T posSwitch;
} struct_mqGi1jsItEOG7cf1bNqMu;
```

View the file `rtwdemo_tunable_init_struct.h`. The `struct` type definition of the global parameters structure contains a substructure, `UnitDelay_InitialCondition`, which represents the **Initial condition** parameter of the Unit Delay block.

```
struct P_rtwdemo_tunable_init_struct_T_ {
  struct_mqGi1jsItEOG7cf1bNqMu UnitDelay_InitialCondition;/* Mask Parameter: UnitDelay_
```

View the file `rtwdemo_tunable_init_struct_data.c`. This source file allocates memory for the global parameters structure. The substructure `UnitDelay_InitialCondition` appears.

```
/* Block parameters (auto storage) */
P_rtwdemo_tunable_init_struct_T rtwdemo_tunable_init_struct_P = {
  {
    15.23,
    79U,
    0
  },                                   /* Mask Parameter: UnitDelay_InitialCondition
```

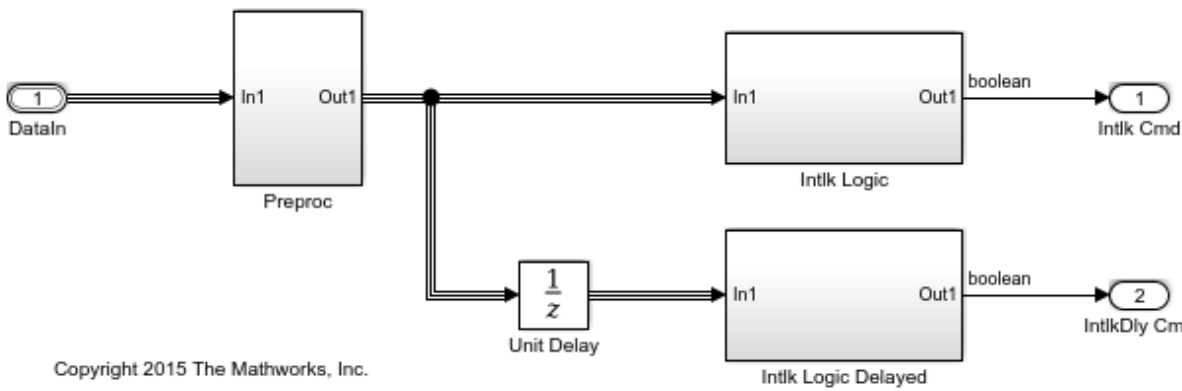
View the file `rtwdemo_tunable_init_struct.c`. The model initialization function uses the fields of the substructure to initialize the block states.

```
/* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
rtwdemo_tunable_init_struct_DW.UnitDelay_1_DSTATE =
  rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.thermocpl;
rtwdemo_tunable_init_struct_DW.UnitDelay_2_DSTATE =
  rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.magFlow;
rtwdemo_tunable_init_struct_DW.UnitDelay_3_DSTATE =
  rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.posSwitch;
```

Use Bus Object to Specify Data Types

If you create a bus object, you can use it to specify the data type of the bus signal and the tunable initial condition structure. Before code generation, the `Simulink.Parameter` object casts the values of the structure fields to the data types of the signal elements. For basic information about creating bus objects and using them in models, see "When to Use Bus Objects" (Simulink).

Open the example model rtwdemo_init_struct_busobj.



In the base workspace, double-click the `Simulink.Bus` object `ComponentData`. The object defines three signal elements: `thermocpl`, `magFlow`, and `posSwitch`. The elements each use a different data type.

Open the block dialog box for the Inport block DataIn. The output data type is set to `Bus: ComponentData`.

Create the tunable structure parameter `initStruct`. You can specify the field values by using untyped expressions. To improve readability, specify the field `posSwitch` with a Boolean value. Specify the `DataType` property of the parameter object as `'Bus: ComponentData'`.

```
initStruct = struct(...
    'thermocpl',15.23,...
    'magFlow',79,...
    'posSwitch',false ...
    );

initStruct = Simulink.Parameter(initStruct);
initStruct.StorageClass = 'ExportedGlobal';
initStruct.DataType = 'Bus: ComponentData';
```

In the Unit Delay block dialog box, specify **Initial condition** as `initStruct`.

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_init_struct_busobj
### Successful completion of build procedure for model: rtwdemo_init_struct_busobj
```

In the code generation report, view the file `rtwdemo_init_struct_busobj_types.h`. The code creates a structure type `ComponentData` whose fields use the data types in the bus object.

```
#ifndef DEFINED_TYPEDEF_FOR_ComponentData_
#define DEFINED_TYPEDEF_FOR_ComponentData_

typedef struct {
  real_T thermocpl;
  uint32_T magFlow;
  boolean_T posSwitch;
} ComponentData;
```

View the file `rtwdemo_init_struct_busobj.c`. The code creates a global variable to represent the tunable parameter object `initStruct`.

```
/* Exported block parameters */
ComponentData initStruct = {
  15.23,
  79U,
```

```
  0
} ;                                    /* Variable: initStruct
```

The model initialization function uses the structure fields to initialize the block states.

```
  /* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
  rtwdemo_init_struct_busobj_DW.UnitDelay_1_DSTATE = initStruct.thermocpl;
  rtwdemo_init_struct_busobj_DW.UnitDelay_2_DSTATE = initStruct.magFlow;
  rtwdemo_init_struct_busobj_DW.UnitDelay_3_DSTATE = initStruct.posSwitch;
```

To change the data type of any of the three signal elements, specify the new type in the bus object. The signal element in the model uses the new type. Before simulation and code generation, the parameter object `initStruct` casts the corresponding structure field to the new type.

Continuous Block State Naming in Generated Code

In this section...

To determine the variable or field name generated for a continuous block state, do one of the following:

- Use a default name created by the code generator.
- In the block parameter dialog box, in the **State name** field, specify a name.

These names apply to the following continuous blocks:

- Integrator
- Integrator Limited
- Second-Order Integrator
- Second-Order Integrator Limited
- PID Controller
- PID Controller (2DOF)
- State Space
- Transfer Fcn
- Variable Time Delay
- Variable Transport Delay
- Zero-Pole

To name states for other types of blocks, see "Discrete Block State Naming in Generated Code" on page 19-160.

Default Block State Naming Convention

If you do not define a symbolic name for a block state, the code generator uses the following default naming convention:

```
Name#_CSTATE
```

- `Name` is the name of the block type, such as `Integrator`. If you edit the block type name displayed in the model, the code generator uses that name in the identifier.
- `#` is a unique ID number (#) assigned by the code generator if multiple instances of the same block type appear in the model. The ID number is appended to `Name`.
- `_CSTATE` is a suffix that is appended to the name and ID number.

For example, if you do not specify a state name for an Integrator block, the code generator creates the identifier:

```
rtX.Integrator_CSTATE = rtP.Integrator_IC;
```

If you specify, in the **State Name** field, `'myintegratorblockname'` for an Integrator block, the code generator creates this identifier:

```
rtX.myintegratorblockname = rtP.Integrator_IC;
```

Define User Block State Names

In the block parameters dialog box, you can define your own symbolic name for a block state.

1. In your model, double-click the block.
2. At the bottom of the block parameters dialog box, in the **State Name** field, enter the name that you want to use for the state.
3. Click **OK** or **Apply** to accept the value.
4. Generate code and examine it to see the new identifier name.

Discrete Block State Naming in Generated Code

In this section...

To determine the variable or field name generated for a block's state, you can:

- Use a default name generated by the code generator
- Define a symbolic name by using the **State name** field of the **State Attributes** tab in a block dialog box

To name states for certain continuous blocks, see “Continuous Block State Naming in Generated Code” on page 19-158.

For certain discrete block types, you can control how block states in your model are stored and represented in the generated code. In a block dialog box, using the **State Attributes** tab, you can:

- Assign symbolic names to block states in generated code.
- Control whether states declared in generated code are interfaceable (visible) to externally written code.
- Specify that states be stored in locations declared by externally written code.

Discrete blocks that you can control how block states are stored and represented in the generated code are:

- Discrete Filter
- Discrete PID Controller
- Discrete PID Controller (2DOF)
- Discrete State-Space
- Discrete-Time Integrator
- Discrete Transfer Fcn
- Discrete Zero-Pole
- Memory
- Unit Delay

- Delay

These blocks require persistent memory to store values representing the state of the block between consecutive time intervals. By default, such values are stored in a *data type work vector*. This vector is usually referred to as the DWork vector. It is represented in generated code as `model_DWork`, a global data structure.

If you want to interface a block state to your handwritten code, you can specify that the state is stored to a location other than the `DWork` vector. You do this by assigning a storage class to the block state.

Default Block State Naming Convention

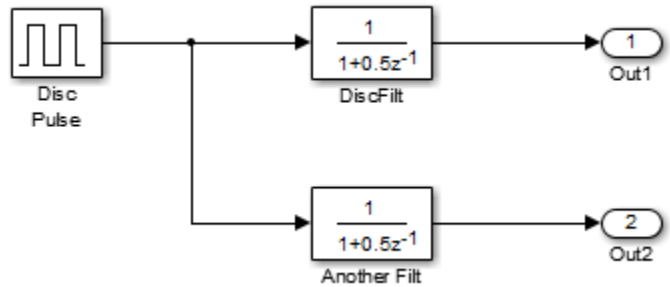
If you do not define a symbolic name for a block state, the code generator uses the following default naming convention:

```
BlockType#_DSTATE
```

where

- `BlockType` is the name of the block type (for example, Discrete_Filter). If you edit the block type name displayed in the model, the code generator uses that name in the identifier.
- `#` is a unique ID number (#) assigned by the code generator if multiple instances of the same block type appear in the model. The ID number is appended to `BlockType`.
- `_DSTATE` is a suffix that is appended to the block type and ID number.

For example, consider the model shown in the next figure.



Model with Two Discrete Filter Block States

Examine the code generated for the states of the two Discrete Filter blocks. Assume that:

- Neither blocks state has a user-defined name.
- The upper Discrete Filter block has `Auto` storage class (and is therefore stored in the `DWork` vector).
- The lower Discrete Filter block has `ExportedGlobal` storage class.

The states of the two Discrete Filter blocks are stored in `DWork` vectors, initialized as shown in the code:

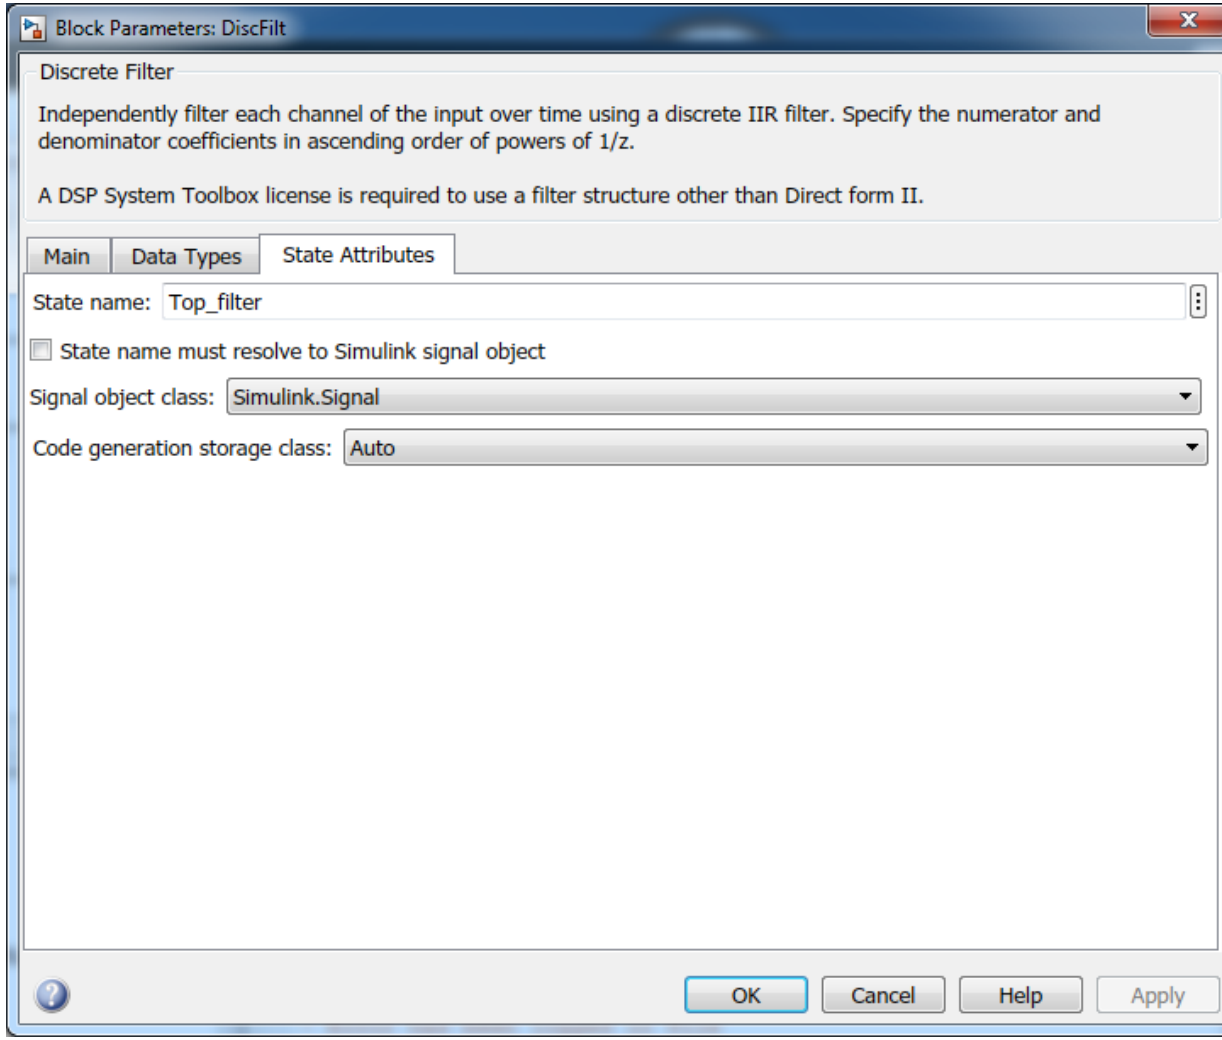
```
/* data type work */
disc_filt_states_M->Work.dwork = ((void *)
&disc_filt_states_DWork);
    (void)memset((char_T *) &disc_filt_states_DWork, 0,
     sizeof(D_Work_disc_filt_states));
    {
      int_T i;
      real_T *dwork_ptr = (real_T *)
&disc_filt_states_DWork.DiscFilt_DSTATE;

      for (i = 0; i < 2; i++) {
        dwork_ptr[i] = 0.0;
      }
    }
```

Define User Block State Names

Using the **State Attributes** tab of a block dialog box, you can define your own symbolic name for a block state:

1. In your block diagram, double-click the desired block. This action opens the block dialog box, containing two or more tab, which includes **State Attributes**.
2. Click the **State Attributes** tab.
3. Enter the symbolic name in the **State name** field. For example, enter the state name `Top_filter`.
4. Click **Apply**.



5 Click **OK**.

The following state initialization code was generated from the example model shown in “Default Block State Naming Convention” on page 19-161, under the following conditions:

- The upper Discrete Filter block has the state name `Top_filter`, and `Auto` storage class (and is therefore stored in the `DWork` vector).
- The lower Discrete Filter block has the state name `Lower_filter`, and storage class `ExportedGlobal`.

`Top_filter` is placed in the `Dwork` vector.

```
/* data type work */
    disc_filt_states_M->Work.dwork = ((void *)
&disc_filt_states_DWork);
    (void)memset((char_T *) &disc_filt_states_DWork, 0,
    sizeof(D_Work_disc_filt_states));
    disc_filt_states_DWork.Top_filter = 0.0;

    /* exported global states */
    Lower_filter = 0.0;
```

Initialization of Signal, State, and Parameter Data in the Generated Code

Signal lines, block parameters, and block states in a model can appear in the generated code as data, for example, as global variables. By default, the code initializes this data before execution of the primary algorithm. To match the numerics of simulation in Simulink, the code generator chooses the initial values based on specifications that you make in the model.

By understanding how the generated code initializes data, you can:

- Model a system that reinitializes states during execution, which means that the application can restart the entire system.
- Store initial values in memory as variables, which can persist between execution runs. You can then overwrite these values before starting or restarting a system.
- Generate efficient code by eliminating storage for invariant initial values and by preventing the generation of code that unnecessarily or redundantly initializes data.

For basic information about initializing signals and states in a model, see "Initialize Signals and Discrete States" (Simulink) and "Load State Information" (Simulink).

Static Initialization and Dynamic Initialization

To initialize a data item such as a global variable, an application can use either static or dynamic initialization.

- Static initialization occurs in the same statement that defines (allocates memory for) the variable. The initialization does not occur inside a function definition.

  The code can be more efficient because none of the generated model functions execute initialization statements.
- Dynamic initialization occurs inside a function. For each model or nonvirtual subsystem, the code generator typically creates one or more functions that are dedicated to initialization.

  The generated code or your code can restart a system by calling the initialization function or functions at any time during execution.

Real-World Ground Initialization Requiring Nonzero Bit Pattern

Each data item has a real-world *ground value*. This value can depend on the data type of the item. For example, for a signal whose data type is `double` or `int8`, the real-world ground value is zero. For an enumeration, the ground value is the default enumeration member.

For some kinds of data, to represent a real-world ground value, a computer stores zero in memory (all bits zero). However, for some other data, a computer stores a nonzero value in memory. This data includes, for example:

- Fixed-point data with bias. The code initializes such a data item to the stored integer value that, given the scaling and bias, represents real-world zero.
- An enumeration whose default member maps to an integer value other than zero. For example, if the default member is `High` with an underlying integer value of 3, the code initializes such a data item to `High`.

Initialization of Signal and State Data

In a model, you can control signal and state initial values through block parameters. For example, to set the initial value of a Unit Delay block, you use the **Initial condition** parameter. In some cases, you can also use the `InitialValue` property of a `Simulink.Signal` object. For most of these block parameters, the default value is `0`.

You can also initialize states by using State Writer blocks in Initialize Function subsystems and the **Initial states** model configuration parameter.

By default, the generated code dynamically initializes signal and state data (and other data, such as the model error status) in the generated initialization function. The function, named *`model`*`_initialize` by default, performs signal and state initialization operations in this order:

1. Initializes all of the signal and state data in the default generated structures, such as the DWork structure, to a stored value of zero.
2. Initializes additional signal and state data that are not in the default generated structures to the relevant real-world ground value.

   This initialization applies only to data that meet both of these criteria:

   - The generated code defines (allocates memory for) the data.

- The data use a storage class other than `Auto` (the default storage class) or `SimulinkGlobal`.

For example, the code applies this operation to data items that use the storage class `ExportedGlobal`.

3. Initializes each signal and state to the real-world value that the model specifies, for example, through the **Initial condition** parameter of a Unit Delay block.
4. Initializes each state to the real-world value that you assign by using a State Writer block. The function performs this initialization only if you use an Initialize Function subsystem in the model.
5. Initializes each state to the real-world value that you specify with the configuration parameter **Initial states**.

After this initialization function executes, each data item has the last real-world value that the function assigned. For example, if you use a State Writer block to initialize a block state to `5` while also using the **Initial states** configuration parameter to initialize the same state to `10`, the state ultimately uses `10` as an initial value.

`memset` for Bulk Initialization

To initialize signal or state data items that have contiguous storage to a stored value of zero, the generated code can call `memset` in an initialization function. Data items that have contiguous storage include the DWork structure, arrays, or data items that use a multiword data type.

If your application requires it, you can prevent the generated code from using `memset` for initializing floating-point data to stored zero. See "Use memset to initialize floats and doubles to 0.0" (Simulink).

Tunable Initial Values

You can configure the way that tunable block parameters, such as the **Gain** parameter of a Gain block, appear in the generated code. Most block parameters that set initial values (for example, **Initial condition**) are tunable. For example, the configuration parameter **Default parameter behavior** can determine whether the initial values appear in the generated code as inlined constants or as tunable global data. You can also use parameter objects and storage classes to control the representation of these initial values.

For tunable initial values, in the model initialization function, the right-hand side of the assignment statement is a global variable, structure field, or other data whose value you can change in memory.

To make initial values tunable in the generated code, see “Control Signal and State Initialization in the Generated Code” on page 19-147.

Initialization of Parameter Data

The generated code statically initializes parameter data to the values that you specify in Simulink. For example, these model elements appear in the generated code as parameter data:

- Tunable block parameters, such as the **Gain** parameter of a Gain block, when you set **Default parameter behavior** to `Tunable`. Each parameter appears as a field of a dedicated global structure.
- Some tunable block parameters when you set **Default parameter behavior** to `Inlined`. When the code generator cannot inline the value of a parameter as a literal number, the parameter appears as a field of a dedicated global `const` structure.
- `Simulink.Parameter` objects to which you apply a storage class or custom storage class that has an exported data scope. For example, the built-in storage class `ExportedGlobal` has an exported data scope, but the storage class `ImportedExtern` does not.

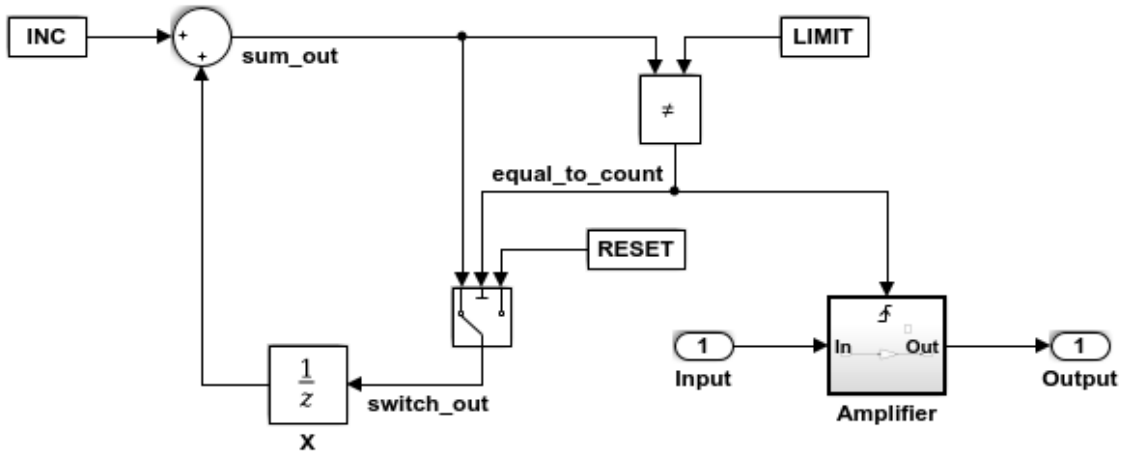
Data Initialization in the Generated Code

This example shows how the generated code initializes signal, state, and parameter data.

Explore Example Model

Open the example model, `rtwdemo_rtwintro`.

```
open_system('rtwdemo_rtwintro')
```



In the Unit Delay block, the **Initial condition** parameter is set to `0`, the default, which means the initial value of the block state is zero.

Set **Initial condition** to a nonzero number, for example, `5`.

```
set_param('rtwdemo_rtwintro/X','InitialCondition','5')
```

Inspect the **State Attributes** tab. The block state is named `X`.

Set **Code generation storage class** to `ExportedGlobal`. When you choose this setting, the block state appears in the generated code as a separate global variable.

```
set_param('rtwdemo_rtwintro/X','StateStorageClass','ExportedGlobal')
```

In the model, open the `Amplifier` subsystem, which is a triggered subsystem.

In the subsystem, in the Outport block, inspect the **Initial output** parameter. The value is `0`, the default. This subsystem output requires an initial value because the subsystem executes conditionally. Leave the initial value at the default.

In the model, clear **Configuration Parameters > All Parameters > Signal storage reuse**. When you clear this setting, signal lines appear in the generated code as fields of a generated structure whose purpose is to store signal data. This representation of the signals makes it easier to see how the code generator initializes data.

```
set_param('rtwdemo_rtwintro','OptimizeBlockIOStorage','off')
```

In the model, inspect the configuration parameter **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior**. The configuration parameter is set to `Inlined`, which means block parameters, including initial values, appear in the generated code as inlined literals or as `const` data.

In the model, inspect the Constant block labeled `INC`. The **Constant value** parameter of the block is set to `INC`. `INC` is a MATLAB variable in the base workspace.

At the command prompt, convert `INC` to a `Simulink.Parameter` object and apply the storage class `ExportedGlobal`. With these settings, the generated code defines `INC` as a global variable. Concerning initialization, `INC` is an item of parameter data.

```
INC = Simulink.Parameter(INC);
INC.StorageClass = 'ExportedGlobal';
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_rtwintro');
```

```
### Starting build procedure for model: rtwdemo_rtwintro
### Successful completion of build procedure for model: rtwdemo_rtwintro
```

In the generated file `rtwdemo_rtwintro.c`, outside the definition of any function, the code statically initializes the parameter data `INC`. The value of `INC` is `1`.

```
file = fullfile('rtwdemo_rtwintro_grt_rtw','rtwdemo_rtwintro.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T INC = 1U;',1,1)
```

```
/* Exported block parameters */
uint8_T INC = 1U;                      /* Variable: INC
```

In the same file, inspect the definition of the `rtwdemo_rtwintro_initialize` function. First, the function uses `memset` to initialize all of the internal signals in the model to a stored value of `0`.

```
rtwdemodbtype(file,'/* block I/O */','sizeof(B_rtwdemo_rtwintro_T));',1,1)
```

```
  /* block I/O */
  (void) memset(((void *) &rtwdemo_rtwintro_B), 0,
                sizeof(B_rtwdemo_rtwintro_T));
```

The function then initializes the Unit Delay state, `X`, to the appropriate ground value. In this case, the ground value is zero.

```
rtwdemodbtype(file,'/* exported global states */','X = 0U;',1,1)
```

```
  /* exported global states */
  X = 0U;
```

The function also initializes other data, including the root-level inputs and outputs (Inport and Outport blocks), to the appropriate ground values.

```
rtwdemodbtype(file,'/* external inputs */','Amplifier_Trig_ZCE = POS_ZCSIG;',1,1)
```

```
  /* external inputs */
  rtwdemo_rtwintro_U.Input = 0;

  /* external outputs */
  rtwdemo_rtwintro_Y.Output = 0;
  rtwdemo_rtwintro_PrevZCX.Amplifier_Trig_ZCE = POS_ZCSIG;
```

The function then initializes `X` to the value that you specified in the **Initial condition** block parameter.

```
rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: ''<Root>/X'' */',...
    'X = 5U;',1,1)
```

```
  /* InitializeConditions for UnitDelay: '<Root>/X' */
  X = 5U;
```

Finally, the function initializes the output of the `Amplifier` subsystem.

```
rtwdemodbtype(file,'SystemInitialize for Triggered SubSystem',...
    'End of SystemInitialize for SubSystem',1,1)
```

```
/* SystemInitialize for Triggered SubSystem: '<Root>/Amplifier' */
/* SystemInitialize for Outport: '<Root>/Output' incorporates:
 *  SystemInitialize for Outport: '<S1>/Out'
 */
rtwdemo_rtwintro_Y.Output = 0;
```

Inspect Difference Between Stored Value and Real-World Value

For some data, even if the real-world initial value is zero, a computer stores a nonzero value in memory. To observe this difference, apply a slope-bias fixed-point data type to the block state, `X`. To run this example, you must have Fixed-Point Designer™.

In the Switch block that feeds the Unit Delay block, on the **Signal Attributes** tab, set **Output data type** to `fixdt(1,16,1,3)`. This expression represents a fixed-point data type with a slope of `1` and a bias of `3`.

```
set_param('rtwdemo_rtwintro/Switch','OutDataTypeStr',...
    'fixdt(1,16,1,3)')
```

In the Sum block, on the **Signal Attributes** tab, clear **Require all inputs to have the same data type**.

```
set_param('rtwdemo_rtwintro/Sum','InputSameDT','off')
```

To prevent compilation errors on different platforms, select the model configuration parameter **Generate code only**. This setting causes the model to generate only code.

```
set_param('rtwdemo_rtwintro','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_rtwintro')
```

```
### Starting build procedure for model: rtwdemo_rtwintro
### Successful completion of code generation for model: rtwdemo_rtwintro
```

The model initialization function first initializes `X` to the appropriate real-world ground value, `0`. Due to the slope-bias data type, which has bias `3`, this real-world value corresponds to a stored value of `-3`.

```
rtwdemodbtype(file,'/* exported global states */','X = -3;',1,1)
```

```
  /* exported global states */
```

```
X = -3;
```

The function then initializes `X` to the real-world initial value that you specified in the **Initial condition** block parameter, `5`. This real-world value corresponds to a stored value of `2`.

```
rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: ''<Root>/X'' */',...
    'X = 2;',1,1)
```

```
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 2;
```

Modeling Goals

Goal	More Information
Explicitly model initialization behavior by using blocks	You can explicitly model initialization and reset behavior by using Initialize Function and Reset Function subsystems. In the subsystems, use State Writer blocks to calculate and assign an initial value for a state dynamically. The corresponding code appears in the model initialization function. For more information, see “Generate Code That Responds to Initialize, Reset, and Terminate Events” on page 9-2.
Prevent generation of code that explicitly initializes data to zero	If your application environment already initializes global variables to zero, for more efficient code, you can prevent the generation of statements that explicitly initialize global variables to zero. This optimization applies only to signals and states whose initial values are stored in memory as zero. For example, the code generator does not apply the optimization to: • Data for which you specify a nonzero initial value by using a block parameter. • Data whose real-world initial value is zero but whose corresponding stored value is not zero. • Enumerated data whose default member maps to a nonzero integer. The optimization requires Embedded Coder. For more information, see “Remove Initialization Code” on page 56-3.

Goal	More Information
Generate code that imports data from your handwritten code	You can generate code that reuses (imports) data that your handwritten code defines. For example, you can apply the storage class `ImportedExtern` to a signal line, block state, or parameter object. For imported data: • The generated code does not initialize parameter data. Your code must initialize imported parameter data. • The generated initialization functions dynamically initialize signal and state data. Your code does not need to initialize imported signal or state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world value that you specify in Simulink. To prevent initialization of signal, state, or parameter data by the generated code, you can create a custom storage class and apply it to the data items. In the Custom Storage Class Designer, in the definition of your custom storage class, set **Data initialization** to `None`. For more information about integrating the generated code with external code, see “What Is External Code Integration?” on page 39-3. For information about custom storage classes, see “Introduction to Custom Storage Classes” on page 23-2.

Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box

You can use the Model Parameter Configuration dialog box to declare numeric MATLAB variables in the base workspace as tunable parameters. You can select code generation options, such as storage class, for each tunable parameter.

However, it is a best practice to instead use parameter objects to declare tunable parameters. Do not use the Model Parameter Configuration dialog box to select parameter objects in the base workspace. To use parameter objects, instead of the Model Parameter Configuration dialog box, to declare tunable parameters, see "Override Default Parameter Behavior by Creating Global Variables in the Generated Code" on page 19-49.

Note You cannot use the Model Parameter Configuration dialog box to declare tunable parameters for a referenced model. Use `Simulink.Parameter` objects instead.

Declare Existing Workspace Variables as Tunable Parameters

Use the Model Parameter Configuration dialog box to declare existing workspace variables as tunable parameters for a model.

1. In the Configuration Parameters dialog box, on the **Optimization > Signals and Parameters** pane, click **Configure**.
2. In the Model Parameter Configuration dialog box, under **Source list**, select a method to populate the list of available workspace variables.
   - Select `MATLAB workspace` to view all of the numeric variables that are defined in the base workspace.
   - Select `Referenced workspace variables` to view only the numeric variables in the base workspace that the model uses. Selecting this option begins a diagram update and a search for used variables, which can take time for a large model.
3. In the Model Parameter Configuration dialog box, under **Source list**, select one or more workspace variables.
4. Click **Add to table**. The variables appear as tunable parameters under **Global (tunable) parameters**, and appear in italic font under **Source list**.

5 Optionally, select a parameter under **Global (tunable) parameters**, and adjust the code generation settings for the parameter. For more information about adjusting the code generation options for tunable parameters, see "Set Tunable Parameter Code Generation Options" on page 19-179

6 Click **OK** to apply your selection of tunable parameters and close the dialog box.

Declare New Tunable Parameters

Use the Model Parameter Configuration dialog box to declare new tunable parameters. You can use this technique to declare the names of tunable parameters, and to adjust their code generation settings, before you create the corresponding workspace variables.

1 In the Configuration Parameters dialog box, on the **Optimization > Signals and Parameters** pane, click **Configure**.

2 In the Model Parameter Configuration dialog box, under **Global (tunable) parameters**, click **New**.

3 Under the **Name** column, specify a name for the new tunable parameter.

4 Optionally, adjust the code generation settings for the new parameter. For more information about adjusting the code generation options for tunable parameters, see "Set Tunable Parameter Code Generation Options" on page 19-179

5 Click **OK** to apply your changes and close the dialog box.

Set Tunable Parameter Code Generation Options

To set the properties of tunable parameters listed under **Global (tunable) parameters** in the Model Parameter Configuration dialog box, select a parameter and specify a storage class and, optionally, a storage type qualifier.

Property	Description
Storage class	Select one of the following to use for code generation: • `SimulinkGlobal (Auto)` • `ExportedGlobal` • `ImportedExtern` • `ImportedExternPointer` For more information about tunable parameter storage classes, see "Override Default Parameter Behavior by

Property	Description
	Creating Global Variables in the Generated Code" on page 19-49.
Storage type qualifier	For variables with a storage class other than `SimulinkGlobal (Auto)`, you can add a qualifier (such as `const` or `volatile`) to the generated storage declaration. To do so, you can select a predefined qualifier from the list, or add qualifiers not in the list by typing them in. The code generator does not check the storage type qualifier for validity, and includes the qualifier text in the generated code without checking syntax .

Programmatically Declare Workspace Variables as Tunable Parameters

Tune Parameters from the Command Line

When parameters are MATLAB workspace variables, the Model Parameter Configuration dialog box is the recommended way to see or set the properties of tunable parameters. In addition to that dialog box, you can also use MATLAB `get_param` and `set_param` commands.

Note You can also use `Simulink.Parameter` objects for tunable parameters. See "Block Parameter Representation in the Generated Code" (Simulink Coder) for details.

The following commands return the tunable parameters and corresponding properties:

- `get_param(gcs,'TunableVars')`
- `get_param(gcs,'TunableVarsStorageClass')`
- `get_param(gcs,'TunableVarsTypeQualifier')`

The following commands declare tunable parameters or set corresponding properties:

- `set_param(gcs,'TunableVars',str)`

  The argument `str` (character vector) is a comma-separated list of variable names.
- `set_param(gcs,'TunableVarsStorageClass',str)`

The argument `str` (character vector) is a comma-separated list of storage class settings.

The valid storage class settings are

- `Auto`
- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`

- `set_param(gcs,'TunableVarsTypeQualifier',str)`

  The argument `str` (character vector) is a comma-separated list of storage type qualifiers.

The following example declares the variable `k1` to be tunable, with storage class `ExportedGlobal` and type qualifier `const`. The number of variables and number of specified storage class settings must match. If you specify multiple variables and storage class settings, separate them with a comma.

```
set_param(gcs,'TunableVars','k1')
set_param(gcs,'TunableVarsStorageClass','ExportedGlobal')
set_param(gcs,'TunableVarsTypeQualifier','const')
```

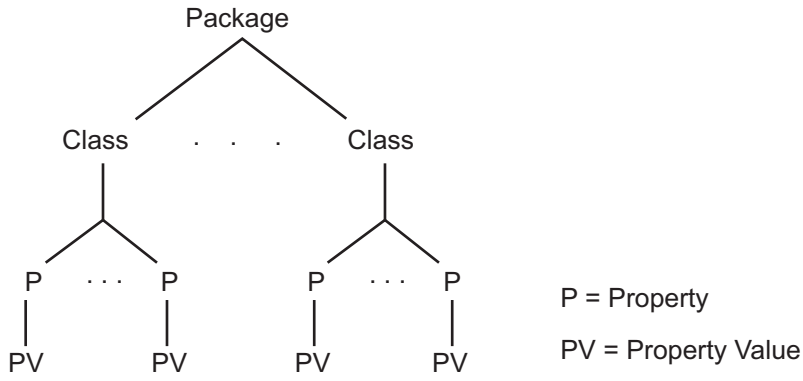
Data Definition and Declaration Management in Embedded Coder

Overview of Data Objects

Data objects include the parameters and signals that the source code uses, and a description of their properties. Data objects appear in the middle pane of the Model Explorer. They also appear in the MATLAB workspace. You can control the property values for each data object, thereby determining how each parameter and signal is defined and declared in generated code.

Simulink uses a hierarchy of terms that are drawn from object-oriented programming. For details, see "Data Objects" (Simulink). The sketch below summarizes this hierarchy.



You can use the `Simulink.Parameter` class to declare a data object for a parameter, where `Simulink` is the package name and Parameter is the class name. Likewise, an instance of a `Simulink.Signal` class, creates a data object for a signal. Signal data objects have a different set of properties than a parameter data objects. When you create a data object, you specify a value for each of the properties, which defines that object. For more information, see Simulink.Parameter class (Simulink) and Simulink.Signal (Simulink).

Related Examples

- "Create Data Objects for Code Generation with Data Object Wizard" on page 24-2
- "Place Global Data Declarations and Definitions in Separate Files" on page 20-3

Place Global Data Declarations and Definitions in Separate Files

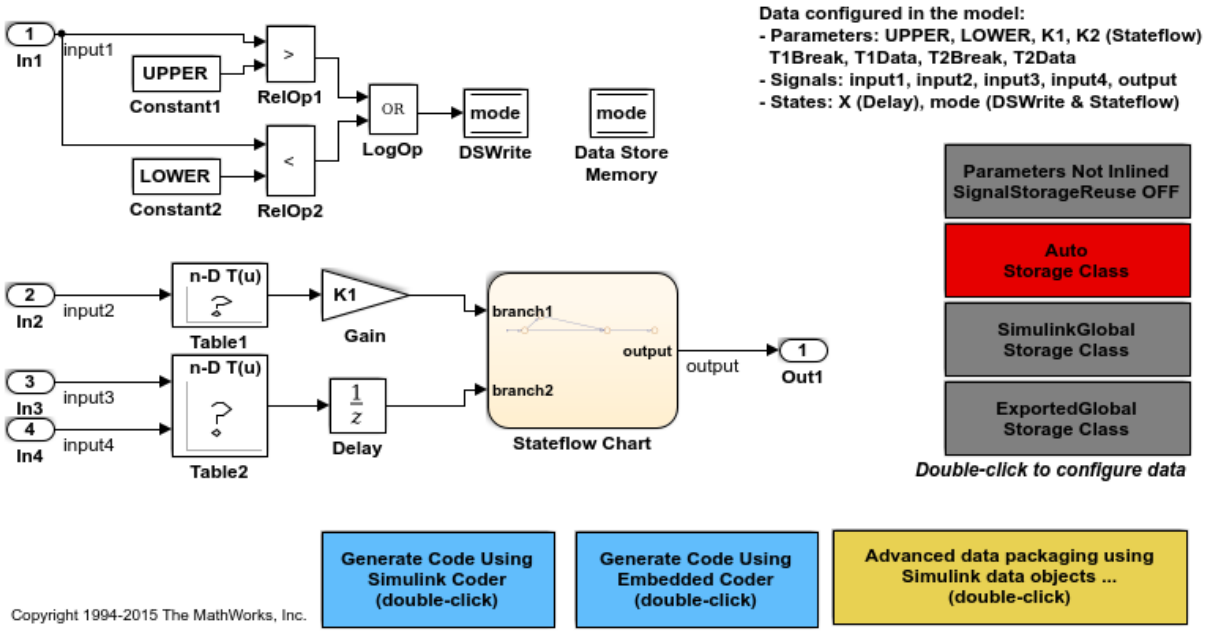
These examples show how to control the file placement of data items (signals, parameters, and states) to which you apply storage classes and custom storage classes.

Place Multiple Data Items in Single File by Default

By default, the declarations and definitions generated for individual data items typically appear in the model source file. This example shows how to modularize the code by placing these global data in a separate file.

Open the example model rtwdemo_basicsc.

```
open_system('rtwdemo_basicsc')
```



The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the **Gain** parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as `input1`.

1. Select **Code > Data Objects > Data Object Wizard**.
2. In the Data Object Wizard, click **Find**. The Data Object Wizard proposes the creation of `Simulink.Parameter` objects to replace the workspace variables and the creation of `Simulink.Signal` objects to represent the named signals and states.
3. Click **Select All** and **Create**. The Data Object Wizard creates the data objects in the base workspace. You can use these objects to specify code generation settings for the corresponding signals, parameters, and states in the model.
4. In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
5. In the **Contents** pane, set **Column View** to `Storage Class`.
6. For all of the data objects, use the **StorageClass** column to apply the custom storage class `Default`. With this custom storage class, each data object appears in the generated code as a separate global variable.
7. In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors custom storage classes such as `Default`.
8. Specify that global data items be defined in a separate file. Set **Configuration Parameters > Code Generation > Code Placement > Data definition** to `Data defined in a single separate source file`. Accept the default for **Data definition filename**, `global.c`.
9. Specify that data be declared in a separate file. Set **Data declaration** to `Data declared in a single separate header file` and accept the default for **Data declaration filename**, `global.h`. Then, click **Apply**.
10. Generate code from the model. Notice that the code generation report lists `global.c` and `global.h` files.
11. Inspect the code generation report. Notice that:

- The global data are defined and, for parameters, initialized in `global.c`.
- The file `rtwdemo_basicsc.c` includes `(#include) rtwdemo_basicsc.h`.
- The file `rtwdemo_basicsc.h` includes `global.h`.

Place Each Data Item in Individual File

In the previous example, you place global data in a separate definition file and a declaration file. You name the files `global.c` and `global.h`. You can override this specification and place each individual data item in its own file. In this example, move the `output` signal to a file named `outputsig.c`. Keep the other data defined in `global.c`.

1. In your current folder, delete the `slprj` subfolder.
2. In the Model Explorer, display the base workspace and select the `output` signal object. The **Simulink.Signal** properties appear in the right pane.
3. In the **Code generation options** section, set **Storage class** to `ExportToFile`. Set **HeaderFile** to `outputsig.h` and **DefinitionFile** to `outputsig.c`. Click **Apply**.
4. Generate code from the model. The code generation report still lists `global.c` and `global.h`, but adds `outputsig.c` and `outputsig.h`.
5. Inspect the new files. The `output` signal is defined in `outputsig.c`. Other data are still defined in `global.c`.

Data Types in Embedded Coder

What Are User-Defined Data Types?

User-defined data types are objects of the following data type classes.

- `Simulink.AliasType`
- `Simulink.NumericType`

You can apply user-defined data types to achieve the following objectives in the generated code.

- Specify custom data type names for individual block parameters and signals by creating aliases of the built-in Simulink types. You can configure the aliases to appear in the block diagram and in generated code. For more information, see "Create Data Type Alias in the Generated Code" on page 21-12.
- Map your own data type definitions to the built-in data types, and specify that your data types are to be used in generated code. For more information, see "Data Type Replacement" on page 21-36.
- Optionally, generate `#include` directives to import header files that contain your data type definitions. This technique allows you to use legacy data types in generated code.

In general, code generated from user-defined data objects conforms to the properties and attributes of the objects as defined for use in simulation. When generating code from user-defined data objects, the name of the object is the name of the data type that is used in the generated code. For `Simulink.NumericType` objects whose `IsAlias` property is `false` or `0`, the name of the functionally equivalent built-in or fixed-point Simulink data type is used instead.

- To create your own data type as an alias of a built-in data type and share the type between data items in a model, you can use a `Simulink.AliasType` object or a `Simulink.NumericType` object. For a `Simulink.NumericType` object, set the `IsAlias` property to `true`.

  To create an alias of an enumerated data type, you must use a `Simulink.AliasType` object.
- To share a numeric data type such as `single`, `int16`, or a fixed-point data type without renaming the type, use a `Simulink.NumericType` object and set `IsAlias` to `false` (the default).

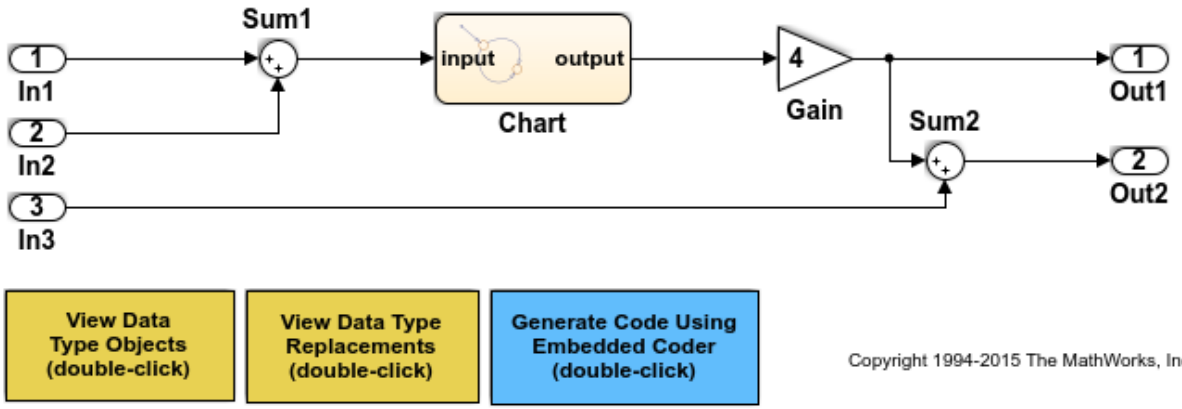
Define Abstract Numeric Types and Rename Types

This model shows user-defined types, consisting of numeric and alias types. Numeric types allow you to define abstract numeric types, which is particularly useful for fixed-point types. Alias types allow you to rename types, which allows you create a relationship for types.

Explore Example Model

Open the example model.

```
open_system('rtwdemo_udt')
```



Key Features of User-Defined Types

- Displayed and propagated on signal lines
- Used to parameterize a model by type (e.g., In1 specifies its **Output data type** as `ENG_SPEED`)
- Types with a common ancestor can be mixed, whereby the common ancestor is propagated (e.g., output of Sum1)
- Intrinsically supported by the Simulink Model Explorer
- Include an optional header file attribute that is ideal for importing legacy types (ignored for GRT targets)
- Types used in the generated code (ignored for GRT targets)

Instructions

1. Inspect the user-defined types in the Model Explorer by double-clicking the first yellow button below.
2. Inspect the replacement data type mapping by double-clicking the second yellow button below.
3. Compile the diagram to display the types in this model (Simulation > Update Diagram or **Ctrl+D**).
4. Generate code with the blue button below and inspect model files to see how user-defined types appear in the generated code.
5. Modify the attributes of `ENG_SPEED` and `ENG_SPEED_OFFSET` and repeat steps 1-4.

Notes

- User-defined types are a feature of Simulink that facilitate parameterization of the data types in a model. Embedded Coder preserves alias data type names (e.g., `ENG_SPEED`) in the generated code, whereas Simulink Coder implements user-define types as their base type (e.g., `real32_T`).
- Embedded Coder also enables you to replace the built-in data types with user-defined data types in the generated code.

Rename Data Type Object

To rename a data type object after you create it (for example, to rename an alias when coding standards change or when you encounter a naming conflict), you can allow Simulink to rename the object and correct all of the references to the object that appear in a model or models. In the Model Explorer, right-click the variable and select **Rename All**. For more information, see "Rename Variable" (Simulink).

Enumerations and Structures

To generate Simulink representations of custom `struct` and `enum` data types that your C code defines, use the `Simulink.importExternalCTypes` function to create corresponding `Simulink.Bus` objects and enumeration classes.

Control File Placement of User-Defined Types

In this section...

When you use data type objects such as `Simulink.AliasType` to specify data types for signals and block parameters, the code generated from the model defines the types with `typedef` statements. To ease integration of the generated code with other existing code, you can control the file placement of the `typedef` statements by adjusting the properties of the objects.

Data Scope and Header File

To control the file placement of a `typedef` statement in generated code, set the `DataScope` and `HeaderFile` properties of the data type object according to the table.

- *`typename`* is the name of the custom data type.
- *`filename`* is the name of a header file.
- *`model`* is the name of the model.

Goal	Specify `DataScope` as	Specify `HeaderFile` as
Export type definition to *`model`*`_types.h`	`Auto`	Empty
Import type definition from a header file that you create, *`filename`*`.h`	`Auto` or `Imported`	*`filename`*`.h`
Export type definition to a generated header file, *`filename`*`.h`	`Exported`	*`filename`*`.h`
Import type definition from a header file that you create, *`typename`*`.h`	`Imported`	Empty
Export type definition to a generated header file, *`typename`*`.h`	`Exported`	Empty

When you import a data type definition, the generated model code creates an `#include` directive for your header file in place of a `typedef` statement. You must supply the header file that contains the `typedef` statement.

By default, the generated `#include` directives use the preprocessor delimiter `"` instead of `<` and `>`. To generate the directive `#include <myTypes.h>`, specify the `HeaderFile` property as `<myTypes.h>`.

Data Type Replacement

If you use Data Type Replacement to replace a built-in Simulink data type with your own data type in generated code, `typedef` statements and `#include` directives appear in `rtwtypes.h` instead of *`model`*`_types.h`.

Macro Guards

When you export one or more data type definitions to a generated header file, the file contains a file-level macro guard of the form `RTW_HEADER_`*`filename`*`_h`.

Suppose you use several `Simulink.AliasType` objects: `mySingleAlias`, `myDoubleAlias`, and `myIntAlias` with these properties:

- `DataScope` set to `Exported`
- `HeaderFile` set to `myTypes.h`

When you generate code, the guarded file `myTypes.h` contains the `typedef` statements:

```
#ifndef RTW_HEADER_myTypes_h_
#define RTW_HEADER_myTypes_h_
#include "rtwtypes.h"

typedef real_T myDoubleAlias;
typedef real32_T mySingleAlias;
typedef int16_T myIntAlias;

#endif
```

When you export data type definitions to *`model`*`_types.h`, the file contains a macro guard of the form `_DEFINED_TYPEDEF_FOR_`*`typename`*`_` for each `typedef` statement. Suppose you use a `Simulink.AliasType` object `mySingleAlias` with these properties:

- `DataScope` set to `Auto`

- `HeaderFile` not specified

When you generate code, the file *`model`*`_types.h` contains the guarded `typedef` statement:

```
#ifndef _DEFINED_TYPEDEF_FOR_mySingleAlias_
#define _DEFINED_TYPEDEF_FOR_mySingleAlias_

typedef real32_T mySingleAlias;

#endif
```

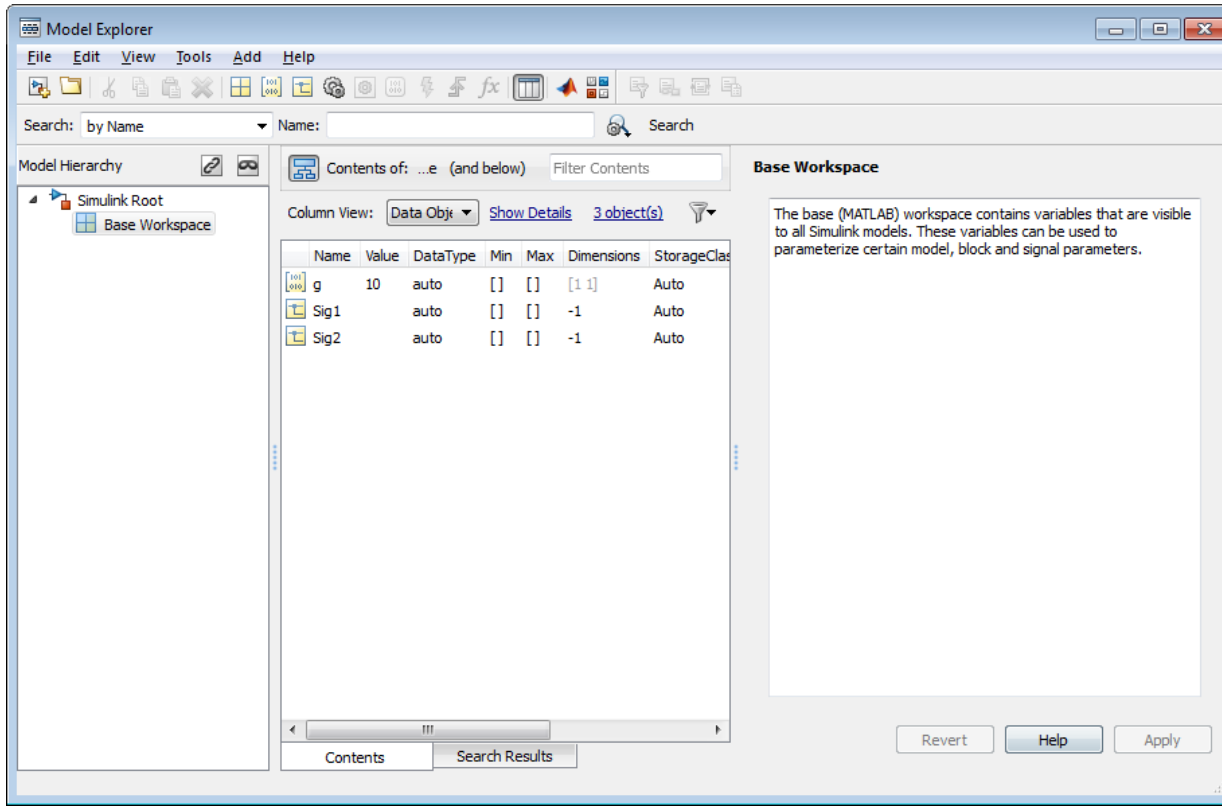
- “Data Type Replacement” on page 21-36
- “What Are User-Defined Data Types?” on page 21-2

Create and Apply User-Defined Data Types

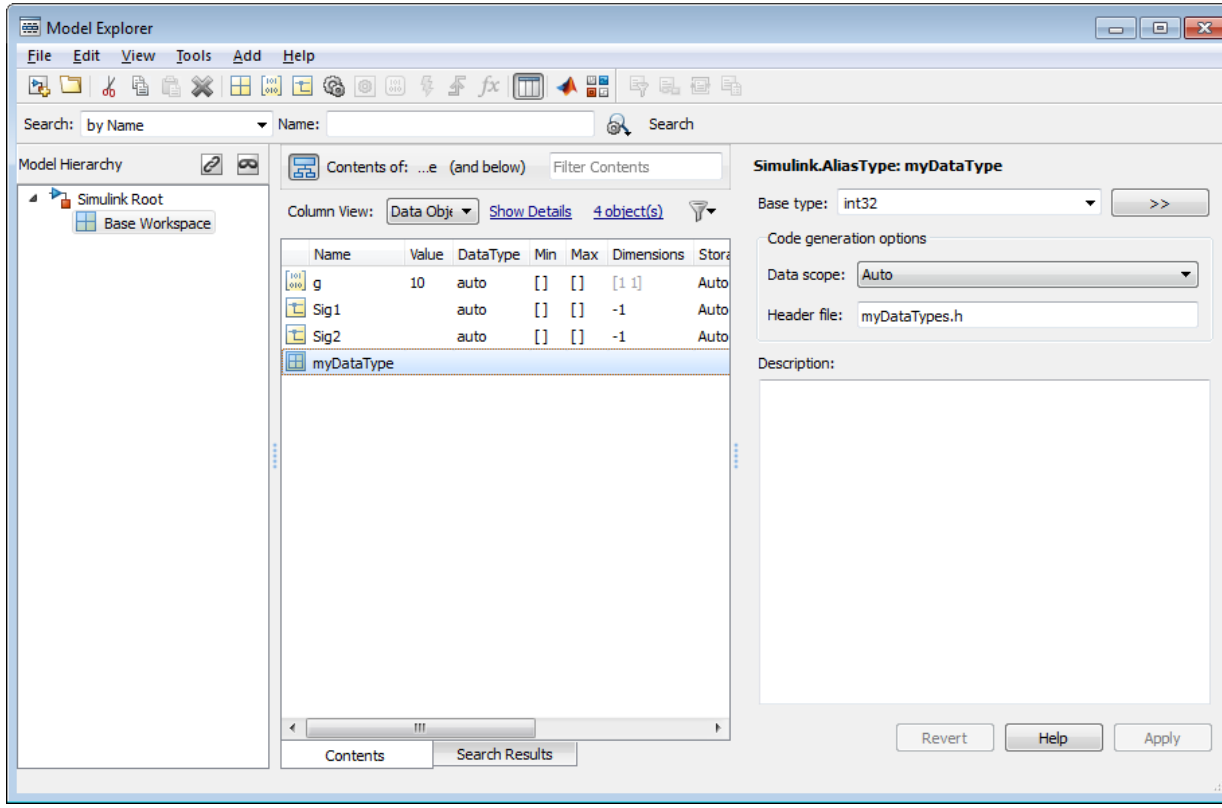
This example shows how to create user-defined data types and specify them for data objects.

1 Open the Model Explorer and create `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace.



2 Click **Add** > **Simulink.AliasType** to create a data type object.

3 Name the object and set its **Base type** to `int32` and **Header file** to `myDataTypes.h`.



4 Select the data object for which you want to specify the user-defined data type. Click its **Data Type** field and from the drop down select **Refresh data types**.

   This action updates the data type list with the user-defined data type you created.

5 Select the user-defined data type.

- “Data Objects” (Simulink)
- “Parameter Data Types in the Generated Code” on page 19-79
- “Data Type Replacement” on page 21-36
- “Create a Named Fixed-Point Data Type in the Generated Code” on page 21-18

Create Data Type Alias in the Generated Code

You can create your own data type in code that a model generates by using an alias of an existing type. You can use the alias to specify parameter and signal data types throughout a model diagram and in generated code.

You can use an alias for the built-in Simulink data types, custom enumerated types that you create, and fixed-point data types that you create. To create a data type alias, you use an object of the class `Simulink.AliasType`.

You can also rename a built-in Simulink type in code generated from a model without using a data type alias in the model diagram. For more information, see "Data Type Replacement".

Export Type Definition

When you integrate code generated from a model with code from other sources, your model code can create an exported `typedef` statement. Therefore, all of the integrated code can use the type. This example shows how to export the definition of a data type to a generated header file.

Create a `Simulink.AliasType` object named `mySingleAlias` that acts as an alias for the built-in data type `single`.

```
mySingleAlias = Simulink.AliasType('single')
```

```
mySingleAlias =

  AliasType with properties:

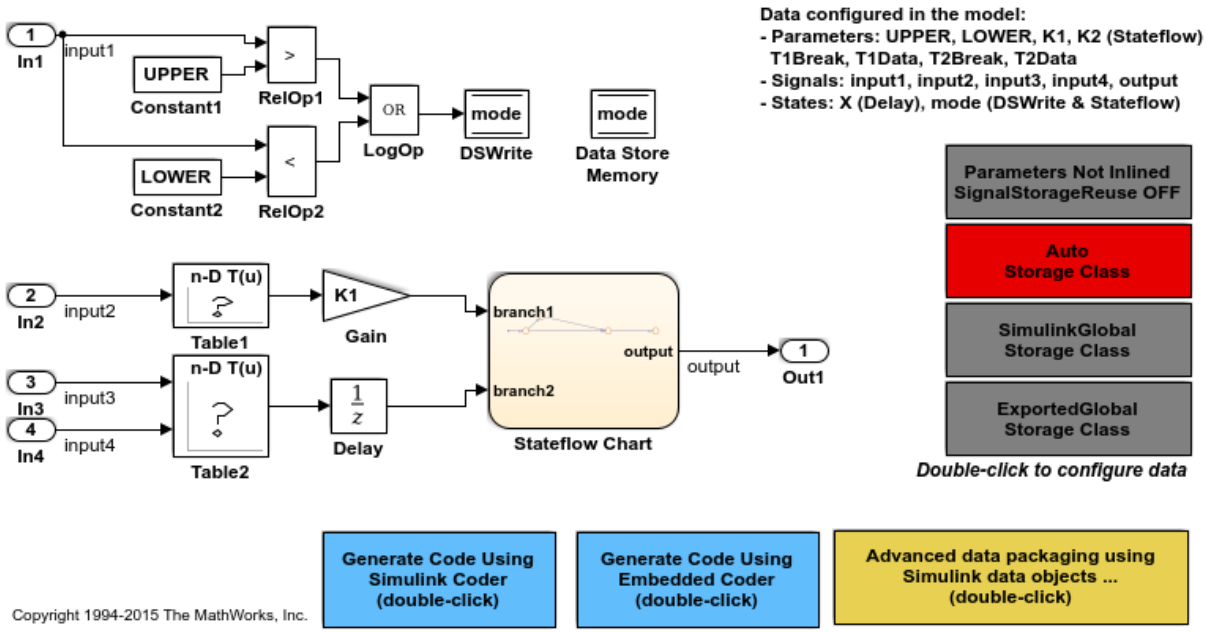
    Description: ''
      DataScope: 'Auto'
     HeaderFile: ''
       BaseType: 'single'
```

Configure the object to export its definition to a header file called `myHdrFile.h`.

```
mySingleAlias.DataScope = 'Exported';
mySingleAlias.HeaderFile = 'myHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```



Inspect the parameters of the Inport block labeled `In1`. On the **Signal Attributes** tab, **Data type** is set to `single`.

Set **Data type** to the alias `mySingleAlias`.

```
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','mySingleAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors data type aliases such as `mySingleAlias`.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for the generated file `myHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "myHdrFile.h"',...
    '#include "myHdrFile.h"',1,1)
```

```
#include "myHdrFile.h"
```

View the file `myHdrFile.h`. The code uses the identifier `mySingleAlias` as an alias for the data type `real32_T`. By default, generated code represents the Simulink data type `single` by using the identifier `real32_T`.

The code also provides a macro guard of the form `RTW_HEADER_filename_h_`. When you export a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent identifier clashes.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','myHdrFile.h');
rtwdemodbtype(file,'#ifndef RTW_HEADER_myHdrFile_h_',...
    '/* RTW_HEADER_myHdrFile_h_ */',1,1)
```

```
#ifndef RTW_HEADER_myHdrFile_h_
#define RTW_HEADER_myHdrFile_h_
#include "rtwtypes.h"

typedef real32_T mySingleAlias;
typedef creal32_T cmySingleAlias;
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `mySingleAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* External inputs (root inport signals with auto storage) */',...
    '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  mySingleAlias input1;                /* '<Root>/In1' */
  real32_T input2;                     /* '<Root>/In2' */
  real32_T input3;                     /* '<Root>/In3' */
  real32_T input4;                     /* '<Root>/In4' */
```

```
} ExtU_rtwdemo_basicsc_T;
```

Import Type Definition

When you integrate code generated from a model with code from other sources, to avoid redundant `typedef` statements, you can import a data type definition to the model code. This example shows how to import your own definition of a data type from a header file that you create.

Use a text editor to create a header file to import. Name the file `myImportedHdrFile.h`. Place it in your working folder. Copy the following code into the file.

```
#ifndef HEADER_myImportedHdrFile_h_
#define HEADER_myImportedHdrFile_h_

typedef float myTypeAlias;

#endif
```

The code uses the identifier `myTypeAlias` to create an alias for the data type `float`. The code also uses a macro guard of the form `HEADER_filename_h`. When you import a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent identifier clashes.

At the command prompt, create a `Simulink.AliasType` object named `myTypeAlias` that creates an alias for the built-in type `single`. The Simulink data type `single` corresponds to the data type `float` in generated code.

```
myTypeAlias = Simulink.AliasType('single')
```

```
myTypeAlias =

  AliasType with properties:

    Description: ''
      DataScope: 'Auto'
     HeaderFile: ''
       BaseType: 'single'
```

Configure the object so that generated code imports the type definition from the header file `myImportedHdrFile.h`.

```
myTypeAlias.DataScope = 'Imported';
myTypeAlias.HeaderFile = 'myImportedHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

Inspect the parameters of the Inport block labeled `In1`. On the **Signal Attributes** tab, **Data type** is set to `single`.

Set **Data type** to the alias `myTypeAlias`.

```
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','myTypeAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors data type aliases such as `myTypeAlias`.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for your header file `myImportedHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "myImportedHdrFile.h',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#include "myImportedHdrFile.h"
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `myTypeAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* External inputs (root inport signals with auto storage) */',...
    '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  myTypeAlias input1;                  /* '<Root>/In1' */
  real32_T input2;                     /* '<Root>/In2' */
  real32_T input3;                     /* '<Root>/In3' */
  real32_T input4;                     /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;
```

Display Base Data Types and Aliases on Model Diagram

When you display signal data types on the model diagram by selecting **Display > Signals and Ports > Port Data Types**, by default, the diagram displays aliases instead of base data types (such as `int16`). To display the base types, choose an option for **Display > Signals and Ports > Port Data Type Display Format**. For more information, see "Port Data Types" (Simulink).

- "Group Signals into Structures in the Generated Code Using Buses" on page 19-139
- "Data Objects" (Simulink)

Create a Named Fixed-Point Data Type in the Generated Code

This example shows how to create and name a fixed-point data type in generated code. You can use the name of the type to specify parameter and signal data types throughout a model and in generated code.

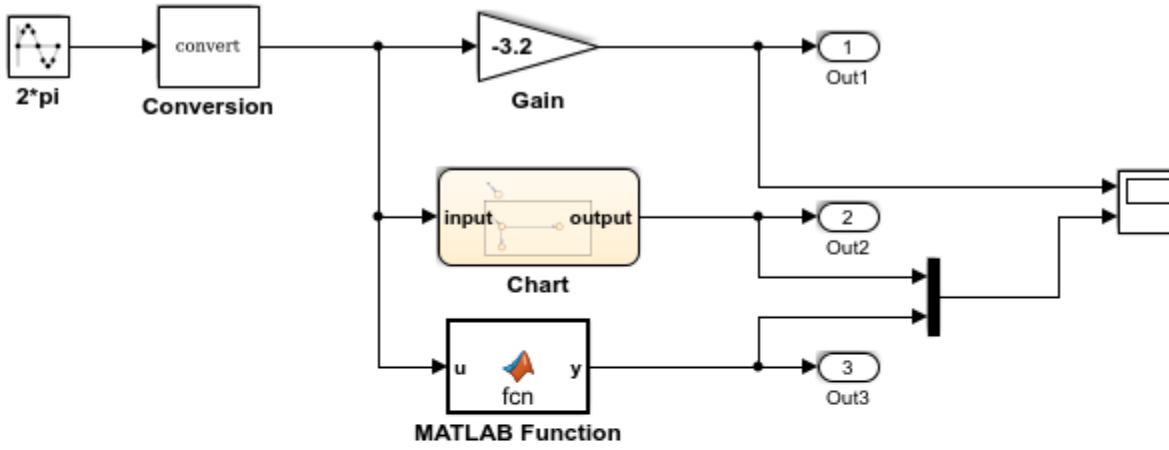
The example model `rtwdemo_fixpt1` uses fixed-point data types. So that you can more easily see the fixed-point data type in the generated code, in this example, you create a `Simulink.Parameter` object that appears in the code as a global variable.

Create a `Simulink.AliasType` object that defines a fixed-point data type. Name the object `myFixType`. The generated code uses the name of the object as a data type.

```
myFixType = Simulink.AliasType('fixdt(1,16,4)');
```

Open the model `rtwdemo_fixpt1`.

```
open_system('rtwdemo_fixpt1')
```



Inspect the parameters of the Gain block. For example, open the block dialog box.

Set the value of the **Gain** parameter to `myKParam`.

Click the action button next to the parameter value. Select **Create Variable**.

In the **Create New Data** dialog box, set `Value` to `Simulink.Parameter(8)`. Click **Create**. A `Simulink.Parameter` object named `myKParam` appears in the base workspace. The object stores the real-world value `8`, which the Gain block uses for the value of the **Gain** parameter.

In the **Simulink.Parameter** property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**. With this setting, `myKParam` appears in the generated code as a separate global variable.

In the block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myFixType`.

On the **Parameter Attributes** tab, set **Parameter data type** to `myFixType`.

Alternatively, you can use these commands at the command prompt to configure the block and create the object:

```
set_param('rtwdemo_fixpt1/Gain','Gain','myKParam','OutDataTypeStr','myFixType',...
    'ParamDataTypeStr','myFixType')
myKParam = Simulink.Parameter(8);
myKParam.StorageClass = 'ExportedGlobal';
```

Inspect the parameters of the Data Type Conversion block labeled `Conversion`. Set **Output data type** to `myFixType`.

```
set_param('rtwdemo_fixpt1/Conversion','OutDataTypeStr','myFixType')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors data type aliases such as `myFixType`.

```
set_param('rtwdemo_fixpt1','SystemTargetFile','ert.tlc')
```

Select the configuration parameter **Generate code only**.

```
set_param('rtwdemo_fixpt1','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_fixpt1')
```

```
### Starting build procedure for model: rtwdemo_fixpt1
### Successful completion of code generation for model: rtwdemo_fixpt1
```

In the code generation report, view the file `rtwdemo_fixpt1_types.h`. The code defines the type `myFixType` based on an integer type of the specified word length (16).

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_myFixType_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_myFixType_
#define DEFINED_TYPEDEF_FOR_myFixType_

typedef int16_T myFixType;
typedef cint16_T cmyFixType;

#endif
```

View the file `rtwdemo_fixpt1.c`. The code uses the type `myFixType`, which is an alias of the integer type `int16`, to define the variable `myKParam`.

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1.c');
rtwdemodbtype(file,'myFixType myKParam = 128;','myFixType myKParam = 128;',1,1)
```

```
myFixType myKParam = 128;              /* Variable: myKParam
```

The stored integer value `128` of `myKParam` is not the same as the real-world value `8` because of the scaling that the fixed-point data type `myFixType` specifies. For more information, see "Scaling" (Fixed-Point Designer) in the Fixed-Point Designer documentation.

The line of code that represents the Gain block applies a right bit shift corresponding to the fraction length specified by `myFixType`.

```
rtwdemodbtype(file,...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)(myKParam * rtb_Conversion >> 4);',...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)(myKParam * rtb_Conversion >> 4);',1,1)
```

```
  rtwdemo_fixpt1_Y.Out1 = (myFixType)(myKParam * rtb_Conversion >> 4);
```

Conform to Coding Standards by Replacing and Renaming Data Types

By default, the generated code uses Simulink Coder data type aliases such as `real_T` and `int32_T`. The code uses these aliases to define global and local variables. If your coding standards require that you use other data type aliases, including aliases that your existing code defines, you can:

- Configure data type replacement for the entire model.
- Configure individual data items (such as signals, parameters, and states) to use specific data type aliases.

For basic information about controlling data types in a model, see "Control Signal Data Types" (Simulink).

Inspect Custom C Code

Save this custom C code into a file named `my_types.h` in your current folder. This file represents a header file in your existing code that defines custom data type aliases by using `typedef` statements.

```
#include <stdbool.h>

typedef double my_dblPrecision;
typedef short my_int16;
typedef bool my_bool;
```

Explore Example Model and Default Generated Code

1. Open the example model ex_data_type_replacement.

   ```
   open_system(fullfile(docroot,'toolbox','ecoder','examples',...
   'ex_data_type_replacement'))
   ```

2. Right-click one of the named signal lines, such as `temp`, and select **Properties**.
3. In the Signal Properties dialog box, select the **Code Generation** tab.

   For the named signals, **Storage class** is set to `ExportedGlobal`. With this setting, the signal lines appear in the generated code as separate global variables.
4. Update the block diagram.

The signals in the model use a mix of the data types `int16`, `double`, and `boolean`.

5 Generate code from the model.

6 In the code generation report, inspect the shared utility file `rtwtypes.h`. The code uses `typedef` statements to rename the primitive C data types by using standard Simulink Coder aliases. For example, the code renames the primitive type `double` by using the alias `real_T`.

```
typedef double real_T;
```

7 Inspect the file `ex_data_type_replacement.c`. The code uses the Simulink Coder data type aliases to declare and define variables. For example, the code uses the data types `real_T`, `int16_T`, and `boolean_T` to define the global variables `flowIn`, `temp`, and `intlk`.

```
real_T flowIn;                          /* '<Root>/In3' */
int16_T temp;                           /* '<Root>/Add2' */
boolean_T intlk;                        /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the same data type aliases.

```
real_T rtb_Add;
real_T rtb_FilterCoefficient;
```

Reuse Custom Data Type Definitions

1 At the command prompt, create a `Simulink.AliasType` object for each data type alias that your custom code defines.

```
Simulink.importExternalCTypes('my_types.h');
```

In the base workspace, the `Simulink.importExternalCTypes` function creates the objects `my_dblPrecision`, `my_int16`, and `my_bool`.

For each object, the function sets the `DataScope` property to `'Imported'` and the `HeaderFile` property to `'my_types.h'`. With these settings, the code generator does not create a `typedef` statement for each object, but instead the generated code reuses the statements from `my_types.h` by including (`#include`) the file.

2 In the model, in the Configuration Parameters dialog box, on the **Code Generation > Data Type Replacement** pane, select **Replace data type names in the generated code**.

3 Specify the options in the **Replacement Name** column according to the table.

Simulink Name	Replacement Name
`double`	`my_dblPrecision`
`int16`	`my_int16`
`boolean`	`my_bool`

4 Generate code from the model.

5 In the code generation report, inspect the file `rtwtypes.h`. Now, the code uses an `#include` directive to import the contents of the custom header file `my_types.h`, which contains the custom data type aliases.

```
#include "my_types.h"                  /* User defined replacement datatype for int
```

6 Inspect the file `ex_data_type_replacement.c`. The code uses the custom data type aliases `my_dblPrecision`, `my_int16`, and `my_bool` to define the global variables such as `flowIn`, `temp`, and `intlk`.

```
my_dblPrecision flowIn;                /* '<Root>/In3' */
my_int16 temp;                         /* '<Root>/Add2' */
my_bool intlk;                         /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the custom data type aliases.

```
my_dblPrecision rtb_Add;
my_dblPrecision rtb_FilterCoefficient;
```

Create Meaningful Data Type Aliases for Individual Data Items

Suppose your coding standards require that important data items use a data type whose name indicates the real-world significance. You can create more `Simulink.AliasType` objects to represent these custom data type aliases. Use the objects to set the data types of data items in the model.

1 In the model, set these block parameters.

Block	Parameter	Parameter Value
In3	**Data type**	`flow_T`
Flow Setpoint	**Output data type**	`flow_T`

Block	Parameter	Parameter Value
Add2	**Output data type**	`diffTemp_T`
Flow Controller	**Sum output**	`ctrl_T`

With these settings, some of the named signals, such as `temp` and `flowIn`, use data types that evoke real-world quantities, such as liquid flow rate and temperature.

2. At the command prompt, create `Simulink.AliasType` objects to represent these new custom data type aliases.

```
flow_T = Simulink.AliasType('double');
diffTemp_T = Simulink.AliasType('int16');
ctrl_T = Simulink.AliasType('double');
```

In the model, the signals `flowIn` and `flowSetPt` use the primitive data type `double`, so the data type alias `flow_T` maps to `double`.

3. Update the block diagram.

Due to data type inheritance, other signals also use the custom data type aliases. For example, in the Add block dialog box, on the **Signal Attributes** tab, the **Output data type** parameter is set to the default value, `Inherit: Inherit via internal rule`. The internal rule chooses the same data type that the block inputs use, `flow_T`.

4. Generate code from the model.

5. The file `ex_data_type_replacement_types.h` defines the new data types `flow_T`, `diffTemp_T`, and `ctrl_T` as aliases of `my_dblPrecision` and `my_int16`.

```
typedef my_dblPrecision flow_T;
typedef my_int16 diffTemp_T;
typedef my_dblPrecision ctrl_T;
```

6. In the file `ex_data_type_replacement.c`, the code defines global variables by using the new type names.

```
flow_T flowIn;                          /* '<Root>/In3' */
flow_T flowSetPt;                       /* '<Root>/Flow Setpoint' */
ctrl_T flowCtrl;                        /* '<Root>/Interlock' */
diffTemp_T temp;                            /* '<Root>/Add2' */
```

7. For blocks that do not use the new data types, the corresponding generated code continues to use the replacement types that you specified earlier. For example, in the

file `ex_data_type_replacement.h`, the blocks In1 and In2 appear as structure fields that use the replacement type `my_int16`.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  my_int16 In1;                        /* '<Root>/In1' */
  my_int16 In2;                        /* '<Root>/In2' */
} ExtU_ex_data_type_replacement_T;
```

Create Single Point of Definition for Primitive Types

The custom data type aliases `flow_T` and `ctrl_T` map to the primitive data type `double`. If you want to change this underlying data type from `double` to `single` (`float`), you must remember to modify the `BaseType` property of both `Simulink.AliasType` objects.

To more easily make this change, you can create a `Simulink.NumericType` object and configure both `Simulink.AliasType` objects to refer to it. Then, you need to modify only the `Simulink.NumericType` object. A `Simulink.NumericType` object enables you to share a data type without creating a data type alias.

1. At the command prompt, create a `Simulink.NumericType` object to represent the primitive data type `single`.

   ```
   sharedType = Simulink.NumericType;
   sharedType.DataTypeMode = 'Single';
   ```

2. Configure the `Simulink.AliasType` objects `flow_T` and `ctrl_T` to acquire an underlying data type from this new object.

   ```
   flow_T.BaseType = 'sharedType';
   ctrl_T.BaseType = 'sharedType';
   ```

3. In the model, select **Display > Signals and Ports > Port Data Type Display Format > Base and Alias Types** (see "Port Data Types" (Simulink)). Update the block diagram.

   The data type indicators in the model show that the aliases `flow_T` and `ctrl_T` map to the primitive type `single`. To change this underlying primitive type, you can modify the `DataTypeMode` property of the `Simulink.NumericType` object, `sharedType`.

By default, the `Simulink.NumericType` object does not cause another `typedef` statement to appear in the generated code.

If you generate code from the model while the `Simulink.NumericType` object represents the data type `single`, the generated code maps `flow_T` and `ctrl_T` to the default Simulink Coder data type alias `real32_T`, which maps to the C data type `float`. You can replace `real32_T` in the same way that you replaced `real_T`, `int16_T`, and `boolean_T` (**Configuration Parameters** > **Code Generation** > **Data Type Replacement**).

Permanently Store Data Type Objects

The `Simulink.NumericType` and `Simulink.AliasType` objects in the base workspace do not persist if you end your current MATLAB session. To permanently store these objects, consider migrating your model to a data dictionary. See "Migrate Models to Use Simulink Data Dictionary" (Simulink).

Create and Maintain Objects Corresponding to Multiple C `typedef` Statements

To create `Simulink.AliasType` objects for a large number of `typedef` statements in your external C code, consider using the `Simulink.importExternalCTypes` function.

Exchange Structured and Enumerated Data Between Generated and External Code

This example shows how to generate code that exchanges data with some external, handwritten code. You construct and configure a model to match data types with the external code and to avoid duplicating type definitions and memory allocation (definition of global variables). You then compile the generated code together with the external code into a single application.

Inspect External Code

Create the file `ex_cc_algorithm.c` in your current folder.

```
#include "ex_cc_algorithm.h"

inSigs_T inSigs;

float_32 my_alg(void)
{
    if (inSigs.err == TMP_HI) {
        return 27.5;
    }
    else if (inSigs.err == TMP_LO) {
        return inSigs.sig1 * calPrms.cal3;
    }
    else {
        return inSigs.sig2 * calPrms.cal3;
    }
}
```

The C code defines a function, `my_alg`, that uses global structure variables such as `inSigs` and `calPrms`. The code also allocates memory for `inSigs`.

Create the file `ex_cc_algorithm.h` in your current folder.

```
#ifndef ex_cc_algorithm_h
#define ex_cc_algorithm_h

typedef float float_32;
```

```
typedef enum {
    TMP_HI = 0,
    TMP_LO,
    NORM,
} err_T;

typedef struct inSigs_tag {
    err_T err;
    float_32 sig1;
    float_32 sig2;
} inSigs_T;

typedef struct calPrms_tag {
    float_32 cal1;
    float_32 cal2;
    float_32 cal3;
} calPrms_T;

extern calPrms_T calPrms;
extern inSigs_T inSigs;

float_32 my_alg(void);

#endif
```

The file defines `float_32` as an alias of the C data type `float`. The file also defines an enumerated data type and two structure types.

The function `my_alg` is designed to calculate a return value by using the fields of `inSigs` and `calPrms`, which are global structure variables of the types `inSigs_T` and `calPrms_T`. The function requires another algorithm to supply the signal data that `inSigs` stores.

This code allocates memory for `inSigs`, but not for `calPrms`. You must create a model whose generated code:

- Defines and initializes `calPrms`.
- Calculates values for the fields of `inSigs`.
- Reuses the type definitions (such as `err_T` and `float_32`) that the external code defines.

Create Simulink Model

So that you can create enumerated and structured data in the Simulink model, first create Simulink representations of the data types that the external code defines. Store the Simulink types in a new data dictionary named `ex_cc_integ.sldd`.

```
Simulink.importExternalCTypes('ex_cc_algorithm.h',...
    'DataDictionary','ex_cc_integ.sldd');
```

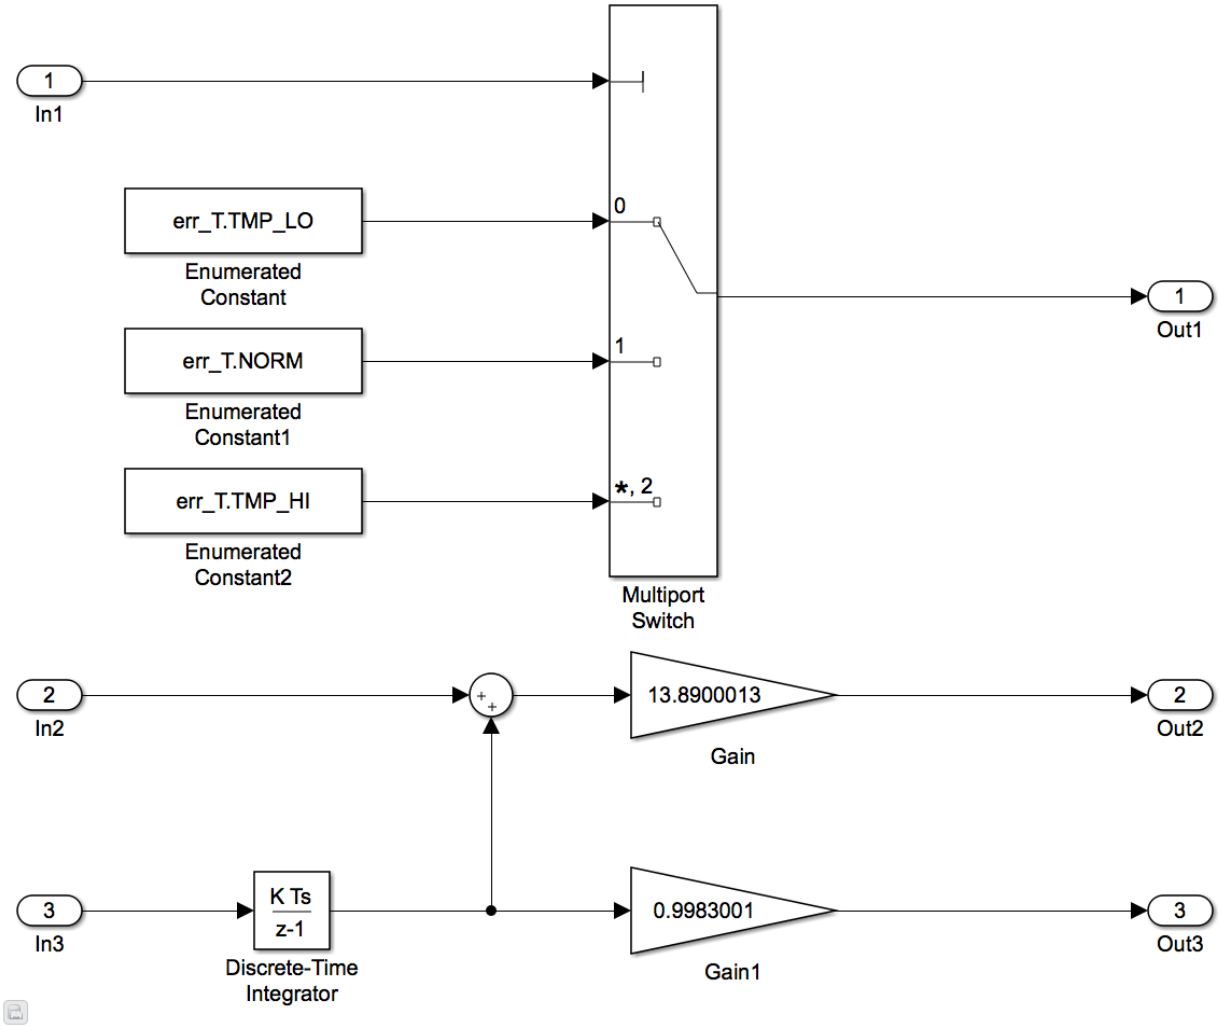
The data dictionary appears in your current folder.

In your current folder, double-click the file to inspect the dictionary contents in the Model Explorer. The `Simulink.importExternalCTypes` function creates `Simulink.Bus`, `Simulink.AliasType`, and `Simulink.data.dictionary.EnumTypeDefinition` objects that correspond to the custom C data types from `ex_cc_algorithm.h`.

Create a new, empty model named `ex_struct_enum_integ`.

Link the model to the data dictionary. In the model, select **File** > **Model Properties** > **Link to Data Dictionary**.

Add algorithmic blocks that calculate the fields of `inSigs`.



Now that you have the basic algorithmic model, you must:

- Organize the output signals into a structure variable named `inSigs`.
- Create the structure variable `calPrms`.
- Include `ex_cc_algorithm.c` in the build process that compiles the code after code generation.

Configure Generated Code to Write Outputs to Existing Structure Variable

Add a Bus Creator block near the existing Outport blocks.

In the Bus Creator block, set these parameters:

- **Number of inputs** to `3`
- **Output data type** to `Bus: inSigs_T`
- **Output as nonvirtual bus** to selected

Delete the three existing Outport blocks (but not the signals that enter the blocks).

Connect the three remaining signal lines to the inputs of the Bus Creator block.

Add an Outport block after the Bus Creator block. Connect the output of the Bus Creator to the Outport.

In the Outport block, set the **Data type** parameter to `Bus: inSigs_T`.

In the model, select **View** > **Model Data**.

On the **Inports/Outports** tab, for the Inport blocks labeled `In2` and `In3`, change **Data Type** from `Inherit: auto` to `float_32`.

Change the **Change View** drop-down list from `Design` to `Code`.

For the Outport block, set **Signal Name** to `inSigs`.

Set **Storage Class** to `ImportFromFile`.

Set **Header File** to `ex_cc_algorithm.h`.

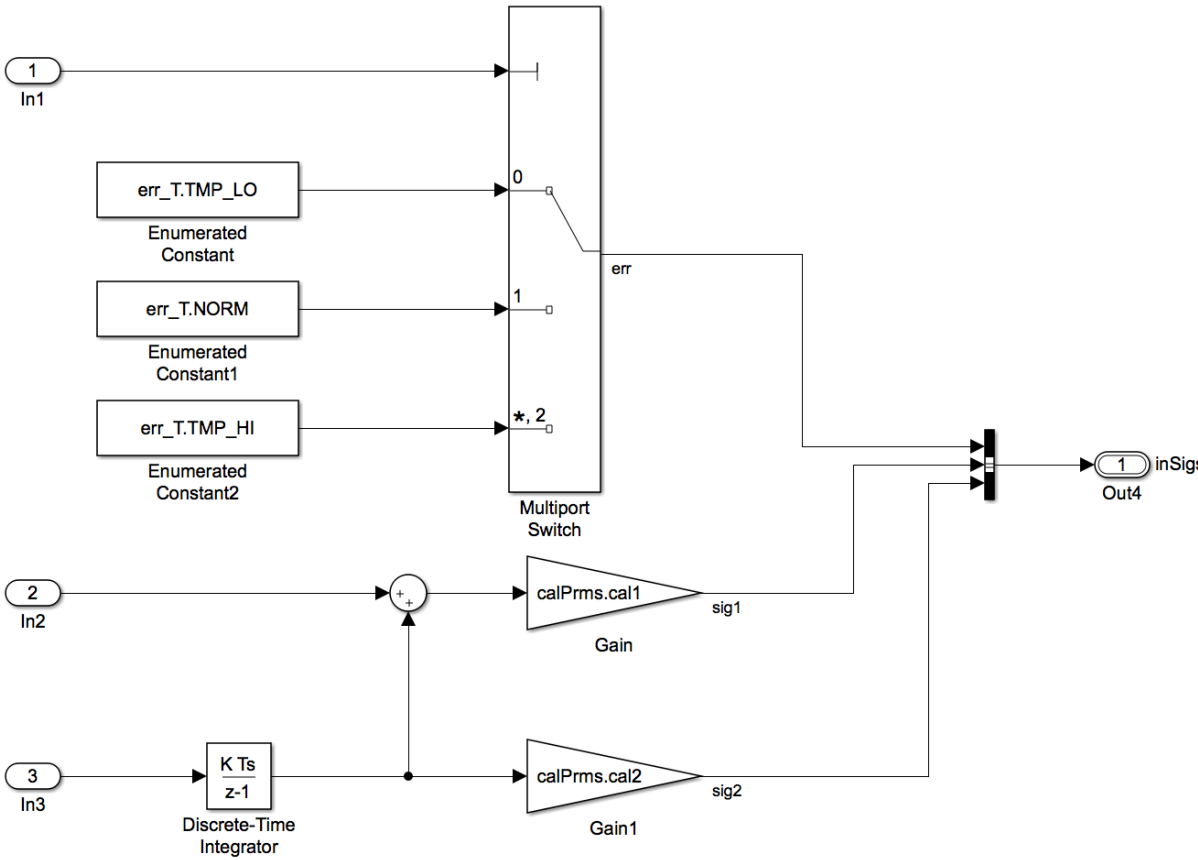
Inspect the **Signals** tab.

In the model, select the output signal of the Multiport Switch block.

In the Model Data Editor, for the selected signal, set **Name** to `err`.

Set the name of the output signal of the Gain block to `sig1`. Set the name of the output signal of the Gain1 block to `sig2`.

When you finish, the model stores output signal data (such as the signals `err` and `sig1`) in the fields of a structure variable named `inSigs`.



Because you set **Storage Class** to `ImportFromFile`, the generated code does not allocate memory for `inSigs`.

Configure Model to Generate Parameter Data

In the Model Explorer **Model Hierarchy** pane, under the dictionary node **ex_cc_integ**, select the **Design Data** node.

In the **Contents** pane, select the `Simulink.Bus` object `calPrms_T`.

In the Dialog pane (the right pane), click **Launch Bus Editor**.

In the Bus Editor, in the left pane, select `calPrms_T`.

On the toolbar, click the **Create/Edit a Simulink.Parameter Object from a Bus Object** button.

In the MATLAB Editor, copy the generated MATLAB code and run the code at the command prompt. The code creates a `Simulink.Parameter` object in the base workspace.

At the command prompt, set the field values in the parameter object. For the fields `cal1` and `cal2`, use the same values as the Gain blocks in the model. For `cal3`, use a nonzero number such as `15.2299995`.

```
calPrms_T_Param.Value.cal1 = 13.8900013;
calPrms_T_Param.Value.cal2 = 0.9983001;
calPrms_T_Param.Value.cal3 = 15.2299995;
```

In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.

Move the parameter object from the base workspace to the Design Data section of the data dictionary.

With the data dictionary selected, in the **Contents** pane, rename the parameter object as `calPrms`.

In the right pane, set **Storage class** to `ExportedGlobal`.

Save the changes that you made to the dictionary.

In the Model Data Editor, select the **Parameters** tab.

For the Gain block, replace the value `13.8900013` with `calPrms.cal1`.

In the other Gain block, use `calPrms.cal2`.

Generate, Compile, and Inspect Code

Configure the model to include `ex_cc_algorithm.c` in the build process. Set **Configuration Parameters** > **Code Generation** > **Custom Code** > **Additional build information** > **Source files** to `ex_cc_algorithm.c`.

Generate code from the model.

Inspect the generated file `ex_struct_enum_integ.c`. The file defines and initializes `calPrms`.

```
/* Exported block parameters */
calPrms_T calPrms = {
  13.8900013F,
  0.998300076F,
  15.23F
} ;                                    /* Variable: calPrms
```

The generated algorithm in the model `step` function defines a local variable for buffering the value of the signal `err`.

```
err_T rtb_err;
```

The algorithm then calculates and stores data in the fields of `inSig`.

```
inSigs.err = rtb_err;
inSigs.sig1 = (rtU.In2 + rtDW.DiscreteTimeIntegrator_DSTATE) * calPrms.cal1;
inSigs.sig2 = calPrms.cal2 * rtDW.DiscreteTimeIntegrator_DSTATE;
```

Replace Data Type Names Throughout Model

To generate code that uses `float_32` instead of the default, `real32_T`, instead of manually specifying the data types of block output signals and bus elements, you can use data type replacement (**Configuration Parameters** > **Code Generation** > **Data Type Replacement**). For more information, see "Conform to Coding Standards by Replacing and Renaming Data Types" on page 21-22.

Data Type Replacement

In this section...

When you generate code for a model, you can replace the default Simulink Coder data type names, such as `real_T` and `boolean_T`, with your own custom names. The model code creates `typedef` statements to define your replacement names. It uses your replacement names instead of the default type names to, for example, define variables and functions.

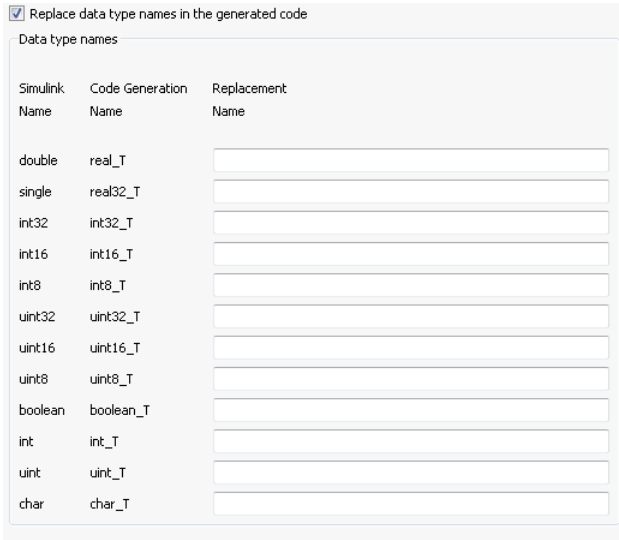
You can specify many-to-one data type replacement to replace multiple built-in data types with one name in the generated code. For example, you can replace the built-in data types `uint8` and `boolean` with a single data type name that you specify.

In generated code, data type replacement uses the replacements that you specify instead of the default Simulink Coder data type names. If you want to create custom data type names for individual block parameters and signals in generated code and in a block diagram, see “Create Data Type Alias in the Generated Code” on page 21-12.

Replace Built-In Data Types

To configure replacement data type names:

1. In the Configuration Parameters dialog box, select **Code Generation > Data Type Replacement** and **Replace data type names in the generated code**. The **Data type names** table lists each Simulink built-in data type name with the corresponding code generation name.



2 Specify the **Replacement Name** column with values that replace the default names in the **Code Generation Name** column. Specify one of these options:

- The name of a `Simulink.AliasType` object that is in the base workspace or a data dictionary. When you use a `Simulink.AliasType` object, you can replace a data type name with the name of the object.

  Set the `BaseType` property of the object to the corresponding **Simulink Name** data type. Set the `DataScope` property of the object to `Auto` (default) or `Imported`. If you want to use your own header file to define replacement names, set the `HeaderFile` property of the object to the header file name and set `DataScope` to `Imported`.
- The data type name from the **Simulink Name** column. This name replaces the data type name in the generated code. Using the **Simulink Name**, you can replace data types except `real_T` and `real32_T`. To specify replacement names for `boolean_T`, `int_T`, `uint_T`, and `char_T`, see the following table.
- The name of a `Simulink.NumericType` object that is in the base workspace or a data dictionary. When you use a `Simulink.NumericType` object, you can define replacement names for `real_T`, `real32_T`, and `boolean_T`.

Set the `DataTypeMode` property of the object to the corresponding data type name from the **Simulink Name** column.

Specify the Replacement Name for a Data Type

To replace the Code Generation Name	Specify a `Simulink.AliasType` object with `BaseType`	Specify the corresponding Simulink Name	Specify a `Simulink.NumericType` object with `DataTypeMode`
`real_T`	`double`	–	`Double`
`real32_T`	`single`	–	`Single`
`int32_T`	`int32`	`int32`	–
`int16_T`	`int16`	`int16`	–
`int8_T`	`int8`	`int8`	–
`uint32_T`	`uint32`	`uint32`	–
`uint16_T`	`uint16`	`uint16`	–
`uint8_T`	`uint8`	`uint8`	–
`boolean_T`	`uint8` or `int8` or `intn*`	`uint8` or `int8` or `intn*`	`Boolean`
`int_T`	`intn*`	`intn*`	–
`uint_T`	`uintn*`	`uintn*`	–
`char_T`	`intn*`	`intn*`	–

* Replace *n* with the number of bits displayed in the Configuration Parameters dialog box **Hardware Implementation** pane in either **Number of bits: int** or **Number of bits: char**, depending on the data type that you want to replace.

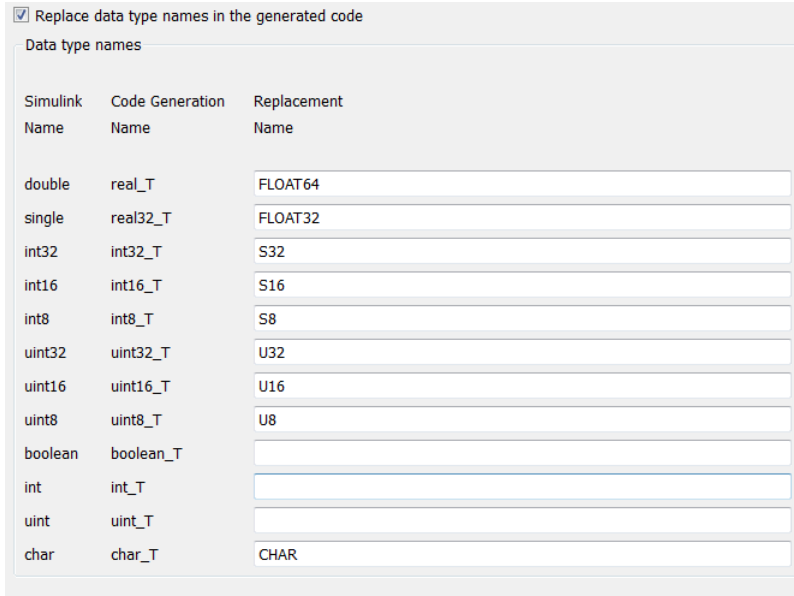
Note: The `boolean_T` `BaseType` must promote to a signed `int`.

Suppose that in the base workspace you define these replacement data types as `Simulink.AliasType` objects.

Replacement Name	Description
`FLOAT64`	64-bit floating point

Replacement Name	Description
FLOAT32	32-bit floating point
S32	32-bit integer
S16	16-bit integer
S8	8-bit integer
U32	Unsigned 32-bit integer
U16	Unsigned 16-bit integer
U8	Unsigned 8-bit integer
CHAR	Character data

You can specify data type replacements with a one-to-one replacement mapping as shown.

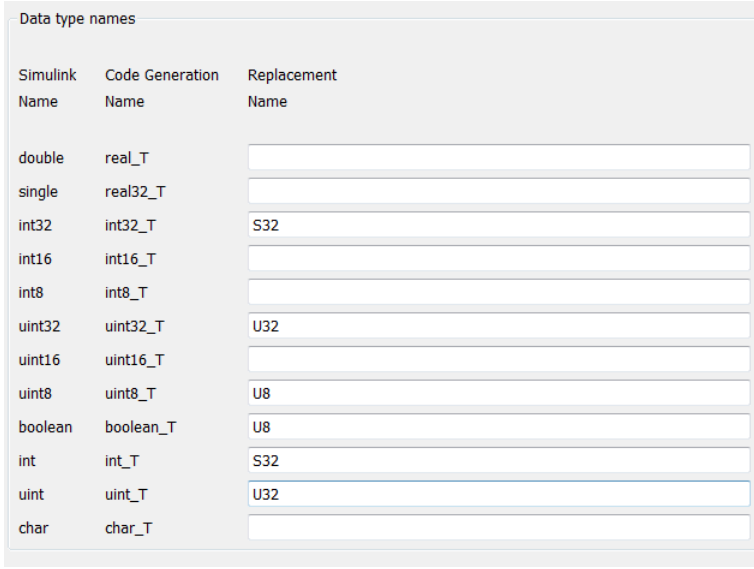


You can also apply a many-to-one data type replacement mapping. For example, you can replace these data types:

- `int32` and `int` with the name `S32`.

- `uint32` and `uint` with the name `U32`.
- `uint8` and `boolean` with the name `U8`.

Note: Many-to-one data type replacement does not support the `char` (`char_T`) built-in data type. Use `char` only in one-to-one data type replacements.



Programmatically Replace Built-In Data Types

To programmatically replace the built-in data type names for your model, adjust the `ReplacementTypes` model parameter, which is a structure. This example code shows how to modify the `ReplacementTypes` parameter to replace the built-in data type names `int8`, `uint8`, and `boolean` with the custom data type names `my_T_S8`, `my_T_U8`, and `my_T_BOOL`.

```
model = bdroot;
cs = getActiveConfigSet(model);
set_param(cs,'EnableUserReplacementTypes','on');

struc = get_param(cs,'ReplacementTypes');
struc.int8 = 'my_T_S8';
```

```
struc.uint8 = 'my_T_U8';
struc.boolean = 'my_T_BOOL';

set_param(cs,'ReplacementTypes',struc);
```

Data Type Replacement Limitations

When you select the model configuration parameter **Replace data type names in the generated code** on the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box, these limitations apply.

- Data type replacement does not support multiple levels of mapping. Each replacement data type name maps directly to one or more built-in data types.
- Data type replacement is not supported for simulation target code generation for referenced models.
- If you select the **Classic call interface** configuration parameter for your model, data type replacement is not supported.
- Code generation performs data type replacements while generating `.c`, `.cpp`, and `.h` files. Code generation places these files in build folders (including top and referenced model build folders) and in the `_sharedutils` folder. *Exceptions* are as follows:
  `rtwtypes.h`
  `multiword_types.h`
  `model_reference_types.h`
  `builtin_typeid_types.h`
  `model_sf.c` or `.cpp` (ERT S-function wrapper)
  `model_dt.h` (C header file supporting external mode)
  `model_capi.c` or `.cpp`
  `model_capi.h`
- Data type replacement is not supported for complex data types.
- Many-to-one data type replacement is not supported for the `char` data type. Attempting to use `char` as part of a many-to-one mapping to a custom data type represents a violation of the MISRA C specification. For example, if you map `char` (`char_T`) and either `int8` (`int8_T`) or `uint8` (`uint8_T`) to the same replacement type, the result is a MISRA C violation. If you try to generate C++ code, the code generator makes invalid implicit type casts, resulting in compile-time errors. Use `char` only in one-to-one data type replacements.
- For ERT S-functions, replace the `boolean` data type with only an 8-bit integer, `int8`, or `uint8`.

- Set the `DataScope` property of a `Simulink.AliasType` object to `Auto` (default) or `Imported`.

Specify Boolean and Data Type Limit Identifiers

You can use command-line parameters to replace the default Boolean and data type limit identifiers. If you want to associate the data type limit identifiers with the data type names, consider replacing the default identifiers. You can also use command-line parameters to import a header file with the Boolean and data type limit identifier definitions.

Data Type Limit Identifiers

You can control the data type limit identifiers in the generated code by using the command-line parameters in this table.

Data Type Limit	Default Identifier	Command-Line Parameter
8-bit integer maximum	`MAX_int8_T`	`MaxIdInt8`
16-bit integer maximum	`MAX_int16_T`	`MaxIdInt16`
32-bit integer maximum	`MAX_int32_T`	`MaxIdInt32`
8-bit unsigned integer maximum	`MAX_uint8_T`	`MaxIdUint8`
16-bit unsigned integer maximum	`MAX_uint16_T`	`MaxIdUint16`
32-bit unsigned integer maximum	`MAX_uint32_T`	`MaxIdUint32`
8-bit integer minimum	`MIN_int8_T`	`MinIdInt8`
16-bit integer minimum	`MIN_int16_T`	`MinIdInt16`
32-bit integer minimum	`MIN_int32_T`	`MinIdInt32`

For example, to change the default identifiers for the 8-bit integer data limit minimum and maximum to `s4g_S4MIN` and `s4g_S4MAX`, respectively:

```
set_param(gcs,'MinIdInt8','s4g_S4MIN');
set_param(gcs,'MaxIdInt8','s4g_S4MAX')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the 8-bit integer data minimum and maximum identifiers:

```
#define s4g_S4MAX                      ((int8_T)(127))
#define s4g_S4MIN                      ((int8_T)(-128))
```

If you do import a header file defining the data type limit identifiers, the header file is included in `rtwtypes.h`.

Boolean Identifiers

You can control the Boolean identifiers in the generated code by using the command-line parameters in this table. When changing boolean identifiers, you must define `false` to be numerically equivalent to `0`, and `true` to be numerically equivalent to `1`.

Boolean	Default Identifier	Command-Line Parameter
True	`true`	`BooleanTrueId`
False	`false`	`BooleanFalseId`

For example, to change the default Boolean true and false identifiers:

```
set_param(gcs,'BooleanTrueId','bTrue');
set_param(gcs,'BooleanFalseId','bFalse')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the Boolean identifiers:

```
#define bFalse                         (0U)
#define bTrue                          (1U)
```

If you do import a header file defining the Boolean identifiers, the header file is included in `rtwtypes.h`.

Note: When changing boolean identifiers, you must define `false` to be numerically equivalent to `0`, and `true` to be numerically equivalent to `1`.

Boolean and Data Type Limit Identifier Header Files

You can import a header file that defines Boolean and data type limit identifiers using the command-line parameter `TypeLimitIdReplacementHeaderFile`. The header file is included in `rtwtypes.h`. You must use the command-line parameters to specify the Boolean and data type limit identifiers that are included in the imported header file.

For example, if you have a header file `myfile.h` with data type limit definitions, use `TypeLimitIdReplacementHeaderFile` to include the definitions in the generated code:

```
set_param(gcs,'TypeLimitIdReplacementHeaderFile','myfile.h');
```

The generated file `rtwtypes.h` includes `myfile.h`.

```
/* Import type limit identifier replacement definitions. */
#include "myfile.h"
```

Module Packaging Tool (MPT) Data Objects in Embedded Coder

MPT Data Object Properties

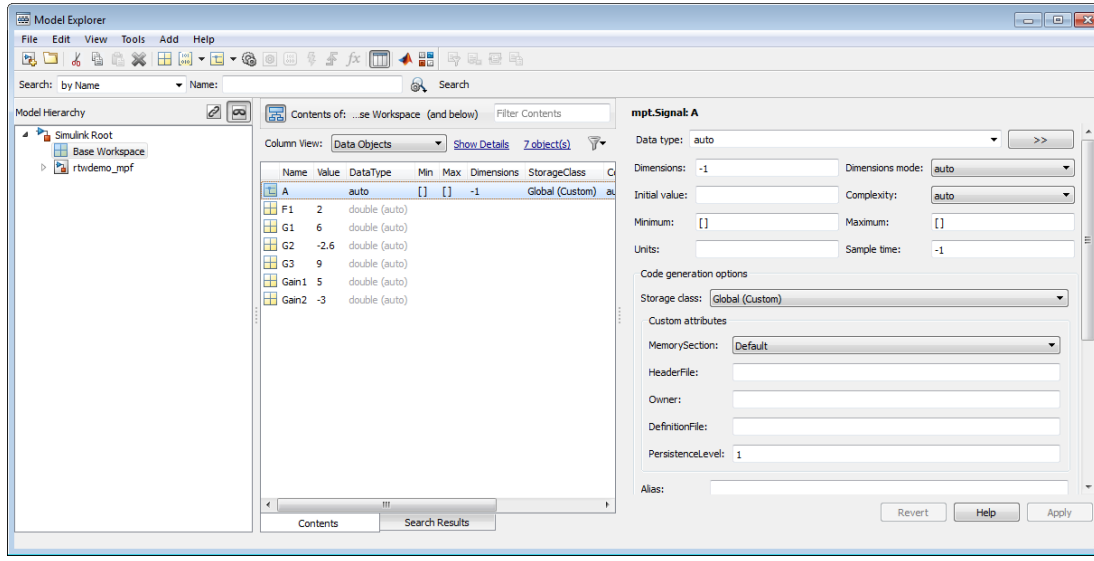
In this section...

The following table describes the properties and property values for `mpt.Parameter` and `mpt.Signal` data objects that appear in the Model Explorer.

Note: You can create `mpt.Signal` and `mpt.Parameter` objects in the base MATLAB or model workspace. However, if you create the object in a model workspace, the object's storage class must be set to `auto`.

The figure below shows an example of the Model Explorer. When you select an `mpt.Parameter` or `mpt.Signal` data object in the middle pane, its properties and property values display in the rightmost pane.

In the Properties column, the table lists the properties in the order in which they appear on the Model Explorer.



Parameter and Signal Property Values

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	User object type	`*auto`	Prenamed and predefined property sets that are registered in the `sl_customization.m` file. (See "Register mpt User Object Types" on page 22-16.) This field is active when a user object type is registered. Select `auto` if this field is available but you do not want to apply the properties of a user object type to a selected data object. The fields on the Model Explorer are populated with default values.
		Listed user object type name	Select a user object type name to apply the properties and values that you associated with this name in the `sl_customization.m` file. The fields on the Model Explorer are automatically populated with those values.
Parameter	`Value`	`*0`	The data type and numeric value of the data object. For example, `int8(5)`. The numeric value is used as an initial parameter value in the generated code.
Both	Data type		Used to specify the data type for an `mpt.Signal` data object, but not for an `mpt.Parameter` data object. The data type for an `mpt.Parameter` data object is specified in the **Value** field above. See "About Data Types in Simulink" (Simulink).
Both	Unit	`*null`	Units of measurement of the signal or parameter. (Enter text in this field.)

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	Dimensions	`*-1`	The dimension of the signal or parameter. For a parameter, the dimension is derived from its value.

Both	Complexity	`*auto`
		`real`
		`complex`
			Complexity specifies whether the signal or parameter is a real or complex number. Select `auto` for the code generator to decide. For a parameter, the complexity is derived from its value.

Signal	Sample time	`*-1`	Model or block execution rate.
Signal	Sample mode	`*auto`	Determines how the signal propagates through the model. Select `auto` for the code generator to decide.
		`Sample based`	The signal propagates through the model one sample at a time.
		`Frame based`	The signal propagates through the model in batches of samples.
Both	Minimum	`*0.0`	The minimum value to which the parameter or signal is expected to be bound.
		Number within the minimum range of the parameter or signal. (Based on the data type and resolution of the parameter or signal.)	
Both	Maximum	`*0.0`	Maximum value to which the parameter or signal is expected to be bound. (Enter information using a dialog box.)
	Code generation options		

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
	Storage class		Note that an `auto` selection for a storage class tells the build process to decide how to declare and store the selected parameter or signal.
Both	Default (Custom)		Code generation decides how to declare the data object.
Both	Global (Custom)	`Global (Custom)` is the default storage class for `mpt` data objects.	Specifies that a code generator not place a qualifier in the data object's declaration.
Both	Memory section	`*Default`	**Memory section** allows you to specify storage directives for the data object. `Default` specifies that the code generator not place a type qualifier and `pragma` statement with the data object's declaration.
Parameter		`MemConst`	Places the `const` type qualifier in the declaration.
Both		`MemVolatile`	Places the `volatile` type qualifier in the declaration.
Parameter		`MemConstVolatile`	Places the `const volatile` type qualifier in the declaration.
Both	Header file		Name of the file used to import or export the data object. This file contains the declaration (`extern`) to the data object. Also, you can specify this header filename between the double-quotation or angle-bracket delimiter. You can specify the delimiter with or without the `.h` extension. For example, specify `"object.h"` or `"object"`. For the selected data object, this overrides the general delimiter selection in the

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
			#include file delimiter field on the Configuration Parameters dialog box.
Both	Owner	*Blank	The name of the module that owns this signal or parameter. This is used to help determine the ownership of a definition. For details, see “Ownership Settings” on page 36-106 and the table “Ownership Settings” on page 36-116.
Both	Definition file	*Blank	Name of the file that defines the data object.
		Valid character vector	
Both	Persistence level		The number you specify is relative to **Signal display level** or **Parameter tune level** on the **Code Placement** pane of the Configuration Parameters dialog box. For a signal, allows you to specify whether or not the code generator declares the data object as global data. For a parameter, allows you to specify whether or not the code generator declares the data object as tunable global data. See **Signal display level** and **Parameter tune level** in “Model Configuration Parameters: Code Generation Code Placement”.
Both	Bitfield (Custom)		Embeds Boolean data in a named bit field.
	Struct name		Name of the `struct` into which the object's data will be packed.
Parameter	Const (Custom)		Places the `const` type qualifier in the declaration.
Parameter	Header file		See above.
Parameter	Owner		See above.

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Parameter	Definition file		See above.
Parameter	Persistence level		See above.
Both	Volatile (Custom)		Places the `volatile` type qualifier in the declaration.
Both	Header file		See above.
Both	Owner		See above.
Both	Definition file		See above.
Both	Persistence level		See above.
Parameter	ConstVolatile (Custom)		Places the `const volatile` type qualifier in declaration.
Parameter	Header file		See above.
Parameter	Owner		See above.
Parameter	Definition file		See above.
Parameter	Persistence level		See above.
Parameter	Define (Custom)		Represents parameters with a `#define` macro.
Parameter	Header file		See above.
Both	ExportToFile (Custom)		Generates global variable definition, and generates a user-specified header (`.h`) file that contains the declaration (`extern`) to that variable.
Both	Memory section		See above.
Both	Header file		See above.
Both	Definition file		See above.
Both	ImportFromFile (Custom)		Includes predefined header files containing global variable declarations,

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
			and places the `#include` in a corresponding file. Assumes external code defines (allocates memory) for the global variable.
Both	Data access	`*Direct`	Allows you to specify whether the identifier that corresponds to the selected data object stores data of a data type (`Direct`) or stores the address of the data (a pointer).
Both		`Pointer`	If you select `Pointer`, the code generator places `*` before the identifier in the generated code.
	Header file		See above.
Both	Struct (Custom)		Embeds data in a named `struct` to encapsulate sets of data.
Both	Struct name		See above.
Signal	GetSet (Custom)		Reads (gets) and writes (sets) data using functions.
Signal	Header file		See above.
Signal	Get function		Specify the Get function.
Signal	Set function		Specify the Set function.
Both	Alias	`*null`	As explained in detail in "Override Data Object Naming Rules" on page 36-18, for a Simulink or `mpt` data object (identifier), specifying a name in the **Alias** field overrides the global naming rule selection you make on the Configuration Parameters dialog box.
		Valid ANSI[a] C/C++ variable name	
Both	`Description`	`*null`	Text description of the parameter or signal. Appears as a comment beside the

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
			signal or parameter's identifier in the generated code.
		Character vector	
Signal	Reusable (Custom)		Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either `Reusable (Custom)` or derived from `Reusable (Custom)`.
Signal	Data Scope	`*Auto`	You can specify the scope of symbols code generation generates for a data object of this class by selecting a value for **DataScope**. When you take the default of `Auto`, code generation determines the symbol scope internally. If possible, symbols have `File` scope. Otherwise, they have `Exported` scope.
		`File`	Code generation defines the scope of each symbol as the file that defines it. File scope requires each symbol to be used in a single file. If the same symbol is referenced in multiple files, code generation reports an error.
		`Exported`	Code generation exports symbols to external code in the header file specified by the **HeaderFile** field. If a **HeaderFile** is not specified, symbols are exported to external code in *`model`*`.h`.
		`Imported`	Code generation imports symbols from external code in the header file specified by the **HeaderFile** field. If you do not specify a header file, code generation generates an `extern` directive in *`model`*_private.h.

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Signal	Header file		See above.
Signal	Owner		See above.
Signal	Definition file		See above.

`mpt` Package Custom Storage Classes

CSC Name	Purpose	Signals?	Parameters?
`BitField`	Generate a `struct` declaration that embeds Boolean data in named bit fields.	Y	Y
`CompilerFlag`	Supports preprocessor conditionals defined via compiler flag. See "Generate Preprocessor Conditionals for Variant Systems" on page 14-33.	N	Y
`Const`	Generate a constant declaration with the `const` type qualifier.	N	Y
`ConstVolatile`	Generate declaration of volatile constant with the `const volatile` type qualifier.	N	Y
`Default`	The default custom storage class for the `Simulink` package. Export the declaration of data objects to a default generated header file.	Y	Y
`Define`	Generate `#define` directive.	Y	Y
`ExportToFile`	Generate header (`.h`) file, with user-specified name, containing global variable declarations.	Y	Y
`FileScope`	Generate a static qualifier suffix for a variable declaration so that the scope of the variable is limited to the current file.	Y	Y
`GetSet`	Supports specialized function calls to read and write the memory associated with a Data Store Memory block. See "Access Data Through Functions with Custom Storage Class `GetSet`" on page 23-92.	Y	Y

CSC Name	Purpose	Signals?	Parameters?
`Global`	The default custom storage class for the `mpt` package. Generate the declaration and definition of a data object in specified files, and use the specified memory section.	Y	Y
`ImportedDefin`	Supports preprocessor conditionals defined via legacy header file. See “Generate Preprocessor Conditionals for Variant Systems” on page 14-33.	N	Y
`ImportFromFil`	Generate directives to include predefined header files containing global variable declarations.	Y	Y
`Reusable`	Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either `Reusable (Custom)` or derived from `Reusable (Custom)`.	Y	N
`Struct`	Generate a `struct` declaration encapsulating parameter or signal object data.	Y	Y
`StructConst`	Generate a `struct` declaration, with a `const` type qualifier, encapsulating parameter object data.	N	Y
`StructVolatil`	Generate a `struct` declaration, with a `volatile` type qualifier, encapsulating parameter or signal object data.	Y	Y
`Volatile`	Use `volatile` type qualifier in declaration.	Y	Y

Examples of Property Value Changes on Generated Code

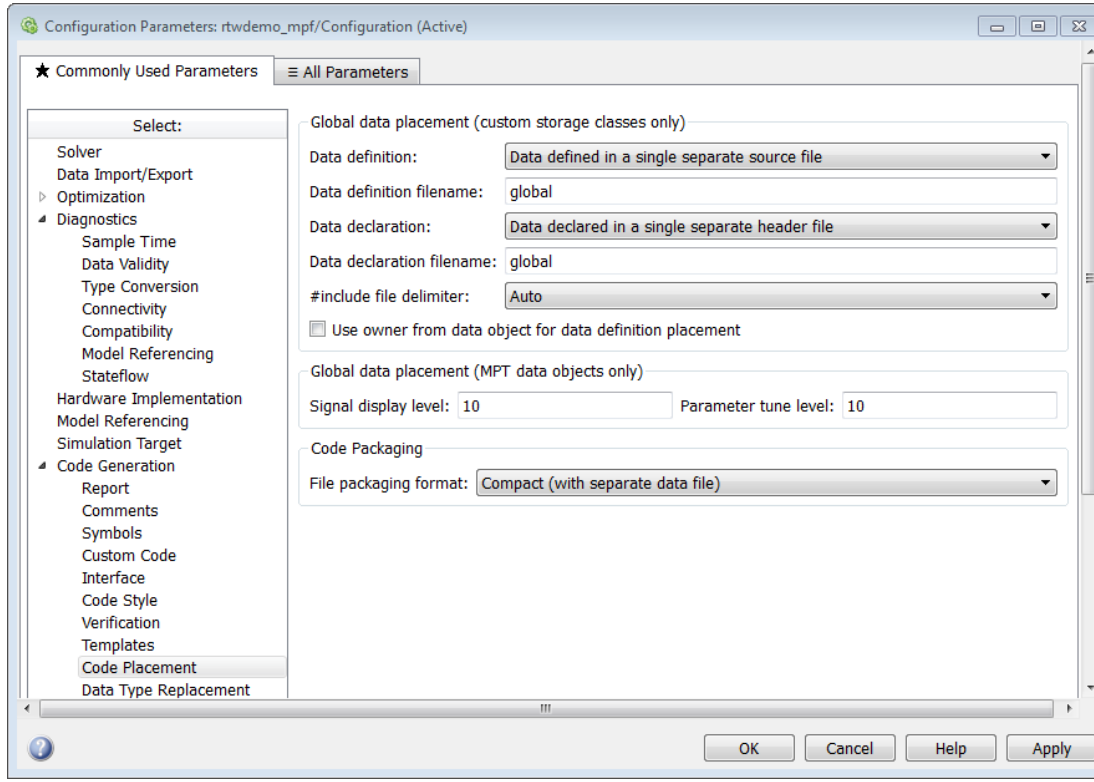
What I noticed when inspecting the .c/.cpp file	Change I made to property value settings	What I noticed after regenerating and reinspecting the file
Example 1: Parameter data objects can be declared or defined as constants. I know that the data object `GAIN` is a parameter. I want this to be declared or defined in the `.c` file as a variable. But I notice that `GAIN` is declared as a constant by the statement `const real_T GAIN = 5.0;`. Also, this statement is in the constant section of the file.	In the Model Explorer, I clicked the data object `GAIN`. I noticed that the property value for its **Memory section** property is set at `MemConst`. I changed this to `Default`.	I notice two differences. One is that now `GAIN` is declared as a variable with the statement `real_T GAIN = 5.0;`. The second difference is that the declaration now is located in the `MemConst` memory section in the `.c` or `.cpp` file.
Example 2: I notice again the declaration of `GAIN` in the `.c` file mentioned in Example 1. It appears as `real_T GAIN = 5.0;`. But I have changed my mind. I want data object `GAIN` to be `#define`.	I changed the **Storage class** selection to `Define (Custom)`.	`GAIN` is not declared in the `.c` file as a `MemConst` parameter. Rather, it is defined as a `#define` macro by the code `#define GAIN 5.0`, and this is located near the top of the `.c` file with the other preprocessor directives.
Example 3: I changed my mind again after doing Example 2. I do want `GAIN` defined using the `#define` preprocessor directive. But I do not want to include the `#define` in this file. I know it exists in another file and I want to reference that file.	On the Model Explorer, I notice that the property value for the **Header file** property is blank. I changed this to `filename.h`. (I chose the ANSI C/C++ double quote mechanism for the `#include`, but could have chosen the angle bracket mechanism.) Also, I must make the user-defined `filename.h` available to the compiler, placing it either in the system path or local directory.	`#define GAIN 5.0` is not present in this `.c` file. Instead, the `#include filename.h` code appears as a preprocessor directive at the top of the file.

What I noticed when inspecting the .c/.cpp file	Change I made to property value settings	What I noticed after regenerating and reinspecting the file
Example 4: I have one more change I want to make. Let us say that we have declared the data object `data_in`, and that its declaration statement in the `.c` file reads `real_T data_in = 0.0;`. I want to replace this statement with an alias in the `.c` file.	In the Model Explorer, I selected the data object `data_in`. I noticed that the **Alias** field is blank. I changed this to `data_in_alias`, which I know is a valid ANSI C/C++ variable name.	The identifier `data_in_alias` now appears in the `.c` file everywhere `data_in` appeared.

Specify Persistence Level for Signals and Parameters

With this procedure, you can control the persistence level of signal and parameter objects associated with a model. Persistence level allows you to make intermediate variables or parameters global during initial development. At the later stages of development, you can use this procedure to remove these signals and parameters for efficiency. Use the **Persistence Level** property of `mpt.Signal` and `mpt.Parameter` data objects. For descriptions of the properties on the Model Explorer, see "MPT Data Object Properties" on page 22-2.

Notice also the **Signal display level** and **Parameter tune level** fields on the **Code Placement** pane of the Configuration Parameters dialog box, as illustrated in the next figure.



The **Signal display level** field allows you to specify whether or not the code generator defines a signal data object as global data in the generated code. The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Signal display level** number is for `mpt` (module packaging tool) signal data objects in the model. The **Persistence level** number is for a *particular* `mpt` signal data object. If the data object's **Persistence level** is equal to or less than the **Signal display level**, the signal appears in the generated code as global data with the custom attributes that you specified. For example, this would occur if **Persistence level** is `2` and **Signal display level** is `5`.

Otherwise, the code generator automatically determines how the particular signal data object appears in the generated code. Depending on the settings on the **Optimization** pane of the Configuration Parameters dialog box, the signal data object could appear in the code as local data without the custom attributes you specified for that data object. Or,

based on expression folding, the code generator could remove the data object so that it does not appear in the code.

The **Parameter tune level** field allows you to specify whether or not the code generator declares a parameter data object as tunable global data in the generated code.

The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Parameter tune level** number is for `mpt` parameter data objects in the model. The **Persistence level** number is for a *particular* `mpt` parameter data object. If the data object's **Persistence level** is equal to or less than the **Parameter tune level**, the parameter appears tunable in the generated code with the custom attributes that you specified. For example, this would occur if **Persistence level** is `2` and **Parameter tune level** is `5`.

Otherwise, the parameter is inlined in the generated code, and the code generation settings determine its exact form.

Note that, in the initial stages of development, you might be more concerned about debugging than code size. Or, you might want one or more particular data objects to appear in the code so that you can analyze intermediate calculations of an equation. In this case, you might want to specify the **Parameter tune level** (**Signal display level** for signals) to be higher than **Persistence level** for some `mpt` parameter (or signal) data objects. This results in larger code size, because the code generator defines the parameter (or signal) data objects as global data, which have the custom properties you specified. As you approach production code generation, however, you might have more concern about reducing the size of the code and less need for debugging or intermediate analyses. In this stage of the tradeoff, you could make the **Parameter tune level** (**Signal display level** for signals) greater than **Persistence level** for one or more data objects, generate code and observe the results. Repeat until satisfied.

1. With the model open, in the Configuration Parameters dialog box, select **Code Generation** > **Code Placement**.
2. Type the desired number in the **Signal display level** or **Parameter tune level** field, and click **Apply**.
3. In the Model Explorer, type the desired number in the **Persistence** field for the selected signal or parameter, and click **Apply**.
4. Save the model and generate code.

Register mpt User Object Types

- “Introduction” on page 22-17

Introduction

Embedded Coder allows you to create custom `mpt` object types and specify properties and property values to be associated with them. Once created, a user object type can be applied to data objects displayed in Model Explorer. When you apply a user object type to a data object, by selecting a type name in the **User object type** pull-down list in Model Explorer, the data object is automatically populated with the properties and property values that you specified for the user object type.

To register `mpt` user object type customizations, use the Simulink customization file `sl_customization.m`. This file is a mechanism that allows you to use MATLAB code to perform customizations of the standard Simulink user interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see "Registering Customizations" (Simulink).

Register mpt User Object Types Using sl_customization.m

To register `mpt` user object type customizations, you create an instance of `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.slDataObjectCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following methods for registering `mpt` user object type customizations:

- `addMPTObjectType(hObj, objectTypeName, classtype, propName1, propValue1, propName2, propValue2, ...)`

  `addMPTObjectType(hObj, objectTypeName, classtype, {propName1, propName2, ...}, {propValue1, propValue2, ...})`

Registers the specified user object type, along with specified values for object properties, and adds the object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `objectTypeName` — Name of the user object type
- `classType` — Class to which the user object type applies: `'Signal'`, `'Parameter'`, or `'Both'`
- `propName` — Name of a property of an `mpt` or `mpt`-derived data object to be populated with a corresponding `propValue` when the registered user object type is selected
- `propValue` — Specifies the value for a corresponding `propName`

- `moveMPTObjectTypeToTop(hObj, objectTypeName)`

  Moves the specified user object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `moveMPTObjectTypeToEnd(hObj, objectTypeName)`

  Moves the specified user object type to the end of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `removeMPTObjectType(hObj, objectTypeName)`

  Removes the specified user object type from the user object type list.

Your instance of the `sl_customization` function should use these methods to register `mpt` object type customizations for your Simulink installation.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, to use the changes, you must restart your MATLAB session.

mpt User Object Type Customization Using sl_customization.m

The `sl_customization.m` file shown in sl_customization.m for mpt Object Type Customizations uses the `addMPTObjectType` method to register the user signal types `EngineType` and `FuelType` for `mpt` objects.

sl_customization.m for mpt Object Type Customizations

```
function sl_customization(cm)
```

```
% Register user customizations

% Get default (factory) customizations
hObj = cm.slDataObjectCustomizer;

% Add commonly used signal types
hObj.addMPTObjectType(...
    'EngineType','Signal',...
    'DataType', 'uint8',...
    'Min', 0,...
    'Max', 255,...
    'Unit','m/s');

hObj.addMPTObjectType(...
    'FuelType','Signal',...
    'DataType', 'int16',...
    'Min', -12,...
    'Max', 3000,...
    'Unit','mg/hr');

end
```

If you include the above file on the MATLAB path of the Simulink installation that you want to customize, the specified customizations will appear in Model Explorer. For example, you could view the customizations as follows:

1. Start a MATLAB session.
2. Open Model Explorer, for example, by entering the MATLAB command `daexplr`.
3. Select **Base Workspace**.
4. Add an `mpt` signal, for example, by selecting **Add** > **Add Custom**.
5. In the right-hand pane display for the added `mpt` signal, examine the **User object type** drop-down list, noting the impact of the changes specified in sl_customization.m for mpt Object Type Customizations.
6. From the **User object type** drop-down list, select one of the registered user signal types, for example, `FuelType`, and verify that the displayed settings are consistent with the arguments specified to the `addMPTObjectType` method in `sl_customization.m`.

Custom Storage Classes in Embedded Coder

Introduction to Custom Storage Classes

In this section...

During the build process, the *storage class* specification of a signal, tunable parameter, block state, or data object specifies how that entity is declared, stored, and represented in generated code. Note that in the context of the build process, the term "storage class" is not synonymous with the term "storage class specifier", as used in the C language.

The code generator defines four built-in storage classes for use with system target files: `Auto`, `ExportedGlobal`, `ImportedExtern`, and `ImportedExternPointer`. These storage classes provide limited control over the form of the code generated for references to the data. For example, data of storage class `Auto` is typically declared and accessed as an element of a structure, while data of storage class `ExportedGlobal` is declared and accessed as unstructured global variables. For information about built-in storage classes, see "Control Signals and States in Code by Applying Storage Classes" (Simulink Coder) and "Block Parameter Representation in the Generated Code" (Simulink Coder).

If the built-in storage classes do not provide data representation required by your application, you can define *custom storage classes* (CSCs). Embedded Coder CSCs extend the built-in storage classes provided by Simulink Coder. CSCs can provide application-specific control over the constructs required to represent data in an embedded algorithm. For example, you can use CSCs to:

- Define structures for storage of parameter or signal data.
- Conserve memory by storing Boolean data in bit fields.
- Integrate generated code with legacy software whose interfaces cannot be modified.
- Generate data structures and definitions that comply with your organization's software engineering guidelines for safety-critical code.

Custom storage classes affect only code generated for ERT targets. When **Configuration Parameters > Code Generation > Target Selection > System target file** specifies a GRT target, the names of custom storage classes sometimes appear in dialog boxes, but selecting a CSC is functionally the same as selecting `Auto`. For information about ERT and GRT targets, see "Compare System Target File Support" (Simulink Coder).

Custom Storage Class Memory Sections

Every custom storage class has an associated *memory section* definition. A memory section is a named collection of properties related to placement of an object in memory; for example, in RAM, ROM, or flash memory. Memory section properties let you specify storage directives for data objects. For example, you can specify `const` declarations, or compiler-specific `#pragma` statements for allocation of storage in ROM or flash memory sections.

See "Create and Edit Memory Section Definitions" on page 23-52 for details about using the Custom Storage Class designer to define memory sections. While memory sections are often used with data in custom storage classes, they can also be used with various other constructs. See "Control Data and Function Placement in Memory by Inserting Pragmas" on page 27-2 for more information about using memory sections with custom storage classes, and complete information about using memory sections with other constructs.

Custom Storage Classes and Data Class Packages

CSCs are associated with Simulink data class packages (such as the `Simulink` package) and with classes within packages (such as the `Simulink.Parameter` and `Simulink.Signal` classes). A custom storage class is available only to data classes that are defined by the associated package.

You cannot add or change CSCs associated with built-in packages and classes, but you can create your own packages and subclasses, then associate customized CSCs with those packages. To create your own packages and custom storage classes, see "Design Custom Storage Classes and Memory Sections" on page 23-34.

Custom Storage Class Examples

These examples show Custom Storage Class capabilities:

"Configure Data Interface by Applying Custom Storage Classes" — Shows how custom storage classes can support data-object-driven modeling

rtwdemo_cscpredef — Shows predefined custom storage classes and embedded signal objects

rtwdemo_importstruct — Shows custom storage classes used to access imported data efficiently

Click the links above, or type the name in the MATLAB Command Window.

Simulink Package Custom Storage Classes

The `Simulink` package includes a set of built-in custom storage classes. These are categorized as custom storage classes, even though they are built-in, because they:

- Extend the storage classes provided by Simulink Coder
- Are functionally the same as if you had defined them yourself using the CSC Designer

You cannot change the CSCs built into the `Simulink` package, but you can subclass the package and add CSCs to the subclass, following the steps in "Resources for Defining Custom Storage Classes" on page 23-34.

Some CSCs in the `Simulink` package are valid for parameter objects (`Simulink.Parameter`, `Simulink.LookupTable`, and `Simulink.Breakpoint`) but not signal objects (`Simulink.Signal`) and vice versa. For example, you can assign the storage class `Const` to a parameter but not to a signal, because signal data is not constant. The next table defines the CSCs built into the `Simulink` package and shows where each of the CSCs can be used.

The code generator defines four built-in storage classes for use with targets: `Auto`, `ExportedGlobal`, `ImportedExtern`, and `ImportedExternPointer`. These storage classes provide limited control over the form of the code generated for references to the data. For example, data of storage class `Auto` is typically declared and accessed as an element of a structure, while data of storage class `ExportedGlobal` is declared and accessed as unstructured global variables. For information about built-in storage classes, see "Control Signals and States in Code by Applying Storage Classes" (Simulink Coder) and "Block Parameter Representation in the Generated Code" (Simulink Coder).

CSC Name	Purpose	Signals?	Parameters?
`BitField`	Generate a `struct` declaration that embeds Boolean data in named bit fields. For an example, see "Bitfields" on page 13-95.	Y	Y
`CompilerFlag`	Supports preprocessor conditionals defined via compiler flag. See "Generate Preprocessor Conditionals for Variant Systems" on page 14-33. To specify the compiler option, use the model configuration parameter	N	Y

CSC Name	Purpose	Signals?	Parameters?
	Configuration Parameters > **Code Generation** > **Custom Code** > **Additional build information** > **Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).		
`Const`	Generate a constant declaration with the `const` type qualifier.	N	Y
`ConstVolatile`	Generate declaration of volatile constant with the `const volatile` type qualifier. For an example, see "Type Qualifiers" on page 13-15.	N	Y
`Default`	`Default` is a placeholder CSC that the code generator assigns to the `CoderInfo.CustomStorageClass` property of signal and parameter objects when they are created. The signal, state, or parameter appears in the generated code as a global variable.	Y	Y
`Define`	Generate `#define` directive. The generated code defines the macro value. For an example, see "Macro Definitions (#define)" on page 13-77. Also supports generation of preprocessor conditionals for variant systems. See "Generate Preprocessor Conditionals for Variant Systems" on page 14-33.	Y	Y
`ExportToFile`	Generate header (`.h`) file, with user-specified name, containing global variable declarations.	Y	Y

CSC Name	Purpose	Signals?	Parameters?
`FileScope`	Generate a static qualifier suffix for a variable declaration so that the scope of the variable is limited to the current file.	Y	Y
`GetSet`	Supports specialized function calls to read and write memory. You can use this custom storage class with data stores. For examples, see "Access Data Through Functions with Custom Storage Class `GetSet`" on page 23-92.	Y	Y
`ImportedDefine`	Generate `#define` directive. You supply the macro definition in a legacy header file. For an example, see "Macro Definitions (#define)" on page 13-77. Also supports preprocessor conditionals, for variant systems, defined via legacy header file. See "Generate Preprocessor Conditionals for Variant Systems" on page 14-33.	N	Y
`ImportFromFile`	Generate directives to include predefined header files containing global variable declarations.	Y	Y

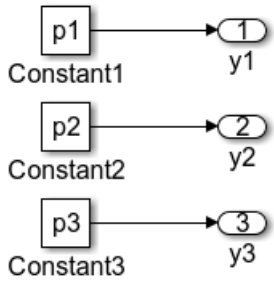
CSC Name	Purpose	Signals?	Parameters?
`Reusable`	Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either `Reusable (Custom)` or derived from `Reusable (Custom)`. For an example, see "Specify Buffer Reuse for Multiple Signals in a Path" on page 55-19. You can apply this storage class only to `Simulink.Signal` objects. For example, you cannot apply the storage class by using a Signal Properties dialog box.	Y	N
`Struct`	Generate a `struct` declaration encapsulating parameter or signal object data. For examples, see "Organize Parameter Data into a Structure by Using the `Struct` Custom Storage Class" on page 23-8 and "Structures of Signals" on page 13-87.	Y	Y
`Volatile`	Use `volatile` type qualifier in declaration.	Y	Y

Organize Parameter Data into a Structure by Using the `Struct` Custom Storage Class

This example shows how to use the `Struct` custom storage class to organize block parameter values into a structure in the generated code.

To create a structure of parameter data in the generated code, consider creating a corresponding structure in Simulink. See "Organize Block Parameter Values into Structures in the Generated Code" on page 19-97.

1. Create the `ex_struct_param` model with three Constant blocks and three Outport blocks.



2. Create a data object for each parameter, `p1`, `p2`, and `p3`. At the MATLAB command line, enter:

```
p1 = Simulink.Parameter;
p2 = Simulink.Parameter;
p3 = Simulink.Parameter;
```

3. In the base workspace, double-click one of the parameter data objects to open the `Simulink.Parameter` dialog box.
4. Specify a **Value** parameter for each parameter object.
5. Specify the **Storage class** parameter as `Struct` for each parameter object.
6. In the **Custom Attributes** section, specify the **StructName** as `my_struct`. Click **Apply** and **OK**.
7. Press **Ctrl+B** to generate code.

The generated code includes the `typedef` definition for a structure, which is declared in the `ex_struct_param_types.h` file.

```
/* Type definition for custom storage class: Struct */
   typedef struct my_struct_tag {
      real_T p1;
      real_T p2;
      real_T p3;
   } my_struct_type;
```

The generated code also includes the declaration of `my_struct` in `ex_struct_param.c`.

```
/* Definition for custom storage class: Struct */
my_struct_type my_struct = {
     /* p1 */
     1.0,

     /* p2 */
```

```
    2.0,

    /* p3 */
    3.0
};
```

Exchange and Reuse Parameter Data Between Generated Code and Existing Code

Blocks have numeric parameters that determine how they calculate output values, for example, the **Gain** parameter of a Gain block. In the generated code, you can configure block parameters to appear as parameter data, which include global variables and the formal parameters of a function (see "Block Parameter Representation in the Generated Code" on page 19-47).

When you integrate the generated code with your existing custom code, you can configure the generated code to reuse parameter data that your custom code defines. You can also generate code that defines parameter data for your custom code to use. For example, you can configure a **Gain** parameter to refer to a `Simulink.Parameter` object, which you can configure to appear in the generated code as a global variable. You can then use that variable in your existing code.

When you generate code that defines (allocates memory for and initializes) parameter data, the generated code exports that data. When your custom code defines parameter data, the generated code imports that data.

To export or import global parameter data:

1. Create a `Simulink.Parameter` object to represent the parameter data. Use the `Value` property of the object to store the parameter value for simulation in Simulink and for generation of an exported definition.

   To package lookup table data according to the ASAP2 or AUTOSAR standards (for example, STD_AXIS or MAP), use Simulink.LookupTable or Simulink.Breakpoint objects instead of `Simulink.Parameter` objects.
2. Optionally, specify the data type (for example, `int32`) of the parameter data by configuring the parameter object. You can generate code that uses custom data types (`typedef`) from your code. You can also represent structures, enumerations, and Boolean data. If you have Fixed-Point Designer, you can represent fixed-point data types.
3. Apply a storage class or custom storage class to the parameter object. Use the storage class to control the *scope* of the data. The data scope indicates whether the generated code imports or exports the data definition.

   For most storage classes, the generated code algorithm accesses the data through global reference.

For an example, see “Reuse Parameter Data from Custom Code in the Generated Code” on page 23-17.

Control Data Scope

To specify whether global parameter data are imported or exported, use storage classes and custom storage classes . Typically, storage classes that import data have the word `Import` in the storage class name, for example `ImportedExternPointer`.

For more information about the storage classes that are built into the code generator, see “Override Default Parameter Behavior by Creating Global Variables in the Generated Code” on page 19-49. For more information about using and creating custom storage classes, see “Introduction to Custom Storage Classes” on page 23-2 and “Simulink Package Custom Storage Classes” on page 23-5.

Control File Placement of Exported Parameter Data

When you export parameter data from the generated code by using storage classes or custom storage classes, the code generator creates an `extern` declaration. By default, this declaration typically appears in the generated header file *`model`*`.h`. You can include (`#include`) this header file in your code.

By default, the definition (memory allocation) and static initialization of exported parameter data typically appear in *`model`*`.c`.

You can control the file placement of the declarations and definitions to:

- Create separate object files that store only global parameter data.
- Modularize the generated code by organizing declarations into separate files.

To control the default file placement for parameter data that use custom storage classes, use the model configuration parameters **Configuration Parameters > Code Generation > Code Placement > Data definition** and **Data declaration** (see “Data definition” and “Data declaration”).

To control file placement for individual parameter data items (parameter objects), use the custom storage class `ExportToFile` or create your own similar custom storage class. For an example, see “Definition, Initialization, and Declaration of Parameter Data” on page 13-8.

For more information about controlling file placement of declarations and definitions, see “Manage Placement of Data Definitions and Declarations” on page 36-100.

Customize and Control Parameter Data Types

When your code uses `typedef` statements to define custom data types as aliases of integer and floating-point data types, such as `typedef int my_int;`, you can generate code that uses these different data types.

1. Create a `Simulink.AliasType` or `Simulink.NumericType` object.
2. Use the `DataScope` and `HeaderFile` properties of the object to import the type definition from your code.
3. Use the object as the data type of block parameters and parameter objects.

When you share parameter data between the generated code and your custom code, if you leave the data type of block parameters and `Simulink.Parameter` objects at the default settings (typically `Inherit: Inherit via internal rule` and `auto`), Simulink chooses the parameter and object data types. In some cases, when you make changes to the model (for instance, by changing the data types of signals), Simulink chooses different data types. Unless you modify your custom code so that it uses the new parameter data type, this change can cause compiler errors when you integrate the generated code with your custom code. To prevent the errors, you can explicitly specify the data type of the parameter object by using the `DataType` property. The corresponding global variable in the generated code uses the data type that you specify. For an example, see "Reuse Parameter Data from Custom Code in the Generated Code" on page 23-17 .

For more information about using data type objects to set data types in a model, see "Create and Apply User-Defined Data Types" on page 21-9 and "Conform to Coding Standards by Replacing and Renaming Data Types" on page 21-22. For more information about controlling parameter data types, see "Parameter Data Types in the Generated Code" on page 19-79.

To replace data type names throughout a model by default, consider using data type replacement. See "Data Type Replacement" on page 21-36.

Enumerated Parameters

You can export or import the definition of an enumerated data type to the generated code. For instance, use this technique to import parameter data that uses an enumerated type defined by your code.

To create a Simulink representation of an enumeration that your existing C code defines, use the `Simulink.importExternalCTypes` function. For an example that shows

how to export enumerated parameter data, see “Enumeration” on page 13-24. For more information, see “Use Enumerated Data in Generated Code” on page 19-22.

Pass Imported Parameter Data to Generated Algorithm as Arguments

You can generate a reusable algorithm that accepts parameter data through formal parameters of the model entry-point functions. You can then pass a different parameter value to each function call in the generated code or in your code.

To parameterize reusable referenced models and subsystems, use model arguments and mask parameters. For information, see “Parameter Interfaces for Reusable Components” (Simulink).

When you write custom code that calls the generated model `step` function multiple times, you can configure the model to generate a reentrant function that accepts signal, state, and parameter data as formal parameters. Set the model configuration parameter **Code interface packaging** to `Reusable function` (see “Code interface packaging” (Simulink Coder)).

When you use this technique, to pass parameter data through the reentrant interface, you must configure the parameter data to appear in the generated code as fields of the global parameter structure.

- Set the model configuration parameter **Default parameter behavior** (see “Default parameter behavior” (Simulink)) to `Tunable`. By default, block parameters appear in the generated code as fields of the parameter structure.

  Use this technique for rapid prototyping.
- In the model, create parameter objects (for example, `Simulink.Parameter` or `Simulink.LookupTable`) to set block parameter values. Optionally, use structures to group multiple parameter values into a single object (see “Organize Related Block Parameter Definitions in Structures” (Simulink)). Apply the storage class `SimulinkGlobal` to the parameter objects. These parameter objects appear in the generated code as fields of the parameter structure.

  Use this technique when you set **Default parameter behavior** to `Inlined` for production code generation.

For more information about **Code interface packaging** and reentrancy, see “Generate Reentrant Code from Top-Level Models” on page 34-20. For information about

creating instance-specific data in your custom code, see “Modify Static Main to Allocate and Access Model Instance Data” on page 49-14.

Considerations for Other Modeling Goals

Goal	Considerations and More Information
Use multidimensional parameters (arrays)	The generated code defines and accesses multidimensional data, including matrices, as column-major serialized vectors. If your custom code uses a different format, consider using alternative techniques to integrate the generated code. See “Code Generation of Matrices and Arrays” on page 33-76.
Use parameter structures	You can export or import a structure of parameter values by creating a `Simulink.Bus` object to represent the structure type. Use the bus object as the data type of a parameter object. You can also use custom storage classes for greater modeling flexibility. See “Organize Block Parameter Values into Structures in the Generated Code” on page 19-97.
Use macros (`#define`)	To export a macro to your custom code, you can use the custom storage class `Define`. To import a macro, use `ImportedDefine`. With macros, you can reuse a parameter value in multiple locations in an algorithm and change the parameter value between code compilations without consuming memory to store the value. Typically, macros represent engineering constants that you do not expect to change during code execution. For examples, see “Macro Definitions (#define)” on page 13-77.
Generate code that imports parameter data through custom functions	When your code contains functions, such as device drivers, that return parameter data, you can use custom storage classes to generate code that calls the functions. See “Access Data Through Functions with Custom Storage Class `GetSet`” on page 23-92.
Use storage type qualifiers such as `const` and `volatile`	When you import parameter data from your code, you can generate code that matches the storage type qualifiers that your code applies to the data. Use custom storage classes and memory sections. See “Type Qualifiers” on page 13-15.
Generate code comments that describe attributes of data including physical units, real-	Generating these comments can help you match data interfaces while handwriting integration code. See “Add Custom Comments for Variables in the Generated Code” on page 36-5.

Goal	Considerations and More Information
world initial value, and data type	
Use Simulink to simulate an external executable	You can use SIL, PIL, and external mode simulations to connect your model to the corresponding generated executable for simulation. When you import parameter data from your custom code: • At the time that you begin an external mode simulation, the external executable uses the value that your code uses to initialize the parameter data. However, when you change the corresponding value in Simulink during the simulation (for example by modifying the `Value` property of the corresponding parameter object), Simulink downloads the new value to the executable. • SIL and PIL simulations do not import the parameter value from your code. Instead, the simulations use the parameter value from Simulink.

Reuse Parameter Data from Custom Code in the Generated Code

This example shows how to generate code that imports a parameter value from your external, custom code.

Create Custom Code Files

Suppose your custom code defines a vector parameter `myGains` with three elements. Save the definition in your current folder in a file called `ex_vector_import_src.c`.

```
#include "ex_vector_import_decs.h"

my_int8 myGains[3] = {
    2,
    4,
    6
};
```

Save the declaration in your current folder in a file called `ex_vector_import_decs.h`.

```
#include "ex_vector_import_cust_types.h"

extern my_int8 myGains[3];
```

Save the custom data type definition `my_int8` in your current folder in a file called `ex_vector_import_cust_types.h`.

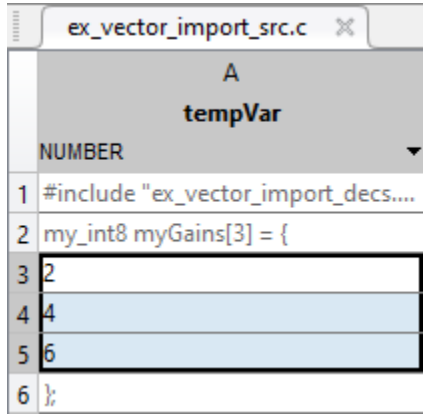
```
typedef signed char my_int8;
```

Import Parameter Value for Simulation

In your current folder, right-click the file `ex_vector_import_src.c` and select **Import Data**.

In the Import dialog box, set the name of the generated MATLAB variable to `tempVar`.

Select only the parameter values (`2`, `4`, and `6`) to import.



Import the data by clicking the green check mark. The MATLAB variable `tempVar` appears in the base workspace.

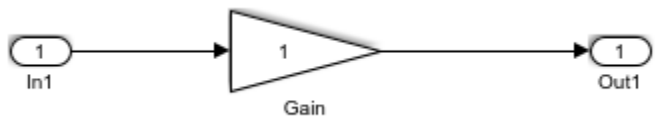
Alternatively, use the command prompt to manually create `tempVar`.

```
tempVar = [2;4;6];
```

Create and Configure Model

Create the model `ex_vector_import`.

```
open_system('ex_vector_import')
```



In the Gain block dialog box, on the **Parameter Attributes** tab, set **Parameter data type** to `Inherit: Inherit from 'Gain'`.

On the **Main** tab, set **Gain** to `myGains`. Click **Apply**.

Click the action button next to the parameter value. Select **Create Variable**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and click **Create**.

In the myGains dialog box, set these property values and click **OK**:

- **Data type** to `my_int8`
- **Storage class** to `ImportFromFile`
- **HeaderFile** to `ex_vector_import_decs.h`

Alternatively, use these commands at the command prompt to create the object and set the property values:

```
myGains = Simulink.Parameter;
set_param('ex_vector_import/Gain','Gain','myGains',...
    'ParamDataTypeStr','Inherit: Inherit from ''Gain''')
myGains.DataType = 'my_int8';
myGains.CoderInfo.StorageClass = 'Custom';
myGains.CoderInfo.CustomStorageClass = 'ImportFromFile';
myGains.CoderInfo.CustomAttributes.HeaderFile = 'ex_vector_import_decs.h';
```

At the command prompt, set the `Value` property by using the value of `tempVar`.

```
myGains.Value = tempVar;
```

At the command prompt, create a `Simulink.AliasType` object to represent your custom data type `my_int8`. Set the `DataScope` and `HeaderFile` properties to import the type definition from your custom code.

```
my_int8 = Simulink.AliasType('int8');
my_int8.DataScope = 'Imported';
my_int8.HeaderFile = 'ex_vector_import_cust_types.h';
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vector_import_src.c`.

```
set_param('ex_vector_import','CustomSource','ex_vector_import_src.c')
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_vector_import')
```

```
### Starting build procedure for model: ex_vector_import
### Successful completion of build procedure for model: ex_vector_import
```

The generated file `ex_vector_import.h` includes the custom header files `ex_vector_import_decs.h` and `ex_vector_import_cust_types.h`, which contain the parameter variable declaration (`myGains`) and custom type definition (`my_int8`).

```
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.h');
rtwdemodbtype(file,'/* Includes for objects with custom storage classes. */',...
    '#include "ex_vector_import_cust_types.h"',1,1)
```

```
/* Includes for objects with custom storage classes. */
#include "ex_vector_import_decs.h"
#include "ex_vector_import_cust_types.h"
```

The generated code algorithm in the model `step` function in the generated file `ex_vector_import.c` uses `myGains` for calculations.

```
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)
```

```
/* Model step function */
void ex_vector_import_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In1'
   */
  rtY.Out1[0] = (real_T)myGains[0] * rtU.In1;
  rtY.Out1[1] = (real_T)myGains[1] * rtU.In1;
  rtY.Out1[2] = (real_T)myGains[2] * rtU.In1;
}
```

The generated code does not define (allocate memory for) or initialize the global variable `myGains` because the data scope of the corresponding parameter object is imported.

When you simulate the model in Simulink, the model uses the value stored in the `Value` property of the parameter object. However, if you use external mode simulation, the external executable begins the simulation by using the value from your code. See "Considerations for Other Modeling Goals".

Import Parameter Data with Conditionally Compiled Dimension Length

Suppose your custom code conditionally allocates memory for and initializes lookup table and breakpoint set data based on a dimension length that you specify as a `#define` macro. This example shows how to generate code that imports this external global data.

Create Custom Code Files

Save the definition of the breakpoint set data `T1Break` and lookup table data `T1Data` in your current folder in a file called `ex_vec_symdim_src.c`. These global variables have either 9 or 11 elements depending on the value of the macro `bpLen`.

```
#include "ex_vec_symdim_decs.h"

#if bpLen == 11
double T1Break[bpLen] = {
    -5.0,
    -4.0,
    -3.0,
    -2.0,
    -1.0,
    0.0,
    1.0,
    2.0,
    3.0,
    4.0,
    5.0
} ;

double T1Data[bpLen] = {
    -1.0,
    -0.99,
    -0.98,
    -0.96,
    -0.76,
    0.0,
    0.76,
    0.96,
    0.98,
    0.99,
    1.0
```

```
} ;
#endif

#if bpLen == 9
double T1Break[bpLen] = {
    -4.0,
    -3.0,
    -2.0,
    -1.0,
    0.0,
    1.0,
    2.0,
    3.0,
    4.0
} ;

double T1Data[bpLen] = {
    -0.99,
    -0.98,
    -0.96,
    -0.76,
    0.0,
    0.76,
    0.96,
    0.98,
    0.99
} ;
#endif
```

Save the declarations of the variables and the definition of the macro in your current folder in a file called `ex_vec_symdim_decs.h`.

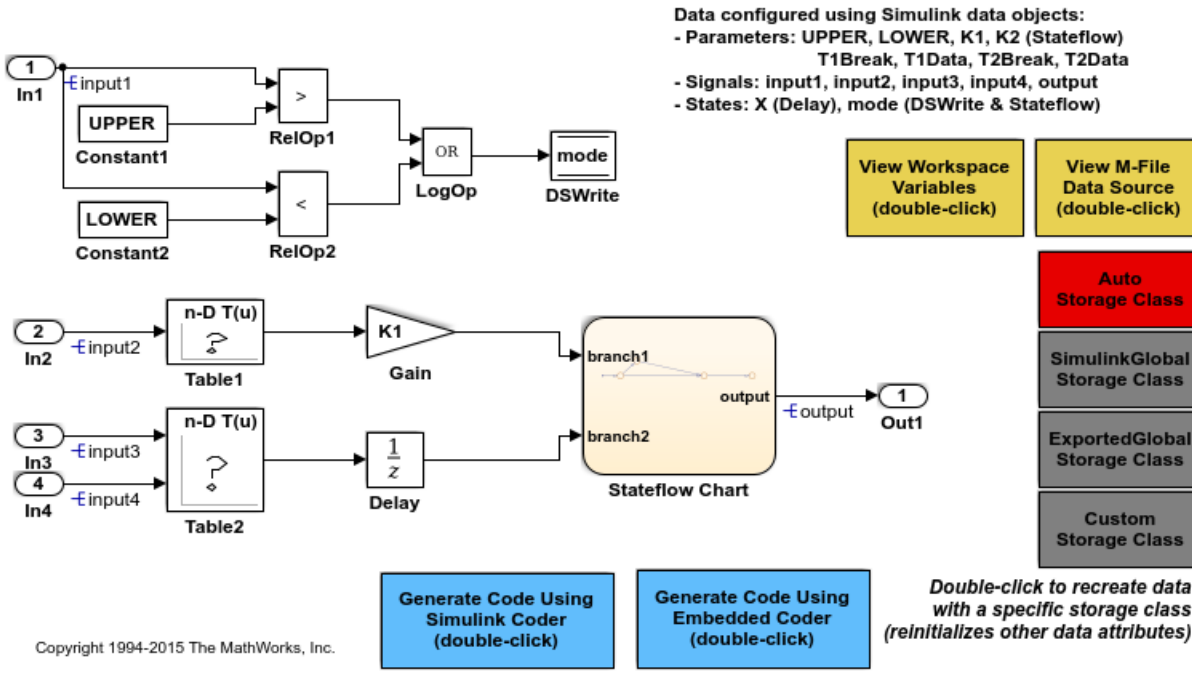
```
#define bpLen 11

extern double T1Break[bpLen];
extern double T1Data[bpLen];
```

Explore and Configure Example Model

Open the example model `rtwdemo_advsc`.

```
open_system('rtwdemo_advsc')
```



Open the Table1 block dialog box. The block refers to `Simulink.Parameter` objects, `T1Data` and `T1Break`, in the base workspace. These objects store the lookup table and breakpoint set data with 11 elements.

At the command prompt, configure the objects to import the data definitions from your custom code.

```
T1Data.CoderInfo.StorageClass = 'Custom';
T1Data.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Data.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';

T1Break.CoderInfo.StorageClass = 'Custom';
T1Break.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Break.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';
```

At the command prompt, create a `Simulink.Parameter` object to represent the custom macro `bpLen`.

```
bpLen = Simulink.Parameter(11);
```

```
bpLen.Min = 9;
bpLen.Max = 11;
bpLen.DataType = 'int32';
bpLen.CoderInfo.StorageClass = 'Custom';
bpLen.CoderInfo.CustomStorageClass = 'ImportedDefine';
bpLen.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';
```

Use `bpLen` to set the dimensions of the lookup table and breakpoint set data. Configure the model to enable symbolic dimensions by selecting the configuration parameter **Allow symbolic dimension specification**.

```
T1Data.Dimensions = '[1 bpLen]';
T1Break.Dimensions = '[1 bpLen]';
set_param('rtwdemo_advsc','AllowSymbolicDim','on')
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vec_symdim_src.c`.

```
set_param('rtwdemo_advsc','CustomSource','ex_vec_symdim_src.c')
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_advsc')
```

```
### Starting build procedure for model: rtwdemo_advsc
### Successful completion of build procedure for model: rtwdemo_advsc
```

The generated code algorithm is in the model `step` function in the generated file `rtwdemo_advsc.c`. The algorithm passes `T1Break`, `T1Data`, and `bpLen` as argument values to the function that performs the table lookup. In this case, `bpLen` controls the upper bound of the binary search that the function uses.

```
file = fullfile('rtwdemo_advsc_ert_rtw','rtwdemo_advsc.c');
rtwdemodbtype(file,' look1_binlc','bpLen - 1U',1,1)
```

```
    rtwdemo_advsc_DWork.X = look1_binlc(rtwdemo_advsc_U.input2, (&(T1Break[0])),
      (&(T1Data[0])), bpLen - 1U) * 2.0;
```

For more information about symbolic dimensions, see “Implement Dimension Variants for Array Sizes in Generated Code”.

Access Structured Data Through a Pointer That External Code Defines

This example shows how to generate code that uses global data that some handwritten code defines. In the handwritten code, a pointer variable points to one of two structure variables that contain parameter data. A handwritten function switches the pointer between the two structures. The generated code accesses the parameter data by dereferencing the pointer variable.

Explore Custom Code

Open the example source file rtwdemo_importstruct_user.c. The code defines a structure variable `ReferenceStruct` as constant (`const`) data and statically initializes each field.

```
/* Constant default data struct: ReferenceStruct */
const DataStruct_type ReferenceStruct =
{
  11,   /* OFFSET */
  2     /* GAIN */
};
```

The code defines another structure variable, `WorkingStruct`, as volatile (`volatile`) data.

```
/* Volatile data struct: WorkingStruct */
volatile DataStruct_type WorkingStruct;
```

The code defines a function that copies the field values from `ReferenceStruct` to `WorkingStruct`.

```
/* Function to initialize WorkingStruct with data from ReferenceStruct */
void Init_WorkingStruct(void)
{
      memcpy((void*)&WorkingStruct, &ReferenceStruct, sizeof(ReferenceStruct));
}
```

The code defines `StructPointer`, which is a `const volatile` pointer to a structure. The code initializes the pointer to the address of `ReferenceStruct`.

```
/* Create pointer to the default data struct, e.g. ReferenceStruct */
const volatile DataStruct_type *StructPointer = &ReferenceStruct;
```

Finally, the code defines a function that can dynamically set `StructPointer` to point to either `ReferenceStruct` or `WorkingStruct`.

```
/* Function to switch between structures */
void SwitchStructPointer(Dataset_T Dataset)
{
    switch (Dataset)
    {
        case Working:
          StructPointer = &WorkingStruct;
          break;
        default:
          StructPointer = &ReferenceStruct;
    }
}
```

The example header file rtwdemo_importstruct_user.h defines the enumeration `Dataset_T` and the structure type `Datastruct_type`. The file includes (`#include`) the built-in Simulink® Coder™ header file `rtwtypes.h`, which defines (`typedef`) Simulink Coder data types such as `int16_T`.

```
#include "rtwtypes.h"

typedef enum {
    Reference=0,
    Working
} Dataset_T;

typedef struct DataStruct_tag {
  int16_T   OFFSET; /* OFFSET */
  int16_T   GAIN;   /* GAIN */
} DataStruct_type;
```

The file also declares the global variables and the functions.

Purpose of Custom Code

The code is designed so that the source code of a control algorithm (whether generated or handwritten) can read data from either `ReferenceStruct` or `WorkingStruct`

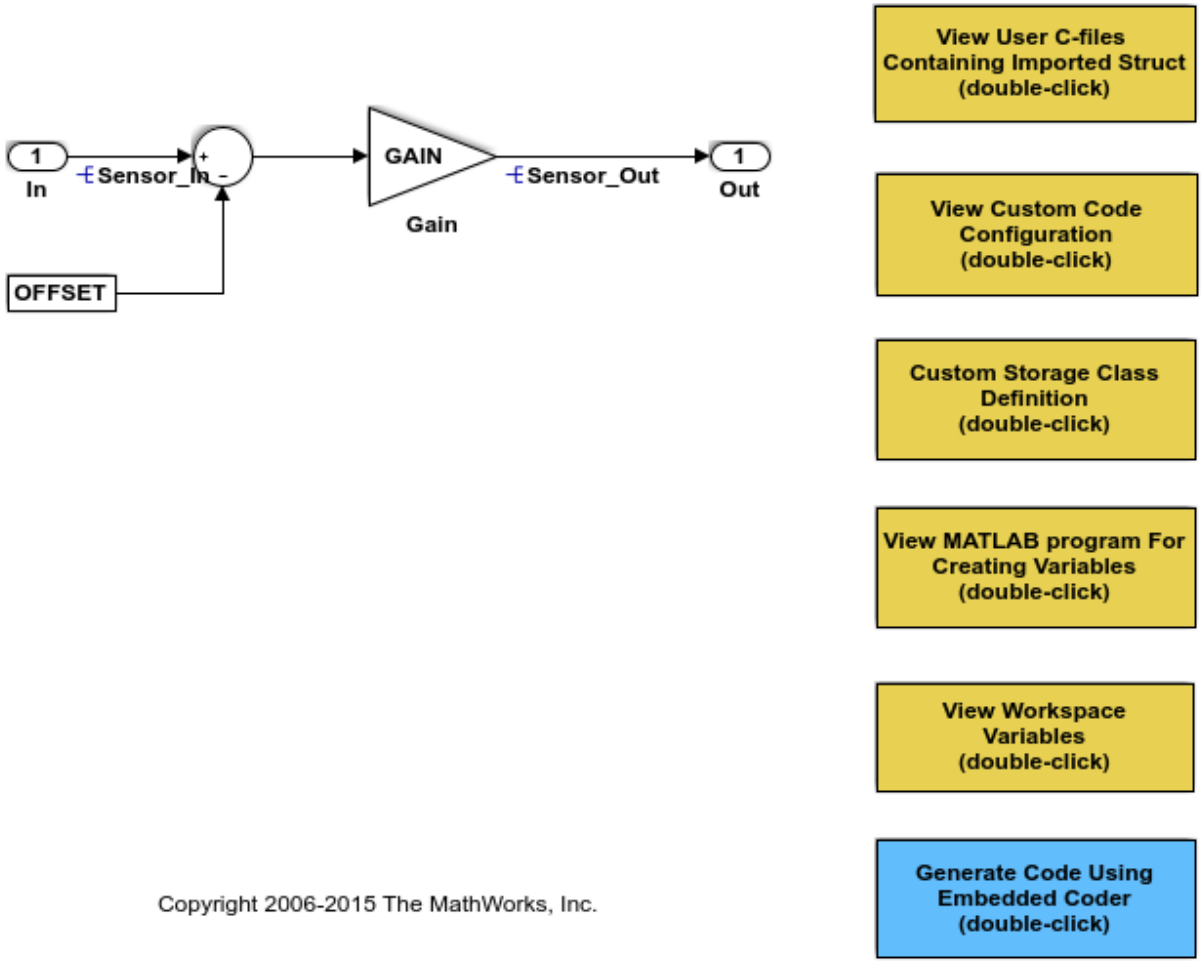
by dereferencing (->) `StructPointer`. A software engineer can write code that dynamically switches `StructPointer` between the address of `WorkingStruct` and `ReferenceStruct` by passing the corresponding enumeration member as the input argument in calls to the `SwitchStructPointer` function.

Later, in preparation for calibration while the algorithm executes, a calibration tool can make `StructPointer` point to `WorkingStruct`. The tool can then modify the fields of `WorkingStruct`.

If necessary for safety or in preparation for shutting down the application, the calibration tool can point `StructPointer` to `ReferenceStruct` instead. `ReferenceStruct` stores default parameter values that do not change during execution.

Explore Example Model

Open the example model, rtwdemo_importstruct.



The model creates variables and objects in the base workspace. The Constant block and the Gain block use the `ECoderDemos.Parameter` objects `GAIN` and `OFFSET` to set the **Constant value** and **Gain** block parameters. `ECoderDemos` is an example custom package that defines two classes, `Parameter` and `Signal`, and some custom storage classes.

In the Constant block dialog box, next to the value of the **Constant value** parameter, click the action button. Select **Open Variable**. In the property dialog box for `OFFSET`,

Storage class is set to `StructPointer`, which is a custom storage class that the `ECoderDemos` package defines. `GAIN` also uses this custom storage class.

Open the Custom Storage Class Designer and inspect the custom storage classes in the `ECoderDemos` package. At the command prompt, use this command:

```
cscdesigner('ECoderDemos')
```

This example package defines multiple custom storage classes, including `StructPointer`. You cannot edit the definitions. However, you can create your own packages and custom storage classes later. For an example that shows how to create a package and a custom storage class, see "Control Data Code by Creating Custom Storage Class".

Under **Custom storage class definitions**, click `StructPointer`. The settings for this custom storage class enable the generated code to interact with the pointer variable, `StructPointer`, from the custom code. For example, the custom storage class uses these settings:

- **Data scope** is set to `Imported` because the example custom code defines (allocates memory for) `StructPointer`. With this setting, the code generator avoids generating unnecessary, duplicate definitions for the data items, such as the `ECoderDemos.Parameter` objects, that use the custom storage class.
- **Data access** is set to `Pointer` because in the example custom code, `StructPointer` is a pointer.
- **Memory section** is set to `ConstVolatile` because the example custom code defines `StructPointer` as constant, volatile data (`const volatile`).
- **Type** is set to `FlatStructure` because in the example custom code, `StructPointer` points to a structure. With this setting, the generated code treats each data item (`ECoderDemos.Parameter` object) as a field of a flat structure whose variable name and type name you can specify.
- On the **Structure Attributes** tab, **Struct name** is set to `StructPointer`. For a `FlatStructure` custom storage class, **Struct name** specifies the name of the structure variable in the generated code. In this example, `StructPointer` is the name of the variable that the custom code defines.
- **Type name** is set to `DataStruct_type`, which is the name of the structure type that the example custom code defines.

In the model, in the **Configuration Parameters** dialog box, inspect the **Code Generation > Custom Code** pane.

Under **Insert custom C code in generated**, select **Initialize function**. In this model, this configuration parameter is set so that the generated code calls the `Init_WorkingStruct` function before execution of the primary algorithm. `Init_WorkingStruct` initializes the fields of `WorkingStruct` with the values from `ReferenceStruct`.

Under **Additional build information**, select **Source files**. This configuration parameter identifies the example custom code file `rtwdemo_importstruct_user.c` for inclusion in the build process after code generation.

Generate and Inspect Code

Generate code from the model.

In the generated file `rtwdemo_importstruct.c`, the model initialization function calls `Init_WorkingStruct`.

```
/* Model initialize function */
void rtwdemo_importstruct_initialize(void)
{
  /* user code (Initialize function Body) */

  /* Initialize the volatile memory data set before switching to it */
  Init_WorkingStruct();
}

/*
```

The algorithm in the model execution (`step`) function dereferences the pointer variable `StructPointer`.

```
/* Model step function */
void rtwdemo_importstruct_step(void)
{
  /* Gain: '<Root>/Gain' incorporates:
   *  Constant: '<Root>/Offset'
   *  Inport: '<Root>/In'
   *  Sum: '<Root>/Sum'
   */
  Sensor_Out = (int16_T)((int16_T)(Sensor_In - StructPointer->OFFSET) *
    StructPointer->GAIN);
```

```
}
```

Design Custom Storage Classes and Memory Sections

In this section...

Resources for Defining Custom Storage Classes

The resources for working with custom storage class definitions are:

- Use MATLAB class syntax to create a data class in a package. You can assign properties to the data class and add initialization code to enable custom storage class definition. For complete instructions, see "Define Data Classes" (Simulink).
- A set of ready-to-use CSCs. These CSCs are designed to be useful in code generation for embedded systems development. CSC functionality is integrated into the `Simulink.Signal`, `Simulink.Parameter`, `Simulink.LookupTable`, and `Simulink.Breakpoint` classes; you do not need to use special object classes to generate code with CSCs.
- The Custom Storage Class Designer (`cscdesigner`) tool, which is described in this chapter. This tool lets you define CSCs that are tailored to your code generation requirements. The Custom Storage Class Designer provides a graphical user interface that you can use to implement CSCs. You can use your CSCs in code generation immediately, without a Target Language Compiler (TLC) or other programming. See "Design Custom Storage Classes and Memory Sections" on page 23-34 for details.

Create Packages for Custom Storage Class Definitions

Use MATLAB class syntax to create a data class in a package. You can assign properties to the data class and add initialization code to enable custom storage class definition. For complete instructions, see "Define Data Classes" (Simulink).

Use Custom Storage Class Designer

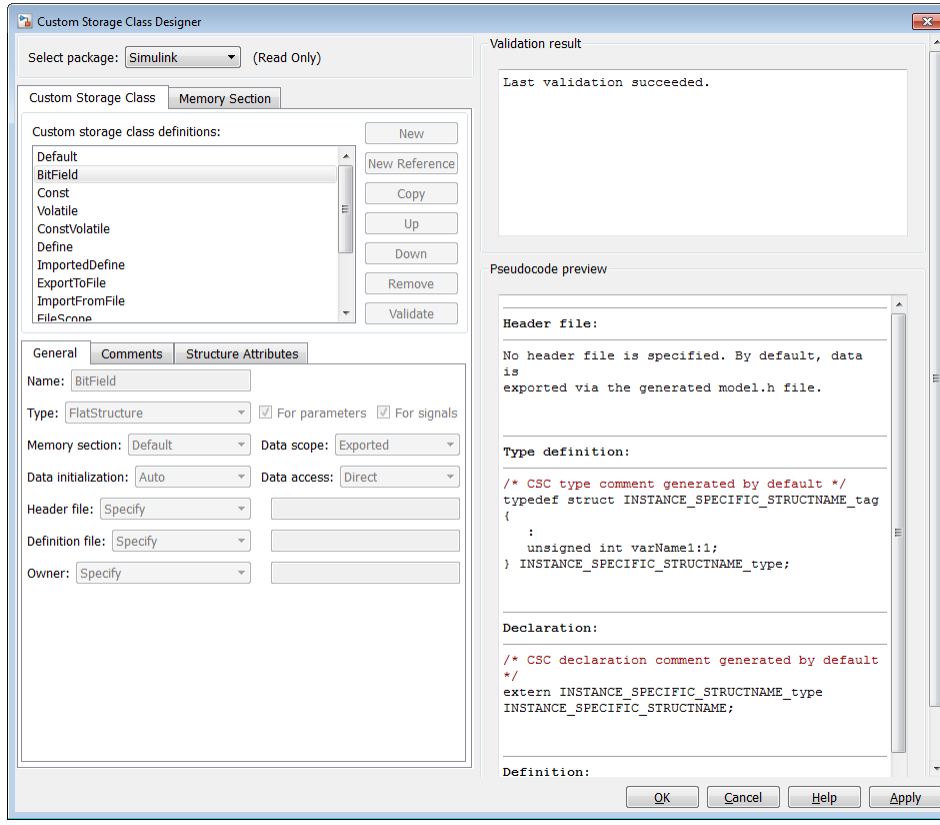
The Custom Storage Class Designer (`cscdesigner`) is a tool for creating and managing custom storage classes and memory sections. You can use the Custom Storage Class Designer to:

- Load existing custom storage classes and memory sections and view and edit their properties
- Create new custom storage classes and memory sections
- Create references to custom storage classes and memory sections defined in other packages
- Copy and modify existing custom storage class and memory section definitions
- Check a custom storage class and memory section definitions
- Preview pseudocode generated from custom storage class and memory section definitions
- Save custom storage class and memory section definitions

To open the Custom Storage Class Designer for a particular package, type the following command at the MATLAB prompt:

```
cscdesigner ('mypkg')
```

When first opened, the Custom Storage Class Designer scans data class packages on the MATLAB path to detect packages that have a CSC registration file. A message is displayed while scanning proceeds. When the scan is complete, the Custom Storage Class Designer window appears:



The Custom Storage Class Designer window is divided into several panels:

- **Select package**: Lets you select from a menu of data class packages that have CSC definitions associated with them. See “Select Data Class Package” on page 23-37 for details.
- **Custom Storage Class / Memory Section** properties: Lets you select, view, edit, copy, verify, and perform other operations on CSC definitions or memory section definitions. The common controls in the **Custom Storage Class / Memory Section** properties panel are described in “Manipulate Custom Storage Classes and Memory Sections” on page 23-38.

  - When the **Custom Storage Class** tab is selected, you can select a CSC definition or reference from a list and edit its properties. See "Edit Custom Storage Class Properties" on page 23-41 for details.
  - When the **Memory Section** tab is selected, you can select a memory section definition or reference from a list and edit its properties. See "Create and Edit Memory Section Definitions" on page 23-52 for details.
- **Filename**: Displays the filename and location of the current CSC registration file, and lets you save your CSC definition to that file. See "Save Definitions" on page 23-40 for details.
- **Pseudocode preview**: Displays a preview of code that is generated from objects of the given class. The preview is pseudocode, since the actual symbolic representation of data objects is not available until code generation time. See "Preview Generated Code" on page 23-54 for details.
- **Validation result**: Displays errors encountered when the currently selected CSC definition is validated. See "Validate Definitions Category" on page 23-47 for details.

Select Data Class Package

A CSC or memory section definition or reference is uniquely associated with a Simulink data class package. The link between the definition/reference and the package is formed when a CSC registration file (`csc_registration.m`) is located in the package directory.

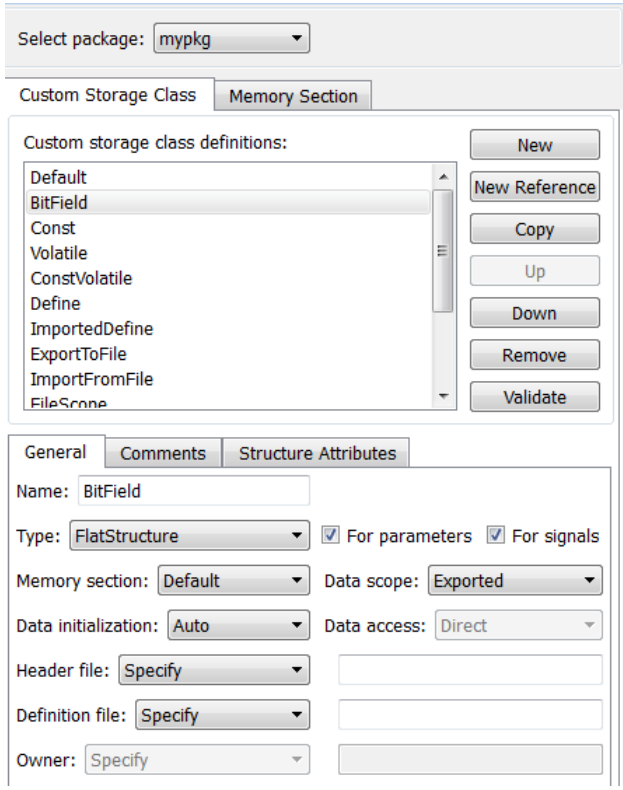
You need not search for or edit a CSC registration file directly: the Custom Storage Class Designer locates available CSC registration files. The **Select package** menu contains names of data class packages that have a CSC registration file on the MATLAB search path.

When you select a package, the CSCs and memory section definitions belonging to the package are loaded into memory and their names are displayed in the scrolling list in the **Custom storage class** panel. The name and location of the CSC registration file for the package is displayed in the **Filename** panel.

If you select a user-defined package, by default you can use the Custom Storage Class Designer to edit its custom storage classes and memory sections. If you select a built-in package, you cannot edit its custom storage classes or memory sections.

Manipulate Custom Storage Classes and Memory Sections

The **Custom Storage Class / Memory Section** panel lets you select, view, and (if the CSC is writable) edit CSC and memory section definitions and references. In the next figure and the subsequent examples, the selected package is `mypkg`. Instructions for creating a user-defined package like `mypkg` appear in "Design Custom Storage Classes and Memory Sections" on page 23-34.



The list at the top of the panel displays the definitions/references for the currently selected package. To select a definition/reference for viewing and editing, click on the desired list entry. The properties of the selected definition/reference appear in the area below the list. The number and type of properties vary for different types of CSC and memory section definitions. See:

- "Edit Custom Storage Class Properties" on page 23-41 for information about the properties of the predefined CSCs.
- "Create and Edit Memory Section Definitions" on page 23-52 for information about the properties of the predefined memory section definitions.

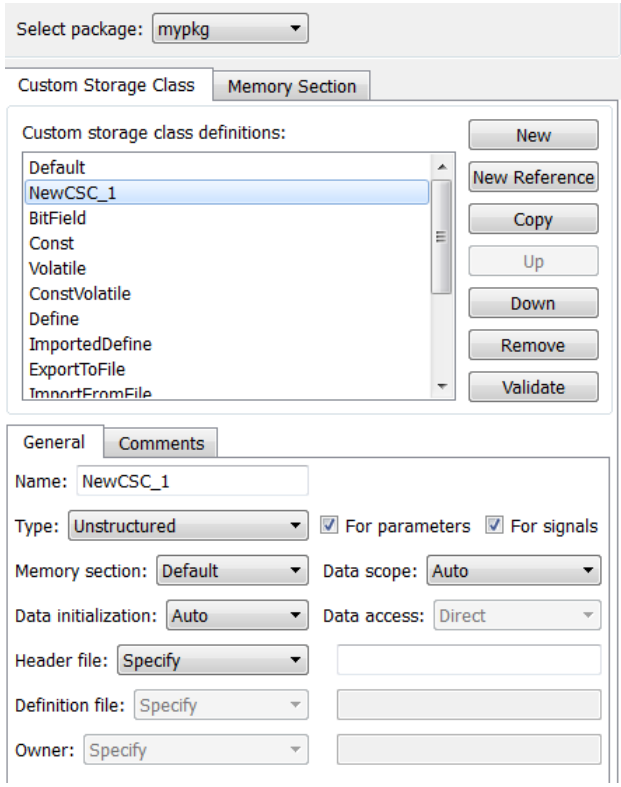
The buttons to the right of the list perform these functions, which are common to both custom storage classes and memory definitions:

- **New**: Creates a new CSC or memory section with default values.
- **New Reference:** Creates a reference to a CSC or memory section definition in another package. The default initially has a default name and properties. See "Use Custom Storage Class References" on page 23-47 and "Use Memory Section References" on page 23-55.
- **Copy**: Creates a copy of the selected definition / reference. The copy initially has a default name using the convention:

  ```
  definition_name_n
  ```

  where `definition_name` is the name of the original definition, and `n` is an integer indicating successive copy numbers (for example: `BitField_1`, `BitField_2`, ...)
- **Up**: Moves the selected definition one position up in the list.
- **Down**: Moves the selected definition one position down in the list
- **Remove**: Removes the selected definition from the list.
- **Validate**: Performs a consistency check on the currently selected definition. Errors are reported in the **Validation result** panel.

For example, if you click **New**, a new custom storage class is created with a default name:



You can now rename the new class by typing the desired name into the **Name** field, and specify other fields.

Note: The class name must be a valid MATLAB variable name. See "Variable Names" (MATLAB)

Click **Apply** or **OK**.

Save Definitions

After you have created or edited a CSC or memory section definition or reference, you must save the changes to the CSC registration file. To do this, click **Save** in the

Filename panel. When you click **Save**, the current CSC and memory section definitions that are in memory are validated, and the definitions are written out.

If errors occur, they are reported in the **Validation result** panel. The definitions are saved whether or not errors exist. However, you should resolve validation errors and resave your definitions. Trying to use definitions that were saved with validation errors can cause additional errors. Such problems can occur even it you do not try to use the specific parts of the definition that contain the validation errors, making the problems difficult to diagnose.

Restart MATLAB After Changing Definitions

If you add, change, or delete custom storage class or memory section definitions for a user-defined class, and objects of that class already exist, you must restart MATLAB to use the changed definitions and to eliminate obsolete objects. When you save the changed definitions, a message appears indicating that you must restart MATLAB.

Edit Custom Storage Class Properties

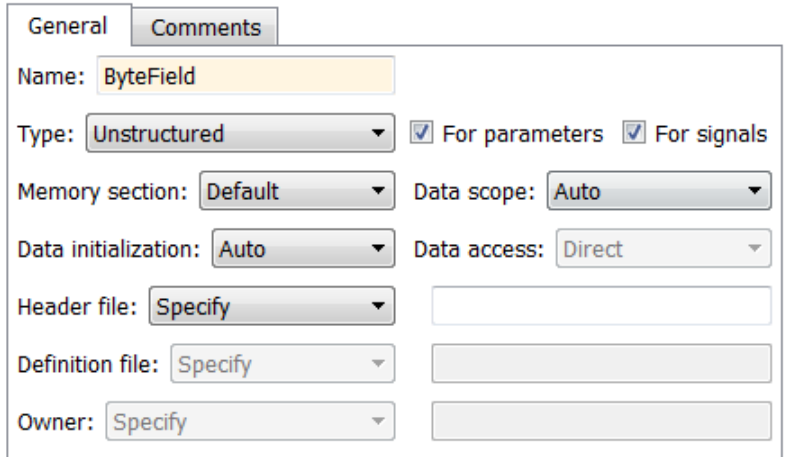
To view and edit the properties of a CSC, click the **Custom Storage Class** tab in the **Custom Storage Class / Memory Section** panel. Then, select a CSC name from the **Custom storage class definitions** list.

The CSC properties are divided into several categories, selected by tabs. Selecting a class, and setting property values for that class, can change the available tabs, properties, and values. As you change property values, the changes in the generated code is immediately displayed in the **Pseudocode preview** panel. In most cases, you can define your CSCs quickly and easily by selecting the **Pseudocode preview** panel and using the **Validate** button frequently.

The property categories and corresponding tabs are as follows:

General Category

Properties in the **General** category are common to CSCs. In the next figure and the subsequent examples, the selected custom storage class is `ByteField`. Instructions for creating a user-defined custom storage class like `ByteField` appear in “Manipulate Custom Storage Classes and Memory Sections” on page 23-38.



Properties in the **General** category, and the possible values for each property, are as follows:

- **Name**: The CSC name, selected from the **Custom storage class definitions** list. The name cannot be a TLC keyword. Violating this rule causes an error.
- **Type**: Specifies how objects of this class are stored. Values:
  - `Unstructured`: Objects of this class generate unstructured storage declarations (for example, scalar or array variables), for example:

    ```
    datatype dataname[dimension];
    ```

  - `FlatStructure`: Objects of this class are stored as members of a struct. A **Structure Attributes** tab is also displayed, allowing you to specify additional properties such as the struct name. See "Structure Attributes Category" on page 23-45.
  - `AccessFunction`: The generated code accesses objects of this class by calling custom `get` and `set` functions whose definitions you provide. See "Access Function Attributes Category" on page 23-46.
  - `Other`: Used for certain data layouts, such as nested structures, that cannot be generated using the standard `Unstructured` and `FlatStructure` custom storage class types. If you want to generate other types of data, you can create a new custom storage class from scratch by writing TLC code. See "Define Advanced Custom Storage Classes Types" on page 23-78 for more information.

- **For parameters** and **For signals**: These options let you enable a CSC for use with only certain classes of data objects. For example, it does not make sense to assign storage class `Const` to a `Simulink.Signal` object. Accordingly, the **For signals** option for the `Const` class is deselected, while the **For parameters** is selected.
- **Memory section**: Selects one of the memory sections defined in the **Memory Section** panel. See "Create and Edit Memory Section Definitions" on page 23-52.
- **Data scope**: Controls the scope of symbols generated for data objects of this class. Values:
  - `Auto`: Symbol scope is determined internally by code generation. If possible, symbols have `File` scope. Otherwise, they have `Exported` scope.
  - `Exported`: Symbols are exported to external code in the header file specified by the **Header File** field. If a **Header File** is not specified, symbols are exported to external code in *`model`*`.h`.
  - `Imported`: Symbols are imported from external code in the header file specified by the **Header File** field. If you do not specify a header file, an `extern` directive is generated in *`model`*`_private.h`.
  - `File`: The scope of each symbol is the file that defines it. File scope requires each symbol to be used in a single file. If the same symbol is referenced in multiple files, an error occurs at code generation time.
  - `Instance specific`: Symbol scope is defined by the **Data scope** field of the `CoderInfo.CustomAttributes` property of each data object.
- **Data initialization**: Controls how storage is initialized in generated code. Values:
  - `Auto`: Storage initialization is determined internally by the code generation. Parameters have `Static` initialization, and signals have `Dynamic` initialization.
  - `None`: Initialization code is not generated.
  - `Static`: A static initializer of the following form is generated:

    ```
    datatype dataname[dimension] = {...};
    ```

  - `Dynamic`: Variable storage is initialized at runtime, in the *`model`*`_initialize` function.
  - `Macro`: A macro definition of the following form is generated:

    ```
    #define data numeric_value
    ```

The `Macro` initialization option is available only for use with unstructured parameters. It is not available when the class is configured for generation of structured data, or for signals. If you set **Data scope** to `Imported`:

- To import a macro that you define by creating a preprocessor directive (`#define`), use the option **Header file** to configure the name of the header file that contains the directive.
- To import a macro that you define by configuring a compiler option, omit the header file.

  To specify the compiler option, use the model configuration parameter **Configuration Parameters** > **Code Generation** > **Custom Code** > **Additional build information** > **Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

- `Instance specific`: Initialization is defined by the **Data initialization** property of each data object.

Note: The code generator might include dynamic initialization code for signals and states even if the CSC has **Data initialization** set to `None` or `Static`, if the initialization is required.

- **Data access**: Controls whether imported symbols are declared as variables or pointers. This field is enabled only when **Data scope** is set to `Imported` or `Instance-specific`. Values:
  - `Direct`: Symbols are declared as simple variables, such as

    ```
    extern myType myVariable;
    ```

  - `Pointer`: Symbols are declared as pointer variables, such as

    ```
    extern myType *myVariable;
    ```

  - `Instance specific`: Data access is defined by the **Data access** property of each data object.
- **Header file**: Defines the name of a header file that contains exported or imported variable declarations for objects of this class. If you set **Type** to `AccessFunction`, **Header file** defines the name of the header file that contains your `get` and `set` function prototypes. Values:

- `Specify`: An edit field is displayed to the right of the property. This lets you specify a header file for exported or imported storage declarations. Specify the full filename, including the filename extension (such as `.h`). Use quotes or brackets as in C code to specify the location of the header file. Leave the edit field empty to not specify a header file.
- `Instance specific`: The header file for each data object is defined by the **Header file** property of the object. Leave the property undefined to not specify a header file for that object.

If the **Data scope** is `Exported`, specifying a header file is optional. If you specify a header file name, the custom storage class generates a header file containing the storage declarations to be exported. Otherwise, the storage declarations are exported in *`model`*`.h`.

If the **Data scope** of the class is `Imported`, a `#include` directive for the header file is generated.

Comments Category

Comments

The **Comments** panel lets you specify comments to be generated with definitions and declarations.

Comments must conform to the ANSI C standard (`/*...*/`). Use `\n` to specify a new line.

Properties in the **Comments** tab are as follows:

- **Comment rules**: If `Specify` is selected, edit fields are displayed for entering comments. If `Default` is selected, comments are generated under control of the code generation software.
- **Type comment**: The comment entered in this field precedes the `typedef` or `struct` definition for structured data.
- **Declaration comment**: Comment that precedes the storage declaration.
- **Definition comment**: Comment that precedes the storage definition.

Structure Attributes Category

The **Structure Attributes** panel gives you detailed control over code generation for structs (including bitfields). The **Structure Attributes** tab is displayed for CSCs whose

Type parameter is set to `FlatStructure`. The following figure shows the **Structure Attributes** panel.

The **Structure Attributes** properties are as follows:

- **Struct name**: If you select `Instance specific`, specify the struct name when configuring each instance of the class.

  If you select `Specify`, an edit field appears for entry of the name of the structure to be used in the `struct` definition. Edit fields **Type tag**, **Type token**, and **Type name** are also displayed.
- **Is typedef**: When this option is selected a `typedef` is generated for the struct definition, for example:

  ```
  typedef struct {
     ...
  } SignalDataStruct;
  ```

  Otherwise, a simple struct definition is generated.
- **Bit-pack booleans**: When this option is selected, signals and/or parameters that have Boolean data type are packed into bit fields in the generated struct.
- **Type tag**: Specifies a tag to be generated after the `struct` keyword in the struct definition.
- **Type name**: Specifies the name to be used in `typedef` definitions. This field is visible if **Is typedef** is selected.
- **Type token**: Some compilers support an additional token (which is simply another string) after the type tag. To generate such a token, enter the string in this field.

Access Function Attributes Category

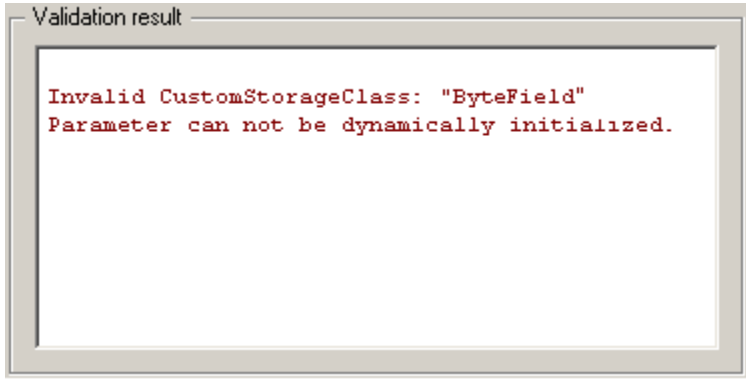
When you set **Type** to `AccessFunction` in the **General** panel, use the **Access Function Attributes** panel to control the `get` and `set` function names.

To apply the same `get` or `set` function naming scheme to all data items that use the custom storage class, set **Get function** or **Set function** to `Specify`. Then, in the new box, specify the function naming scheme, for example `get_myData_$N`. Use the token `$N` in each naming scheme to represent the name of each data item. If you do not use the token, each data item uses the same `get` or `set` function name, so the model generates an error when you generate code.

To specify a `get` or `set` function for each data item, set **Get function** or **Set function** to `Instance specific`. Later, when you create a data item and apply the custom storage class, specify the function name by configuring the custom attributes of the data item.

Validate Definitions Category

To validate a CSC definition, select the definition on the **Custom Storage Class** panel and click **Validate**. The Custom Storage Class Designer then checks the definition for consistency. The **Validation result** panel displays a errors encountered when the selected CSC definition is validated. The next figure shows the **Validation result** panel with a typical error message:



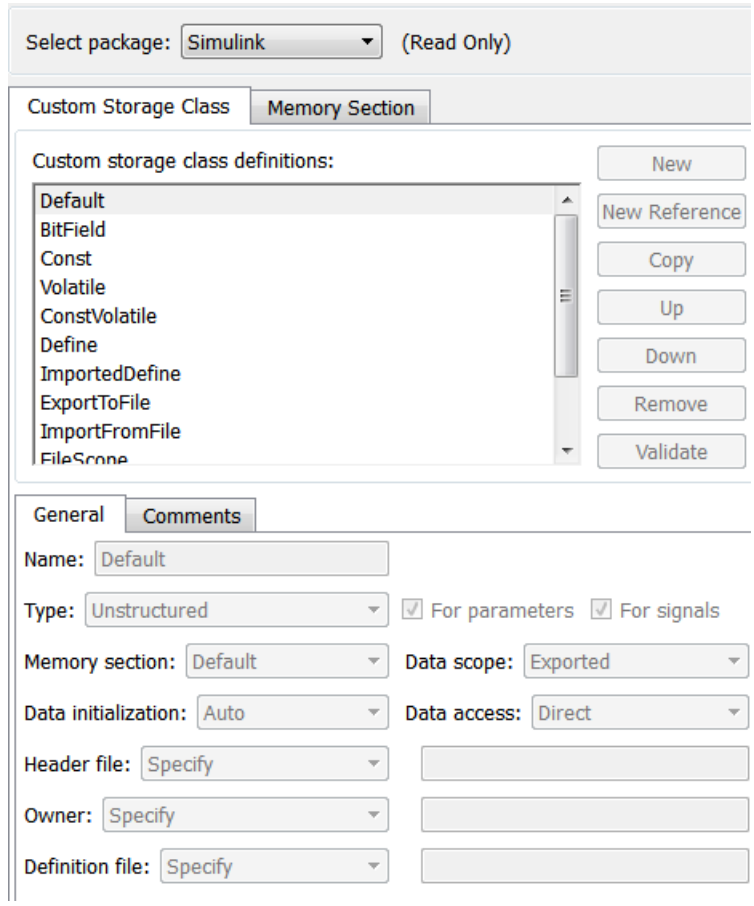
Validation is also performed whenever CSC definitions are saved. In this case, all CSC definitions are validated. (See “Save Definitions” on page 23-40.)

Use Custom Storage Class References

Packages can access and use custom storage classes that are defined in other packages, including both user-defined packages and predefined packages such as `Simulink`. Only one copy of the storage class exists, in the package that first defined it. Other packages refer to it by pointing to it in its original location. Changes to the class, including changes to a predefined class in later MathWorks product releases, are immediately available in every referencing package.

To configure a package to use a custom storage class that is defined in another package:

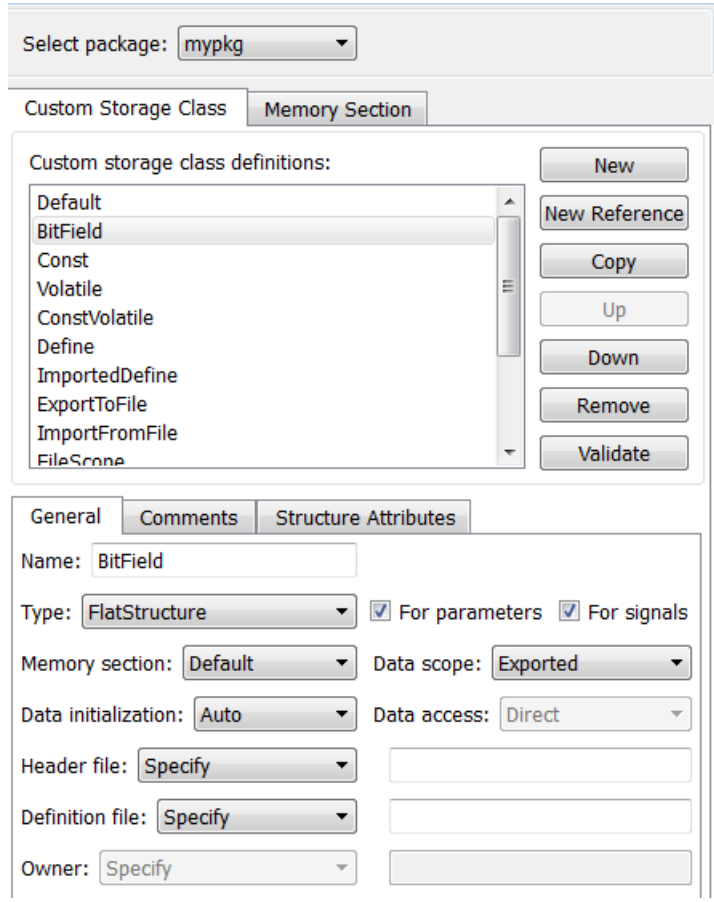
1. Type `cscdesigner` to launch the Custom Storage Class Designer.



2 Select the **Custom Storage Class** tab.

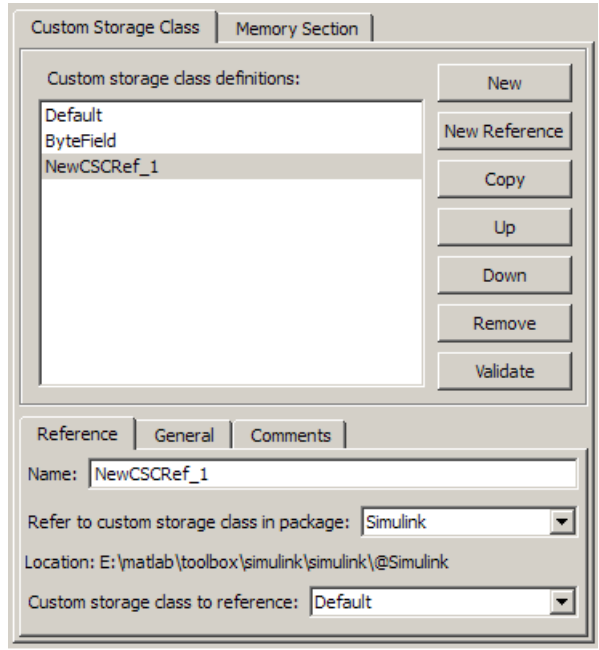
3 Use **Select Package** to select the package in which you want to reference a class or section defined in some other package. The selected package must be writable.

4 In the **Custom storage class definitions** pane, select the existing definition below which you want to insert the reference. For example:



5 Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected, and a **Reference** tab appears that shows the reference's initial properties. A typical appearance is:



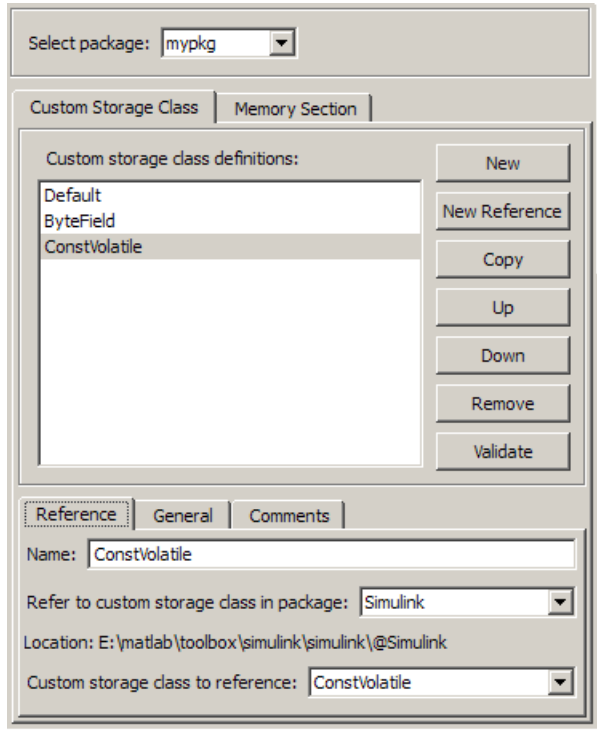
6 Use the **Name** field to enter a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package. The name cannot be a TLC keyword. Violating this rule causes an error.

7 Set **Refer to custom storage class in package** to specify the package that contains the custom storage class you want to reference.

8 Set **Custom storage class to reference** to specify the custom storage class to be referenced. Trying to create a circular reference generates an error and leaves the package unchanged.

9 Click **OK** or **Apply** to save the changes to memory. See "Save Definitions" on page 23-40 for information about saving changes permanently.

For example, the next figure shows the custom storage class `ConstVolatile` imported from the `Simulink` package into `mypkg`, and given the same name that it has in the source package. Other names could have been used without affecting the properties of the storage class.



You can use Custom Storage Class Designer capabilities to copy, reorder, validate, and otherwise manage classes that have been added to a class by reference. However, you cannot change the underlying definitions. You can change a custom storage class only in the package where it was originally defined.

Change Existing Custom Storage Class References

To change an existing CSC reference, select it in the **Custom storage class definitions** pane. The **Reference** tab appears, showing the current properties of the reference. Make changes, then click **OK** or **Apply** to save the changes to memory. See "Save Definitions" on page 23-40 for information about saving changes permanently.

Protect Custom Storage Class Definitions

You can prevent changes to the custom storage class definitions of an entire data class package by converting the package CSC registration file from a MATLAB file to a P-file.

To learn more about CSC registration files, see “Custom Storage Class Implementation” on page 23-81.

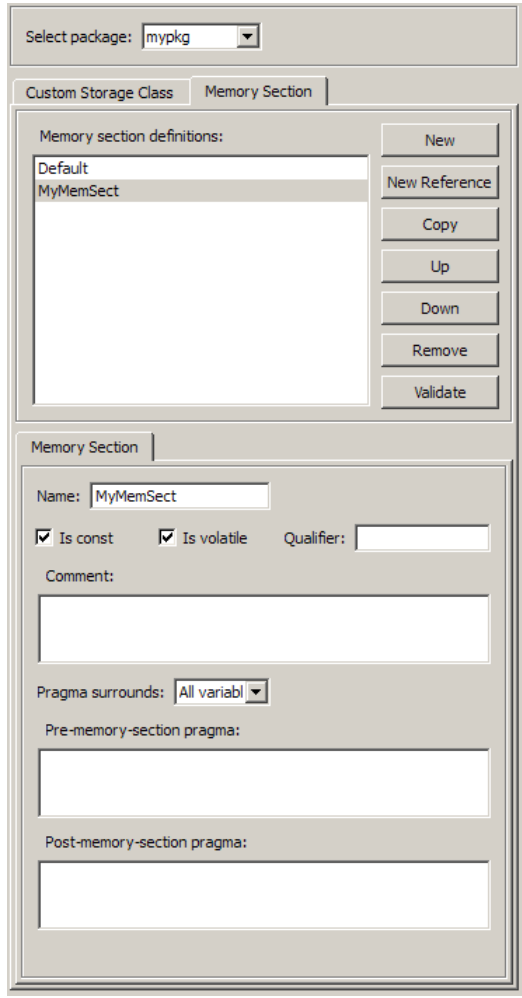
Create and Edit Memory Section Definitions

Memory section definitions add comments, qualifiers, and `#pragma` directives to generated symbol declarations. The **Memory Section** tab lets you create, view, edit, and verify memory section definitions. The steps for creating a memory section definition are essentially the same as for creating a custom storage class definition:

1. Select a writable package in the **Select package** field.
2. Select the **Memory Section** tab. In a new package, only a `Default` memory section initially appears.
3. Select the existing memory section below which you want to create a new memory section.
4. Click **New**.

   A new memory section definition with a default name appears below the selected memory section.
5. Set the name and other properties of the memory section.
6. Click **OK** or **Apply**.

The next figure shows `mypkg` with a memory section called `MyMemSect`:



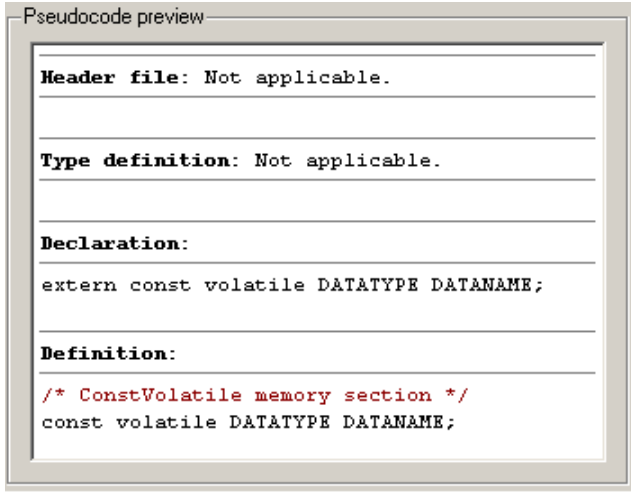
The **Memory section definitions** list lets you select a memory section definition to view or edit. The available memory section definitions also appear in the **Memory section name** menu in the **Custom Storage Class** panel. The properties of a memory section definition are as follows:

- **Memory section name**: Name of the memory section (displayed in **Memory section definitions** list).
- **Is const**: If selected, a `const` qualifier is added to the symbol declarations.

- **Is volatile**: If selected, a `volatile` qualifier is added to the symbol declarations.
- **Qualifier**: The text entered into this field is added to the symbol declarations as a further qualifier. Note that verification is not performed on this qualifier.
- **Memory section comment**: Comment inserted before declarations belonging to this memory section. Comments must conform to the ANSI C standard (`/*...*/`). Use `\n` to specify a new line.
- **Pragma surrounds**: Specifies whether the pragma should surround `All variables` or `Each variable`. When **Pragma surrounds** is set to `Each variable`, the `%<identifier>` token is allowed in pragmas and will be replaced by the variable or function name.
- **Pre-memory section pragma**: `pragma` directive that precedes the storage definition of data belonging to this memory section. The directive must begin with `#pragma`.
- **Post-memory section pragma**: `pragma` directive that follows the storage definition of data belonging to this memory section. The directive must begin with `#pragma`.

Preview Generated Code

If you click **Validate** on the **Memory Section** panel, the **Pseudocode preview** panel displays a preview of code that is generated from objects of the given class. The panel also displays messages (in blue) to highlight changes as they are made. The code preview changes dynamically as you edit the class properties. The next figure shows a code preview for the `MemConstVolatile` memory section.



Use Memory Section References

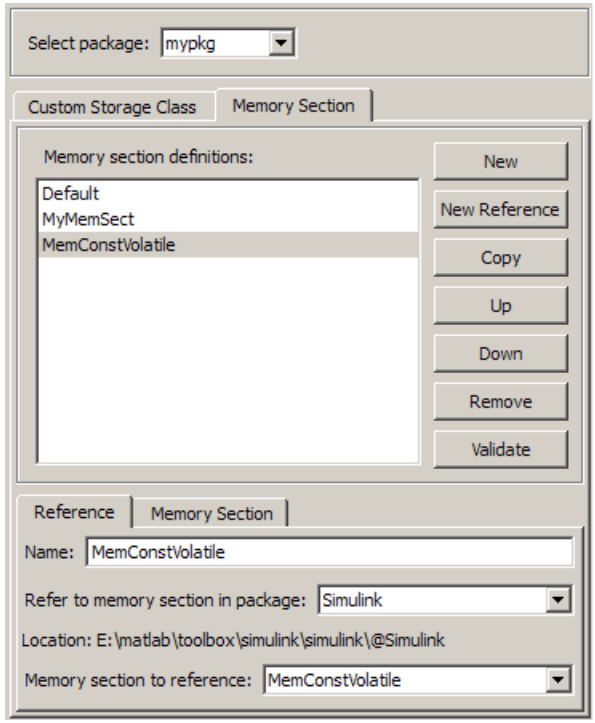
Packages can access and use memory sections that are defined in other packages, including both user-defined packages and predefined packages such as `Simulink`. Only one copy of the section exists, in the package that first defined it; other packages refer to it by pointing to it in its original location. Changes to the section, including changes to a predefined section in later MathWorks product releases, are immediately available in every referencing package.

To configure a package to use a memory section that is defined in another package:

1. Type `cscdesigner` to launch the Custom Storage Class Designer.
2. Select the **Memory Section** tab.
3. Use **Select Package** to select the package in which you want to reference a class or section defined in some other package.
4. In the **Memory section definitions** pane, select the existing definition below which you want to insert the reference.
5. Click **New Reference**.

   A new reference with a default name and properties appears below the previously selected definition. The new reference is selected, and a **Reference** tab appears that shows the reference's initial properties.
6. Use the **Name** field to enter a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package.
7. Set **Refer to memory section in package** to specify the package that contains the memory section you want to reference.
8. Set **Memory section to reference** to specify the memory section to be referenced. Trying to create a circular reference generates an error and leaves the package unchanged.
9. Click **OK** or **Apply** to save the changes to memory. See “Save Definitions” on page 23-40 for information about saving changes permanently.

For example, the next figure shows the memory section `MemConstVolatile` imported from the `Simulink` package into `mypkg`, and given the same name that it has in the source package. Other names could have been used without affecting the properties of the memory section.



You can use Custom Storage Class Designer capabilities to copy, reorder, validate, and otherwise manage memory sections that have been added to a class by reference. However, you cannot change the underlying definitions. You can change a memory section only in the package where it was originally defined.

Change Existing Memory Section References

To change an existing memory section reference, select it in the **Memory section definitions** pane. The **Reference** tab appears, showing the current properties of the reference. Make changes, then click **OK** or **Apply** to save the changes to memory. See "Save Definitions" on page 23-40 for information about saving changes permanently.

Control Data Representation by Applying Custom Storage Classes

To control the declaration and definition of variables in the generated code, use the custom storage classes available with Embedded Coder. You can use custom storage classes to, for example, export multiple definitions or declarations to a single generated file, create structures and bit fields, and append storage type qualifiers to declarations.

To use custom storage classes, you can:

- Apply them to data objects, such as `Simulink.Parameter` and `Simulink.Signal`, that you associate with signal lines, block parameters, and states. See "Data Objects" (Simulink)

  You can also apply custom storage classes to `Simulink.LookupTable` and `Simulink.Breakpoint` objects, which you use to package lookup table data according to the ASAP2 and AUTOSAR standards.
- Specify them for signal lines and block states through dialog boxes and embedded signal objects. These techniques do not require you to store a data object in a workspace.

The custom storage classes then determine how the generated code represents the signals, parameters, and states.

To achieve a range of goals such as grouping variables into flat structures, or controlling declaration and definition file placement, use the custom storage classes from the built-in package `Simulink`. For more information about the capabilities of these custom storage classes, see "Simulink Package Custom Storage Classes" on page 23-5.

If the custom storage classes from the `Simulink` package do not satisfy your requirements, you can define your own custom storage classes. For basic information about defining your own custom storage class, see "Design Custom Storage Classes and Memory Sections" on page 23-34.

In this section...

In this section...

Apply a Custom Storage Class from the `Simulink` Package Using Data Objects

To apply a custom storage class from the built-in package `Simulink` to a signal, block parameter, or state:

1. Create a data object such as `Simulink.Parameter` or `Simulink.Signal`.
2. Configure the data object properties, including code generation settings. Specify the custom storage class.
3. Associate the data object with a signal, block parameter, or state in a model. For example:

   - In a block parameter dialog box, specify the name of a parameter data object.
   - Use the name of a signal data object to name a signal in a model. In the Signal Properties dialog box, select **Signal name must resolve to Simulink signal object**.

Specify Custom Storage Class for Data Object

1. In the Model Explorer **Model Hierarchy** pane, select the workspace that you want to contain the data object.
2. Click Add Parameter  to create a `Simulink.Parameter` object.
3. In the **Contents** pane, click the new data object, which is named `Param` by default.

4 In the **Dialog** pane, in the drop-down list **Storage class**, select `ExportToFile (Custom)`.

5 Under **Custom attributes**, specify additional code generation settings that the custom storage class requires. For example, specify **HeaderFile** as `myDataHdr.h`.

Programmatically Specify Custom Storage Class for Data Object

```
% Create a data object. For example, create a
% Simulink.Parameter object.
myParam = Simulink.Parameter(15.23);

% Specify the custom storage class called ExportToFile.
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'ExportToFile';

% Specify custom attributes for this data object.
myParam.CoderInfo.CustomAttributes.HeaderFile = 'myDataHdr.h';
```

Create and Apply Your Own Custom Storage Class Using Data Objects

To create your own custom storage class, you must create a data class package and define the custom storage class in the package. Afterward, you can apply the custom storage class to signals, block parameters, and states:

1 Create a data object from your data class package. For example, if you name your package `myPackage`, you create data objects such as `myPackage.Parameter` and `myPackage.Signal`.

2 Configure the data object properties, including code generation settings. Specify the custom storage class that you defined.

3 Associate the data object with a signal, block parameter, or state in a model. For example, specify the name of a parameter object in a block parameter dialog box, or use the name of a signal object to name a signal in a model.

For an example that shows how to control the generated code by creating and applying a custom storage class, see “Control Data Code by Creating Custom Storage Class” on page 23-73.

Specify Custom Storage Class for Data Object

Suppose that you define a data class package `myPackage` and a custom storage class `ExportDefToFile` in that package.

1. In the Model Explorer **Model Hierarchy** pane, select the workspace that you want to contain the data object.
2. Click the arrow next to Add Parameter  . In the drop-down list, select **Customize class lists**.
3. In the dialog box, under **Parameter classes**, select the check box next to `myPackage.Parameter`. Click **OK**.
4. Click the arrow next to Add Parameter again. In the drop-down list, select **myPackage Parameter**.

   A new data object appears in the workspace. The default object name is `Param`.
5. In the **Contents** pane, select the new data object. In the **Dialog** pane, in the drop-down list **Storage class**, select `ExportDefToFile (Custom)`.
6. Under **Custom attributes**, specify additional code generation settings that the custom storage class requires. For example, suppose that data objects that use `ExportDefToFile` require you to specify a definition file. You can specify **DefinitionFile** as `myDataSrc.c`.

Programmatically Specify Custom Storage Class for Data Object

Suppose that you define a data class package `myPackage` and a custom storage class `ExportDefToFile` in that package.

```
% Create a data object from your package. For example, create a
% myPackage.Parameter object.
myParam = myPackage.Parameter(15.23);

% Specify the custom storage class ExportDefToFile.
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'ExportDefToFile';

% Specify custom attributes for this data object. For example, suppose that
% ExportDefToFile requires a definition file for each data object.
myParam.CoderInfo.CustomAttributes.DefinitionFile = 'myDataSrc.c';
```

Apply Custom Storage Classes Directly to Signal Lines, Block States, and Outport Blocks

Through dialog boxes and the Model Data Editor (see “Configure Data Properties by Using a Table” (Simulink)), you can apply custom storage classes directly to signal lines

and block states. You do not need a data object that you store in a workspace or data dictionary. However, you cannot use a signal object in a workspace to specify other characteristics of the signal or state, such as data type.

To apply a storage class directly to a signal line, use the Signal Properties dialog box. For a block state, use the **State Attributes** tab in the block dialog box.

To apply a custom storage class from the built-in package `Simulink`:

1. Open the **Code Generation** tab in a Signal Properties dialog box, or the **State Attributes** tab in a block dialog box.
2. Specify a name in the **Signal name** box or the **State name** box. Click **Apply**.
3. In the **Storage class** drop-down list, select a custom storage class.

To apply a custom storage class from a different package:

1. Open the **Code Generation** tab in a Signal Properties dialog box or the **State Attributes** tab in a block dialog box.
2. Specify a name in the **Signal name** box or the **State name** box. Click **Apply**.
3. In the **Signal object class** drop-down list, choose a package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `Simulink`, select `Simulink.Signal`.

   If the class that you want does not appear in the list:

   a. From the drop-down list, select `Customize class lists`.
   b. In the dialog box, under **Signal classes**, select the check box next to the class that you want. For example, to use custom storage classes from the built-in package `mpt`, select the check box next to `mpt.Signal`. Click **OK**.

      If you created your own package, the classes that the package defines appear in the dialog box only if you put the package folder in your current folder or on the MATLAB path.
   c. From the drop-down list, select the option that corresponds to what you selected. For example, select `mpt.Signal`.
4. In the **Storage class** drop-down list, select a custom storage class.

To apply a custom storage class to a root-level Outport block, use the Model Data Editor. You can also use the Model Data Editor to apply custom storage classes to signals

through a list that you can sort, group, and filter. See "Configure Data Interface by Using Model Data Editor" on page 23-69.

Programmatically Apply Custom Storage Classes Directly to Signals, States, and Outport Blocks Using Embedded Signal Objects

You can use *embedded signal objects* to apply custom storage classes to signal lines and block states. The embedded signal object does not appear in a workspace, so you do not need to save the object in a separate file. However, you can use embedded signal objects to specify only a custom storage class, the associated custom attributes, and an alias for the object. You must specify other signal or state characteristics, such as data type, in the source block dialog box.

If you create an embedded signal object for a signal or state, you cannot use a signal object in a workspace to specify other characteristics of the signal or state. The signal or state name resolves only to the embedded signal object.

To attach an embedded signal object to a signal or state:

1. Create a temporary signal object in a workspace such as the base workspace.
2. Specify a custom storage class and associated custom attributes.
3. Programmatically assign the object to:
   - The corresponding block outport if the target is a signal
   - The corresponding block state if the target is a state
4. Optionally, delete the temporary signal object from the workspace.

This example shows how to attach an embedded signal object to a signal in a model.

1. Open the example model `rtwdemo_secondOrderSystem`.

   ```
   rtwdemo_secondOrderSystem
   ```

2. Create a handle to the output of the block named Force: f(t).

   ```
   portHandles = get_param('rtwdemo_secondOrderSystem/Force: f(t)','PortHandles');
   outportHandle = portHandles.Outport;
   ```

3. Set the name of the corresponding signal to `ForceSignal`.

   ```
   set_param(outportHandle,'Name','ForceSignal')
   ```

4 In the base workspace, create a signal object and specify a custom storage class and relevant custom attributes.

```
tempObj = Simulink.Signal;
tempObj.CoderInfo.StorageClass = 'Custom';
tempObj.CoderInfo.CustomStorageClass = 'ExportToFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myHdrFile.h';
```

You can create the object from the data class package `Simulink`, or from any other package, such as a package that you create.

5 Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```
set_param(outportHandle,'SignalObject',tempObj);
```

6 Clear the object from the base workspace. The signal now uses an embedded copy of the object.

```
clear tempObj
```

To modify an existing embedded signal object, copy the object into the base workspace, modify the copy, and reattach the copy. For example, to change the custom storage class of the embedded signal object attached to the signal `ForceSignal`:

1 Copy the existing embedded signal object into the base workspace.

```
tempObj = get_param(outportHandle,'SignalObject');
```

2 Modify the properties of the object in the workspace.

```
tempObj.CoderInfo.CustomStorageClass='ImportFromFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myOtherHdrFile.h';
```

3 Reattach a copy of the signal object.

```
set_param(outportHandle,'SignalObject',tempObj);
clear tempObj
```

To attach an embedded signal object to a root-level Outport block, using the function `set_param`, specify the block parameter `SignalName` to name the signal that the block represents. Use the parameter `SignalObject` to embed the signal object.

To attach an embedded signal object to a block state, using the `set_param` function, specify the block parameter `StateIdentifier` to name the state. Use the parameter `StateSignalObject` to embed the signal object.

To attach an embedded signal object to a data store that you define by using a Data Store Memory block, use the block parameter `StateSignalObject`. You do not need to specify a state name because the data store already has a name.

Specify Instance-Specific Attributes

A custom storage class can have properties that define attributes that are specific to that CSC. Such properties are called *instance-specific attributes*. For example, if you specify the `Struct` custom storage class, you must specify the name of the C language structure that will store the data. That name is an instance-specific attribute of the `Struct` CSC.

Data objects have a property called `CoderInfo`, which stores an object of the class `Simulink.CoderInfo`. Instance-specific attributes are stored in the `Simulink.CoderInfo` property `CustomAttributes`. This property is initially defined as follows:

```
SimulinkCSC.AttribClass_Simulink_Default
1x1 struct array with no fields
```

When you specify a custom storage class, Simulink automatically populates `CoderInfo.CustomAttributes` with fields to represent instance-specific attributes of that CSC. For example, if you set the storage class of a data object `MyObj` to `Struct`, then enter:

```
MyObj.CoderInfo.CustomAttributes
```

MATLAB displays:

```
SimulinkCSC.AttribClass_Simulink_Struct
    StructName: ''
```

To specify that `StructName` is `MyStruct`, enter:

```
MyObj.CoderInfo.CustomAttributes.StructName='MyStruct'
```

MATLAB displays:

```
SimulinkCSC.AttribClass_Simulink_Struct
    StructName: 'MyStruct'
```

The table lists instance-specific attributes that the custom storage classes from the built-in package `Simulink` define. When a data object uses one of these custom storage classes, you can specify the corresponding instance-specific attribute values in the object.

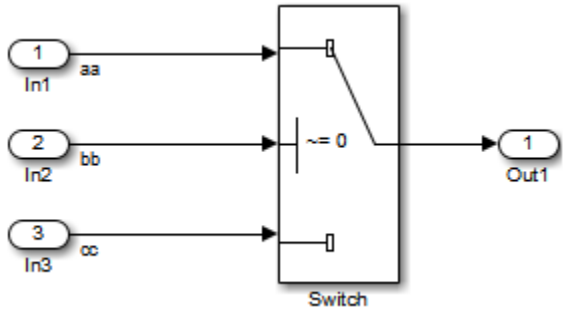
Custom Storage Class Name	Instance-Specific Attribute	Purpose
`BitField`	`CustomAttributes.StructName`	Name of the bitfield `struct` into which the code generator packs the object's Boolean data.
`ExportToFile`	`CustomAttributes.HeaderFile`	Name of header (`.h`) file that contains exported variable declarations and export directives for the object.
`GetSet`	`CustomAttributes.HeaderFile`	Name of header (`.h`) file to `#include` in the generated code. See "Access Data Through Functions with Custom Storage Class `GetSet`" on page 23-92.
	`CustomAttributes.GetFunction`	Specify the name of a function call to read data.
	`CustomAttributes.SetFunction`	Specify the name of a function call to write data.
`ImportedDefine`	`CustomAttributes.HeaderFile`	The header file that defines the values of code variant preprocessor conditionals. See "Generate Preprocessor Conditionals for Variant Systems" on page 14-33.
`ImportFromFile`	`CustomAttributes.HeaderFile`	Name of header (`.h`) file containing global variable declarations the code generator imports for the object.
`Struct`	`CustomAttributes.StructName`	Name of the `struct` into which the code generator packs the object's data.

If you use a *grouped* custom storage class, you cannot specify many of its properties on an instance-specific basis. A grouped custom storage class combines multiple pieces of data into a single data structure. Data that use this format must have the same properties such as **Header file**, **Data scope**, and **Data initialization**. For example, the custom storage classes `BitField` and `Struct` represent multiple data objects in the generated code by using a single structure variable.

Generate Code with Custom Storage Classes

This example shows how to control data representation in the generate code by using custom storage classes and data objects.

Before you generate code for a model that uses custom storage classes, clear the **Configuration Parameters > All Parameters > Ignore custom storage classes** model option. Otherwise, the code generator ignores custom storage class specifications and treats data objects as if their **Storage Class** were `SimulinkGlobal`.

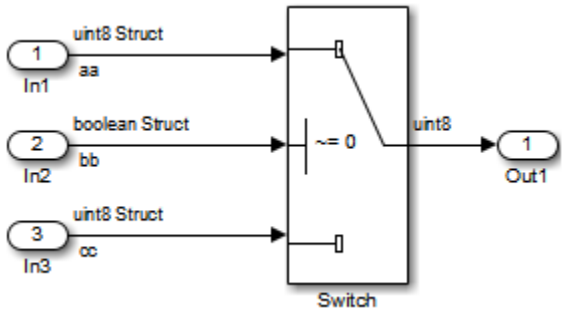


The model above contains three named signals: `aa`, `bb`, and `cc`. Using the `Struct` custom storage class, the example generates code that packs these signals into a `struct` named `mySignals`. The `struct` declaration is then exported to externally written code.

To specify the `struct`, you provide `Simulink.Signal` objects that specify the `Struct` custom storage class, and associate the objects with the signals as described in "Apply a Custom Storage Class from the `Simulink` Package Using Data Objects" on page 23-59. The three objects have the same properties. To view the properties, double-click one of the objects in the workspace browser (base workspace).

The association between identically named model signals and signal objects is formed as described in "Symbol Resolution" (Simulink). In this example, the symbols `aa`, `bb`, and `cc` resolve to the signal objects `aa`, `bb`, and `cc`, which have custom storage class `Struct`. In the generated code, storage for the three signals will be allocated within a `struct` named `mySignals`.

To display the storage class of the signals in the model, select **Display > Signals & Ports > Storage Class** in the Simulink editor. The figure below shows the block diagram with signal data types and signal storage classes displayed.



With the model's signal objects defined and associated with signals, you can generate code that uses the custom storage classes to generate the desired data structure for the signals. After code generation, the relevant definitions and declarations are located in three files:

- *model*`_types.h` defines the following `struct` type for storage of the three signals:

  ```
  typedef struct MySignals_tag {
    boolean_T bb;
    uint8_T aa;
    uint8_T cc;
  } mySignals_type;
  ```

- *model*`.c` (or `.cpp`) defines the variable `mySignals`, as specified in the object's instance-specific `StructName` attribute. The code generated for the Switch block references the variable:

  ```
  /* Definition for Custom Storage Class: Struct */

  mySignals_type mySignals = {
  /* cc */
  FALSE,
  /* bb */
  0,
  /* aa */
    0
  };
  ...
  /*  Switch: '<Root>/Switch1'  */
    if(mySignals.cc) {
      rtb_Switch1 = mySignals.aa;
    } else {
  ```

```
    rtb_Switch1 = mySignals.bb;
  }
```

- *model*`.h` exports the `mySignals Struct` variable:

```
/* Declaration for Custom Storage Class: Struct */

extern mySignals_type mySignals;
```

Configure Data Interface by Using Model Data Editor

Use the Model Data Editor to apply storage classes to Inport and Outport blocks, signal lines, and Data Store Memory blocks. Use this technique to apply storage classes without locating the blocks and signals in the model and to configure the data interface of the model by using a single list.

To apply custom storage classes from a specific package, use the Model Explorer to create a signal object from the target package. Then, when you open the Model Data Editor, the **Storage class** column displays custom storage classes from the target package.

1. In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
2. In the toolbar, click the arrow next to the **Add Signal**  button.
3. In the drop-down list, select `Customize class lists`.
4. In the **Customize class lists** dialog box, select a signal class from the target package. Click **OK**.
5. In the Model Explorer toolbar, click the arrow next to the **Add Signal** button.
6. In the drop-down list, select the target signal class.

   An object of the target signal class appears in the base workspace. Optionally, delete this unnecessary object.
7. Use the Model Data Editor to apply custom storage classes from the target package to other data items. In the Model Data Editor, in the **Storage class** column, the drop-down list allows you to select custom storage classes from the target package.

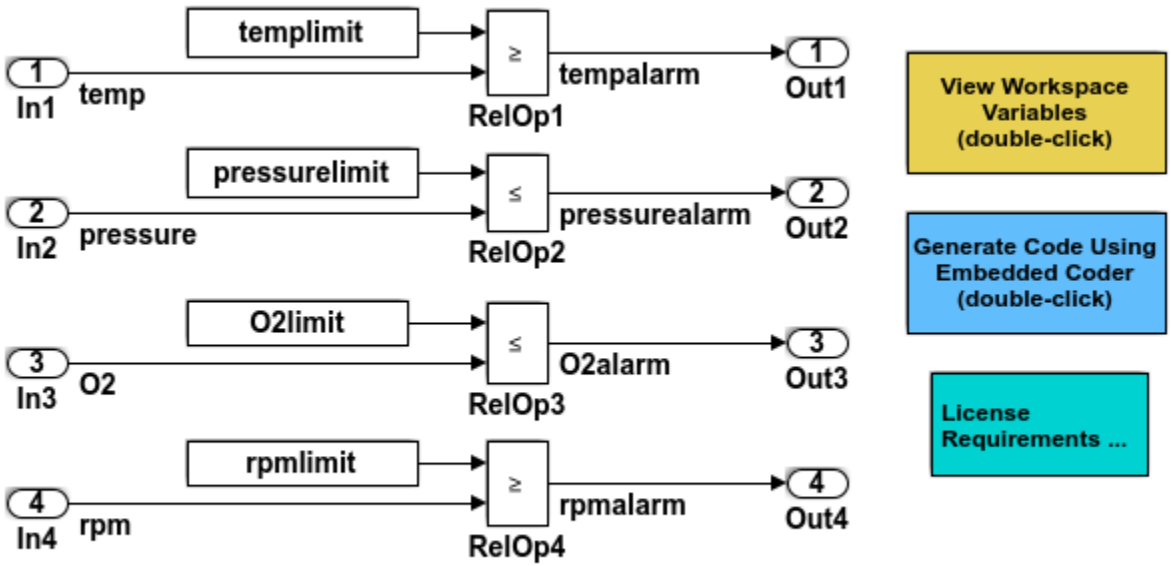
To learn how to use the Model Data Editor to configure a data interface, see “Use Model Data Editor to Configure Data Interface” on page 19-127.

Declare and Interface with Data Using Custom Storage Classes

Custom storage classes allow you to declare and interface with virtually any type of data. This model shows three of the several predefined custom storage classes provided with Embedded Coder. In this example, custom storage classes are specified for signals via the "Signal Properties..." dialog of a line and for parameters via Simulink parameter objects in the MATLAB Workspace.

Open the example model `rtwdemo_cscpredef`.

```
open_system('rtwdemo_cscpredef')
```



- The input signals use the custom storage class `Struct`.
- The constant parameters use the custom storage class `ConstVolatile`.
- The output signals use the custom storage class `BitField`.

You can use the Custom Storage Class Designer to:

- Create new custom storage classes

- Reference custom storage classes from other packages

To launch the Custom Storage Class Designer, type `cscdesigner` at the command prompt.

Specify Default `#include` Syntax for Data Header Files

To control the file placement of a data item such as a signal line or block state in the generated code, you can apply a custom storage class to the data item (see "Introduction to Custom Storage Classes" on page 23-2). You then use the `HeaderFile` custom attribute to specify the generated or custom header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify `HeaderFile`, you can omit delimiters (`"` or `<>`) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters** > **Code Generation** > **Code Placement** > **#include file delimiters** to `#include <header.h>`.

Custom Storage Class Limitations

- Data objects cannot have a custom storage class and a multiword data type.
- The Fcn block does not support parameters with a custom storage class in code generation.
- For custom storage classes in models that use referenced models:
  - If you apply a grouped custom storage class to multiple data items, the custom storage class **Data scope** property must be set to `Imported` and you must provide the data declaration in a custom header file. Grouped custom storage classes use a single variable in the generated code to represent multiple data objects. For example, the custom storage classes `BitField` and `Struct` are grouped custom storage classes.
  - You cannot apply the custom storage class `FileScope` to parameters that referenced models use.
  - If data is assigned an ungrouped CSC, such as `Const`, and the data's **Data scope** property is `Exported`, its **Header file** property must be unspecified. This results in the data being exported with the standard header file, *`model`*`.h`. Note that for ungrouped data, the **Data scope** and **Header file** properties are either specified by the selected CSC, or as one of the data object's instance-specific properties.

- You cannot apply the custom storage class `FileScope` to data items used by a data exchange interface (C API, external mode, or ASAP2) or MAT-file logging. File-scoped data are not externally accessible.

Control Data Code by Creating Custom Storage Class

When you integrate code generated from a model with existing code from another source, you can design custom storage classes to control the declaration and definition of model signals and block parameters. This example shows how to control code generated from a model by creating and applying your own custom storage class.

In this section...

Explore Example Model

Open the model rtwdemo_cscpredef. You can control code generated from this model by defining your own data classes and creating your own custom storage classes.

This example shows you how to export the declarations and definitions of multiple signals and parameters in the model to one declaration header file and one definition file.

Create Data Class Package

To create custom storage classes, you first create a data class package to contain the custom storage class definitions. Data objects created from your package can use all of the custom storage classes that the package defines.

1. Create your own data class package by copying the example package folder `+SimulinkDemos`. Navigate to the example package folder.

```
% Remember the current folder path
currentPath = pwd;

% Navigate to the example package folder
demoPath = '\toolbox\simulink\simdemos\dataclasses';
cd([matlabroot,demoPath])
```

2. Copy the `+SimulinkDemos` folder to your clipboard.

3. Return to your working folder.

   ```
   cd(currentPath)
   ```

4. Paste the `+SimulinkDemos` folder from your clipboard into your working folder. Rename the copied folder to `+myPackage`.
5. Navigate inside the `+myPackage` folder to the file `Signal.m` to edit the definition of the `Signal` class.
6. Uncomment the `methods` section that defines the method `setupCoderInfo`. In the call to the function `useLocalCustomStorageClasses`, replace `'packageName'` with `'myPackage'`. When you finish, the section appears as follows:

   ```
   methods
     function setupCoderInfo(h)
       % Use custom storage classes from this package
       useLocalCustomStorageClasses(h, 'myPackage');
     end
   end % methods
   ```

   The function `useLocalCustomStorageClasses` allows you to apply the custom storage classes that `myPackage` defines to data objects that you create from `myPackage`.
7. Save and close the file.
8. Navigate inside the `+myPackage` folder to the file `Parameter.m` to edit the definition of the `Parameter` class. Uncomment the `methods` section that defines the method `setupCoderInfo` and replace `'packageName'` with `'myPackage'`.
9. Save and close the file.

Create Custom Storage Class

You can use the Custom Storage Class Designer to create or to edit the custom storage classes that a data class package defines.

1. Set your current folder to the folder that contains the package `myPackage`.
2. Open the Custom Storage Class Designer.

   ```
   cscdesigner('myPackage')
   ```

3. Select the custom storage class `ExportToFile`.
4. In the **Name** field, rename the custom storage class to `ExportToGlobal`.

5 In the **Header file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the header file name `global.h`.

6 In the **Definition file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the definition file name `global.c`.

7 Click **OK**. Click **Yes** to save changes to the data class package `myPackage`.

Apply Custom Storage Class

To apply your own custom storage class, you create data objects from your package and configure the objects to use your custom storage class.

1 Create data objects to represent some of the parameters and signals in the example model. Create the objects using the data class package `myPackage`.

```
% Parameters
templimit = myPackage.Parameter(202);
pressurelimit = myPackage.Parameter(45.2);
O2limit = myPackage.Parameter(0.96);
rpmlimit = myPackage.Parameter(7400);

% Signals
tempalarm = myPackage.Signal;
pressurealarm = myPackage.Signal;
O2alarm = myPackage.Signal;
rpmalarm = myPackage.Signal;
```

2 Set the custom storage class of each object to `ExportToGlobal`.

```
% Parameters
templimit.CoderInfo.StorageClass = 'Custom';
templimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurelimit.CoderInfo.StorageClass = 'Custom';
pressurelimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2limit.CoderInfo.StorageClass = 'Custom';
O2limit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmlimit.CoderInfo.StorageClass = 'Custom';
rpmlimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';

% Signals
tempalarm.CoderInfo.StorageClass = 'Custom';
tempalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurealarm.CoderInfo.StorageClass = 'Custom';
pressurealarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
```

```
O2alarm.CoderInfo.StorageClass = 'Custom';
O2alarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmalarm.CoderInfo.StorageClass = 'Custom';
rpmalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
```

3 Select the **Signal name must resolve to Simulink signal object** option for each of the target signals in the model. You can select the option by using the Signal Properties dialog box or by using the command prompt.

```
% Signal tempalarm
portHandles = get_param('rtwdemo_cscpredef/RelOp1','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal pressurealarm
portHandles = get_param('rtwdemo_cscpredef/RelOp2','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal O2alarm
portHandles = get_param('rtwdemo_cscpredef/RelOp3','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal rpmalarm
portHandles = get_param('rtwdemo_cscpredef/RelOp4','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')
```

Generate Code

1 Generate code for the example model.

```
rtwbuild('rtwdemo_cscpredef')
```

2 In the code generation report, view the generated header file `global.h`. The file contains the `extern` declarations of all of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```
/* Declaration for custom storage class: ExportToGlobal */
extern boolean_T O2alarm;
extern real_T O2limit;
extern boolean_T pressurealarm;
extern real_T pressurelimit;
extern boolean_T rpmalarm;
```

```
extern real_T rpmlimit;
extern boolean_T tempalarm;
extern real_T templimit;
```

3 View the generated file `global.c`. The file contains the definitions of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```
/* Definition for custom storage class: ExportToGlobal */
boolean_T O2alarm;
real_T O2limit = 0.96;
boolean_T pressurealarm;
real_T pressurelimit = 45.2;
boolean_T rpmalarm;
real_T rpmlimit = 7400.0;
boolean_T tempalarm;
real_T templimit = 202.0;
```

Define Advanced Custom Storage Classes Types

In this section...

Introduction

Certain data layouts, such as nested structures, cannot be generated using the standard `Unstructured` and `FlatStructure` custom storage class types. You can define an *advanced custom storage class* if you want to generate other types of data. Creating advanced CSCs requires understanding TLC programming and using a special advanced mode of the Custom Storage Class Designer. These sections explain how to define advanced CSC types. For more information about TLC programming, see "Why Use the Target Language Compiler?" (Simulink Coder).

For an example, see "Generate Code That Dereferences Data from a Literal Memory Address" on page 23-83.

Create Your Own Parameter and Signal Classes

The first step is to create your own package containing classes derived from `Simulink.Parameter` or `Simulink.Signal`. This procedure is described in "Define Data Classes" (Simulink).

Create Custom Attributes Classes for Custom Storage Classes

If you have instance-specific properties that are relevant only to your CSC, you should create a *custom attributes class* for the package. A custom attributes class is a subclass of `Simulink.CustomStorageClassAttributes`. The name, type, and default value properties you set for the custom attributes class define the user view of instance-specific properties. For instructions, see "Define Data Classes" (Simulink).

For example, the `ExportToFile` custom storage class requires that you set the `CoderInfo.CustomAttributes.HeaderFile` property to specify a `.h` file used for exporting each piece of data. See "Simulink Package Custom Storage Classes" on page 23-5 for further information on instance-specific properties.

Note: If you rename or remove custom attributes, you may need to manually edit the `csc_registration` file for the associated package to remove references to the custom attributes that you renamed or removed.

Write TLC Code for Custom Storage Classes

The next step is to write TLC code that implements code generation for data of your new custom storage class. A template TLC file is provided for this purpose. To create your TLC code, follow these steps:

1. Create a `tlc` directory inside your package's +directory (if it does not already exist). The naming convention to follow is

   ```
   +PackageName/tlc
   ```

2. Copy `TEMPLATE_v1.tlc` (or another CSC template) from the folder *matlabroot*`/toolbox/rtw/targets/ecoder/csc_templates` (open) into your `tlc` directory to use as a starting point for defining your custom storage class.
3. Write your TLC code, following the comments in the CSC template file. Comments describe how to specify code generation for data of your custom storage class (for example, how data structures are to be declared, defined, and whether they are accessed by value or by reference).

Alternatively, you can copy a custom storage class TLC file from another existing package as a starting point for defining your custom storage class.

Register Custom Storage Class Definitions

After you have created a package for your new custom storage class and written its associated TLC code, you must register your class definitions with the Custom Storage Class Designer, using its advanced mode.

The advanced mode supports selection of an additional storage class **Type**, designated `Other`. The `Other` type is designed to support special CSC types that cannot be accommodated by the standard `Unstructured` and `FlatStructure` custom storage

class types. The `Other` type cannot be assigned to a CSC except when the Custom Storage Class Designer is in advanced mode.

To register your class definitions:

1. Launch the Custom Storage Class Designer in advanced mode by typing the following command at the MATLAB prompt:

   ```
   cscdesigner -advanced
   ```

2. Select your package and create a new custom storage class.
3. Set the **Type** of the custom storage class to `Other`. Note that when you do this, the **Other Attributes** pane is displayed. This pane is visible only for CSCs whose **Type** is set to `Other`.

   If you specify a customized package, additional options, as defined by the package, also appear on the **Other Attributes** pane.

4. Set the properties shown on the **Other Attributes** pane. The properties are:

   - **Is grouped**: Select this option if you intend to combine multiple data objects of this CSC into a single variable in the generated code. For example, the built-in custom storage classes `BitField` and `Struct` are grouped because they can represent multiple data objects in the generated code by using a single structure variable.
   - **TLC file name**: Enter the name of the TLC file corresponding to this custom storage class. The location of the file is assumed to be in the `/tlc` subdirectory for the package, so you should not enter the path to the file.
   - **CSC attributes class name**: (optional) If you created a custom attributes class corresponding to this custom storage class, enter the full name of the custom attributes class, for example, `myPackage.myCustomAttsClass` (see "Create Custom Attributes Classes for Custom Storage Classes" on page 23-78).

5 Set the remaining properties on the **General** and **Comments** panes based on the layout of the data that you wish to generate (as defined in your TLC file).

Custom Storage Class Implementation

The file that defines a package's custom storage classes is called a *CSC registration file*. The file is named `csc_registration` and resides in the +*package* directory that defines the package. A CSC registration file can be a P-file (`csc_registration.p`) or a MATLAB file (`csc_registration.m`). A built-in package defines custom storage classes in both a P-file and a functionally equivalent MATLAB file. A user-defined package initially defines custom storage classes only in a MATLAB file.

P-files take precedence over MATLAB files, so when MATLAB looks for a package's CSC registration file and finds both a P-file and a MATLAB file, MATLAB loads the P-file and ignores the MATLAB file. The capabilities and tools, including the Custom Storage Class Designer, then use the CSC definitions stored in the P-file. P-files cannot be edited, so CSC Designer editing capabilities are disabled for CSCs stored in a P-file. If a P-file does not exist, MATLAB loads CSC definitions from the MATLAB file. MATLAB files are editable, so CSC Designer editing capabilities are enabled for CSCs stored in a MATLAB file.

Because CSC definitions for a built-in package exist in both a P-file and a MATLAB file, they are uneditable. You can make the definitions editable by deleting the P-file, but it is not recommended to modify built-in CSC registration files or other files under `matlabroot`. The preferred technique is to create packages, data classes, and custom storage classes, as described in “Define Data Classes” (Simulink).

The CSC Designer saves CSC definitions for user-defined packages in a MATLAB file, so the definitions are editable. You can make the definitions uneditable by using the `pcode` function to create an equivalent P-file, which will then shadow the MATLAB file. However, you should preserve the MATLAB file if you may need to make further changes, because you cannot modify CSC definitions that exist only in a P-file.

You can also use tools or techniques other than the Custom Storage Class Designer to create and edit MATLAB files that define CSCs. However, that practice is vulnerable to syntax errors and can give unexpected results. When MATLAB finds an older P-file that shadows a newer MATLAB file, it displays a warning in the MATLAB Command Window.

Generate Code That Dereferences Data from a Literal Memory Address

This example shows how to generate code that reads the value of a signal by dereferencing a memory address that you specify. With this technique, you can generate a control algorithm that interacts with memory that your hardware populates (for example, memory that stores the output of an analog-to-digital converter in a microcontroller).

In this example, you generate an algorithm that acquires input data from a 16-bit block of memory at address `0x8675309`. Assume that a hardware device asynchronously populates only the lower 10 bits of the address. The algorithm must treat the address as read-only (`const`), volatile (`volatile`) data, and ignore the upper 6 bits of the address.

The generated code can access the data by defining a macro that dereferences `0x8675309` and masks the unnecessary bits:

```
#define A2D_INPUT ((*(volatile const uint16_T *)0x8675309)&0x03FF)
```

To configure a model to generate code that defines and uses this macro, you must create an advanced custom storage class and write Target Language Compiler (TLC) code. For an example that shows how to use the Custom Storage Class Designer without writing TLC code, see “Control Data Code by Creating Custom Storage Class”.

Derivation of Macro Syntax

In this example, you configure the generated code to define and use the dereferencing macro. To determine the correct syntax for the macro, start by recording the target address.

```
0x8675309
```

Cast the address as a pointer to a 16-bit integer. Use the Simulink Coder data type name `uint16_T`.

```
(uint16_T *)0x8675309
```

Add the storage type qualifier `const` because the generated code must not write to the address. Add `volatile` because the hardware can populate the address at an arbitrary time.

```
(volatile const uint16_T *)0x8675309
```

Dereference the address.

```
*(volatile const uint16_T *)0x8675309
```

After the dereference operation, apply a mask to retain only the 10 bits that the hardware populates. Use explicit parentheses to control the order of operations.

```
(*(volatile const uint16_T *)0x8675309)&0x03FF
```

As a safe coding practice, wrap the entire construct in another layer of parentheses.

```
((*(volatile const uint16_T *)0x8675309)&0x03FF)
```

Create Example Model

Create the example model `ex_memmap_simple`.

For the Inport block, set the output data type to `uint16`. Name the signal as `A2D_INPUT`. The Inport block and the signal line represent the data that the hardware populates.

For the Gain block, set the output data type to `double`.

Create Package to Contain Definitions of Data Class and Custom Storage Class

In your current folder, create a folder named `+MemoryMap`. The folder defines a package named `MemoryMap`.

To make the package available for use outside of your current folder, you can add the `+MemoryMap` folder to the MATLAB path.

Create Custom Storage Class

To generate code that defines and reads `A2D_INPUT` as a macro, you must create a custom storage class that you can apply to the signal line in the model. Later, you write TLC code that complements the custom storage class.

Open the Custom Storage Class designer in advanced mode. To design a custom storage class that operates through custom TLC code, you must use the advanced mode.

```
cscdesigner('MemoryMap','-advanced');
```

In the Custom Storage Class Designer, click **New**. A new custom storage class, `NewCSC_1`, appears in the list of custom storage class definitions.

Rename the new custom storage class `MemoryMappedAddress`.

For `MemoryMappedAddress`, on the **General** tab, set:

- **Type** to `Other`. The custom storage class can operate through custom TLC code that you write later.
- **Data scope** to `Exported`. For data items that use this custom storage class, Simulink Coder generates the definition (for example, the `#define` statement that defines a macro).
- **Data initialization** to `None`. Simulink Coder does not generate code that initializes the data item. Use this setting because this custom storage class represents read-only data. You do not select `Macro` because the Custom Storage Class Designer does not allow you to use `Macro` for signal data.
- **Definition file** to `Specify` (leave the text box empty). For data items that consume memory in the generated code, **Definition file** specifies the `.c` source file that allocates the memory. However, this custom storage class yields a macro, which does not require memory. Header files (`.h`), not `.c` files, define macros. Setting **Definition file** to `Specify` instead of `Instance specific` prevents users of the custom storage class from unnecessarily specifying a definition file.
- **Header file** to `Instance specific`. To control the file placement of the macro definition, the user of the custom storage class must specify a header file for each data item that uses this custom storage class.
- **Owner** to `Specify` (leave the text box empty). **Owner** applies only to data items that consume memory.

After you finish selecting the settings, click **Apply** and **Save**.

Now, when you apply the custom storage class to a data item, such as the `A2D_INPUT` signal line, you can specify a header file to contain the generated macro definition. However, you cannot yet specify a memory address for the data item. To enable specification of a memory address, create a custom attributes class that you can associate with the `MemoryMappedAddress` custom storage class.

Define Class to Store Custom Attributes for Custom Storage Class

Define a MATLAB class to store additional information for data items that use the custom storage class. In this case, the additional information is the memory address.

In the `MemoryMap` package (the `+MemoryMap` folder), create a folder named `@MemoryMapAttribs`.

In the `@MemoryMapAttribs` folder, create a file named `MemoryMapAttribs`. The file defines a class that derives from the built-in class `Simulink.CustomStorageClassAttributes`.

```
classdef MemoryMapAttribs < Simulink.CustomStorageClassAttributes
    properties( PropertyType = 'char' )
        MemoryAddress = '';
    end
end
```

Later, you associate this MATLAB class with the `MemoryMappedAddress` custom storage class. Then, when you apply the custom storage class to a data item, you can specify a memory address.

Write TLC Code That Emits Correct C Code

Write TLC code that uses the attributes of the custom storage class, such as `HeaderFile` and `MemoryAddress`, to generate correct C code for each data item.

In the `+MemoryMap` folder, create a folder named `tlc`.

Navigate to the new folder.

Inspect the built-in template TLC file, TEMPLATE_v1.tlc.

```
edit(fullfile(matlabroot,...
    'toolbox','rtw','targets','ecoder','csc_templates','TEMPLATE_v1.tlc'))
```

Save a copy of `TEMPLATE_v1.tlc` in the `tlc` folder. Rename the copy `memory_map_csc.tlc`.

In `memory_map_csc.tlc`, find the portion that controls the generation of C-code data declarations.

```
    %case "declare"

      %% LibDefaultCustomStorageDeclare is the default declare function to
      %% declares a global variable whose identifier is the name of the data.
      %return "extern %<LibDefaultCustomStorageDeclare(record)>"
      %%break

    %% ============================================================================
```

The `declare` case (`%case`) constructs a return value (`%return`), which the code generator emits into the header file that you specify for each data item. To control the C code that declares each data item, adjust the return value in the `declare` case.

Replace the existing `%case` content with this new code, which specifies a different return value:

```
%case "declare"

        %% In TLC code, a 'record' is a data item (for example, a signal line).
        %% 'LibGetRecordIdentifier' returns the name of the data item.
        %assign id = LibGetRecordIdentifier(record)

        %assign dt = LibGetRecordCompositeDataTypeName(record)

        %% The 'CoderInfo' property of a data item stores a
        %% 'Simulink.CoderInfo' object, which stores code generation settings
        %% such as the storage class or custom storage class that you specify
        %% for the item.
        %assign ci = record.Object.ObjectProperties.CoderInfo
        %% The 'ci' variable now stores the 'Simulink.CoderInfo' object.

        %% By default, the 'CustomAttributes' property of a 'Simulink.CoderInfo'
        %% object stores a 'Simulink.CustomStorageClassAttributes' object.
        %% This nested object stores specialized code generation settings
        %% such as the header file and definition file that you specify for
        %% the data item.
        %%
        %% The 'MemoryMap' package derives a new class,
        %% 'MemoryMapAttribs', from 'Simulink.CustomStorageClassAttributes'.
        %% The new class adds a property named 'MemoryAddress'.
        %% This TLC code determines the memory address of the data item by
        %% acquiring the value of the 'MemoryAddress' property.
```

```
    %assign ca = ci.Object.ObjectProperties.CustomAttributes
    %assign address = ca.Object.ObjectProperties.MemoryAddress

    %assign width = LibGetDataWidth(record)

    %% This TLC code constructs the full macro, with correct C syntax,
    %% based on the values of TLC variables such as 'address' and 'dt'.
    %% This TLC code also asserts that the data item must be a scalar.
    %if width == 1
            %assign macro = ...
                "#define %<id> ((*(volatile const %<dt>*)%<address>) & 0x03FF)"
    %else
            %error( "Non scalars are not supported yet." )
    %endif

    %return "%<macro>"
  %%break

%% ============================================================================
```

The new TLC code uses built-in, documented TLC functions, such as `LibGetRecordIdentifier`, and other TLC commands and operations to access information about the data item. Temporary variables such as `dt` and `address` store that information. The TLC code constructs the full macro, with the correct C syntax, by expanding the variables, and stores the macro in the variable `macro`.

In the same file, find the portion that controls the generation of data definitions.

```
%case "define"

  %% LibDefaultCustomStorageDefine is the default define function to define
  %% a global variable whose identifier is the name of the data.  If the
  %% data is a parameter, the definition is also statically initialized to
  %% its nominal value (as set in MATLAB).
  %return "%<LibDefaultCustomStorageDefine(record)>"
  %%break

%% ============================================================================
```

The `define` case derives a return value that the code generator emits into a `.c` file, which defines data items that consume memory.

Replace the existing `%case` content with this new content:

```
%case "define"
  %return ""
  %%break

%% ============================================================================
```

`MemoryMappedAddress` yields a macro in the generated code, so you use the `declare` case instead of the `define` case to construct and emit the macro. To prevent the `define` case from emitting a duplicate macro definition, the new TLC code returns an empty string.

Complete the Definition of the Custom Storage Class

Your new MATLAB class, `MemoryMapAttribs`, can enable users of your new custom storage class, `MemoryMappedAddress`, to specify a memory address for each data item. To allow this specification, associate `MemoryMapAttribs` with `MemoryMappedAddress`. To generate correct C code based on the information that you specify for each data item, associate the customized TLC file, `memory_map_csc.tlc`, with `MemoryMappedAddress`.

Navigate to the folder that contains the `+MemoryMap` folder.

Open the Custom Storage Class Designer again.

For `MemoryMappedAddress`, on the **Other Attributes** tab, set:

- **TLC file name** to `memory_map_csc.tlc`.
- **CSC attributes class** to `MemoryMap.MemoryMapAttribs`.

Click **Apply** and **Save**.

Define Signal Data Class

To apply the custom storage class to a signal in a model, in the `MemoryMap` package, you must create a MATLAB class that derives from `Simulink.Signal`. When you configure the signal in the model, you select this new data class instead of the default class, `Simulink.Signal`.

In the `MemoryMap` package, create a folder named `@Signal`.

In the `@Signal` folder, create a file named `Signal.m`.

```
classdef Signal < Simulink.Signal
    methods
        function setupCoderInfo( this )
            useLocalCustomStorageClasses( this, 'MemoryMap' );
            return;
        end
    end
end
```

The file defines a class named `MemoryMap.Signal`. The class definition overrides the `setupCoderInfo` method, which the `Simulink.Signal` class already implements. The new implementation specifies that objects of the `MemoryMap.Signal` class use custom storage classes from the `MemoryMap` package (instead of custom storage classes from the `Simulink` package). When you configure a signal in a model by selecting the `MemoryMap.Signal` class, you can select the new custom storage class, `MemoryMappedAddress`.

Apply Custom Storage Class to Signal Line

Navigate to the folder that contains the example model and open the model.

In the model, select **View > Property Inspector**.

Click the signal named `A2D_INPUT`.

In the Property Inspector, under **Code Generation**, set **Signal object class** to `MemoryMap.Signal`. If you do not see `MemoryMap.Signal`, select `Customize class lists` and use the dialog box to enable the selection of `MemoryMap.Signal`.

In the Property Inspector, set **Storage class** to `MemoryMappedAddress`.

Set **Header file** to `memory_mapped_addresses.h`.

Set **MemoryAddress** to `0x8675309`.

Generate and Inspect Code

Generate code from the model.

```
### Starting build procedure for model: ex_memmap_simple
### Successful completion of build procedure for model: ex_memmap_simple
```

Inspect the generated header file `memory_mapped_addresses.h`. The file defines the macro `A2D_INPUT`, which corresponds to the signal line in the model.

```
/* Declaration of data with custom storage class MemoryMappedAddress */
#define A2D_INPUT                      ((*(volatile const uint16_T*)0x8675309) & 0x03F
```

Inspect the generated file `ex_memmap_simple.c`. The generated algorithmic code (which corresponds to the Gain block) calculates the model output, `rtY.Out1`, by operating on `A2D_INPUT`.

```
/* Model step function */
void ex_memmap_simple_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In1'
   */
  rtY.Out1 = 42.0 * (real_T)A2D_INPUT;
}
```

- "Define Advanced Custom Storage Classes Types" on page 23-78
- "Target Language Compiler"

Access Data Through Functions with Custom Storage Class `GetSet`

To integrate the generated code with legacy code that uses specialized functions to read from and write to data, you can use the custom storage class `GetSet`. Signals, block parameters, and states that use `GetSet` appear in the generated code as calls to accessor functions. You provide the function definitions.

To generate code that conforms to the AUTOSAR standard by accessing data through `Rte` function calls, use the Configure AUTOSAR Interface dialog box. See "AUTOSAR Interface Configuration".

Access Legacy Data Using `Get` and `Set` Functions

This example shows how to generate code that interfaces with legacy code by using specialized `get` and `set` functions to access data.

View the example legacy header file ComponentDataHdr.h. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `scalars` is a substructure that uses the structure type `ScalarData`. The structure type `ScalarData` defines three scalar fields: `inSig`, `scalarParam`, and `outSig`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ScalarData */','} ScalarData;',1,1)
```

```
/* ScalarData */
```

```
typedef struct {
    double inSig;
    double scalarParam;
    double outSig;
} ScalarData;
```

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `scalars`.

```
rtwdemodbtype('getsetSrc.c','/* Field "scalars" */','/* End of "scalars" */',1,1)
```

```
    /* Field "scalars" */
    {
    3.9,

    12.3,

    0.0
    },
    /* End of "scalars" */
```

The file also defines functions that read from and write to the fields of the substructure `scalars`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Scalar get() and set() functions */','/* End of scalar functions */',1,1)
```

```
/* Scalar get() and set() functions */

double get_inSig(void)
{
    return ex_getset_data.scalars.inSig;
}

void set_inSig(double value)
{
    ex_getset_data.scalars.inSig = value;
}
```

```
double get_scalarParam(void)
{
    return ex_getset_data.scalars.scalarParam;
}

void set_scalarParam(double value)
{
    ex_getset_data.scalars.scalarParam = value;
}

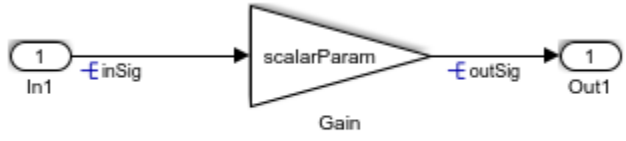
double get_outSig(void)
{
    return ex_getset_data.scalars.outSig;
}

void set_outSig(double value)
{
    ex_getset_data.scalars.outSig = value;
}
```

View the example legacy header file getsetHdrScalar.h. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model rtwdemo_getset_scalar. The model creates the data objects `inSig`, `outSig`, and `scalarParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_scalar')
```



In the base workspace, double-click the object `inSig` to view its properties. The object uses the custom storage class `GetSet`. The `GetFunction` and `SetFunction` properties are set to the defaults, `get_$N` and `set_$N`. The generated code uses the function names that you specify in `GetFunction` and `SetFunction` to read from and write to the data.

The code replaces the token $N with the name of the data object. For example, for the data object inSig, the generated code uses calls to the legacy functions get_inSig and set_inSig.

For the data object inSig, the HeaderFile property is set to getsetHdrScalar.h. This legacy header file contains the get and set function prototypes. The data objects outSig and scalarParam also use the custom storage class GetSet and the header file getsetHdrScalar.h.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, under **Include list of additional**, select **Source files**. The **Source files** box identifies the source file getsetSrc.c for inclusion during the build process. This legacy source file contains the get and set function definitions and the definition of the global structure variable ex_getset_data.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_scalar');
```

```
### Starting build procedure for model: rtwdemo_getset_scalar
### Successful completion of build procedure for model: rtwdemo_getset_scalar
```

In the code generation report, view the file rtwdemo_getset_scalar.c. The model step function uses the legacy get and set functions to execute the algorithm. The generated code accesses the legacy signal and parameter data by calling the custom, handwritten get and set functions.

```
rtwdemodbtype(fullfile('rtwdemo_getset_scalar_ert_rtw','rtwdemo_getset_scalar.c'),...
    '/* Model step function */','}',1,1)
```

```
/* Model step function */
void rtwdemo_getset_scalar_step(void)
{
  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  set_outSig(get_scalarParam() * get_inSig());
}
```

You can generate code that calls your custom get and set functions as long as the functions that you write accept and return the expected values. For scalar data, the functions must have these characteristics:

- The `get` function must return a single scalar numeric value of the appropriate data type, and must not accept any arguments (`void`).
- The `set` function must not return anything (`void`), and must accept a single scalar numeric value of the appropriate data type.

Use `GetSet` with Vector Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are vectors.

View the example legacy header file ComponentDataHdr.h. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `vectors` is a substructure that uses the structure type `VectorData`. The structure type `VectorData` defines three vector fields: `inVector`, `vectorParam`, and `outVector`. The vectors each have five elements.

```
rtwdemodbtype('ComponentDataHdr.h','/* VectorData */','} VectorData;',1,1)
```

```
/* VectorData */

typedef struct {
    double inVector[5];
    double vectorParam[5];
    double outVector[5];
} VectorData;
```

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `vectors`.

```
rtwdemodbtype('getsetSrc.c','/* Field "vectors" */','/* End of "vectors" */',1,1)
```

```
    /* Field "vectors" */
    {
        {5.7, 6.8, 1.2, 3.5, 10.1},

        {12.3, 18.7, 21.2, 28, 32.9},

        {0.0, 0.0, 0.0, 0.0, 0.0}
    },
    /* End of "vectors" */
```

The file also defines functions that read from and write to the fields of the substructure `vectors`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`. To access the vector data, all of the functions accept an integer index argument. The `get` function returns the vector value at the input index. The `set` function assigns the input `value` to the input index.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Vector get() and set() functions */','/* End of vector functions */',1,1)
```

```
/* Vector get() and set() functions */

double get_inVector(int index)
{
    return ex_getset_data.vectors.inVector[index];
}

void set_inVector(int index, double value)
{
    ex_getset_data.vectors.inVector[index] = value;
}

double get_vectorParam(int index)
{
    return ex_getset_data.vectors.vectorParam[index];
}

void set_vectorParam(int index, double value)
{
    ex_getset_data.vectors.vectorParam[index] = value;
}
```

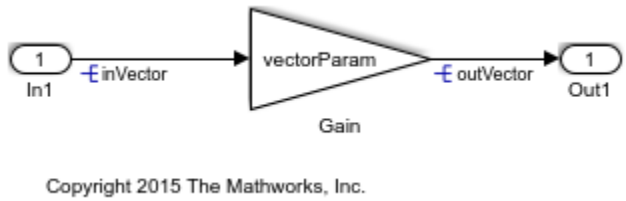
```
double get_outVector(int index)
{
    return ex_getset_data.vectors.outVector[index];
}

void set_outVector(int index, double value)
{
       ex_getset_data.vectors.outVector[index] = value;
}
```

View the example legacy header file getsetHdrVector.h. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model rtwdemo_getset_vector. The model creates the data objects `inVector`, `outVector`, and `vectorParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_vector')
```



In the base workspace, double-click the object `inVector` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrVector.h`. This legacy header file contains the `get` and `set` function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_vector');

### Starting build procedure for model: rtwdemo_getset_vector
### Successful completion of build procedure for model: rtwdemo_getset_vector
```

In the code generation report, view the file `rtwdemo_getset_vector.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_vector_ert_rtw','rtwdemo_getset_vector.c'),...
    '/* Model step function */','}',1,1)

/* Model step function */
void rtwdemo_getset_vector_step(void)
{
  int32_T i;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  for (i = 0; i < 5; i++) {
    set_outVector( i , get_vectorParam( i ) * get_inVector( i ));
  }
```

When you use the custom storage class `GetSet` with vector data, the `get` and `set` functions that you provide must accept an index input. The `get` function must return a single element of the vector. The `set` function must write to a single element of the vector.

Use `GetSet` with Structured Data

This example shows how to apply the custom storage class `GetSet` to nonvirtual bus signals and structure parameters in a model.

View the example legacy header file ComponentDataHdr.h. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ComponentData */','} ComponentData;',1,1)

/* ComponentData */
```

```
typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `structs` is a substructure that uses the structure type `StructData`. The structure type `StructData` defines three fields: `inStruct`, `structParam`, and `outStruct`.

```
rtwdemodbtype('ComponentDataHdr.h','/* StructData */','} StructData;',1,1)
```

```
/* StructData */

typedef struct {
    SigBus inStruct;
    ParamBus structParam;
    SigBus outStruct;
} StructData;
```

The fields `inStruct`, `structParam`, and `outStruct` are also substructures that use the structure types `SigBus` and `ParamBus`. Each of these two structure types define three scalar fields.

```
rtwdemodbtype('ComponentDataHdr.h','/* SigBus */','} ParamBus',1,1)
```

```
/* SigBus */

typedef struct {
    double cmd;
    double sensor1;
    double sensor2;
} SigBus;

/* ParamBus */

typedef struct {
    double offset;
    double gain1;
    double gain2;
} ParamBus;
```

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `structs`.

```
rtwdemodbtype('getsetSrc.c','/* Field "structs" */','/* End of "structs" */',1,1)
```

```
    /* Field "structs" */
    {
        {1.3, 5.7, 9.2},

        {12.3, 9.6, 1.76},

        {0.0, 0.0, 0.0}
    },
    /* End of "structs" */
```

The file also defines functions that read from and write to the fields of the substructure `structs`. The functions simplify data access by dereferencing the fields of the global structure variable `ex_getset_data`. The functions access the data in the fields `inStruct`, `structParam`, and `outStruct` by accepting and returning complete structures of the types `SigBus` and `ParamBus`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Structure get() and set() functions */','/* End of structure functions */',1,1)
```

```
/* Structure get() and set() functions */

SigBus get_inStruct(void)
{
    return ex_getset_data.structs.inStruct;
}

void set_inStruct(SigBus value)
{
    ex_getset_data.structs.inStruct = value;
}

ParamBus get_structParam(void)
{
    return ex_getset_data.structs.structParam;
}
```

```
void set_structParam(ParamBus value)
{
    ex_getset_data.structs.structParam = value;
}

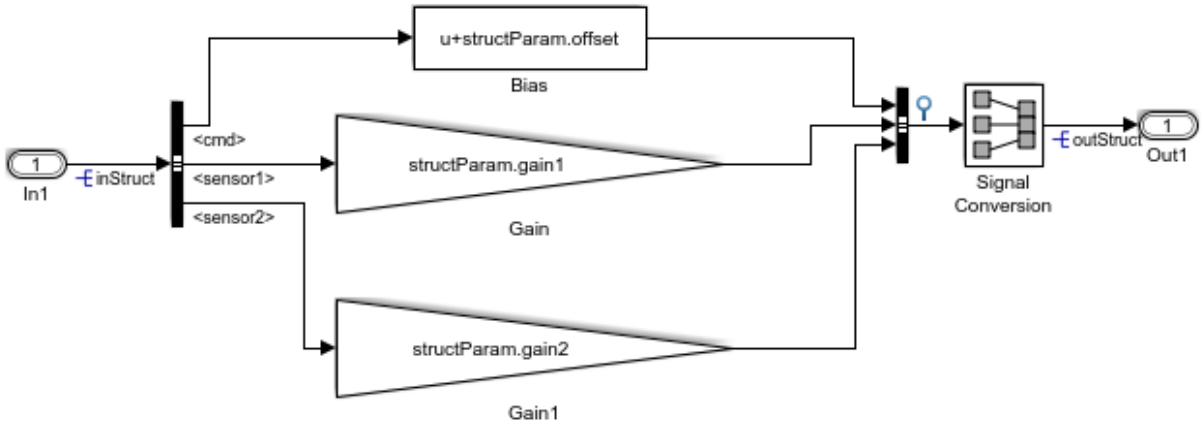
SigBus get_outStruct(void)
{
    return ex_getset_data.structs.outStruct;
}

void set_outStruct(SigBus value)
{
    ex_getset_data.structs.outStruct = value;
}
```

View the example legacy header file getsetHdrStruct.h. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model rtwdemo_getset_struct. The model creates the data objects `inStruct`, `structParam`, and `outStruct` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_struct')
```



In the base workspace, double-click the object `inStruct` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrStruct.h`. This legacy header file contains the `get` and `set` function prototypes.

The model also creates the bus objects `ParamBus` and `SigBus` in the base workspace. The signals and parameter in the model use the bus types that these objects define. The property `DataScope` of each bus object is set to `Imported`. The property `HeaderFile` is set to `ComponentDataHdr.h`. The generated code imports these structure types from the legacy header file `ComponentDataHdr.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_struct');
```

```
### Starting build procedure for model: rtwdemo_getset_struct
### Successful completion of build procedure for model: rtwdemo_getset_struct
```

In the code generation report, view the file `rtwdemo_getset_struct.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_struct_ert_rtw','rtwdemo_getset_struct.c'),...
    '/* Model step function */','}',1,1)
```

```
/* Model step function */
void rtwdemo_getset_struct_step(void)
{
  /* Bias: '<Root>/Bias' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.BusCreator.cmd = get_inStruct().cmd + get_structParam().offset;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.BusCreator.sensor1 = get_structParam().gain1 * get_inStruct().sensor1;
```

```
  /* Gain: '<Root>/Gain1' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.BusCreator.sensor2 = get_structParam().gain2 * get_inStruct().sensor2;

  /* SignalConversion: '<Root>/Signal Conversion' */
  set_outStruct(rtDW.BusCreator);
}
```

When you use the custom storage class `GetSet` with structured data, the `get` and `set` functions that you provide must return and accept complete structures. The generated code dereferences individual fields of the structure that the `get` function returns.

The output signal of the Bus Creator block is a test point. This signal is the input for a Signal Conversion block. The test point and the Signal Conversion block exist so that the generated code defines a variable for the output of the Bus Creator block. To provide a complete structure argument for the function `set_outStruct`, you must configure the model to create this variable.

Use `GetSet` with Matrix Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are matrices.

View the example legacy header file ComponentDataHdr.h. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
    '/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `matrices` is a substructure that uses the structure type `MatricesData`. The structure type `MatricesData` defines three fields: `matrixInput`, `matrixParam`, and

`matrixOutput`. The fields store matrix data as serial arrays. In this case, the input and parameter fields each have 15 elements. The output field has nine elements.

```
rtwdemodbtype('ComponentDataHdr.h'...
    ,'/* MatricesData */','} MatricesData;',1,1)
```

```
/* MatricesData */

typedef struct {
    double matrixInput[15];
    double matrixParam[15];
    double matrixOutput[9];
} MatricesData;
```

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `matrices`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Field "matrices" */','/* End of "matrices" */',1,1)
```

```
    /* Field "matrices" */
    {
        {12.0, 13.9, 7.4,
         0.5, 11.8, 6.4,
         4.7, 5.3, 13.0,
         0.7, 16.1, 13.5,
         1.6, 0.5, 3.1},

        {8.3, 12.0, 11.5, 2.0, 5.7,
         7.5, 12.8, 11.1, 8.4, 9.9,
         10.9, 4.6, 2.7, 16.3, 3.8},

        {0.0, 0.0, 0.0,
         0.0, 0.0, 0.0,
         0.0, 0.0, 0.0}
    }
    /* End of "matrices" */
```

The input matrix has five rows and three columns. The matrix parameter has three rows and five columns. The matrix output has three rows and three columns. The file defines macros that indicate these dimensions.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Matrix dimensions */','/* End of matrix dimensions */',1,1)

/* Matrix dimensions */

#define MATRIXINPUT_NROWS 5
#define MATRIXINPUT_NCOLS 3

#define MATRIXPARAM_NROWS 3
#define MATRIXPARAM_NCOLS 5

#define MATRIXOUTPUT_NROWS MATRIXPARAM_NROWS
#define MATRIXOUTPUT_NCOLS MATRIXINPUT_NCOLS
```

The file also defines functions that read from and write to the fields of the substructure `matrices`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Matrix get() and set() functions */','/* End of matrix functions */',1,1)

/* Matrix get() and set() functions */

double get_matrixInput(int colIndex)
{
    int rowIndexGetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colInde
    return ex_getset_data.matrices.matrixInput[rowIndexGetInput];
}

void set_matrixInput(int colIndex, double value)
{
    int rowIndexSetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colInde
    ex_getset_data.matrices.matrixInput[rowIndexSetInput] = value;
}

double get_matrixParam(int colIndex)
{
    int rowIndexGetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colInde
    return ex_getset_data.matrices.matrixParam[rowIndexGetParam];
}

void set_matrixParam(int colIndex, double value)
{
```

```
    int rowIndexSetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colInde
    ex_getset_data.matrices.matrixParam[rowIndexSetParam] = value;
}

double get_matrixOutput(int colIndex)
{
    int rowIndexGetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colInde
    return ex_getset_data.matrices.matrixOutput[rowIndexGetOut];
}

void set_matrixOutput(int colIndex, double value)
{
    int rowIndexSetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colInde
    ex_getset_data.matrices.matrixOutput[rowIndexSetOut] = value;
}
```

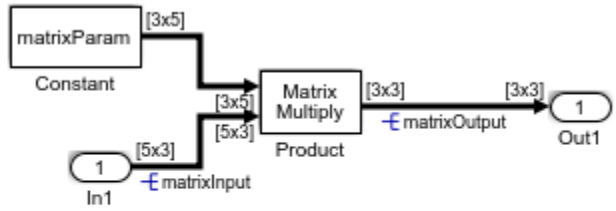
The code that you generate from a model represents matrices as serial arrays. Therefore, each of the `get` and `set` functions accept a single scalar index argument.

The generated code uses column-major format to store and to access matrix data. However, many C applications use row-major indexing. To integrate the generated code with the example legacy code, which stores the matrices `matrixInput` and `matrixParam` using row-major format, the custom `get` functions use the column-major index input to calculate an equivalent row-major index. The generated code algorithm, which interprets matrix data using column-major format by default, performs the correct matrix math because the `get` functions effectively convert the legacy matrices to column-major format. The `set` function for the output, `matrixOutput`, also calculates a row-major index so the code writes the algorithm output to `matrixOutput` using row-major format. Alternatively, to integrate the column-major generated code with your row-major legacy code, you can manually convert the legacy code to column-major format by transposing your matrix data and algorithms.

View the example legacy header file getsetHdrMatrix.h. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model rtwdemo_getset_matrix. The model creates the data objects `matrixInput`, `matrixParam`, and `matrixOutput` in the base workspace. The objects correspond to the signals and parameter in the model.

```
load_system('rtwdemo_getset_matrix')
set_param('rtwdemo_getset_matrix','SimulationCommand','Update')
open_system('rtwdemo_getset_matrix')
```



In the base workspace, double-click the object `matrixInput` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrMatrix.h`. This legacy header file contains the `get` and `set` function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_matrix');
```

```
### Starting build procedure for model: rtwdemo_getset_matrix
### Successful completion of build procedure for model: rtwdemo_getset_matrix
```

In the code generation report, view the file `rtwdemo_getset_matrix.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_matrix_ert_rtw',...
    'rtwdemo_getset_matrix.c'),'/* Model step function */','}',1,1)
```

```
/* Model step function */
void rtwdemo_getset_matrix_step(void)
{
  int32_T i;
  int32_T i_0;
  int32_T i_1;
```

```
/* Product: '<Root>/Product' incorporates:
 *  Constant: '<Root>/Constant'
 *  Inport: '<Root>/In1'
 */
for (i_0 = 0; i_0 < 3; i_0++) {
  for (i = 0; i < 3; i++) {
    set_matrixOutput( i + 3 * i_0 , 0.0);
    for (i_1 = 0; i_1 < 5; i_1++) {
      set_matrixOutput( i + 3 * i_0 , get_matrixParam( 3 * i_1 + i ) *
                        get_matrixInput( 5 * i_0 + i_1 ) + get_matrixOutput( 3 *
        i_0 + i ));
    }
```

Specify Header File or Function Naming Scheme for All Data Items

By default, you specify a header file name, `get` function name, and `set` function name for each data item, such as a signal or parameter, that uses the custom storage class `GetSet`.

To configure a single header file, `get` function naming scheme, or `set` function naming scheme to use for every data item, you can use the Custom Storage Class Designer to create your own copy of `GetSet`. You can specify the header file or function names in a single location.

Follow these steps to create your own custom storage class by creating your own data class package, creating a copy of `GetSet`, and applying the new custom storage class to data items in your model.

1. Create your own data class package, `myPackage`, by copying the example package folder `+SimulinkDemos` and renaming the copied folder as `+myPackage`. Modify the `Parameter` and `Signal` class definitions so that they use the custom storage class definitions from `myPackage`. For an example, see “Create Data Class Package” on page 23-73.
2. Set your current folder to the folder that contains the package folder. Alternatively, add the folder to your MATLAB path.
3. Open the Custom Storage Class Designer.

   ```
   cscdesigner('myPackage')
   ```
4. Select the custom storage class `GetSet`. Click **Copy** to create a copy called `GetSet_1`.

5. Select the new custom storage class `GetSet_1`. In the **General** tab, set **Name** to `myGetSet`.
6. Set the drop-down list **Header file** to `Specify`. In the new text box, set **Header file** to `myFcnHdr.h`. Click **Apply**.
7. On the **Access Function Attributes** tab, set the drop-down lists **Get function** and **Set function** to `Specify`.
8. In the new boxes, set **Get function** to `myGetFcn_$N` and **Set function** to `mySetFcn_$N`. Click **OK**. Click **Yes** in response to the message about saving changes.

   When you generate code, the token `$N` expands into the name of the data item that uses this custom storage class.
9. Apply the custom storage class `myGetSet` from your package to a data item. For example, create a `myPackage.Parameter` object in the base workspace.

   ```
   myParam = myPackage.Parameter(15.23);
   myParam.CoderInfo.StorageClass = 'Custom';
   myParam.CoderInfo.CustomStorageClass = 'myGetSet';
   ```
10. Use the object to set a parameter value in your model. When you generate code, the code algorithm accesses the parameter through the functions that you specified. The code uses a `#include` directive to include the header file that you specified.

`GetSet` Custom Storage Class Restrictions

- `GetSet` does not support complex signals.
- Multiple data in the same model cannot use the same `GetFunction` or `SetFunction`.
- Some blocks do not directly support `GetSet`.
- Custom S-functions do not directly support `GetSet`.

To use `GetSet` with an unsupported block or a custom S-function:

1. Insert a Signal Conversion block at the output of the block or function.
2. In the Signal Conversion block dialog box, select **Exclude this block from 'Block reduction' optimization**.
3. Assign the custom storage class `GetSet` to the output of the Signal Conversion block.

Configure Generated Code According to Interface Control Document

Import specifications from an interface control document (ICD), configure code generation settings for a model according to the specifications, and store the settings in data dictionaries.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

Explore Interface Control Document

Navigate to the folder *`matlabroot`*`/examples/ecoder` (open). Copy these files to a writable, working folder:

- `ICD.xls`
- `importICD.m`

In Microsoft® Excel® or another compatible program, open the `ICD.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus: EngSensors` to represent a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column indicates whether the C code uses the name of the data type (for example, `u8En7`)

or uses the name of the primitive integer data type that corresponds to the word length. The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the `Structure Types` worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the `DataType` column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the `Enumerated Types` worksheet, similar to the `Structure Types` worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

Write Custom Code

Some data items in the ICD belong to `other component`, which is a component that exists outside of MATLAB. Create the custom code files that define and declare this external data.

Create the custom source file `inter_sigs.c` in your current folder. This file defines the imported signal `sensors`.

```
#include "inter_sigs.h"

EngSensors sensors;                    /* Instrument measurements. */
```

Create the custom header file `inter_sigs.h` in your current folder.

```
#include "inter_types.h"

extern EngSensors sensors;   /* Instrument measurements. */
```

Create the custom header file `inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__
```

```
typedef short s16En3;

typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
  /* Throttle angle. */
  s16En3 throttle;

  /* Engine speed. */
  s16En3 speed;

  /* EGO sensors. */
  s16En7 ego;

  /* Manifold pressure. */
  u8En7 map;
} EngSensors;

#endif
```

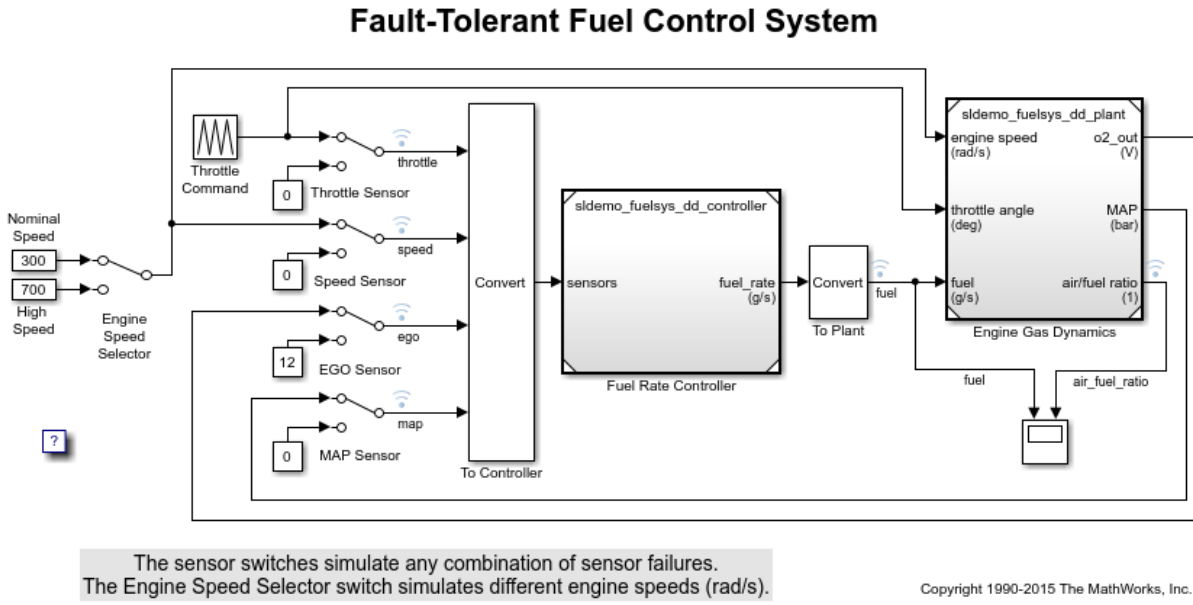
Explore Example Model

Run the script prepare_sldemo_fuelsys_dd. The script prepares a system model, `sldemo_fuelsys_dd`, for this example.

```
run(fullfile(matlabroot,'examples','ecoder','prepare_sldemo_fuelsys_dd'))
```

Open the system model, sldemo_fuelsys_dd.

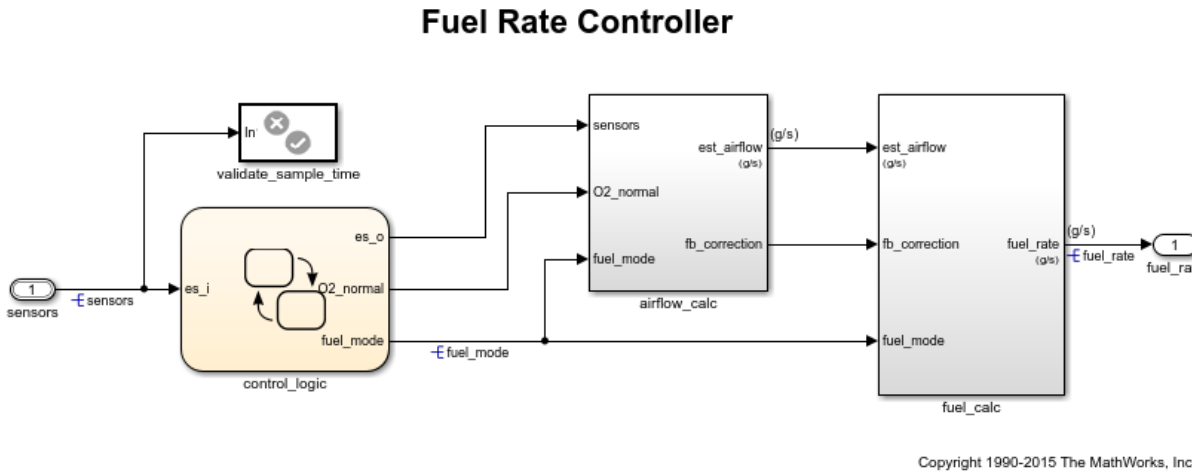
```
sldemo_fuelsys_dd
```



This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model, sldemo_fuelsys_dd_controller.

```
sldemo_fuelsys_dd_controller
```



Data items in the controller model refer to `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace. For example, the input signal `sensors` refers to a `Simulink.Signal` object that has the same name. These objects store settings such as data types, block parameter values, and physical units. The names of these data items and objects match the names of the signals and parameters in the ICD.

Import ICD Specifications into Simulink

To configure code generation settings for the data items, import the settings from the ICD.

Open the example script importICD. The script imports the data from each worksheet of the ICD into variables in the base workspace. It then configures the properties of the `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace by using the imported data.

```
edit('importICD')
```

If the base workspace already contains a data object that corresponds to a target data item in the ICD, the script configures the properties of the existing object. If the object does not exist, the script creates the object.

Run the `importICD` script.

```
run('importICD')
```

The script configures the data objects in the base workspace for code generation according to the specifications in the ICD. The `Simulink.Bus` object `EngSensors` represents the structure type from the ICD. The `Simulink.NumericType` objects, such as `u8En7`, represent the fixed-point data types.

```
ans =

    'Cannot redefine enumerated type sldemo_FuelModes because open models and existing
```

Generate and Inspect Code

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

```
typedef enum {
  LOW = 1,                              /* Default value */
  RICH,
  DISABLED
} sldemo_FuelModes;
```

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the custom header file `inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```
#include "inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the custom header file `inter_sigs.h`. This custom header file contains the `extern` declaration of the signal `sensors`, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];            /* Lookup table to estimate pressure on sensor f
extern s16En15 PumpCon[551];           /* Lookup table to determine pumping constant ba
extern s16En15 RampRateKiZ[25];        /* Lookup table to determine throttle rate. */
extern s16En3 SpeedEst[1305];          /* Lookup table to estimate engine speed on sens
extern s16En7 ThrotEst[551];           /* Lookup table to estimate throttle angle on se
extern sldemo_FuelModes fuel_mode;     /* Fueling mode of engine. Enrich air/fuel mixtu
extern int16_T fuel_rate;              /* Fuel rate setpoint. */
```

The data definitions (memory allocation) appear in the source files that the ICD specifies, `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```
s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146,
  3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932,
  5898, 7864, 9830 } ;                 /* Lookup table to determine throttle rate. */
```

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a `switch` block to control the flow of execution.

```
  /* SwitchCase: '<S10>/Switch Case' incorporates:
   *  Constant: '<S11>/shutoff'
   */
  switch (fuel_mode) {
   case LOW:
    /* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
     *  ActionPort: '<S12>/Action Port'
     */
    /* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
     *  DiscreteIntegrator: '<S1>/Discrete Integrator'
     */
    DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)((int32_T)
      rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
      rtDWork.DiscreteFilter_states_g)) >> 14);
```

Change Ownership of Data in ICD

When you make changes to the ICD, you can reuse the `importICD` script to reconfigure the model. Change the ownership of the signal `sensors`, the structure type, and the fixed-point data types from `other_component` to `sldemo_fuelsys_dd_controller`.

In the ICD, on the `signals` worksheet, for the signal `sensors`, set these cell values:

- `Owner` to `sldemo_fuelsys_dd_controller`
- `HeaderFile` to `global_data.h`
- `DefinitionFile` to `signals.c`

On the `Numeric Types` worksheet, for all of the fixed-point data types, set:

- `DataScope` to `Exported`
- `HeaderFile` to `exported_types.h`.

On the `Structure Types` worksheet, for the structure type `EngSensors`, set:

- `DataScope` to `Exported`
- `HeaderFile` to `exported_types.h`.

Rerun the `importICD` script.

```
ans =

    'Cannot redefine enumerated type sldemo_FuelModes because open models and existing
```

Generate code from the model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated file `exported_types.h` defines the structure type `EngSensors` and the fixed-point data types.

```
typedef int16_T s16En3;
typedef int16_T s16En7;
```

```
typedef uint8_T u8En7;

/* Structure type for instrument measurements. */
typedef struct {
  /* Throttle angle. */
  s16En3 throttle;

  /* Engine speed. */
  s16En3 speed;

  /* EGO sensors. */
  s16En7 ego;

  /* Manifold pressure. */
  u8En7 map;
} EngSensors;

typedef int16_T s16En15;
```

The file `signals.c` now includes the definition of the signal `sensors`.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
sldemo_FuelModes fuel_mode;            /* Fueling mode of engine. Enrich air/fuel mixtu
int16_T fuel_rate;                     /* Fuel rate setpoint. */
EngSensors sensors;                    /* Instrument measurements. */
```

Migrate Base Workspace Data to Data Dictionary

Objects and variables that you create in the base workspace (for example, `Simulink.Parameter` objects) are not saved with the model. When you end your MATLAB session, the objects and variables do not persist. To permanently store the objects and variables, link one or more models to one or more data dictionaries.

Data dictionaries also enable you to track changes made to the objects and variables, which helps you to:

- Reconcile the data stored in MATLAB with the data stored in the ICD.
- Export data from MATLAB to the ICD.

1. In the top model, `sldemo_fuelsys_dd`, select **File > Model Properties > Link to Data Dictionary**.

2. In the Model Properties dialog box, select **Data Dictionary**. Click **New**.
3. In the Create a new Data Dictionary dialog box, set **File name** to `sysDict` and click **Save**.
4. In the Model Properties dialog box, click **OK**.
5. Click **Yes** in response to the message about migrating base workspace data.
6. Click **Yes** in response to the message about removing the imported items from the base workspace.
7. Click **OK** in response to the message about enumerated type migration.

The variables and objects that the models use all exist in the new data dictionary `sysDict.sldd`, which is in your current folder. All three models in the model reference hierarchy are linked to this dictionary.

Create Reference Dictionary

To establish clear ownership of the data that you store in a dictionary, create reference dictionaries.

1. Open the controller model, `sldemo_fuelsys_dd_controller`. Select **File > Model Properties > Link to Data Dictionary**. Click **New**.
2. Set the name of the new dictionary to `ctrlDict.sldd` and click **Save**. In the Model Properties dialog box, click **OK**.
3. In response to the message about changing the dictionary or moving the data, click **Move Data**. Click **Yes** in response to the message about migrating data.

The variables and objects that the controller model uses now exist in the referenced dictionary `ctrlDict.sldd`. Because `sysDict.sldd` references `ctrlDict.sldd`, you can view all of the data by opening `sysDict.sldd` in the Model Explorer.

Now that the model data acquire code generation settings from objects and variables that are stored in data dictionaries, you can modify the `importICD` script so it accesses the dictionaries instead of the base workspace. For more information about the programmatic interface for data dictionaries, see “Store Data in Dictionary Programmatically” (Simulink).

Store Enumerated Type Definition in Data Dictionary

You can import the definition of the enumerated type `sldemo_FuelModes` into the controller dictionary. See “Enumerations in Data Dictionary” (Simulink).

Store Signal and State Design Attributes Inside or Outside of Model File

In this example, you use `Simulink.Signal` objects to specify design attributes such as data types, minimum and maximum values, and physical units. The signal objects store these specifications outside of the model file.

Alternatively, you can store these specifications in the model file by using block and port parameters, which you can access through the Model Data Editor, the Property Inspector, and other dialog boxes.

To decide where to store the specifications, see "Store Design Attributes of Signals and States" (Simulink).

Data Object Wizard in Embedded Coder

Create Data Objects for Code Generation with Data Object Wizard

To specify code generation options for signal lines, block parameters, and states in a model, you can use data objects that you store in a workspace or data dictionary. For basic information about data objects, see “Data Objects” (Simulink).

You can use the Data Object Wizard to create data objects for:

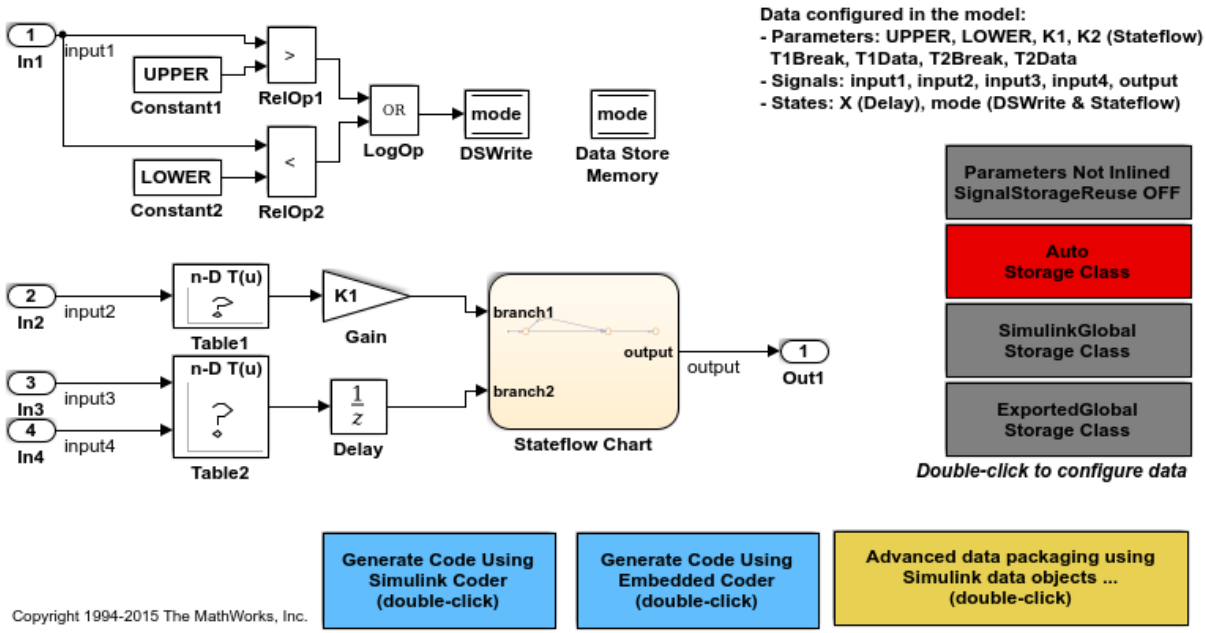
- New or existing models that do not use data objects.
- Existing models to which you have added signal lines or blocks.

This example shows how to use the Data Object Wizard to create and configure data objects for code generation from the built-in package `Simulink`.

Create Data Objects

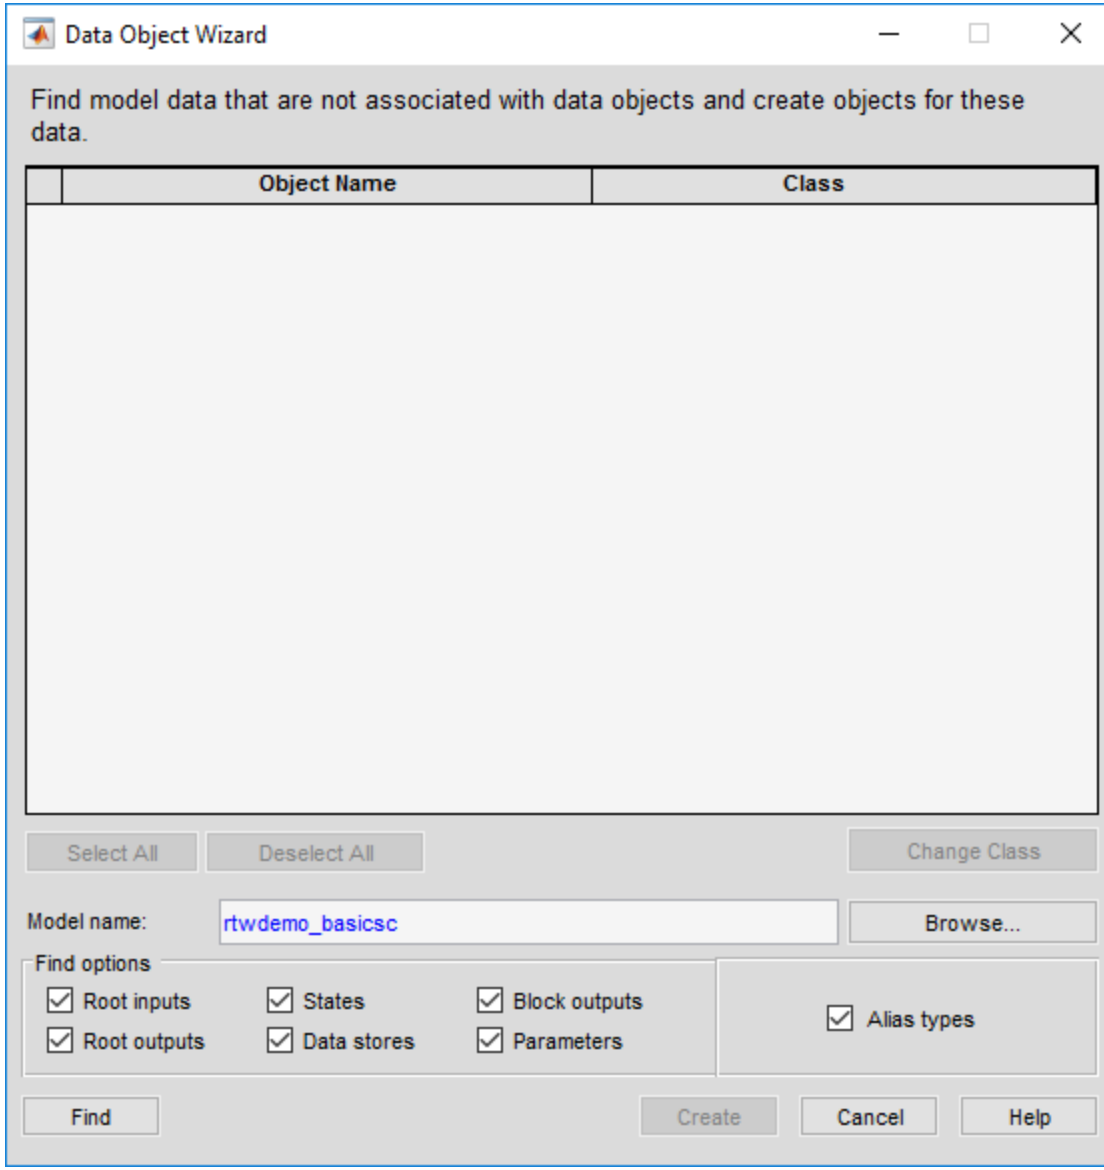
Open the example model rtwdemo_basicsc.

```
open_system('rtwdemo_basicsc')
```



The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the **Gain** parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as `input1`.

In the model, select **Code > Data Objects > Data Object Wizard**.



Data Object Wizard
Find model data that are not associated with data objects and create objects for these data.

Help

The wizard finds only signals, parameters, data stores, and states whose storage class is set to `Auto`. For example, if you use the Signal Properties dialog box to specify a storage class other than `Auto` for a signal line, the wizard does not propose a data object.

Click **Select All**.

Click **Create**. The data objects appear in the base workspace.

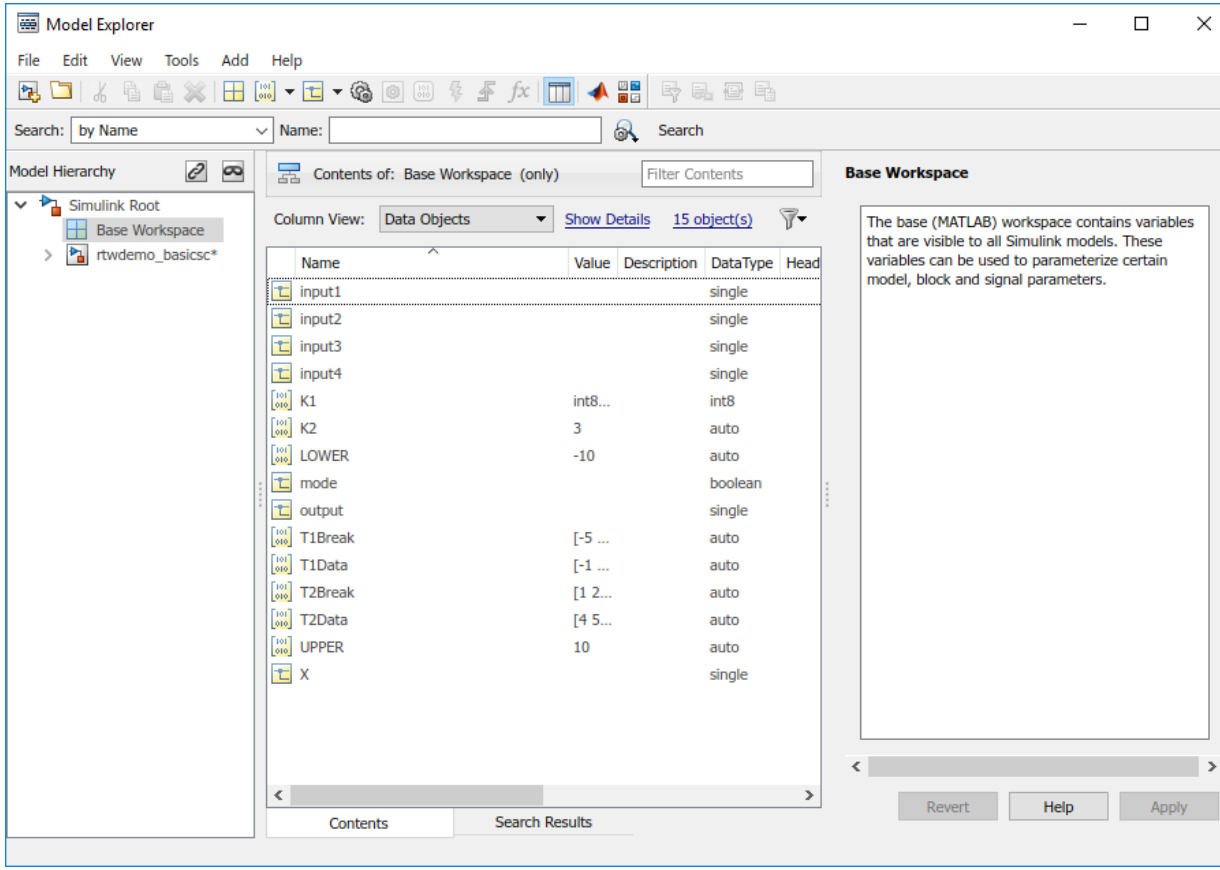
For detailed information about the options that you can choose in the Data Object Wizard, see "Create Data Objects for a Model Using Data Object Wizard" (Simulink).

Set Storage Class for Data Objects

Storage classes determine how the generated code uses variables to represent signals, parameters, and states. For data objects from the built-in package `Simulink`, the default storage class is `Auto`. To specify storage classes for the new data objects, you can use the Model Explorer.

Open the Model Explorer.

In the **Model Hierarchy** pane, select **Base Workspace**.



In the **Contents** pane, from the drop-down list **Column View**, select `Storage Class`.

Select all of the new data objects. For example, select the object `input1`, hold **Shift**, and select the object `X`.

Set the property `StorageClass` for all of the data objects to `ExportToFile`. To change the storage class for all of the selected objects, in the **StorageClass** column, click any of the objects. In the drop-down list, select `ExportToFile`. The change that you make propagates to all of the selected objects.

Specify the `HeaderFile` property for all of the objects as `myExportedHdrFile.h`.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors custom storage classes such as `ExportToFile`.

Generate and Inspect Code

Generate code from the model.

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generaetion report, view the generated file `myExportedHdrFile.h`. The file contains `extern` declarations for the global variables that correspond to the data objects.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern int8_T K1;
extern real_T K2;
extern real32_T LOWER;
extern real32_T T1Break[11];
extern real32_T T1Data[11];
extern real32_T T2Break[3];
extern real32_T T2Data[9];
extern real32_T UPPER;
extern real32_T X;
extern real32_T input1;
extern real32_T input2;
extern real32_T input3;
extern real32_T input4;
extern boolean_T mode;
extern real32_T output;
```

View the file `rtwdemo_basicsc.c`. The file contains the definitions for the global variables. The code assigns numeric values for the variables that correspond to parameter objects.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
int8_T K1 = 2;
real_T K2 = 3.0;
```

```
real32_T LOWER = -10.0F;
real32_T T1Break[11] = { -5.0F, -4.0F, -3.0F, -2.0F, -1.0F, 0.0F, 1.0F, 2.0F,
  3.0F, 4.0F, 5.0F } ;

real32_T T1Data[11] = { -1.0F, -0.99F, -0.98F, -0.96F, -0.76F, 0.0F, 0.76F,
  0.96F, 0.98F, 0.99F, 1.0F } ;

real32_T T2Break[3] = { 1.0F, 2.0F, 3.0F } ;

real32_T T2Data[9] = { 4.0F, 16.0F, 10.0F, 5.0F, 19.0F, 18.0F, 6.0F, 20.0F,
  23.0F } ;

real32_T UPPER = 10.0F;
real32_T X;
real32_T input1;
real32_T input2;
real32_T input3;
real32_T input4;
boolean_T mode;
real32_T output;
```

Entry-Point Functions and Scheduling in Simulink Coder

Entry-Point Functions and Scheduling

The code generator produces the following entry-point functions for a model:

Function	Description
`model_initialize`	Initialization code in the code generated for a model. Call the function *once* at the start of the application code. Do not use this function to reset the real-time model data structure (rtM).
`model_reset`	Code generated if the model includes a Reset Function block. Call the function from the application code to reset conditions or state.
`model_step`	Generated output and update code for blocks in model. If you clear the model configuration parameter "Single output/update function" (Simulink Coder) (selected by default), instead of producing a *`model`*`_step` function, the code generator produces entry-point functions *`model`*`_output` and *`model`*`_update`.
`model_terminate`	Generated code to call for powering off a system. For ERT-based models, suppress generation of this entry-point function by clearing the model configuration parameter "Terminate function required" (Simulink Coder) (set by default).

The calling interface that the code generator produces for each of these entry-point functions differs depending on the value of the model parameter "Code interface packaging" (Simulink Coder):

- `C++ class` (default for C++ language) — Generates a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry-point functions into C++ class methods.
- `Nonreusable function` (default for C language) — Generates nonreusable code. Model entry-point functions pass `(void)`. The code generator statically allocates global model data structures and produces a set of model entry-entry point functions. External code can access the data structures by calling the entry-point functions.
- `Reusable function` — Generates reusable, multi-instance code that is reentrant, as follows:
  - For a GRT-based model, the generated *`model`*`.c` source file contains an allocation function that dynamically allocates model data for each instance of the model. For an ERT-based model, use the "Use dynamic memory allocation for model

initialization" (Simulink Coder) parameter to control whether the code generator produces an allocation function.

- The generated code passes the real-time model data structure in, by reference, as an argument to *`model`*`_step` and the other model entry-point functions.
- The code generator exports the real-time model data structure in the *`model`*`.h` header file.

For an ERT-based model, you can use the "Pass root-level I/O as" (Simulink Coder) parameter to control how the code generator passes root-level input and output arguments to the reusable model entry-point functions. You can include them in the real-time model data structure that the code generator passes to the functions, passes as individual arguments, or passes as references to an input structure and an output structure.

To call the generated entry-point functions from external code, add an `#include` *`model`*`.h` directive to your code.

For more information, see the reference pages for the listed functions.

Note: The function reference pages document the C language default (`Nonreusable function`) calling interface generated for these functions.

More About

- "Generate Reentrant Code from Top-Level Models" (Simulink Coder)
- "Generate C++ Class Interface to Model or Subsystem Code" (Simulink Coder)
- "Execution of Code Generated from a Model" (Simulink Coder)
- "Rapid Prototyping Model Functions" (Simulink Coder)
- "Generate Code That Responds to Initialize, Reset, and Terminate Events" (Simulink Coder)
- "Select a System Target File" on page 30-2

Generate Reentrant Code from Top-Level Models

To generate reentrant multi-instance code from a model, select `Reusable function` code interface packaging. When you select the `Reusable function` code interface for a GRT model:

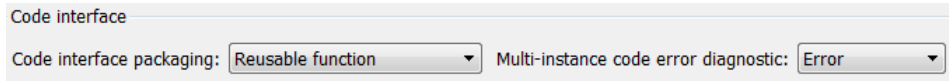
- The generated *`model`*`.c` source file contains an allocation function that dynamically allocates model data for each instance of the model.
- The generated code passes the real-time model data structure in, by reference, as an argument to *`model`*`_step` and the other model entry point functions.
- The real-time model data structure is exported with the *`model`*`.h` header file.

To configure a model to generate reusable, reentrant function code:

1. In the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, set **Code interface packaging** (Simulink Coder) to the value `Reusable function`. This action enables the parameter **Multi-instance code error diagnostic**.

   Note: If you have an Embedded Coder license and you have selected an ERT target for your model, selecting `Reusable function` enables additional parameters for customizing the generated reusable function interface to model code — **Pass root-level I/O as** (Simulink Coder) and **Use dynamic memory allocation for model initialization** (Simulink Coder).

2. Examine the setting of **Multi-instance code error diagnostic** (Simulink Coder). Leave the parameter at its default value `Error` unless you have a specific need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

3. Generate model code.
4. Examine the model entry-point function interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point functions, see “Entry-Point Functions and Scheduling” (Simulink Coder).

For an example of a model configured to generate reusable, reentrant code, open the example model `rtwdemo_reusable`. To generate GRT code for the example model, double-click the button **Generate Code Using Simulink Coder**.

- "Entry-Point Functions and Scheduling" (Simulink Coder)
- "Generate C++ Class Interface to Model or Subsystem Code" (Simulink Coder)
- "Execution of Code Generated from a Model" (Simulink Coder)
- "Rapid Prototyping Model Functions" (Simulink Coder)

Generate C++ Class Interface to Model or Subsystem Code

On the Configuration Parameters dialog box, set the **Code Generation** > **Interface** "Code interface packaging" (Simulink Coder) parameter to `C++ class` for generating a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see "Generate C++ Class Interface to Nonvirtual Subsystem Code" on page 25-7.)

Generate C++ Class Interface to Model Code

To generate encapsulated C++ class code from a GRT-based model:

1. Set the Configuration Parameters dialog box parameter **Code Generation** > **Language** to `C++`. This selection also enables C++ class code interface packaging for the model.
2. On the **Code Generation** > **Interface** pane, verify that the parameter **Code interface packaging** (Simulink Coder) is set to `C++ class`.
3. Examine the setting of **Multi-instance code error diagnostic** (Simulink Coder). Leave the parameter at its default value `Error` unless you have a specific need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

4. Generate code for the model.
5. Examine the C++ model class code in the generated files *`model`*`.h` and *`model`*`.cpp`. For example, the following code excerpt from the H file generated for the example model `rtwdemo_secondOrderSystem` shows the C++ class declaration for the model.

```
/* Class declaration for model rtwdemo_secondOrderSystem */
```

```
class rtwdemo_secondOrderSystemModelClass {
  /* public data and function members */
 public:
  /* External outputs */
  ExtY_rtwdemo_secondOrderSyste_T rtwdemo_secondOrderSystem_Y;

  /* Model entry point functions */

  /* model initialize function */
  void initialize();

  /* model step function */
  void step();

  /* model terminate function */
  void terminate();

  /* Constructor */
  rtwdemo_secondOrderSystemModelClass();

  /* Destructor */
  ~rtwdemo_secondOrderSystemModelClass();

  /* Real-Time Model get method */
  RT_MODEL_rtwdemo_secondOrderS_T * getRTM();
...
};
```

For more information about generating and calling model entry-point functions, see "Entry-Point Functions and Scheduling" (Simulink Coder).

Note: If you have an Embedded Coder license and you have selected an ERT target for your model, you can use additional **Code Generation** > **Interface** pane parameters to customize the generated C++ class interface to model code.

Generate C++ Class Interface to Nonvirtual Subsystem Code

You can generate C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the `C++` language and `C++ class` code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

1. Open the containing model and select the subsystem block.
2. Right-click the subsystem and select **C/C++ Code** > **Build This Subsystem**.
3. When the subsystem build completes, examine the C++ class interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point methods, see "Entry-Point Functions and Scheduling" (Simulink Coder).

Note: If you have an Embedded Coder license and you have selected an ERT target for your model, you can use the MATLAB command `RTW.configSubsystemBuild` to customize the generated C++ class interface to subsystem code.

C++ Class Interface Limitations

- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for `C++ class` code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. On the Simulink Signal Conversion block parameter dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured to generate a C++ class interface, you cannot use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that
  - Has a continuous sample time
  - Saves states

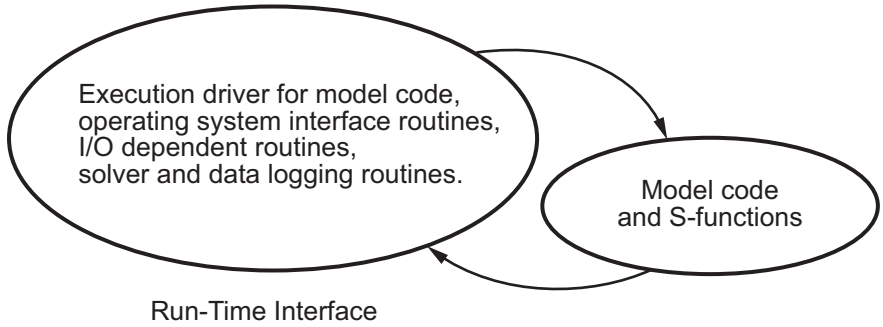
- "Entry-Point Functions and Scheduling" (Simulink Coder)
- "Execution of Code Generated from a Model" (Simulink Coder)
- "Rapid Prototyping Model Functions" (Simulink Coder)

Execution of Code Generated from a Model

The code generator produces algorithmic code as defined by your model. You can include external (for example, custom or legacy) code in a model by using techniques explained in "Choose an External Code Integration Workflow" (Simulink Coder).

The code generator also provides a interface that executes the generated model code. The interface and model code are compiled together to create an executable program. The next figure shows a high-level object-oriented view of the executable.



The Object-Oriented View of a Real-Time Program

In general, the conceptual design of the model execution driver does not change between the rapid prototyping and embedded style of generated code. The following sections describe model execution for single-tasking and multitasking environments both for simulation (non-real-time) and for real time. For most model code, the multitasking environment will provide the most efficient model execution (that is, fastest sample rate).

The following concepts are useful in describing how model code executes.

- **Initialization**: *model*`_initialize` initializes the interface code and the model code.
- **ModelOutputs**: Calls blocks in your model that have a sample hit at the current time and has them produce their output. *model*`_output` can be done in major or minor time steps. In major time steps, the output is a given simulation time step. In minor time steps, the interface integrates the derivatives to update the continuous states.
- **ModelUpdate**: *model*`_update` calls blocks in your model that have a sample hit at the current point in time and has them update their discrete states or similar type objects.

- **ModelDerivatives**: Calls blocks in your model that have continuous states and has them update their derivatives. *model*_derivatives is only called in minor time steps.
- **ModelTerminate**: *model*_terminate terminates the program if it is designed to run for a finite time. It destroys the real-time model data structure, deallocates memory, and can write data to a file.

Program Execution

A real-time program cannot require 100% of the CPU's time. This provides an opportunity to run background tasks during the free time.

Background tasks include operations such as writing data to a buffer or file, allowing access to program data by third-party data monitoring tools, or using Simulink external mode to update program parameters.

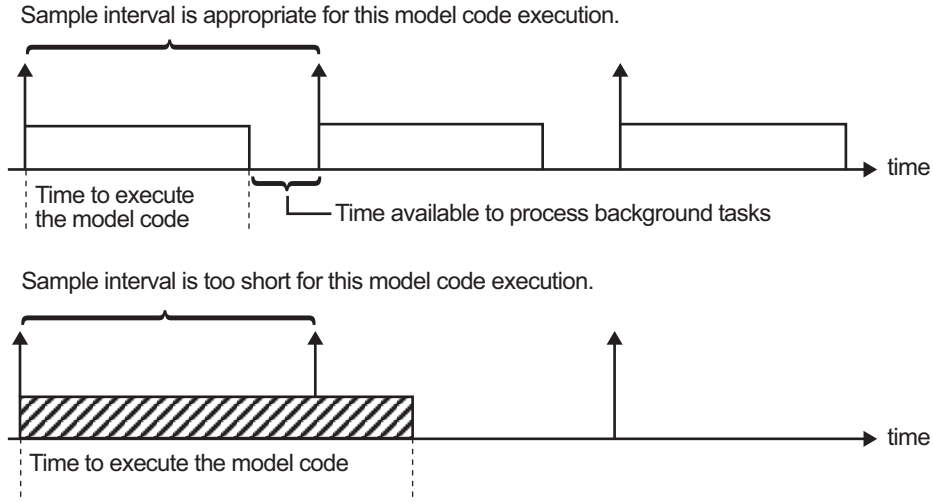
It is important, however, that the program be able to preempt the background task so the model code can execute in real time.

The way the program manages tasks depends on capabilities of the environment in which it operates.

Program Timing

Real-time programs require careful timing of the task invocations (either by using an interrupt or a real-time operating system tasking primitive) so that the model code executes to completion before another task invocation occurs. This includes time to read and write data to and from external hardware.

The next figure illustrates interrupt timing.



Task Timing

The sample interval must be long enough to allow model code execution between task invocations.

In the figure above, the time between two adjacent vertical arrows is the sample interval. The empty boxes in the upper diagram show an example of a program that can complete one step within the interval and still allow time for the background task. The gray box in the lower diagram indicates what happens if the sample interval is too short. Another task invocation occurs before the task is complete. Such timing results in an execution error.

Note also that, if the real-time program is designed to run forever (that is, the final time is 0 or infinite so that the `while` loop never exits), then the shutdown code does not execute.

For more information on how the timing engine works, see "Absolute and Elapsed Time Computation" (Simulink Coder).

External Mode Communication

External mode allows communication between the Simulink block diagram and the standalone program that is built from the generated code. In this mode, the real-time

program functions as an interprocess communication server, responding to requests from the Simulink engine.

Data Logging in Single-Tasking and Multitasking Model Execution

"Debug" on page 28-23 explains how you can save system states, outputs, and time to a MAT-file at the completion of the model execution. The `LogTXY` function, which performs data logging, operates differently in single-tasking and multitasking environments.

If you examine how `LogTXY` is called in the single-tasking and multitasking environments, you will notice that for single-tasking `LogTXY` is called after `ModelOutputs`. During this `ModelOutputs` call, blocks that have a hit at time *t* execute, whereas in multitasking, `LogTXY` is called after `ModelOutputs(tid=0)`, which executes only the blocks that have a hit at time *t* and that have a task identifier of 0. This results in differences in the logged values between single-tasking and multitasking logging. Specifically, consider a model with two sample times, the faster sample time having a period of 1.0 second and the slower sample time having a period of 10.0 seconds. At time t = k*10, k=0,1,2... both the fast (`tid=0`) and slow (`tid=1`) blocks execute. When executing in multitasking mode, when `LogTXY` is called, the slow blocks execute, but the previous value is logged, whereas in single-tasking the current value is logged.

Another difference occurs when logging data in an enabled subsystem. Consider an enabled subsystem that has a slow signal driving the enable port and fast blocks within the enabled subsystem. In this case, the evaluation of the enable signal occurs in a slow task, and the fast blocks see a delay of one sample period; thus the logged values will show these differences.

To summarize differences in logged data between single-tasking and multitasking, differences will be seen when

- Any root outport block has a sample time that is slower than the fastest sample time
- Any block with states has a sample time that is slower than the fastest sample time
- Any block in an enabled subsystem where the signal driving the enable port is slower than the rate of the blocks in the enabled subsystem

For the first two cases, even though the logged values are different between single-tasking and multitasking, the model results are not different. The only real difference is where (at what point in time) the logging is done. The third (enabled subsystem) case results in a delay that can be seen in a real-time environment.

Non-Real-Time Single-Tasking Systems

The pseudocode below shows the execution of a model for a non-real-time single-tasking system.

```
main()
{
  Initialization
  While (time < final time)
    ModelOutputs     -- Major time step.
    LogTXY           -- Log time, states and root outports.
    ModelUpdate      -- Major time step.
    Integrate        -- Integration in minor time step for
                     -- models with continuous states.
      ModelDerivatives
      Do 0 or more
        ModelOutputs
        ModelDerivatives
      EndDo -- Number of iterations depends upon the solver
      Integrate derivatives to update continuous states.
    EndIntegrate
  EndWhile
  Termination
}
```

The initialization phase begins first. This consists of initializing model states and setting up the execution engine. The model then executes, one step at a time. First `ModelOutputs` executes at time *t*, then the workspace I/O data is logged, and then `ModelUpdate` updates the discrete states. Next, if your model has continuous states, `ModelDerivatives` integrates the continuous states' derivatives to generate the states for time $t_{new} = t + h$, where h is the step size. Time then moves forward to t_{new} and the process repeats.

During the `ModelOutputs` and `ModelUpdate` phases of model execution, only blocks that reach the current point in time execute.

Non-Real-Time Multitasking Systems

The pseudocode below shows the execution of a model for a non-real-time multitasking system.

```
main()
```

```
{
  Initialization
  While (time < final time)
    ModelOutputs(tid=0)   -- Major time step.
    LogTXY                -- Log time, states, and root
                          -- outports.
    ModelUpdate(tid=0)    -- Major time step.
    Integrate       -- Integration in minor time step for
                    -- models with continuous states.
      ModelDerivatives
      Do 0 or more
        ModelOutputs(tid=0)
        ModelDerivatives
      EndDo (Number of iterations depends upon the solver.)
      Integrate derivatives to update continuous states.
    EndIntegrate
    For i=1:NumTids
      ModelOutputs(tid=i) -- Major time step.
      ModelUpdate(tid=i)  -- Major time step.
    EndFor
  EndWhile
  Termination
  }
```

Multitasking operation is more complex than single-tasking execution because the output and update functions are subdivided by the *task identifier* (`tid`) that is passed into these functions. This allows for multiple invocations of these functions with different task identifiers using overlapped interrupts, or for multiple tasks when using a real-time operating system. In simulation, multiple tasks are emulated by executing the code in the order that would occur if no preemption existed in a real-time system.

Multitasking execution assumes that all task rates are multiples of the base rate. The Simulink product enforces this when you create a fixed-step multitasking model. The multitasking execution loop is very similar to that of single-tasking, except for the use of the task identifier (`tid`) argument to `ModelOutputs` and `ModelUpdate`.

Note: You cannot use `tid` values from code generated by a target file and not by Simulink Coder. Simulink Coder tracks the use of `tid` when generating code for a specific subsystem or function type. When you generate code in a target file, this argument cannot be tracked because the scope does not have subsystem or function type. Therefore, `tid` becomes an undefined variable and your target file fails to compile.

Real-Time Single-Tasking Systems

The pseudocode below shows the execution of a model in a real-time single-tasking system where the model is run at interrupt level.

```
rtOneStep()
{
  Check for interrupt overflow
  Enable "rtOneStep" interrupt
  ModelOutputs    -- Major time step.
  LogTXY          -- Log time, states and root outports.
  ModelUpdate     -- Major time step.
  Integrate       -- Integration in minor time step for models
                  -- with continuous states.
     ModelDerivatives
     Do 0 or more
       ModelOutputs
       ModelDerivatives
     EndDo (Number of iterations depends upon the solver.)
     Integrate derivatives to update continuous states.
  EndIntegrate
}

main()
{
  Initialization (including installation of rtOneStep as an
  interrupt service routine, ISR, for a real-time clock).
  While(time < final time)
    Background task.
  EndWhile
  Mask interrupts (Disable rtOneStep from executing.)
  Complete any background tasks.
  Shutdown
}
```

Real-time single-tasking execution is very similar to non-real-time single-tasking execution, except that instead of free-running the code, the `rt_OneStep` function is driven by a periodic timer interrupt.

At the interval specified by the program's base sample rate, the interrupt service routine (ISR) preempts the background task to execute the model code. The base sample rate is the fastest in the model. If the model has continuous blocks, then the integration step size determines the base sample rate.

For example, if the model code is a controller operating at 100 Hz, then every 0.01 seconds the background task is interrupted. During this interrupt, the controller reads its inputs from the analog-to-digital converter (ADC), calculates its outputs, writes these outputs to the digital-to-analog converter (DAC), and updates its states. Program control then returns to the background task. All of these steps must occur before the next interrupt.

Real-Time Multitasking Systems

The following pseudocode shows how a model executes in a real-time multitasking system where the model is run at interrupt level.

```
rtOneStep()
{
  Check for interrupt overflow
  Enable "rtOneStep" interrupt
  ModelOutputs(tid=0)     -- Major time step.
  LogTXY                  -- Log time, states and root outports.
  ModelUpdate(tid=0)      -- Major time step.
  Integrate               -- Integration in minor time step for
                          -- models with continuous states.
     ModelDerivatives
     Do 0 or more
       ModelOutputs(tid=0)
       ModelDerivatives
     EndDo (Number of iterations depends upon the solver.)
     Integrate derivatives and update continuous states.
  EndIntegrate
  For i=1:NumTasks
    If (hit in task i)
      ModelOutputs(tid=i)
      ModelUpdate(tid=i)
    EndIf
  EndFor
}

main()
{
  Initialization (including installation of rtOneStep as an
    interrupt service routine, ISR, for a real-time clock).
  While(time < final time)
    Background task.
  EndWhile
```

```
  Mask interrupts (Disable rtOneStep from executing.)
  Complete any background tasks.
  Shutdown
}
```

Running models at interrupt level in a real-time multitasking environment is very similar to the previous single-tasking environment, except that overlapped interrupts are employed for concurrent execution of the tasks.

The execution of a model in a single-tasking or multitasking environment when using real-time operating system tasking primitives is very similar to the interrupt-level examples discussed above. The pseudocode below is for a single-tasking model using real-time tasking primitives.

```
tSingleRate()
{
  MainLoop:
    If clockSem already "given", then error out due to overflow.
    Wait on clockSem
    ModelOutputs            -- Major time step.
    LogTXY                  -- Log time, states and root
                            -- outports
    ModelUpdate             -- Major time step
    Integrate               -- Integration in minor time step
                            -- for models with continuous
                            -- states.
      ModelDeriviatives
      Do 0 or more
        ModelOutputs
        ModelDerivatives
      EndDo (Number of iterations depends upon the solver.)
      Integrate derivatives to update continuous states.
    EndIntegrate
  EndMainLoop
}

main()
{
  Initialization
  Start/spawn task "tSingleRate".
  Start clock that does a "semGive" on a clockSem semaphore.
  Wait on "model-running" semaphore.
  Shutdown
}
```

In this single-tasking environment, the model executes as real-time operating system tasking primitives. In this environment, create a single task (`tSingleRate`) to run the model code. This task is invoked when a clock tick occurs. The clock tick gives a `clockSem` (clock semaphore) to the model task (`tSingleRate`). The model task waits for the semaphore before executing. The clock ticks occur at the fundamental step size (base rate) for your model.

Multitasking Systems Using Real-Time Tasking Primitives

The pseudocode below is for a multitasking model using real-time tasking primitives.

```
tSubRate(subTaskSem,i)
{
  Loop:
    Wait on semaphore subTaskSem.
    ModelOutputs(tid=i)
    ModelUpdate(tid=i)
  EndLoop
}
tBaseRate()
{
  MainLoop:
    If clockSem already "given", then error out due to overflow.
    Wait on clockSem
    For i=1:NumTasks
      If (hit in task i)
        If task i is currently executing, then error out due to
          overflow.
        Do a "semGive" on subTaskSem for task i.
      EndIf
    EndFor
    ModelOutputs(tid=0)    -- major time step.
    LogTXY                 -- Log time, states and root outports.
    ModelUpdate(tid=0)     -- major time step.
    Loop:                  -- Integration in minor time step for
                           -- models with continuous states.
      ModelDeriviatives
      Do 0 or more
        ModelOutputs(tid=0)
        ModelDerivatives
      EndDo (number of iterations depends upon the solver).
      Integrate derivatives to update continuous states.
    EndLoop
```

```
  EndMainLoop
}
main()
{
  Initialization
  Start/spawn task "tSubRate".
  Start/spawn task "tBaseRate".

  Start clock that does a "semGive" on a clockSem semaphore.
  Wait on "model-running" semaphore.
  Shutdown
}
```

In this multitasking environment, the model is executed using real-time operating system tasking primitives. Such environments require several model tasks (`tBaseRate` and several `tSubRate` tasks) to run the model code. The base rate task (`tBaseRate`) has a higher priority than the subrate tasks. The subrate task for `tid=1` has a higher priority than the subrate task for `tid=2`, and so on. The base rate task is invoked when a clock tick occurs. The clock tick gives a `clockSem` to `tBaseRate`. The first thing `tBaseRate` does is give semaphores to the subtasks that have a hit at the current point in time. Because the base rate task has a higher priority, it continues to execute. Next it executes the fastest task (`tid=0`), consisting of blocks in your model that have the fastest sample time. After this execution, it resumes waiting for the clock semaphore. The clock ticks are configured to occur at the fundamental step size for your model.

Rapid Prototyping and Embedded Model Execution Differences

The rapid prototyping program framework provides a common application programming interface (API) that does not change between model definitions.

The Embedded Coder product provides a different framework called the embedded program framework. The embedded program framework provides an optimized API that is tailored to your model. When you use the embedded style of generated code, you are modeling how you would like your code to execute in your embedded system. Therefore, the definitions defined in your model should be specific to your embedded targets. Items such as the model name, parameter, and signal storage class are included as part of the API for the embedded style of code.

One major difference between the rapid prototyping and embedded style of generated code is that the latter contains fewer entry-point functions. The embedded style of code can be configured to have only one function, *`model`*`_step`.

Thus, model execution code eliminates `Loop...EndLoop` statements and groups `ModelOutputs`, `LogTXY`, and `ModelUpdate` into a single statement, *`model`*`_step`.

For more information about how generated embedded code executes, see "Entry-Point Functions and Scheduling" on page 25-2.

- "Sample Times in Systems" (Simulink)
- "Time-Based Scheduling Example Models" on page 16-36

Rapid Prototyping Model Functions

Rapid prototyping code defines the following functions that interface with the main program (`main.c` or `main.cpp`):

- `Model()`: The model registration function. This function initializes the work areas (for example, allocating and setting pointers to various data structures) used by the model. The model registration function calls the `MdlInitializeSizes` and `MdlInitializeSampleTimes` functions. These two functions are very similar to the S-function `mdlInitializeSizes` and `mdlInitializeSampleTimes` methods.
- `MdlStart(void)`: After the model registration functions `MdlInitializeSizes` and `MdlInitializeSampleTimes` execute, the main program starts execution by calling `MdlStart`. This routine is called once at startup.

  The function `MdlStart` has four basic sections:

  - Code to initialize the states for each block in the root model that has states. A subroutine call is made to the "initialize states" routines of conditionally executed subsystems.
  - Code generated by the one-time initialization (start) function for each block in the model.
  - Code to enable the blocks in the root model that have enable methods, and the blocks inside triggered or function-call subsystems residing in the root model. Simulink blocks can have enable and disable methods. An enable method is called just before a block starts executing, and the disable method is called just after the block stops executing.
  - Code for each block in the model whose output value is constant. The block code appears in the `MdlStart` function only if the block parameters are not tunable in the generated code and if the code generator cannot eliminate the block code through constant folding.
- `MdlOutputs(int_T tid)`: `MdlOutputs` updates the output of blocks. The `tid` (task identifier) parameter identifies the task that in turn maps when to execute blocks based upon their sample time. This routine is invoked by the main program during major and minor time steps. The major time steps are when the main program is taking an actual time step (that is, it is time to execute a specific task). If your model contains continuous states, the minor time steps will be taken. The minor time steps are when the solver is generating integration stages, which are points between major outputs. These integration stages are used to compute the derivatives used in advancing the continuous states.

- `MdlUpdate(int_T tid)`: `MdlUpdate` updates the states and work vector state information (that is, states that are neither continuous nor discrete) saved in work vectors. The `tid` (task identifier) parameter identifies the task that in turn indicates which sample times are active, allowing you to conditionally update only states of active blocks. This routine is invoked by the interface after the major `MdlOutputs` has been executed. The solver is also called, and *`model`*`_Derivatives` is called in minor steps by the solver during its integration stages. All blocks that have continuous states have an identical number of derivatives. These blocks are required to compute the derivatives so that the solvers can integrate the states.
- `MdlTerminate(void)`: `MdlTerminate` contains any block shutdown code. `MdlTerminate` is called by the interface, as part of the termination of the real-time program.

The contents of the above functions are directly related to the blocks in your model. A Simulink block can be generalized to the following set of equations.

$$y = f_0(t, x_c, x_d, u)$$

Output y is a function of continuous state x_c, discrete state x_d, and input u. Each block writes its specific equation in a section of `MdlOutputs`.

$$x_{d+1} = f_u(t, x_d, u)$$

The discrete states x_d are a function of the current state and input. Each block that has a discrete state updates its state in `MdlUpdate`.

$$\dot{x} = f_d(t, x_c, u)$$

The derivatives x are a function of the current input. Each block that has continuous states provides its derivatives to the solver (for example, `ode5`) in *`model`*`_Derivatives`. The derivatives are used by the solver to integrate the continuous state to produce the next value.

The output, y, is generally written to the block I/O structure. Root-level Outport blocks write to the external outputs structure. The continuous and discrete states are stored in the states structure. The input, u, can originate from another block's output, which is located in the block I/O structure, an external input (located in the external inputs

structure), or a state. These structures are defined in the *model*.h file that the Simulink Coder software generates.

The next example shows the general contents of the rapid prototyping style of C code written to the *model*.c file.

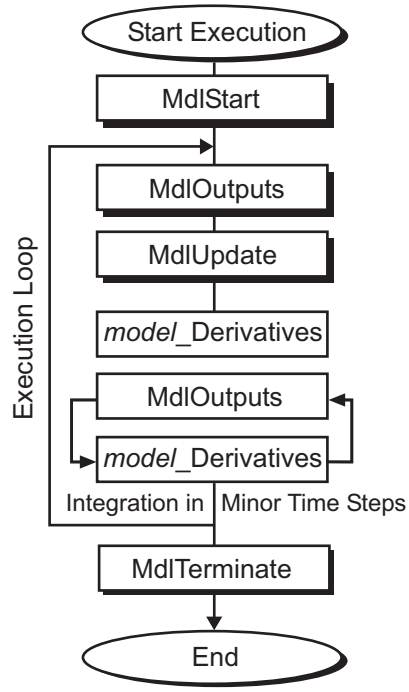
```
/*
 * Version, Model options, TLC options,
 * and code generation information are placed here.
*/
<includes>
void MdlStart(void)
{
  /*
   * State initialization code.
   * Model start-up code - one time initialization code.
   * Execute any block enable methods.
   * Initialize output of any blocks with constant sample times.
   */
}

void MdlOutputs(int_T tid)
{
  /* Compute: y = f0(t,xc,xd,u) for each block as needed. */
}

void MdlUpdate(int_T tid)
{
  /* Compute: xd+1 = fu(t,xd,u) for each block as needed. */

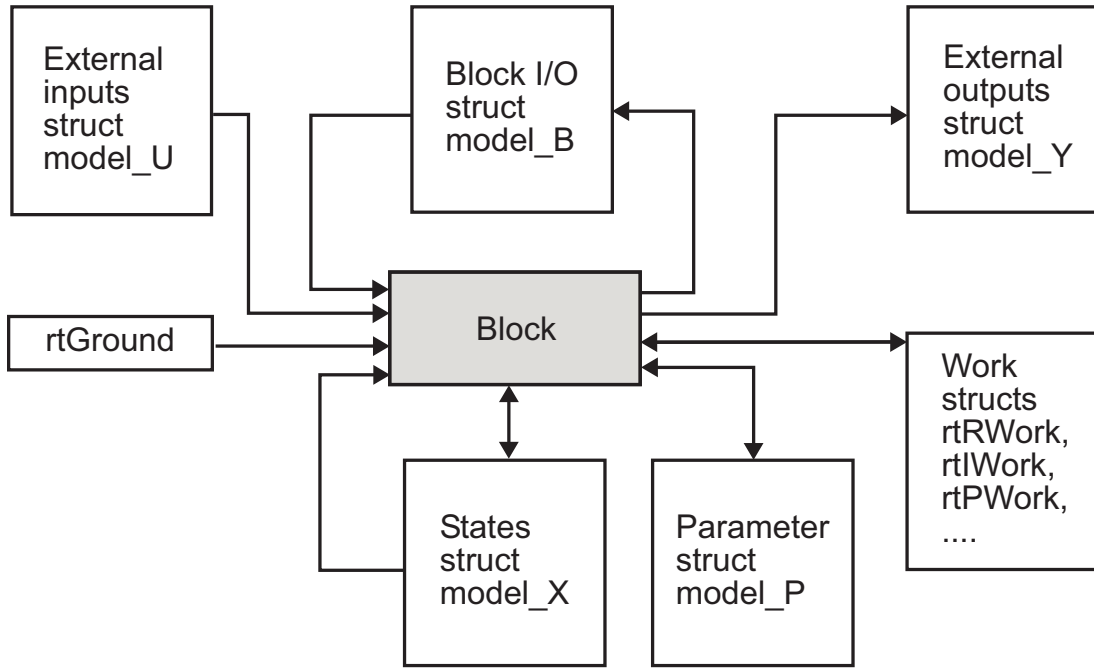
  /* Compute: dxc = fd(t,xc,u) for each block in model_derivatives
                               as needed. */
}
void MdlTerminate(void)
{
  /* Perform shutdown code for any blocks that
     have a termination action */
}
```

The next figure shows a flow chart describing the execution of the rapid prototyping generated code.



Rapid Prototyping Execution Flow Chart

Each block places code in specific `Mdl` routines according to the algorithm that it is implementing. Blocks have input, output, parameters, and states, as well as other general items. For example, in general, block inputs and outputs are written to a block I/O structure (*`model`*`_B`). Block inputs can also come from the external input structure (*`model`*`_U`) or the state structure when connected to a state port of an integrator (*`model`*`_X`), or ground (`rtGround`) if unconnected or grounded. Block outputs can also go to the external output structure (*`model`*`_Y`). The next figure shows the general mapping between these items.



Data View of the Generated Code

The following list defines the structures shown in the preceding figure:

- Block I/O structure (*`model`*`_B`): This structure consists of persistent block output signals. The number of block output signals is the sum of the widths of the data output ports of all nonvirtual blocks in your model. If you activate block I/O optimizations, the Simulink and Simulink Coder products reduce the size of the *`model`*`_B` structure by

  - Reusing the entries in the *`model`*`_B` structure
  - Making other entries local variables

  See “Signal Representation in Generated Code” on page 19-112 for more information on these optimizations.

  Structure field names are determined either by the block's output signal name (when present) or by the block name and port number when the output signal is left unlabeled.

- Block states structures: The continuous states structure (*model*_X) contains the continuous state information for blocks in your model that have continuous states. Discrete states are stored in a data structure called the *DWork vector* (*model*_DWork).
- Block parameters structure (*model*_P): The parameters structure contains block parameters that can be changed during execution (for example, the parameter of a Gain block).
- External inputs structure (*model*_U): The external inputs structure consists of all root-level Inport block signals. Field names are determined by either the block's output signal name, when present, or by the Inport block's name when the output signal is left unlabeled.
- External outputs structure (*model*_Y): The external outputs structure consists of all root-level Outport blocks. Field names are determined by the root-level Outport block names in your model.
- Real work, integer work, and pointer work structures (*model*_RWork, *model*_IWork, *model*_PWork): Blocks might have a need for real, integer, or pointer work areas. For example, the Memory block uses a real work element for each signal. These areas are used to save internal states or similar information.

Function and Class Interfaces in Embedded Coder

Control Generation of Function Prototypes

About Function Prototype Control

For fixed-step, rate-based models that you configure with an ERT-based system target file, you can control the prototypes of functions that the code generator produces. Control the function prototype generation by using the **Configure Model Functions** button, located on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box.

By default, the function prototype of the generated *`model`*`_step` function resembles the following:

```
void model_step(void);
```

The function prototype of the generated *`model`*`_initialize` function resembles the following:

```
void model_initialize(void);
```

(For more detailed information about the default calling interface for the *`model`*`_step` function, see the `model_step` reference page.)

The **Configure Model Functions** button on the **Interface** pane provides you flexible control over the model function prototypes that are generated for your model. Clicking **Configure Model Functions** launches a Model Interface dialog box (see "Configure Function Prototypes Using Graphical Interfaces" on page 26-3). Based on the **Function specification** value you specify for your model function (supported values include `Default model initialize and step functions` and `Model specific C prototypes`), you can preview and modify the function prototypes. Once you validate and apply your changes, you can generate code based on your function prototype modifications.

For more information about using the **Configure Model Functions** button and the Model Interface dialog box, see "Sample Procedure for Configuring Function Prototypes" on page 26-11 and the model `rtwdemo_fcnprotoctrl`, which is preconfigured to demonstrate function prototype control.

Alternatively, you can use function prototype control functions to programmatically control model function prototypes. For more information, see "Configure Function Prototypes Programmatically" on page 26-16.

You can also control model function prototypes for nonvirtual subsystems, if you generate subsystem code using right-click build. To launch the **Model Interface for subsystem** dialog box, use the `RTW.configSubsystemBuild` function.

Right-click building the subsystem generates the step and initialization functions according to the customizations you make. For more information, see "Configure Function Prototypes for Nonvirtual Subsystems" on page 26-9.

For limitations that apply, see "Function Prototype Control Limitations" on page 26-21.

Configure Function Prototypes Using Graphical Interfaces

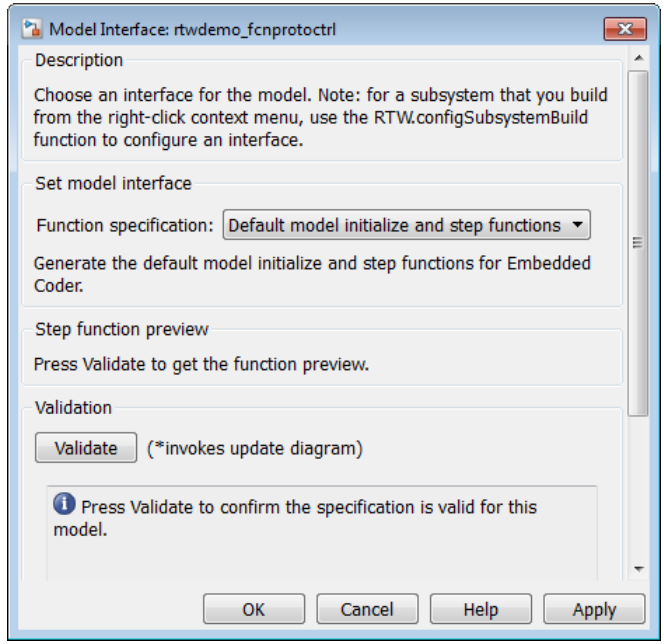
Launch the Model Interface Dialog Boxes

Clicking the **Configure Model Functions** button on the **Interface** pane of the Configuration Parameters dialog box launches the Model Interface dialog box. This dialog box is the starting point for configuring the model function prototypes that are generated during code generation for ERT-based Simulink models. Based on the **Function specification** value you select for your model function (supported values include `Default model initialize and step functions` and `Model specific C prototypes`), you can preview and modify the function prototype. Once you validate and apply your changes, you can generate code based on your function prototype modifications.

To configure function prototypes for a right-click build of a nonvirtual subsystem, invoke the `RTW.configSubsystemBuild` function, which launches the Model Interface for subsystem dialog box. For more information, see "Configure Function Prototypes for Nonvirtual Subsystems" on page 26-9

Default Model Initialize and Step Functions View

The figure below shows the Model Interface dialog box in the `Default model initialize and step functions` view.



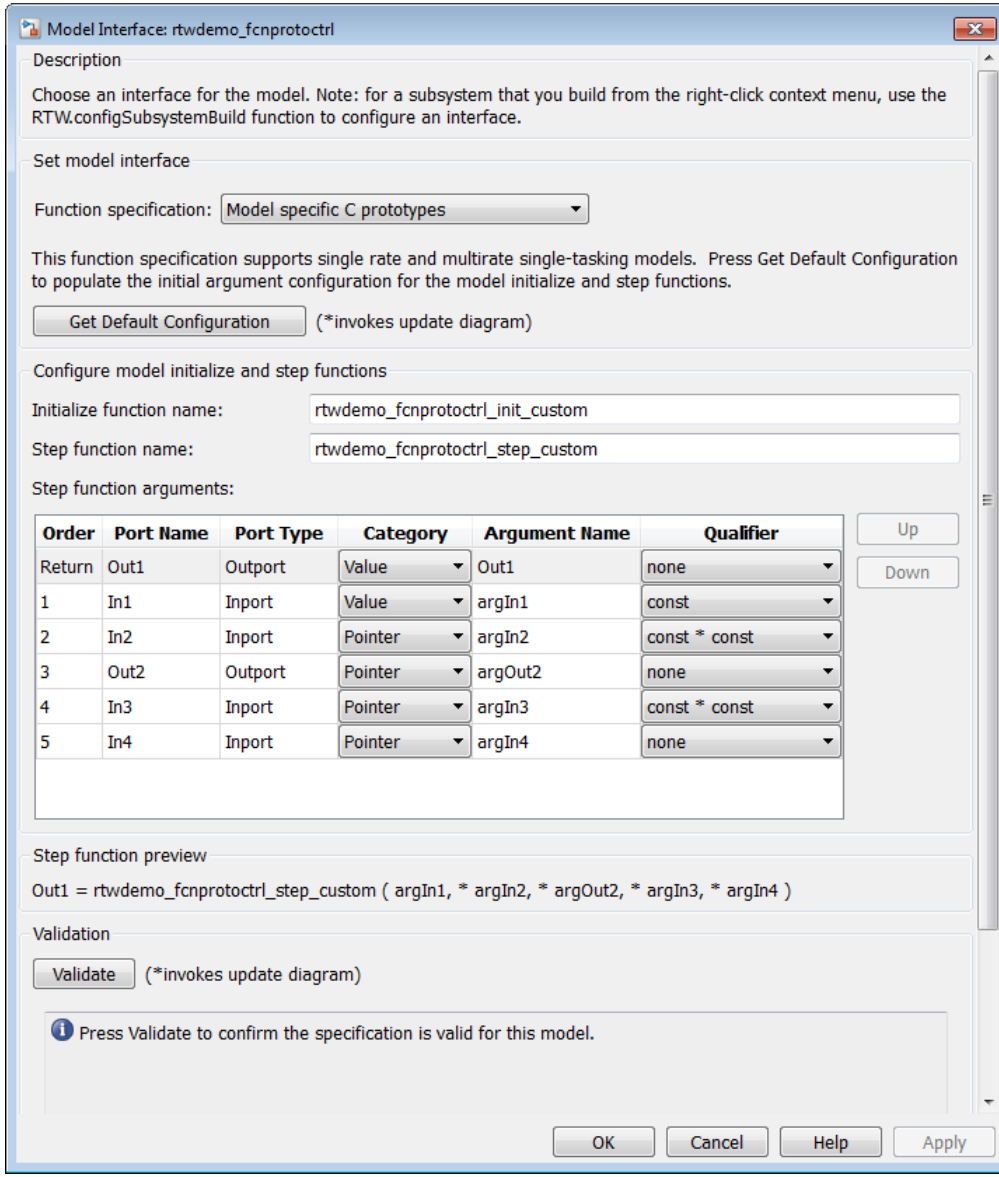
The `Default model initialize and step functions` view allows you to validate and preview the predicted default model step and initialization function prototypes. To validate the default function prototype configuration against your model, click the **Validate** button. If the validation succeeds, the predicted step function prototype appears in the **Step function preview** subpane.

Note: You cannot use the `Default model initialize and step functions` view to modify the function prototype configuration.

Model Specific C Prototypes View

Selecting `Model specific C prototypes` for the **Function specification** parameter displays the `Model specific C prototypes` view of your model function prototypes. This view provides controls that you can use to customize the function names, the order of arguments, and argument attributes including name, passing mechanism, and type qualifier for each of the model's root-level I/O ports.

To begin configuring your function control prototype configuration, click the **Get Default Configuration** button. This activates and initializes the function names and properties in the **Configure model initialize and step functions** subpane, as shown below. If you click **Get Default Configuration** again later, only the properties of the step function arguments are reset to default values.



In the **Configure model initialize and step functions** subpane:

Parameter	Description
Step function name	Name of the *`model`*`_step` function.
Initialize function name	Name of the *`model`*`_initialize` function. **Note:** A referenced model contains at least one initialization function. When the model is not built as a referenced model, this parameter controls the name of the function that initializes states to nonzero values. A model generates this function only if it contains such states or requires the function for some other less common reason. The code generator determines the names of the other initialization functions. When built as a referenced model, this parameter does not control the name of the `Model Initialize fcn for ModelReference Block`. The code generator determines the name of this function for referenced model builds.
Order	Order of the argument. A return argument is listed as `Return`.
Port Name	Name of the port.
Port Type	Type of the port.
Category	Specifies how an argument is passed in or out from the customized step function, either by copying a value (`Value`) or by a pointer to a memory space (`Pointer`).
Argument Name	Name of the argument.

Parameter	Description
Qualifier (optional)	Specifies a `const` type qualifier for a function argument. The available values are dependent on the **Category** specified. When you change the **Category**, if the specified type is not available, the **Qualifier** changes to `none`. The possible values are: • `none` • `const` (value) • `const*` (value referenced by the pointer) • `const*const` (value referenced by the pointer and the pointer itself) **Note:** When a model includes a referenced model, the `const` type qualifier for the root input argument of the referenced model's specified step function interface is set to `none`, and the qualifier for the source signal in the referenced model's parent is set to a value other than `none`, code generation honors the referenced model's interface specification by generating a type cast that discards the `const` type qualifier from the source signal. To override this behavior, add a `const` type qualifier to the referenced model.

The **Step function preview** subpane provides a preview of how your step function prototype is interpreted in generated code. The preview is updated dynamically as you make modifications.

An argument `foo` whose **Category** is `Pointer` is previewed as `* foo`. If its **Category** is `Value`, it is previewed as `foo`. Notice that argument types and qualifiers are not represented in the **Step function preview** subpane.

Note: The list of step function arguments has an entry for each of the model's root-level I/O ports. This list does not include model parameter arguments that can appear in the generated code when the model is used as a referenced model. For example, a model `sldemo_mdlref_counter_paramargs` has an inport with argument name `arg_input`, an outport with argument name `arg_output`, and a saturation block whose

limits have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`.

The step function preview for this model is:

```
sldemo_mdlref_counter_paramargs_custom ( arg__input, * arg_output )
```

The function prototype in the generated code differs from the preview. The prototype in the generated code (with the additional model parameter arguments) is:

```
sldemo_mdlref_counter_paramargs_custom(
   real_T arg__input,
   real_T *arg_output,
   real_T rtp_lower_saturation_limit,
   real_T rtp_upper_saturation_limit)
```

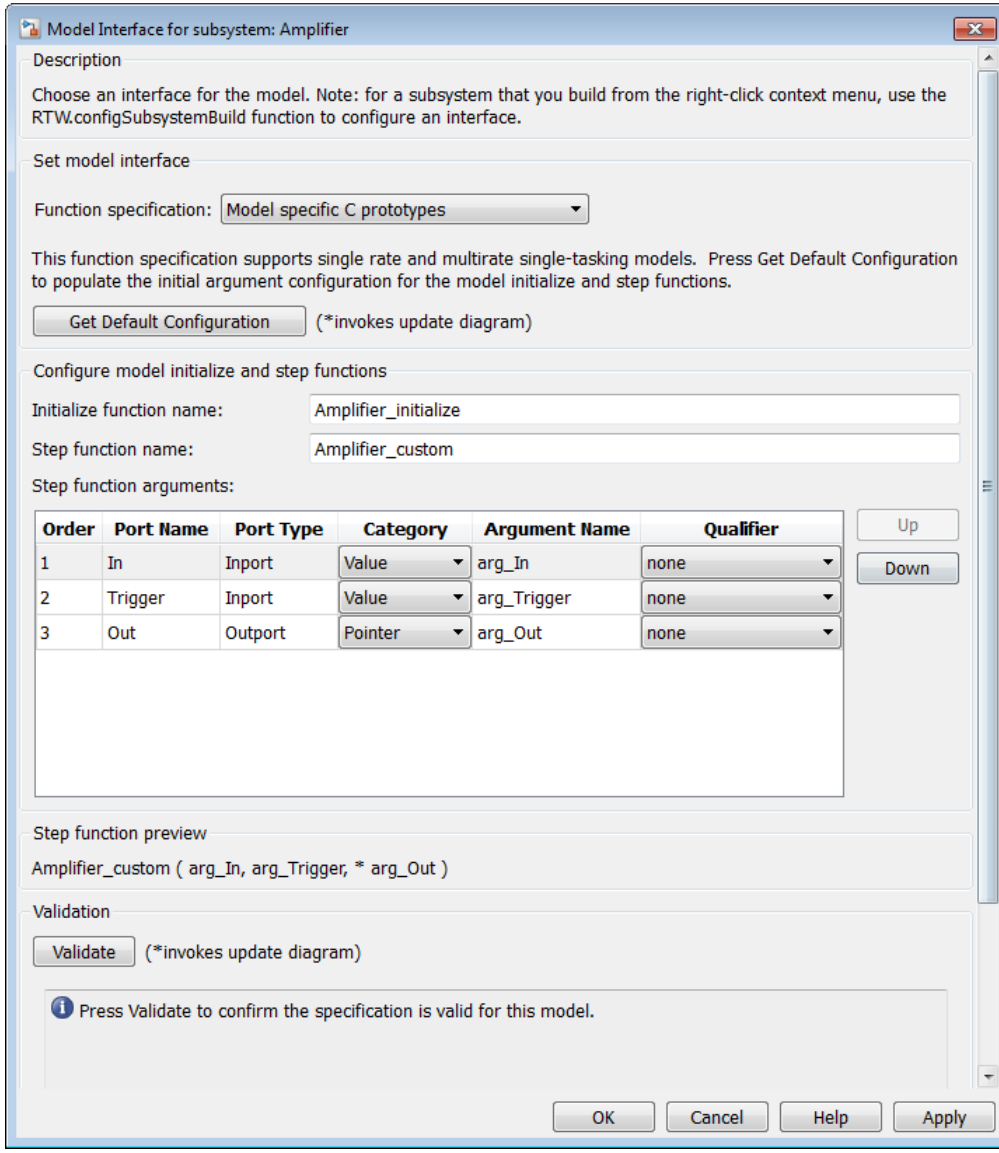
Configure Function Prototypes for Nonvirtual Subsystems

You can control step and initialization function prototypes for nonvirtual subsystems in ERT-based Simulink models, if you generate subsystem code using right-click build. Function prototype control is supported for the following types of nonvirtual blocks:

- Triggered subsystems
- Enabled subsystems
- Enabled trigger subsystems
- While subsystems
- For subsystems
- Stateflow blocks
- MATLAB function block

To launch the Model Interface for Subsystem dialog box, open the model containing the subsystem and invoke the `RTW.configSubsystemBuild` function.

The Model Interface dialog box for modifying the model-specific C prototypes for the `rtwdemo_counter/Amplifier` subsystem appears as follows:



Right-click building the subsystem generates the step and initialization functions according to the customizations you make.

Sample Procedure for Configuring Function Prototypes

The following procedure shows how to use the **Configure Model Functions** button on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box to control the model function prototypes when generating code for your Simulink model.

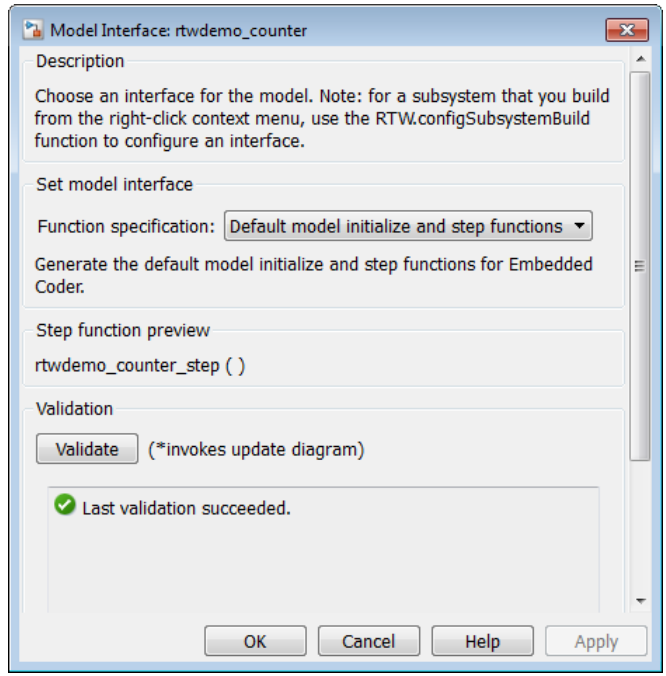
1. Open a MATLAB session and launch the `rtwdemo_counter` model.
2. In the `rtwdemo_counter` Model Editor, double-click the **Generate Code Using Embedded Coder (double-click)** button to generate code for an ERT-based version of `rtwdemo_counter`. The code generation report for `rtwdemo_counter` appears.
3. In the code generation report, click the link for `rtwdemo_counter.c`.
4. In the `rtwdemo_counter.c` code display, locate and examine the generated code for the `rtwdemo_counter_step` and the `rtwdemo_counter_initialize` functions:

   ```
   /* Model step function */
   void rtwdemo_counter_step(void)
   {
    ...
   }

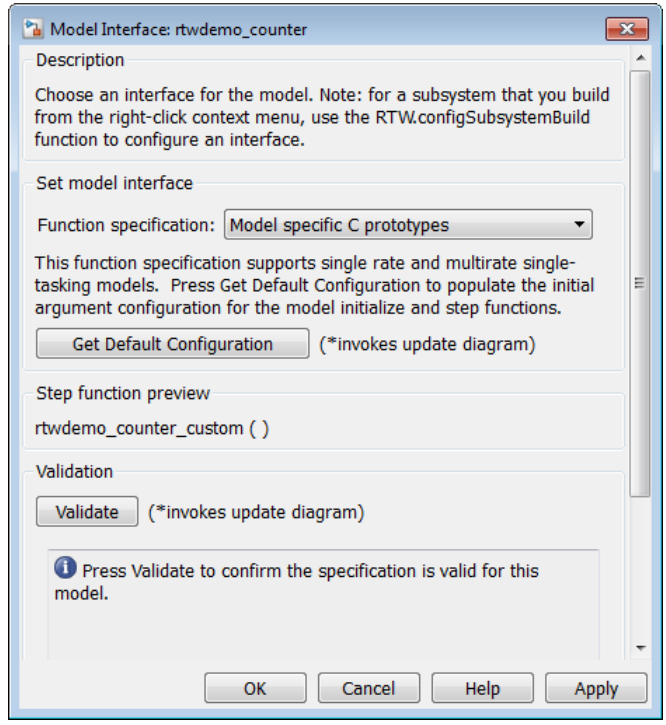
   /* Model initialize function */
   void rtwdemo_counter_initialize(void)
   {
    ...
   }
   ```

   You can close the report window after you have examined the generated code. Optionally, you can save `rtwdemo_counter.c` and other generated files to a different location for later comparison.
5. From the `rtwdemo_counter` model, open the Configuration Parameters dialog box.
6. Navigate to the **Code Generation** > **Interface** pane and click the **Configure Model Functions** button. The Model Interface dialog box appears.
7. In the initial (`Default model initialize and step functions`) view of the Model Interface dialog box, click the **Validate** button to validate and preview the default function prototype for the `rtwdemo_counter_step` function. The function prototype arguments under **Step function preview** should correspond to the default prototype in step 4.

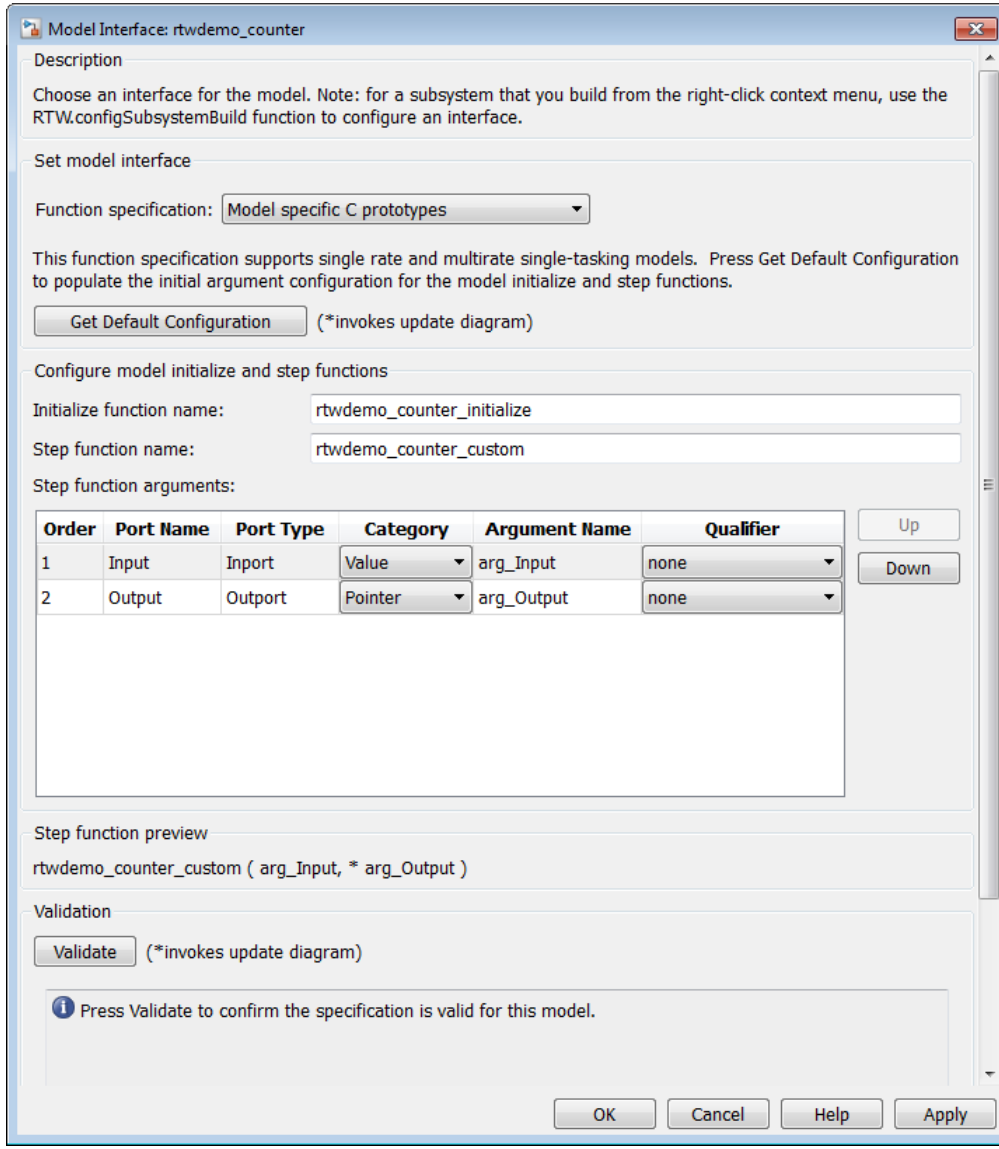
Note: Validation errors in this context prevent successful preview of the default function prototype. Resolve any validation errors to display the preview.



8 In the Model Interface dialog box, set **Function specification** field to `Model specific C prototypes`. Making this selection switches the dialog box from the `Default model initialize and step functions` view to the `Model specific C prototypes` view.

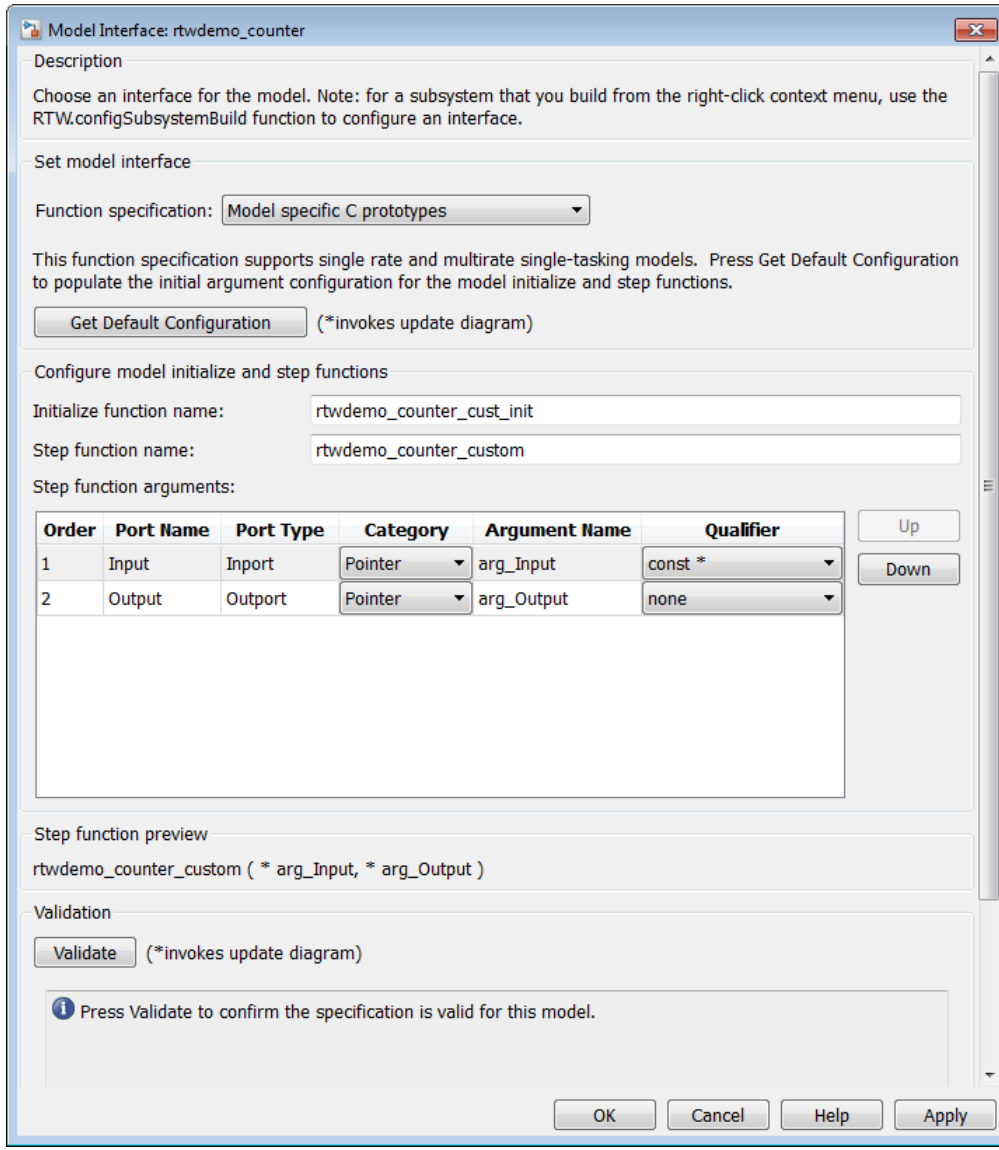


9 In the `Model specific C prototypes` view, click the **Get Default Configuration** button to activate the **Configure model initialize and step functions** subpane.



10 In the **Configure model initialize and step functions** subpane, change **Initialize function name** to `rtwdemo_counter_cust_init`.

11 In the **Configure model initialize and step functions** subpane, in the row for the `Input` argument, change the value of **Category** from `Value` to `Pointer` and change the value of **Qualifier** from `none` to `const *`. The preview reflects your changes.



12 Click the **Validate** button to validate the modified function prototype. The **Validation** subpane displays a message that the validation succeeded.

Note: Validation errors in this context prevent successful code generation. Resolve any validation errors before proceeding. Or, if resolution is not possible, set the **Function specification** field to `Default model initialize and step functions` before proceeding.

---

13 Click **OK** to exit the Model Interface dialog box.

14 Generate code for the model. When the build completes, the code generation report for `rtwdemo_counter` appears.

15 In the code generation report, click the link for `rtwdemo_counter.c`.

16 Locate and examine the generated code for the `rtwdemo_counter_custom` and `rtwdemo_counter_cust_init` functions:

```
/* Model step function */
void rtwdemo_counter_custom(const int32_T *arg_Input, int32_T *arg_Output)
{
 ...
}

 /* Model initialize function */
void rtwdemo_counter_cust_init(void)
{
 ...
}
```

17 Verify that the generated code is consistent with the function prototype modifications that you specified in the Model Interface dialog box.

Configure Function Prototypes Programmatically

You can use the function prototype control functions (listed in Function Prototype Control Functions), to programmatically control model function prototypes. Typical uses of these functions include:

- **Create and validate a new function prototype**

  1 Create a model-specific C function prototype with *`obj`* `= RTW.ModelSpecificCPrototype`, where *`obj`* returns a handle to a newly created, empty function prototype.

  2 Add argument configuration information for your model ports using RTW.ModelSpecificCPrototype.addArgConf.

3. Attach the function prototype to your loaded ERT-based Simulink model using RTW.ModelSpecificCPrototype.attachToModel.
4. Validate the function prototype using RTW.ModelSpecificCPrototype.runValidation.
5. If validation succeeds, save your model and then generate code using the `rtwbuild` function.

- **Modify and validate an existing function prototype**

  1. Get the handle to an existing model-specific C function prototype that is attached to your loaded ERT-based Simulink model with `obj = RTW.getFunctionSpecification(modelName)`, where `modelName` is a character vector specifying the name of a loaded ERT-based Simulink model, and `obj` returns a handle to a function prototype attached to the specified model.

     You can use other function prototype control functions on the returned handle only if the test `isa(obj,'RTW.ModelSpecificCPrototype')` returns 1. If the model does not have a function prototype configuration, the function returns `[]`. If the function returns a handle to an object of type `RTW.FcnDefault`, you cannot modify the existing function prototype.
  2. Use the `Get` and `Set` functions listed in Function Prototype Control Functions to test and reset such items as the function names, argument names, argument positions, argument categories, and argument type qualifiers.
  3. Validate the function prototype using RTW.ModelSpecificCPrototype.runValidation.
  4. If validation succeeds, save your model and then generate code using the `rtwbuild` function.

- **Create and validate a new function prototype, starting with default configuration information from your Simulink model**

  1. Create a model-specific C function prototype using `obj = RTW.ModelSpecificCPrototype`, where `obj` returns a handle to a newly created, empty function prototype.
  2. Attach the function prototype to your loaded ERT-based Simulink model using RTW.ModelSpecificCPrototype.attachToModel.
  3. Get default configuration information from your model using RTW.ModelSpecificCPrototype.getDefaultConf.

4. Use the `Get` and `Set` functions listed in Function Prototype Control Functions to test and reset such items as the function names, argument names, argument positions, argument categories, and argument type qualifiers.
5. Validate the function prototype using RTW.ModelSpecificCPrototype.runValidation.
6. If validation succeeds, save your model and then generate code using the `rtwbuild` function.

- **Reset the model function prototype to the default ERT function configuration** Create an object of the ERT default function signature. Reset the model function prototype and undo any custom settings, by calling the `RTW.FcnDefault` method, `attachToModel`, as follows:

  ```
  obj = RTW.FcnDefault;
  obj.attachToModel(model);
  ```
  `model` must be a loaded ERT-based model.

Note: You should not use the same model-specific C function prototype object across multiple models. If you do, changes that you make to the step and initialization function prototypes in one model are propagated to other models, which is usually not desirable.

Function Prototype Control Functions

Function	Description
RTW.ModelSpecificCPrototype.addArgConf	Add step function argument configuration information for Simulink model port to model-specific C function prototype
RTW.ModelSpecificCPrototype.attachToModel	Attach model-specific C function prototype to loaded ERT-based Simulink model
RTW.ModelSpecificCPrototype.getArgCategory	Get step function argument category for Simulink model port from model-specific C function prototype
RTW.ModelSpecificCPrototype.getArgName	Get step function argument name for Simulink model port from model-specific C function prototype

Function	Description
RTW.ModelSpecificCPrototype.getArgPosition	Get step function argument position for Simulink model port from model-specific C function prototype
RTW.ModelSpecificCPrototype.getArgQualifier	Get step function argument type qualifier for Simulink model port from model-specific C function prototype
RTW.ModelSpecificCPrototype.getDefaultConf	Get default configuration information for model-specific C function prototype from Simulink model to which it is attached
RTW.ModelSpecificCPrototype.getFunctionName	Get function names from model-specific C function prototype
RTW.ModelSpecificCPrototype.getNumArgs	Get number of step function arguments from model-specific C function prototype
RTW.ModelSpecificCPrototype.getPreview	Get model-specific C function prototype code previews
`RTW.configSubsystemBuild`	Launch GUI to configure C function prototype or C++ class interface for right-click build of specified subsystem
`RTW.getFunctionSpecification`	Get handle to model-specific C function prototype object
RTW.ModelSpecificCPrototype.runValidation	Validate model-specific C function prototype against Simulink model to which it is attached
RTW.ModelSpecificCPrototype.setArgCategory	Set step function argument category for Simulink model port in model-specific C function prototype
RTW.ModelSpecificCPrototype.setArgName	Set step function argument name for Simulink model port in model-specific C function prototype
RTW.ModelSpecificCPrototype.setArgPosition	Set step function argument position for Simulink model port in model-specific C function prototype

Function	Description
RTW.ModelSpecificCPrototype.setArgQualifier	Set step function argument type qualifier for Simulink model port in model-specific C function prototype
RTW.ModelSpecificCPrototype.setFunctionName	Set function names in model-specific C function prototype

Sample Script for Configuring Function Prototypes

The following sample MATLAB script configures the model function prototypes for the `rtwdemo_counter` model, using the Function Prototype Control Functions.

```
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Create a model-specific C function prototype
a=RTW.ModelSpecificCPrototype

%% Add argument configuration information for Input and Output ports
addArgConf(a,'Input','Pointer','inputArg','const *')
addArgConf(a,'Output','Pointer','outputArg','none')

%% Attach the model-specific C function prototype to the model
attachToModel(a,gcs)

%% Rename the initialization function
setFunctionName(a,'InitFunction','init')

%% Rename the step function and change some argument attributes
setFunctionName(a,'StepFunction','step')
setArgPosition(a,'Output',1)
setArgCategory(a,'Input','Value')
setArgName(a,'Input','InputArg')
setArgQualifier(a,'Input','none')

%% Validate the function prototype against the model
[status,message]=runValidation(a)

%% if validation succeeded, generate code and build
if status
    rtwbuild(gcs)
end
```

Verify Generated Code for Customized Functions

You can use software-in-the-loop (SIL) testing to verify the generated code for your customized step and initialization functions. This involves creating a SIL block with your generated code, which then can be integrated into a Simulink model to verify that the generated code provides the same result as the original model or nonvirtual subsystem. For more information, see "Choose a SIL or PIL Approach" on page 64-11.

Function Prototype Control Limitations

The following limitations apply to controlling model function prototypes:

- Function prototype control supports only step and initialization functions generated from a Simulink model.
- Function prototype control supports only single-instance implementations. For standalone targets, you must set **Code interface packaging** to `Nonreusable function` (on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box). For model reference targets, you must select `One` for the **Total number of instances allowed per top model** parameter (on the **Model Referencing** pane of the Configuration Parameters dialog box).
- For model reference targets, if **Code interface packaging** is set to `Reusable function`, the code generator ignores the setting.
- You must select the **Single output/update function** parameter (on the **All Parameters** tab of the Configuration Parameters dialog box).
- Function prototype control does not support multitasking models. Multirate models are supported, but you must configure the models for single-tasking.
- You must configure root-level inports and outports to use `Auto` storage classes.
- Do not control function prototypes with the static `ert_main.c` provided by MathWorks. Specifying a function prototype control configuration other than the default creates a mismatch between the generated code and the default static `ert_main.c`.
- The code generator removes the data structure for the root inports of the model unless a subsystem implemented by a nonreusable function uses the value of one or more of the inports.
- The code generator removes the data structure for the root outports of the model except when you enable MAT-file logging, or if the sample time of one or more of the outports is not the fundamental base rate (including a constant rate).

- If you copy a subsystem block and paste it to create a new block in either a new model or the same model, the function prototype control interface information from the original subsystem block does not copy to the new subsystem block.
- If you have a Stateflow license, for a Stateflow chart that uses a model root inport value, or that calls a subsystem that uses a model root inport value, you must do one of the following to generate code:
  - Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.
  - Make the Stateflow function a nonreusable function.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured for function prototype control, do not use virtual buses as inputs or outputs to the referenced model. When bus signals cross referenced model boundaries, use nonvirtual buses.
- If the C function prototype control is not the default, the value is ignored for the **Configuration Parameters > Model Referencing > Pass fixed-size scalar root inputs by value for code generation** parameter. For more information, see "Pass fixed-size scalar root inputs by value for code generation" (Simulink).

Control Generation of C++ Class Interfaces

Using the **Code interface packaging** (Simulink Coder) option `C++ class`, on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see "Configure C++ Class Interfaces for Nonvirtual Subsystems" on page 26-44.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an `ert.tlc` system target file provided by MathWorks.
2. Select the `C++` language for your model.
3. Select `C++ class` code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see "Simple Use of C++ Class Control" on page 26-24. For more details about configuring C++ class interfaces for your model code, see "Customize C++ Class Interfaces Using Graphical Interfaces" on page 26-31 and "Customize C++ Class Interfaces Programmatically" on page 26-45. For limitations that apply, see "C++ Class Interface Control Limitations" on page 26-50.

Note: For an example of C++ class code generation, see the example model `rtwdemo_cppclass`.

In this section...

In this section...

Simple Use of C++ Class Control

This example illustrates a simple use of `C++ class` code interface packaging. It generates C+ class code interfaces from an example model, without extensive modifications to default settings.

Note: For details about setting C++ class parameters, see the sections that follow this example, beginning with “Customize C++ Class Interfaces Using Graphical Interfaces” on page 26-31.

To generate C++ class interfaces for a Simulink model:

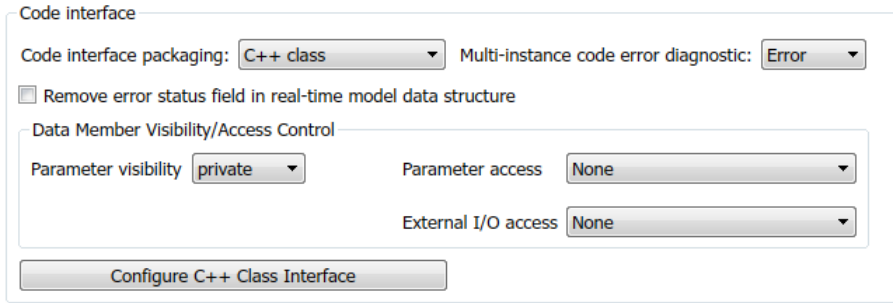
1. Open a model for which you would like to generate C++ class code interfaces. This example uses the model `rtwdemo_counter`.
2. Configure the model to use an `ert.tlc` system target file provided by MathWorks. For example, open the Configuration Parameters dialog box, go to the **Code Generation** pane, select a target value from the **System target file** menu, and click **Apply**.
3. On the **Code Generation** pane of the Configuration Parameters dialog box, set the **Language** parameter to `C++`.

   On the **Code Generation** > **Interface** pane, check that the **Code interface packaging** parameter is set to `C++ class`.

   
   Click **Apply**.

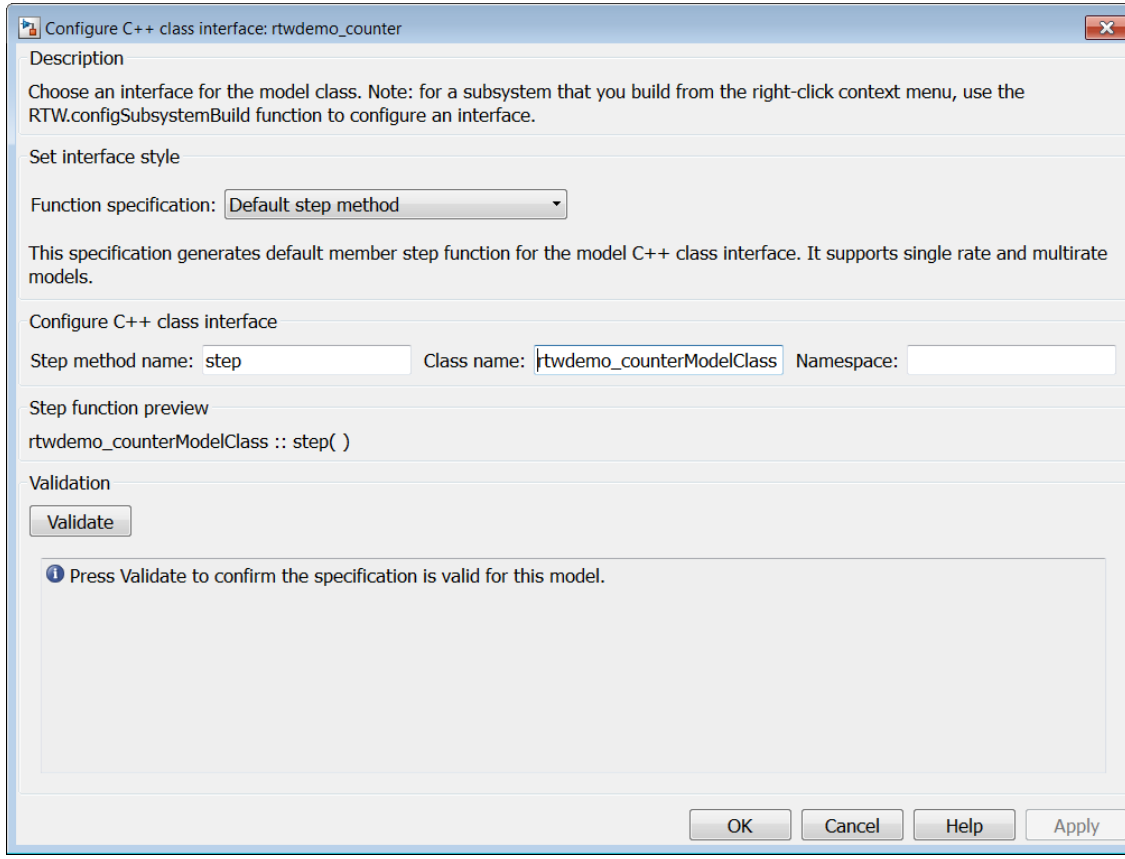
Note: To immediately generate the default style of C++ class code, without exploring the related model configuration options, skip steps 4–8 and go directly to step 9.

4 Go to the **Interface** pane of the Configuration Parameters dialog box and examine the **Code interface** subpane.



When you select `C++ class` code interface packaging for your model, additional C++ class interface controls become available in the **Code interface** subpane. See "Configure Code Interface Options" on page 26-31 for descriptions of these controls. You might want to modify the default settings according to your application.

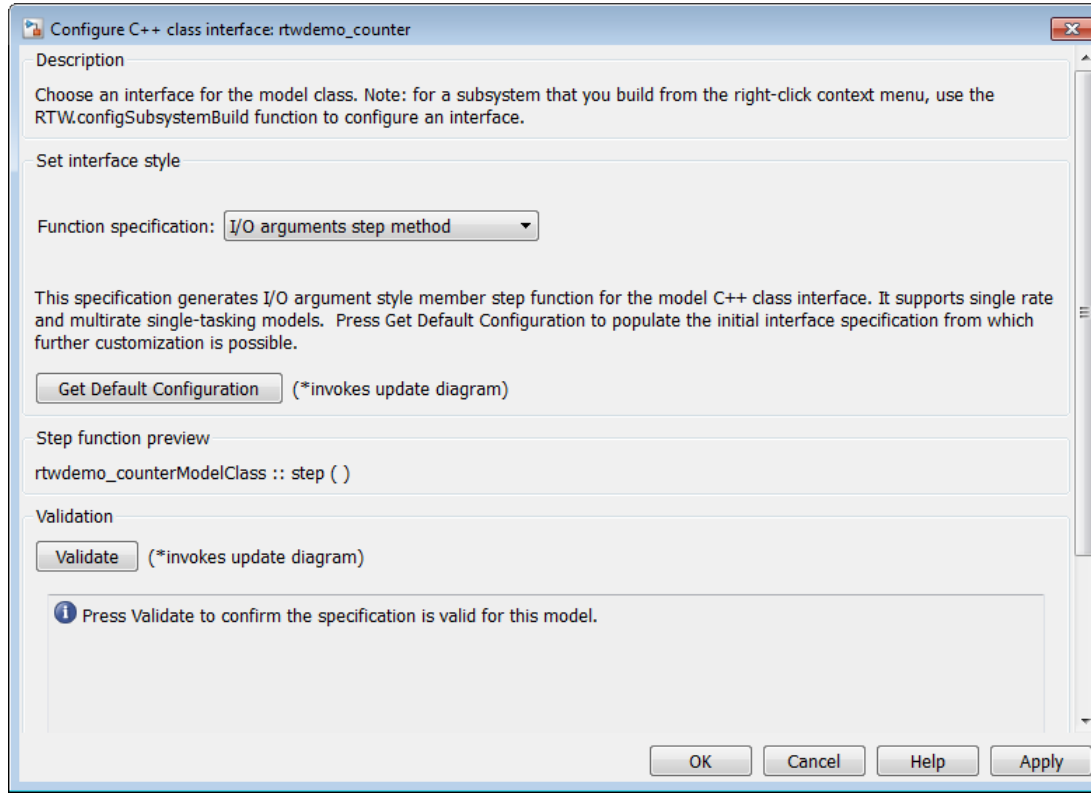
5 Click the **Configure C++ Class Interface** button. This action opens the Configure C++ class interface dialog box, which allows you to configure the step method for your generated model class. The dialog box initially displays a view for configuring a **Default step method** for the model class. In this view, you can specify the model class name, step method name, and namespace for your model.



See “Configure Step Method for Your Model Class” on page 26-34 for descriptions of these controls.

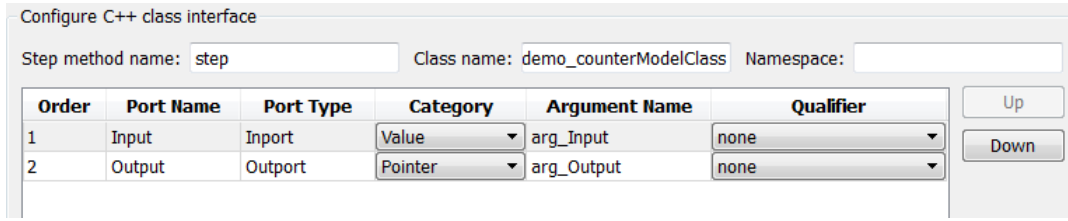
Note: If the default interface style meets your needs, you can skip steps 6–8 and go directly to step 9.

6 If you want root-level model input and output to be arguments on the step method, select the value `I/O arguments step method` from the **Function specification** menu. The dialog box displays a view for configuring an I/O arguments style step method for the model class.



See "Configure Step Method for Your Model Class" on page 26-34 for descriptions of these controls.

7 Click the **Get Default Configuration** button. This action causes a **Configure C ++ class interface** subpane to appear in the dialog box. The subpane displays the initial interface configuration for your model, which provides a starting point for further customization.



See "Passing I/O Arguments" on page 26-37 for descriptions of these controls.

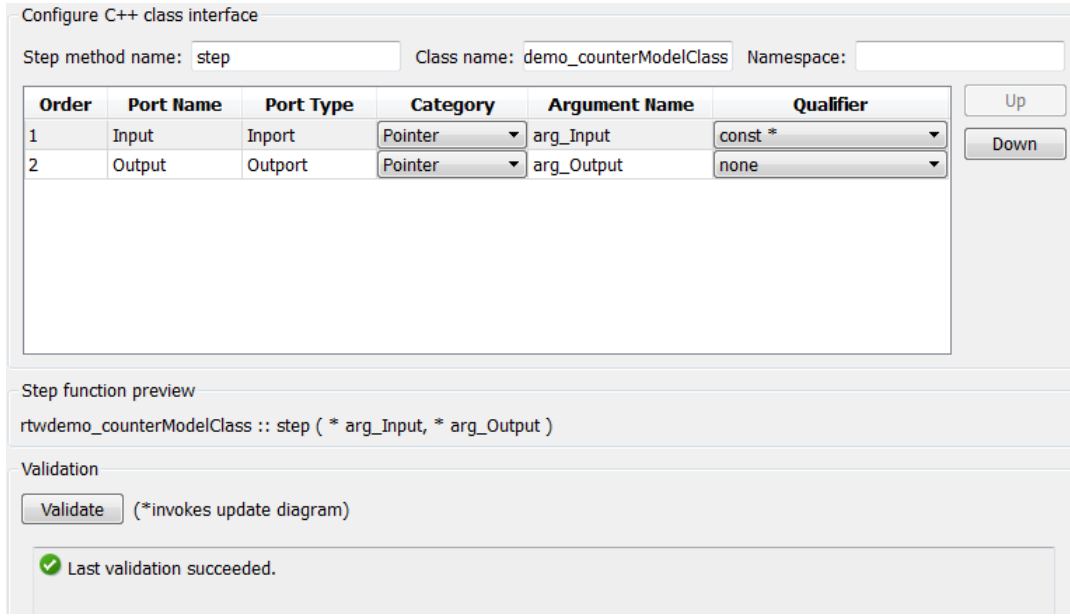
8 Perform this optional step only if you want to customize the configuration of the I/O arguments generated for your model step method.

Note: If you choose to skip this step, you should click **Cancel** to exit the dialog box.

If you choose to perform this step, first you must check that the required option **Remove root level I/O zero initialization** is selected on the **Optimization** pane, and then navigate back to the `I/O arguments step method` view of the Configure C++ class interface dialog box.

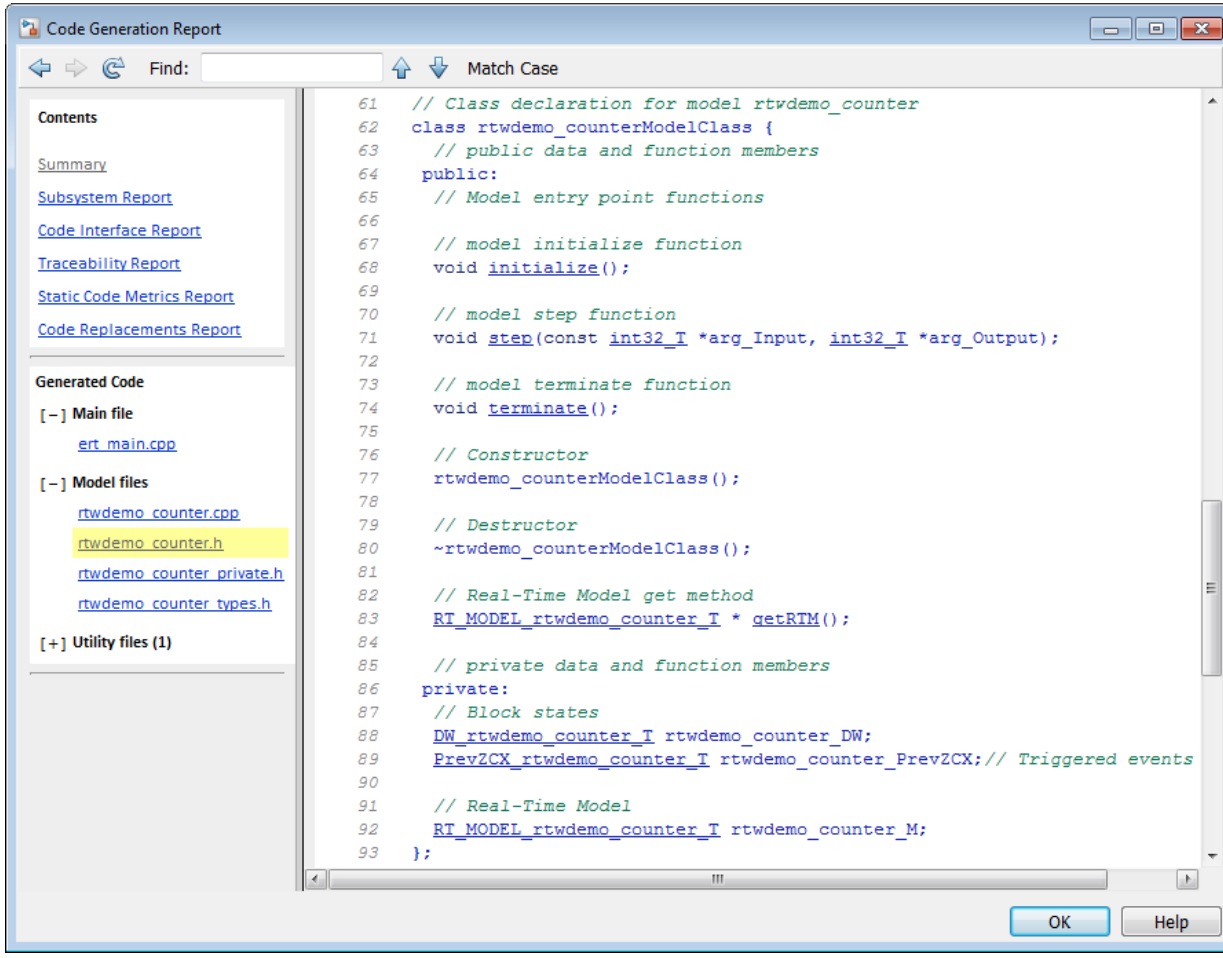
Now you can use the dialog box controls to configure I/O argument attributes. For example, in the **Configure C++ class interface** subpane, in the row for the `Input` argument, you can change the value of **Category** from `Value` to `Pointer` and change the value of **Qualifier** from `none` to `const *`. The preview updates to reflect your changes. Click the **Validate** button to validate the modified interface configuration.

Continue modifying and validating until you are satisfied with the step method configuration.



Click **Apply** and **OK**.

9 Generate code for the model. When the build completes, the code generation report for `rtwdemo_counter` appears. Examine the report and observe that required model data is encapsulated into C++ class attributes and model entry point functions are encapsulated into C++ class methods. For example, click the link for `rtwdemo_counter.h` to see the class declaration for the model.

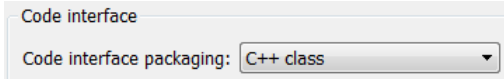


Note: If you configured custom I/O arguments for the model step method (optional step 8), examine the generated code for the step method in `rtwdemo_counter.h` and `rtwdemo_counter.cpp`. The arguments should reflect your changes. For example, if you performed the `Input` argument modifications in step 8, the input argument should appear as `const int32_T *arg_Input`.

Customize C++ Class Interfaces Using Graphical Interfaces

Select C++ Class Code Interface Packaging

To select `C++ class` code interface packaging, in the Configuration Parameters dialog box, on the **Code Generation** pane, set the **Language** parameter to `C++`. Then, in the **Code Generation** > **Interface** pane, check that the **Code interface packaging** parameter is set to `C++ class`:

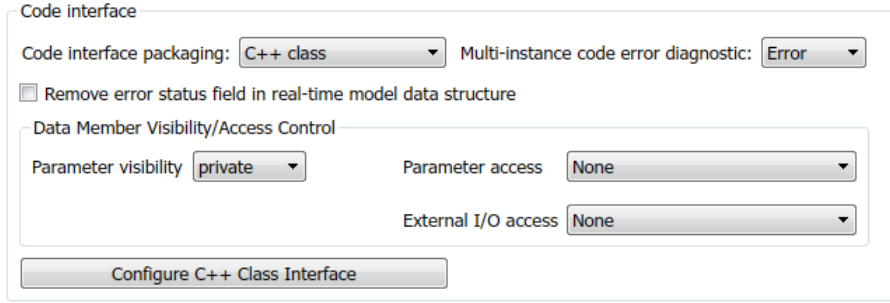


Selecting this value:

- Disables model configuration options that `C++ class` does not support. For details, see "C++ Class Interface Control Limitations" on page 26-50.
- Adds additional C++ class interface parameters, which are described in the next section.

Configure Code Interface Options

When you select `C++ class` code interface packaging for your model, the **Code interface** parameters shown below are displayed on the **Interface** pane.



- **Multi-instance code error diagnostic**

  Specifies the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

  - `None` — Proceed with build without displaying a diagnostic message.
  - `Warning` — Proceed with build after displaying a warning message.
  - `Error` (default) — Abort build after displaying an error message.

- **Remove error status field in real-time model data structure**

  Specifies whether to omit the error status field from the generated real-time model data structure `rtModel` (off by default). Selecting this option reduces memory usage.

  Be aware that selecting this option can cause the code generator to omit the `rtModel` data structure from generated code.

- **Parameter visibility**

  Specifies whether to generate the block parameter structure as a `public`, `private`, or `protected` data member of the C++ model class (`private` by default).

- **Parameter access**

  Specifies whether to generate access methods for block parameters for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).

- **External I/O access**

  Specifies whether to generate access methods for root-level I/O signals for the C++ model class (`None` by default). If you want to generate access methods, you have the following options:

  - Generate either noninlined or inlined access methods.
  - Generate either *per-signal* or *structure-based* access methods. That is, you can generate a series of set and get methods on a per-signal basis, or generate just one set method that takes the address of an external input structure as an argument and, for external outputs (if applicable), just one get method that returns a reference to an external output structure. The generated code for structure-based access methods has the following general form:

    ```
    class ModelClass {
    ...
    ```

```
    // Root inports set method
    void setExternalInputs(const ExternalInputs* pExternalInputs);

    // Root outports get method
    const ExternalOutputs & getExternalOutputs() const;
}
```

Note: This parameter affects generated code only if you are using the default style step method for your model class; *not* if you are explicitly passing arguments for root-level I/O signals using an I/O arguments style step method. For more information, see "Passing Default Arguments" on page 26-35 and "Passing I/O Arguments" on page 26-37.

- **Configure C++ Class Interface**

  Opens the Configure C++ class interface dialog box, which allows you to configure the step method for your model class. For more information, see "Configure Step Method for Your Model Class" on page 26-34.

Interface parameters that are related, but are less commonly used, are displayed in the **All Parameters** tab:

- **Terminate function required**

  Specifies whether to generate the *`model`*`_terminate` method (on by default). This function contains model termination code and should be called as part of system shutdown.

- **Combine signal/state structures**

  Specifies whether to combine global block signals and global state data into one data structure in the generated code (off by default). Selecting this option reduces RAM and improves readability of the generated code.

- **Internal data visibility**

  Specifies whether to generate internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, as `public`, `private`, or `protected` data members of the C++ model class (`private` by default).

- **Internal data access**

  Specifies whether to generate access methods for internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states,

for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).

- **Generate destructor**

  Specifies whether to generate a destructor for the C++ model class (on by default).

- **Use dynamic memory allocation for model block instantiation** (Simulink Coder)

  For a model containing Model blocks, specifies whether generated code should use dynamic memory allocation, during model object registration, to instantiate objects for referenced models configured with a C++ class interface (off by default). If you select this option, during instantiation of an object for the top model in a model reference hierarchy, the generated code uses the operator `new` to instantiate objects for referenced models.

  Selecting this option frees a parent model from having to maintain information about referenced models beyond its direct children. Clearing this option means that a parent model maintains information about its referenced models, including its direct and indirect children.

Note:

- If you select this option, be aware that a `bad_alloc` exception might be thrown, per the C++ standard, if an out-of-memory error occurs during the use

  of `new`. You must provide code to catch and process the `bad_alloc` exception in case an out-of-memory error occurs for a `new` call during construction of a top model object.

- If **Use dynamic memory allocation for model block instantiation** is selected and the base model contains a Model block, the build process might generate copy constructor and assignment operator functions in the private section of the model class. The purpose of the functions is to prevent pointer members within the model class from being copied by other code. For more information, see "Model Class Copy Constructor and Assignment Operator" on page 26-49.

Configure Step Method for Your Model Class

To configure the step method for your model class, on the **Code Generation > Interface** pane, click the **Configure C++ Class Interface** button, which is available when

you select `C++ class` code interface packaging for your model. This action opens the Configure C++ class interface dialog box, where you can configure the step method for your model class in either of two styles:

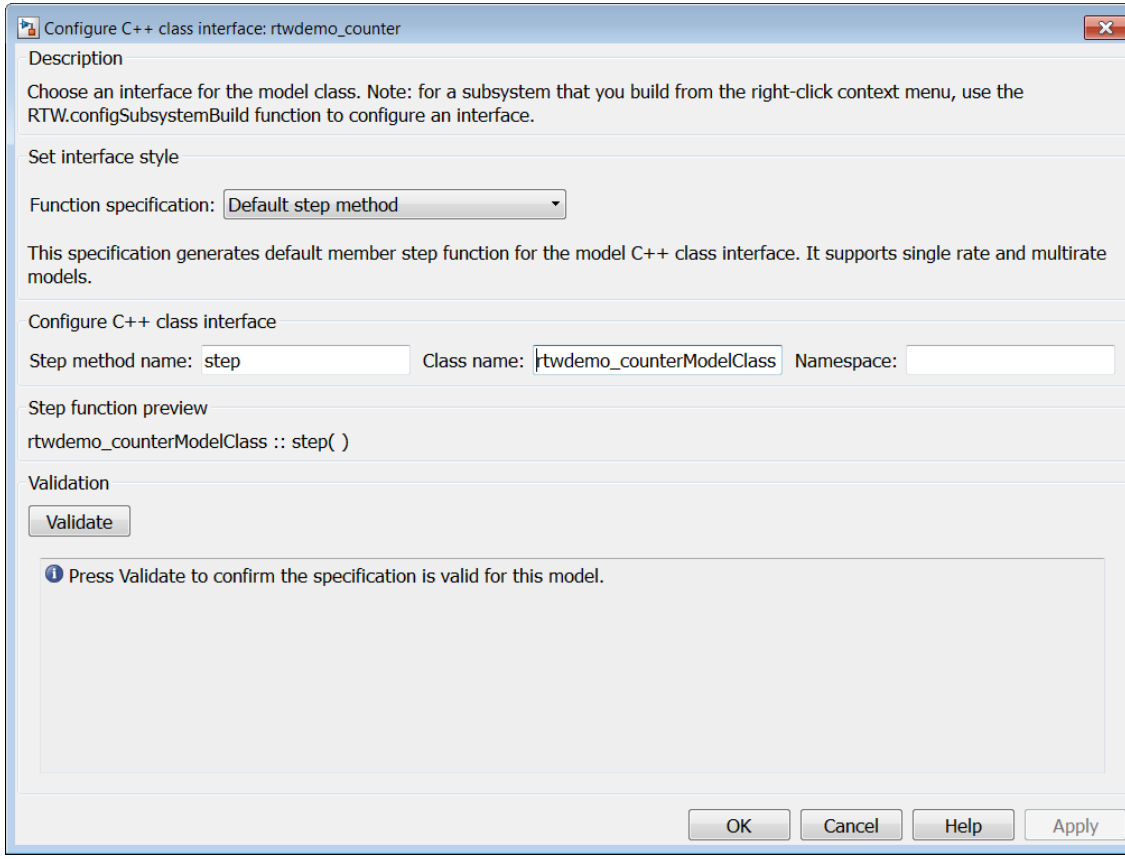
- "Passing Default Arguments" on page 26-35
- "Passing I/O Arguments" on page 26-37

Note: The **Default step method** supports single-rate models and multirate models. The model can be configured for single-tasking operation or multi-tasking operation. This method also supports virtual bus crossing boundaries.

The **I/O arguments step method** supports single-rate models and multirate models. The model can be configured for single-tasking operation.

Passing Default Arguments

The Configure C++ class interface dialog box initially displays a view for configuring a **Default step method** for the model class.



- **Step method name**

  Allows you to specify a step method name other than the default, `step`.

- **Class name**

  Allows you to specify a model class name other than the default, *`model`*`ModelClass`.

- **Namespace**

  Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Step function preview**

  Displays a preview of the model step function prototype as currently configured. The preview display is dynamically updated after you validate your current configuration.

  Note: The list of step function arguments has an entry for each of the model's root-level I/O ports. This list does not include model parameter arguments that can appear in the generated code when the model is used as a referenced model. For example, a model `sldemo_mdlref_counter_paramargs` has an inport with argument name `arg_input`, an outport with argument name `arg_output`, and a saturation block whose limits have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`.

  The step function preview for this model is:

  ```
  sldemo_mdlref_counter_paramargsModelClass :: step ( arg__input, * arg_output )
  ```

  The function prototype in the generated code differs from the preview. The prototype in the generated code (with the additional model parameter arguments) is:

  ```
  sldemo_mdlref_counter_paramargsModelClass::step (
     real_T arg__input,
     real_T *arg_output,
     real_T rtp_lower_saturation_limit,
     real_T rtp_upper_saturation_limit)
  ```

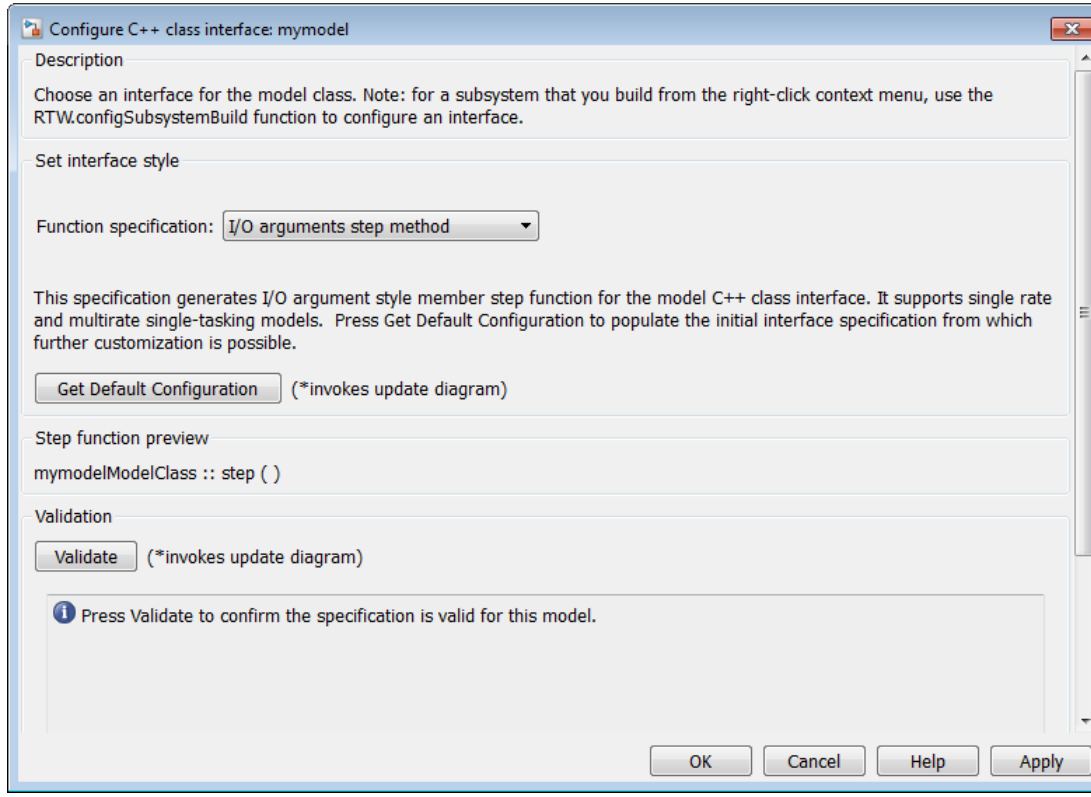
- **Validate**

  Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of any failure.

Passing I/O Arguments

If you select `I/O arguments step method` from the **Function specification** menu, the dialog box displays a view for configuring an I/O arguments style step method for the model class.

Note: To use the I/O arguments style step method, you must select the option **Remove root level I/O zero initialization** on the **Optimization** pane of the Configuration Parameters dialog box.



- **Get Default Configuration**

  Click this button to get the initial interface configuration that provides a starting point for further customization.

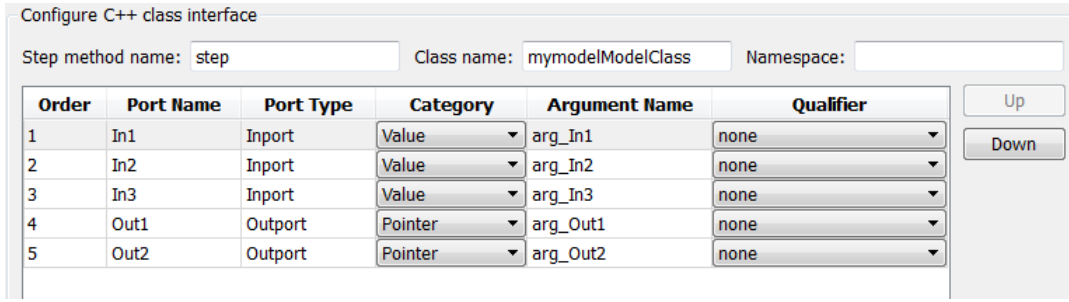
- **Step function preview**

  Displays a preview of the model step function prototype as currently configured. The preview dynamically updates as you make configuration changes.

- **Validate**

  Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of any failure.

When you click **Get Default Configuration**, the **Configure C++ class interface** subpane appears in the dialog box, displaying the initial interface configuration. For example:



- **Step method name**

  Allows you to specify a step method name other than the default, `step`.

- **Class name**

  Allows you to specify a model class name other than the default, *`model`*`ModelClass`.

- **Namespace**

  Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Order**

  Displays the numerical position of each argument. Use the **Up** and **Down** buttons to change argument order.

- **Port Name**

  Displays the port name of each argument (not configurable using this dialog box).

- **Port Type**

  Displays the port type, `Inport` or `Outport`, of each argument (not configurable using this dialog box).

- **Category**

Displays the passing mechanism for each argument. To change the passing mechanism for an argument, select `Value`, `Pointer`, or `Reference` from the argument's **Category** menu.

- **Argument Name**

  Displays the name of each argument. To change an argument name, click in the argument's **Argument name** field, position the cursor for text entry, and enter the new name.

- **Qualifier**

  Displays the `const` type qualifier for each argument. To change the qualifier for an argument, select an available value from the argument's **Qualifier** menu. The possible values are:

  - `none`
  - `const` (value)
  - `const*` (value referenced by the pointer)
  - `const*const` (value referenced by the pointer and the pointer itself)
  - `const &` (value referenced by the reference)

Tip: When a model includes a referenced model, the `const` type qualifier for the root input argument of the referenced model's specified step function interface is set to `none` and the qualifier for the source signal in the referenced model's parent is set to a value other than `none`, code generation honors the referenced model's interface specification by generating a type cast that discards the `const` type qualifier from the source signal. To override this behavior, add a `const` type qualifier to the referenced model.

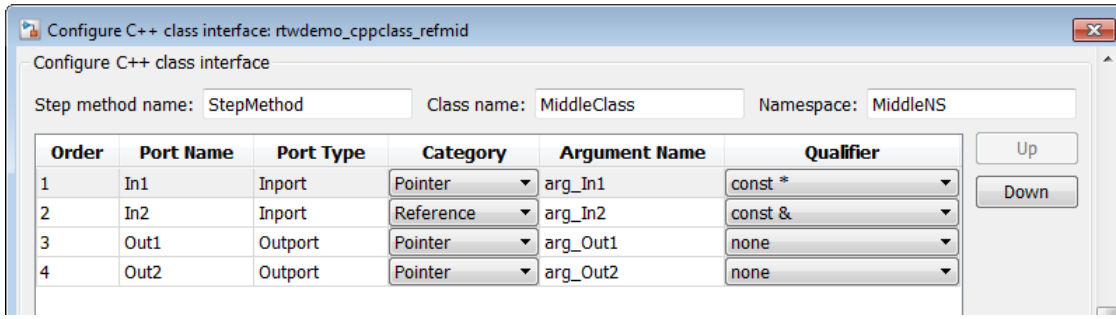
Use Namespaces to Scope C++ Model Classes

Embedded Coder provides namespace control for scoping model classes generated using C++ class code interface packaging. In the Configure C++ class interface dialog box, use the **Namespace** parameter to specify a namespace for a model class. If specified, the namespace is emitted in the generated code for the model class. To scope the C++ model classes in a model reference hierarchy, you can specify a different namespace for each referenced model.

For an example of namespace control, see the example model rtwdemo_cppclass. This model assigns namespaces as follows:

- `TopNS` for top-level model `rtwdemo_cppclass`
- `MiddleNS` for referenced model `rtwdemo_cppclass_refmid`
- `BottomNS` for referenced model `rtwdemo_cppclass_refbot`

If you build the model with its default settings, you can examine the generated header and source files for each model to see where the namespace is emitted. For example, the **Namespace** setting for the model `rtwdemo_cppclass_refmid` is shown below, followed by excerpts of the emitted namespace code in the model header and source files.



```
42   // Class declaration for model rtwdemo_cppclass_refmid
43   namespace MiddleNS {
44     class MiddleClass {
45       // public data and function members
46      public:
47       // Model entry point functions
...
52       // model step function
53       void StepMethod(const real_T *arg_In1, const real_T &arg_In2, real_T
54                       *arg_Out1, real_T *arg_Out2);
...
87     };
88   }
```

```
15   #include "rtwdemo_cppclass_refmid.h"
16   #include "rtwdemo_cppclass_refmid_private.h"
17
18   namespace MiddleNS
19   {
20     // Model step function
21     void MiddleClass::StepMethod(const real_T *arg_In1, const real_T &arg_In2,
22       real_T *arg_Out1, real_T *arg_Out2)
```

```
23      {
...
43      }
...
83    }
```

Combine I/O Arguments in Model Step Interface

When using C function prototype control or C++ class interface control, you can combine a pair of model step function arguments, an input and an output. This merging of input and output allows the code generator to reuse buffers, which can eliminate buffers in the generated code.

The following requirements apply to combining model step function input and output arguments:

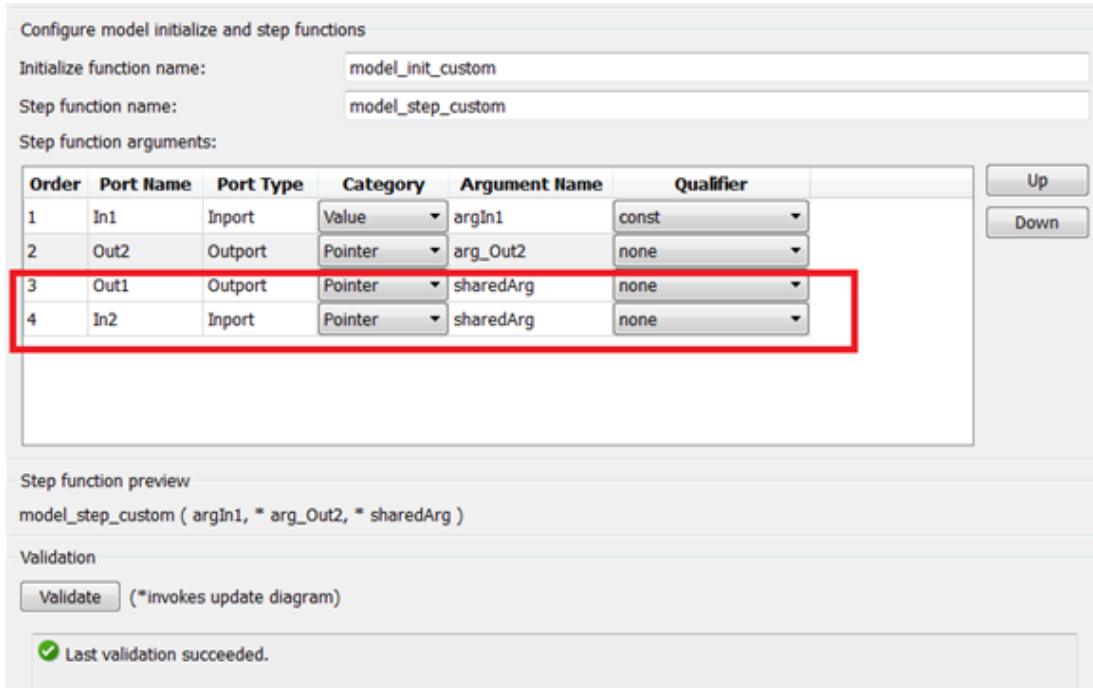
- The input and output arguments must be assigned the same argument name.
- The corresponding inport and outport blocks must have the same data type and sampling rate.

Additionally, the following limitations apply to combining model step function input and output arguments:

- The sample rate of the inport and outport blocks must be the same as the base rate of the model.
- A conditionally executed subsystem cannot drive the outport.
- A single, nonvirtual block output must drive the outport. For example, a Mux block, which merges multiple buffers, cannot drive the outport.

To configure model step function I/O arguments to allow buffer reuse:

1. In the Configuration Parameters dialog box, select the **Code Generation** > **Interface** pane. To initiate C function prototype control, click the **Configure Model Functions** button. To initiate C++ class interface control, click the **Configure C++ Class Interface** button.
2. Navigate to the view that allows you to modify model step function I/O arguments – **Model specific C prototypes** view for C function prototype control or **I/O arguments step method** for C++ class interface control.
3. Select an inport/outport pair, configure their **Category** and **Argument Name** settings to match, and make sure that **Category** is not set to `Value`. Set **Qualifier** to `none` for both ports.



When you generate code from the model, the arguments are combined in the function prototype. For example:

```
35 // Model step function
36 void model_step_custom(const real_T argIn1, boolean_T *arg_Out2, boolean_T
37   *sharedArg)
38 {
```

The shared argument appears in inport read code and outport write code. For example:

```
54
55    *arg_Out2 = !*sharedArg;
56
57    // Update for UnitDelay: '<Root>/Unit Delay' incorporates:
58    //   Update for Inport: '<Root>/In1'
59
60    rtDWork.UnitDelay_DSTATE = argIn1;
61
62    // Logic: '<Root>/LogOp'
63    *sharedArg = (rtb_RelOp1 || rtb_RelOp2);
64  }
```

Configure C++ Class Interfaces for Nonvirtual Subsystems

You can configure C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the `C++` language and `C++ class` code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

1. Open the containing model and select the subsystem block.
2. Enter the following MATLAB command:

   ```
   RTW.configSubsystemBuild(gcb)
   ```

   where `gcb` is the Simulink function `gcb`, returning the full block path name of the current block.

   This command opens a subsystem equivalent of the Configure C++ class interface dialog sequence that is described in detail in the preceding section, “Configure Step Method for Your Model Class” on page 26-34. (For more information about using the MATLAB command, see `RTW.configSubsystemBuild`.)
3. Use the Configure C++ class interface dialog boxes to configure C++ class settings for the subsystem.
4. Right-click the subsystem and select **C/C++ Code** > **Build This Subsystem**.

5 When the subsystem build completes, you can examine the C++ class interfaces in the generated files and the HTML code generation report.

Customize C++ Class Interfaces Programmatically

If you select the **Code interface packaging** option `C++ class` for your model, you can use the C++ class interface control functions (listed in C++ Class Interface Control Functions) to programmatically configure the step method for your model class.

Typical uses of these functions include:

- **Create and validate a new step method interface, starting with default configuration information from your Simulink model**

  1 Create a model-specific C++ class interface with `obj = RTW.ModelCPPDefaultClass` or `obj = RTW.ModelCPPArgsClass`, where `obj` returns a handle to an newly created, empty C++ class interface.

  2 Attach the C++ class interface to your loaded ERT-based Simulink model using `attachToModel`.

  3 Get default C++ class interface configuration information from your model using `getDefaultConf`.

  4 Use the `Get` and `Set` functions listed in C++ Class Interface Control Functions to test or reset the model class name and model step method name. Additionally, if you are using the I/O arguments style step method, you can test and reset argument names, argument positions, argument categories, and argument type qualifiers.

  5 Validate the C++ class interface using `runValidation`. (If validation fails, use the error message information that`runValidation` returns to address the issues.)

  6 Save your model and then generate code using the `rtwbuild` function.

- **Modify and validate an existing step method interface for a Simulink model**

  1 Get the handle to an existing model-specific C++ class interface that is attached to your loaded ERT-based Simulink model using `obj = RTW.getClassInterfaceSpecification(modelName)`, where `modelName` is a character vector specifying the name of a loaded ERT-based Simulink model, and `obj` returns a handle to a C++ class interface attached to the specified model. If the model does not have an attached C++ class interface configuration, the function returns `[]`.

2. Use the `Get` and `Set` functions listed in C++ Class Interface Control Functions to test or reset the model class name and model step method name. Additionally, if the returned interface uses the I/O arguments style step method, you can test and reset argument names, argument positions, argument categories, and argument type qualifiers.
3. Validate the C++ class interface using `runValidation`. (If validation fails, use the error message information that `runValidation` returns to address the issues.)
4. Save your model and then generate code using the `rtwbuild` function.

Note: You should not use the same model-specific C++ class interface control object across multiple models. If you do, changes that you make to the step method configuration in one model propagate to other models, which is usually not desirable.

C++ Class Interface Control Functions

Function	Description
`attachToModel`	Attach model-specific C++ class interface to loaded ERT-based Simulink model
`getArgCategory`	Get argument category for Simulink model port from model-specific C++ class interface
`getArgName`	Get argument name for Simulink model port from model-specific C++ class interface
`getArgPosition`	Get argument position for Simulink model port from model-specific C++ class interface
`getArgQualifier`	Get argument type qualifier for Simulink model port from model-specific C++ class interface
`getClassName`	Get class name from model-specific C++ class interface
`getDefaultConf`	Get default configuration information for model-specific C++ class interface from Simulink model to which it is attached
`getNamespace`	Get namespace from model-specific C++ class interface
`getNumArgs`	Get number of step method arguments from model-specific C++ class interface
`getStepMethodName`	Get step method name from model-specific C++ class interface

Function	Description
`RTW.configSubsystemBuild`	Open GUI to configure C function prototype or C++ class interface for right-click build of specified subsystem
`RTW.getClass-InterfaceSpecification`	Get handle to model-specific C++ class interface control object
`runValidation`	Validate model-specific C++ class interface against Simulink model to which it is attached
`setArgCategory`	Set argument category for Simulink model port in model-specific C++ class interface
`setArgName`	Set argument name for Simulink model port in model-specific C++ class interface
`setArgPosition`	Set argument position for Simulink model port in model-specific C++ class interface
`setArgQualifier`	Set argument type qualifier for Simulink model port in model-specific C++ class interface
`setClassName`	Set class name in model-specific C++ class interface
`setNamespace`	Set namespace in model-specific C++ class interface
`setStepMethodName`	Set step method name in model-specific C++ class interface

Configure Step Method for Model Class

The following sample MATLAB script configures the step method for the `rtwdemo_counter` model class, using the C++ Class Interface Control Functions.

```
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Select C++ as the target language for the model
set_param(gcs,'TargetLang','C++')

%% Select C++ class as the code interface packaging for the model
set_param(gcs,'CodeInterfacePackaging','C++ class')

%% Set required option for I/O arguments style step method (cmd off = GUI on)
set_param(gcs,'ZeroExternalMemoryAtStartup','off')

%% Create a C++ class interface using an I/O arguments style step method
a=RTW.ModelCPPArgsClass
```

```
%% Attach the C++ class interface to the model
attachToModel(a,gcs)

%% Get the default C++ class interface configuration from the model
getDefaultConf(a)

%% Move the Output port argument from position 2 to position 1
setArgPosition(a,'Output',1)

%% Reset the model step method name from step to StepMethod
setStepMethodName(a,'StepMethod')

%% Change the Input port argument name, category, and qualifier
setArgName(a,'Input','inputArg')
setArgCategory(a,'Input','Pointer')
setArgQualifier(a,'Input','const *')

%% Validate the function prototype against the model
[status,message]=runValidation(a)

%% if validation succeeded, generate code and build
if status
    rtwbuild(gcs)
end
```

Specify Custom Storage Class for C++ Class Code Generation

To configure a Simulink parameter, signal, or state to use a custom storage class (CSC) with C++ class code generation:

1. Open an ERT-based model for which **Language** is set to `C++` and **Code interface packaging** is set to `C++ class`.
2. Open the Configuration Parameters dialog box.
3. On the **Code Generation** > **Interface** pane, set the **Multi-instance code error diagnostic** (Simulink Coder) parameter to a value other than `Error`.

4. On the **All Parameters** tab, if the option **Ignore custom storage classes** is selected, clear the option.

   Apply the changes.
5. In the model, select a custom storage class for a parameter, signal, or state. For example, select a signal, open its Properties dialog box, and view its code generation

options. In the **Storage class** drop-down list, select a custom storage class, and then configure its attributes. Apply the changes.

Note: C++ class code generation does not support the following CSCs:

- CSCs with `Volatile` specifications.
- CSCs of type `Other`, except `GetSet`.

---

6 Build the model.

7 In the code generation report, examine the files *`model`*`.h` and *`model`*`.cpp` to observe the use of CSCs in the generated C++ code.

Model Class Copy Constructor and Assignment Operator

Code generation automatically adds a copy constructor and an assignment operator to C++ class declarations when required to securely handle pointer members. The constructor and operator are added as private member functions when both of the following conditions exist:

- The model option **Use dynamic memory allocation for model block instantiation** (Simulink Coder) is set to `on`.
- The base model contains a Model block. The Model block is not directly or indirectly within a subsystem for which **Function packaging** is set to `Reusable function`.

Under these conditions, the software generates a private copy constructor and assignment operator to prevent pointer members within the model class from being copied by other code.

Note: To prevent generation of these functions, consider clearing the option **Use dynamic memory allocation for model block instantiation**.

The code excerpt below shows generated *`model`*`.h` code for a model class that has a pointer member. (Look for instances of `MiddleClass_ptr`). The copy constructor and assignment operator declarations are shown in **bold**.

```
class MiddleClass;    // class forward declaration for <S1>/Bottom model instance
typedef MiddleClass* MiddleClass_ptr;
```

```
...

// Class declaration for model cppclass_top
class Top {
...
  // private data and function members
 private:
  // Block signals
  BlockIO_cppclass_top cppclass_top_B;

  // Block states
  D_Work_cppclass_top cppclass_top_DWork;

  // Real-Time Model
  RT_MODEL_cppclass_top cppclass_top_M;

  // private member function(s) for subsystem '<Root>/Subsystem'
  void cppclass_top_Subsystem_Init();
  void cppclass_top_Subsystem_Start();
  void cppclass_top_Subsystem();

  //Copy Constructor
  Top(const Top &rhs);

  //Assignment Operator
  Top& operator= (const Top &rhs);

  // model instance variable for '<S1>/Bottom model instance'
  MiddleClass_ptr Bottom_model_instanceMDLOBJ1;
};
```

C++ Class Interface Control Limitations

- The `C++ class` code interface packaging option does not support some Simulink model configuration options. Selecting `C++ class` disables the following items in the Configuration Parameters dialog box:
  - **Identifier format control** subpane on the **Symbols** pane
  - **File customization template** parameter on the **Templates** pane

  ---

  Note: The code and data templates on the **Templates** pane are supported for `C++ class` code generation. However, the following template file features that are supported for other language selections are not supported for C++ class generated code:

  - Free-form text outside template sections
  - Custom tokens

    - TLC commands (`<! >` tokens)

  - **Global data placement (custom storage classes only)** subpane on the **Code Placement** pane
  - **Memory Sections** pane
- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for `C++ class` code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- The I/O arguments style of step method specification supports single-rate models and multirate single-tasking models, but not multirate multitasking models.
- If you have a Stateflow license, for a Stateflow chart that resides in a root model configured to use the `I/O arguments step method` function specification, and that uses a model root inport value or calls a subsystem that uses a model root inport value, you must do one of the following to generate code:
  - Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured to generate a C++ class interface:
  - Do not use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that has a continuous sample time or saves states.
  - Do not use virtual buses as inputs or outputs to the referenced model when the referenced model uses the I/O arguments step method. When bus signals cross referenced model boundaries, either use nonvirtual buses or use the Default step method.
- If the C++ encapsulation interface is not the default, the value is ignored for the **Configuration Parameters** > **Model Referencing** > **Pass fixed-size scalar root**

inputs by value for code generation parameter. For more information, see "Pass fixed-size scalar root inputs by value for code generation" (Simulink).

Combine I/O Arguments in Model Step Interface

When using C function prototype control or C++ class interface control, you can combine a pair of model step function arguments, an input and an output. This merging of input and output allows the code generator to reuse buffers, which can eliminate buffers in the generated code.

The following requirements apply to combining model step function input and output arguments:

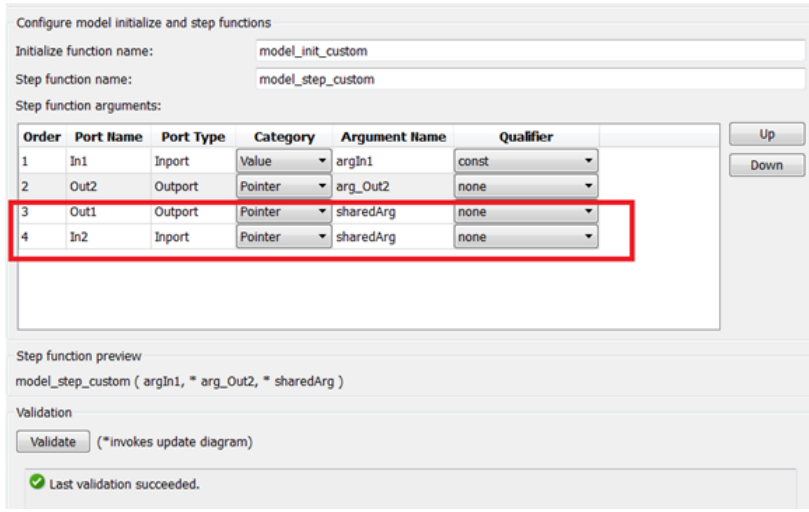
- The input and output arguments must be assigned the same argument name.
- The corresponding inport and outport blocks must have the same data type and sampling rate.

Additionally, the following limitations apply to combining model step function input and output arguments:

- The sample rate of the inport and outport blocks must be the same as the base rate of the model.
- A conditionally executed subsystem cannot drive the outport.
- A single, nonvirtual block output must drive the outport. For example, a Mux block, which merges multiple buffers, cannot drive the outport.

To configure model step function I/O arguments to allow buffer reuse:

1. In the Configuration Parameters dialog box, select the **Code Generation** > **Interface** pane. To initiate C function prototype control, click the **Configure Model Functions** button. To initiate C++ class interface control, click the **Configure C++ Class Interface** button.
2. Navigate to the view that allows you to modify model step function I/O arguments – **Model specific C prototypes** view for C function prototype control or **I/O arguments step method** for C++ class interface control.
3. Select an inport/outport pair, configure their **Category** and **Argument Name** settings to match, and make sure that **Category** is not set to `Value`. Set **Qualifier** to `none` for both ports.



When you generate code from the model, the arguments are combined in the function prototype. For example:

```
// Model step function
void model_step_custom(const real_T argIn1, boolean_T *arg_Out2, boolean_T
  *sharedArg)
{
```

The shared argument appears in inport read code and outport write code. For example:

```

  *arg_Out2 = !*sharedArg;

  // Update for UnitDelay: '<Root>/Unit Delay' incorporates:
  //   Update for Inport: '<Root>/In1'

  rtDWork.UnitDelay_DSTATE = argIn1;

  // Logic: '<Root>/LogOp'
  *sharedArg = (rtb_RelOp1 || rtb_RelOp2);
}
```

Generate Modular Function Code

The Embedded Coder software provides a Subsystem Parameters dialog box option, **Function with separate data**, that allows you to generate modular function code for nonvirtual subsystems, including atomic subsystems and conditionally executed subsystems.

By default, the generated code for a nonvirtual subsystem does not separate a subsystem's internal data from the data of its parent Simulink model. This can make it difficult to trace and test the code, particularly for nonreusable subsystems. Also, in large models containing nonvirtual subsystems, data structures can become large and potentially difficult to compile.

About Nonvirtual Subsystem Code Generation

Function with separate data allows you to generate subsystem function code in which the internal data for a nonvirtual subsystem is separated from its parent model and is owned by the subsystem. The subsystem data structure is declared independently from the parent model data structures. A subsystem with separate data has its own block I/O and `DWork` data structure. As a result, the generated code for the subsystem is easier to trace and test. The data separation also tends to reduce the maximum size of global data structures throughout the model, because they are split into multiple data structures.

To use the **Function with separate data** parameter,

- Your model must use an ERT-based system target file (requires a Embedded Coder license).
- Your subsystem must be configured to be atomic or conditionally executed. For more information, see "Systems and Subsystems" (Simulink).
- Your subsystem must use the `Nonreusable function` setting for **Code Generation** > **Function packaging**.

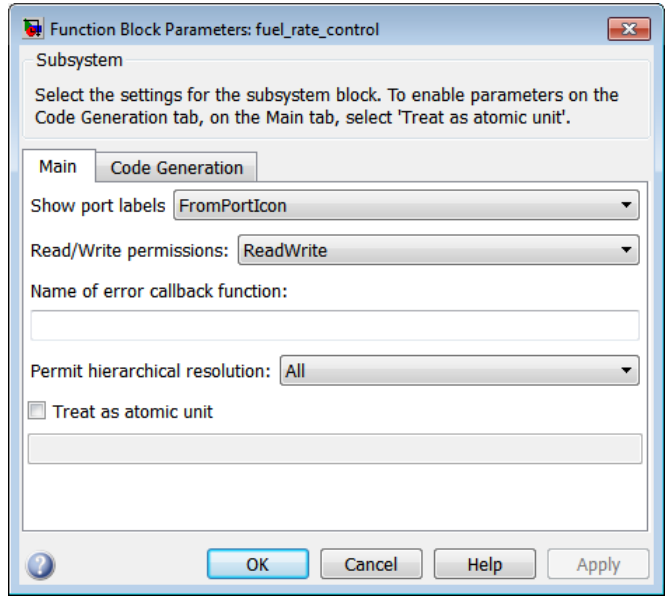
To configure your subsystem for generating modular function code, you invoke the Subsystem Parameters dialog box and make a series of selections to display and enable the **Function with separate data** option. See "Configure Subsystem for Generating Modular Function Code" on page 26-56 and "Modular Function Code for Nonvirtual Subsystems" on page 26-60 for details. For limitations that apply, see "Nonvirtual Subsystem Modular Function Code Limitations" on page 26-66.

For more information about generating code for atomic subsystems, see the sections "Code Generation of Subsystems" (Simulink Coder) and "Generate Code and Executables for Individual Subsystem" (Simulink Coder).

Configure Subsystem for Generating Modular Function Code

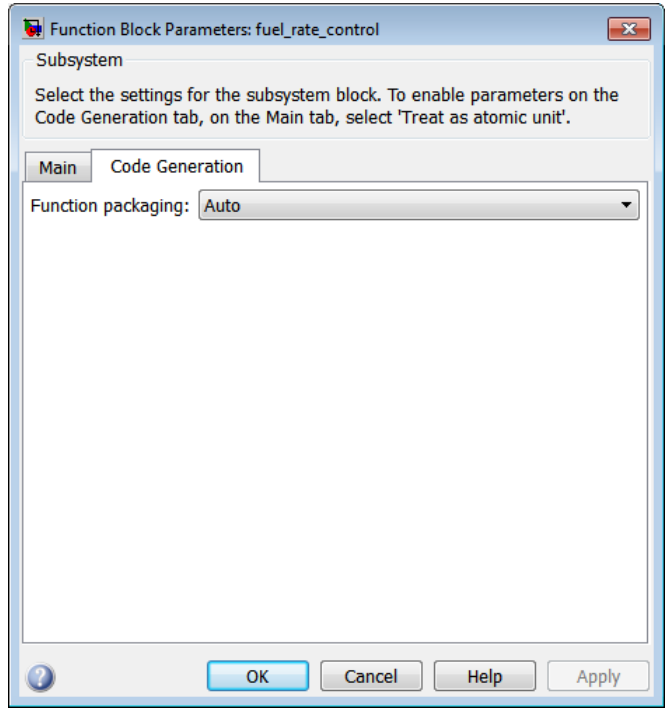
This section summarizes the steps to configure a nonvirtual subsystem in a Simulink model for modular function code generation.

1. Verify that the Simulink model containing the subsystem uses an ERT-based system target file (see the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box).
2. In your Simulink model, select the subsystem for which you want to generate modular function code and launch the Subsystem Parameters dialog box (for example, right-click the subsystem and select **Block Parameters (Subsystem)**). The dialog box for an atomic subsystem is shown below. (In the dialog box for a conditionally executed subsystem, the dialog box option **Treat as atomic unit** is greyed out, and you can skip Step 3.)

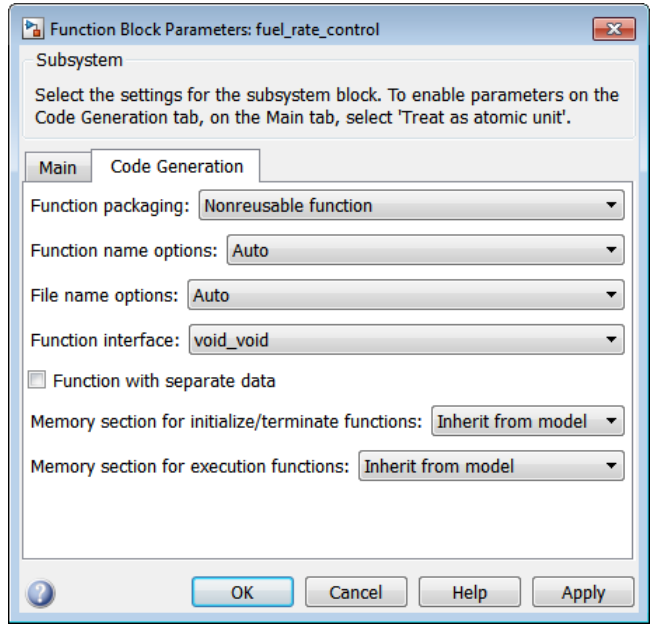


3. If the Subsystem Parameters dialog box option **Treat as atomic unit** is available for selection but not selected, the subsystem is neither atomic nor conditionally

executed. Select the option **Treat as atomic unit**, which enables **Function packaging** on the **Code Generation** tab. Select the **Code Generation** tab.

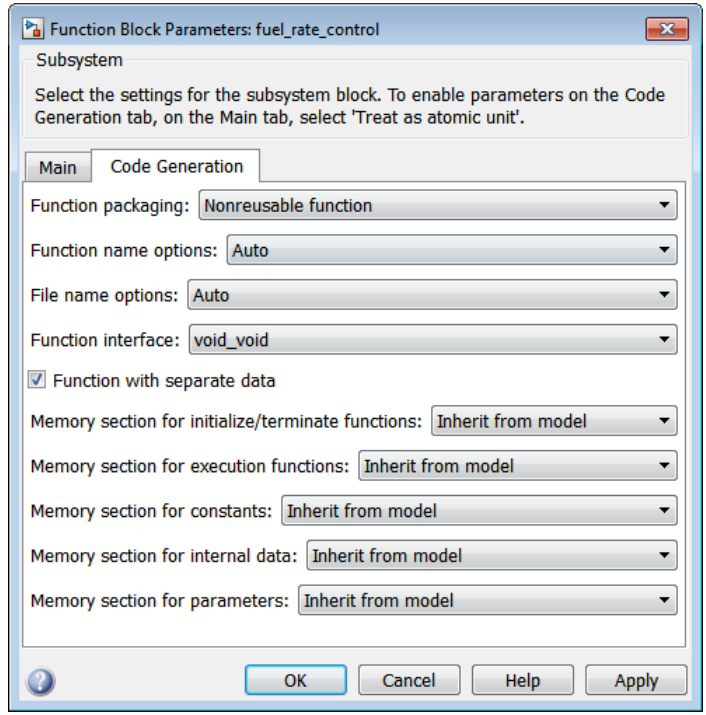


4 For the **Function packaging** parameter, select the value `Nonreusable function`. After you make this selection, the **Function with separate data** option is displayed.



Note: Before you generate nonvirtual subsystem function code with the **Function with separate data** option selected, you might want to generate function code with the option *deselected* and save the generated function `.c` and `.h` files in a separate directory for later comparison.

5 Select the **Function with separate data** option. After you make this selection, additional configuration parameters are displayed.



Note: To control the naming of the subsystem function and the subsystem files in the generated code, you can modify the subsystem parameters **Function name options** and **File name options**.

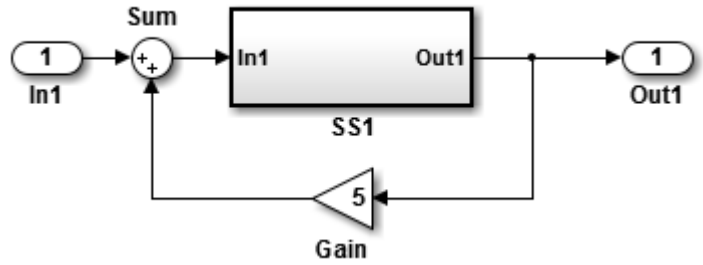
6 To save your subsystem parameter settings and exit the dialog box, click **OK**.

This completes the subsystem configuration for generating modular function code. You can now generate the code for the subsystem and examine the generated files, including the function `.c` and `.h` files named according to your subsystem parameter specifications. For more information on generating code for nonvirtual subsystems, see “Code Generation of Subsystems” (Simulink Coder). For examples of generated subsystem function code, see “Modular Function Code for Nonvirtual Subsystems” on page 26-60.

Modular Function Code for Nonvirtual Subsystems

To illustrate the selection of the **Function with separate data** option for a nonvirtual subsystem, the following procedure generates atomic subsystem function code with and without the option selected and compares the results.

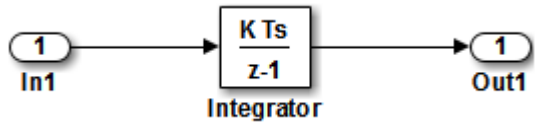
1 Open MATLAB and launch the model `rtwdemo_atomic` using the MATLAB command rtwdemo_atomic.



Examine the Simulink model. This model shows how to preserve the boundary of a virtual subsystem. By selecting the Subsystem Parameters option **Treat as atomic unit**, you guarantee that the code for that subsystem executes as an atomic unit. When a system is marked as atomic, you can specify how the subsystem is represented in code with the Subsystem Parameters option **Code Generation Function Packaging**. You can specify that the subsystem is translated to any of the following types of implementation:

- `Inline`: Inline the subsystem code at the call sites
- `Function`: A void/void function with I/O and internal data in global data structure
- `Reusable Function`: A reentrant function with data passed in as part of function arguments
- `Auto`: Let the code generator optimize the implementation based on context

2 Double-click the SS1 subsystem and examine the contents.



Close the subsystem window when you are finished.

3 Right-click the SS1 subsystem, select Block Parameters (Subsystem) from the context menu, and examine the settings. Simulink and the code generator can avoid "artificial" algebraic loops when the subsystem is made atomic with the subsystem option **Minimize algebraic loop occurrences**.

Close the Block Parameters dialog box when you are finished.

4 Change the **System target file** for the mode from `grt.tlc` to `ert.tlc`. Select the **Configuration Parameters** > **Code Generation** tab and specify `ert.tlc` for the **System target file** parameter. Click **OK** twice to confirm the change. Using the ERT target provides more code generation options for the atomic subsystem.

5 Create a variant of `rtwdemo_atomic` that illustrates function code *without* data separation.

a In the `rtwdemo_atomic` model, right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box that appears, verify that

- On the **Main** tab, **Treat as atomic unit** is selected
- On the **Code Generation** tab, `User specified` is selected for **Function name options**
- On the **Code Generation** tab, `myfun` is specified for **Function name**

b In the Subsystem Parameters dialog box, on the **Code Generation** tab verify that

i `Nonreusable function` is selected for the **Function packaging** parameter. After this selection, additional parameters and options appear.

ii `Use function name` is selected for the **File name options** parameter. This selection is optional but simplifies the later task of code comparison by causing the atomic subsystem function code to be generated into the files `myfun.c` and `myfun.h`.

Do *not* select the option **Function with separate data**. Click **Apply** to apply the changes and click **OK** to exit the dialog box.

c Save this model variant to a personal work directory, for example, `rtwdemo_atomic1` in `d:/atomic`.

6 Create a variant of `rtwdemo_atomic` that illustrates function code *with* data separation.

a In the `rtwdemo_atomic1` model (or `rtwdemo_atomic` with step 3 reapplied), right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box, verify that

- On the **Main** tab, **Treat as atomic unit** is selected
- On the **Code Generation** tab, `Function` is selected for **Function packaging**
- On the **Code Generation** tab, `User specified` is selected for **Function name options**
- On the **Code Generation** tab, `myfun` is specified for **Function name**
- On the **Code Generation** tab, `Use function name` is specified for **File name options**

b In the Subsystem Parameters dialog box, on the **Code Generation** tab, select the option **Function with separate data**. Click **Apply** to apply the change and click **OK** to exit the dialog box.

c Save this model variant, using a different name than the first variant, to a personal work directory, for example, `rtwdemo_atomic2` in `d:/atomic`.

7 Generate code for each model, `rtwdemo_atomic1` and `rtwdemo_atomic2`.

8 In the generated code directories, compare the *`model`*`.c/.h` and `myfun.c/.h` files generated for the two models. For code comparison discussion, see "H File Differences for Nonvirtual Subsystem Function Data Separation" on page 26-63 and "H File Differences for Nonvirtual Subsystem Function Data Separation" on page 26-63"C File Differences for Nonvirtual Subsystem Function Data Separation" on page 26-64.

In this example, there are not significant differences in the generated variants of `ert_main.c`, *`model`*`_private.h`, *`model`*`_types.h`, or `rtwtypes.h`.

H File Differences for Nonvirtual Subsystem Function Data Separation

The differences between the H files generated for `rtwdemo_atomic1` and `rtwdemo_atomic2` help illustrate the selection of the **Function with separate data** option for nonvirtual subsystems.

1. Selecting **Function with separate data** causes `typedef`s for subsystem data to be generated in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Block signals for system '<Root>/SS1' */
typedef struct {
  real_T Integrator;                   /* '<S1>/Integrator' */
} rtB_myfun;

/* Block states (auto storage) for system '<Root>/SS1' */
typedef struct {
  real_T Integrator_DSTATE;            /* '<S1>/Integrator' */
} rtDW_myfun;
```

   By contrast, for `rtwdemo_atomic1`, `typedef`s for subsystem data belong to the model and appear in `rtwdemo_atomic1.h`:

```
/* Block signals (auto storage) */
typedef struct {
...
    real_T Integrator;                 /* '<S1>/Integrator' */
} BlockIO_rtwdemo_atomic1;

/* Block states (auto storage) for system '<Root>' */
typedef struct {
  real_T Integrator_DSTATE;            /* '<S1>/Integrator' */
} D_Work_rtwdemo_atomic1;
```

2. Selecting **Function with separate data** generates the following external declarations in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Extern declarations of internal data for 'system '<Root>/SS1'' */
extern rtB_myfun rtwdemo_atomic2_myfunB;

extern rtDW_myfun rtwdemo_atomic2_myfunDW;

extern void myfun_initialize(void);
```

   By contrast, the generated code for `rtwdemo_atomic1` contains model-level external declarations for the subsystem's `BlockIO` and `D_Work` data, in `rtwdemo_atomic1.h`:

```
/* Block signals (auto storage) */
extern BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
extern D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
```

C File Differences for Nonvirtual Subsystem Function Data Separation

The differences between the C files generated for `rtwdemo_atomic1` and `rtwdemo_atomic2` illustrate the selection of the **Function with separate data** option for nonvirtual subsystems.

1 Selecting **Function with separate data** causes a separate subsystem initialize function, `myfun_initialize`, to be generated in the `myfun.c` file for `rtwdemo_atomic2`:

```
void myfun_initialize(void) {
  {
    ((real_T*)&rtwdemo_atomic2_myfunB.Integrator)[0] = 0.0;
  }
  rtwdemo_atomic2_myfunDW.Integrator_DSTATE = 0.0;
}
```

The subsystem initialize function in `myfun.c` is invoked by the model initialize function in `rtwdemo_atomic2.c`:

```
/* Model initialize function */

void rtwdemo_atomic2_initialize(void)
{
...

  /* Initialize subsystem data */
  myfun_initialize();
}
```

By contrast, for `rtwdemo_atomic1`, subsystem data is initialized by the model initialize function in `rtwdemo_atomic1.c`:

```
/* Model initialize function */

void rtwdemo_atomic1_initialize(void)
{
```

```
...
  /* block I/O */
  {
 ...
    ((real_T*)&rtwdemo_atomic1_B.Integrator)[0] = 0.0;
  }

  /* states (dwork) */

  rtwdemo_atomic1_DWork.Integrator_DSTATE = 0.0;
...
}
```

2 Selecting **Function with separate data** generates the following declarations in the `myfun.c` file for `rtwdemo_atomic2`:

```
/* Declare variables for internal data of system '<Root>/SS1' */
rtB_myfun rtwdemo_atomic2_myfunB;

rtDW_myfun rtwdemo_atomic2_myfunDW;
```

By contrast, the generated code for `rtwdemo_atomic1` contains model-level declarations for the subsystem's `BlockIO` and `D_Work` data, in `rtwdemo_atomic1.c`:

```
/* Block signals (auto storage) */
BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
```

3 Selecting **Function with separate data** generates identifier naming that reflects the subsystem orientation of data items. Notice the references to subsystem data in subsystem functions such as `myfun` and `myfun_update` or in the model's *`model`*`_step` function. For example, compare this code from `myfun` for `rtwdemo_atomic2`

```
/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic2_myfunB.Integrator = rtwdemo_atomic2_myfunDW.Integrator_DSTATE;
```

to the corresponding code from `myfun` for `rtwdemo_atomic1`.

```
/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic1_B.Integrator = rtwdemo_atomic1_DWork.Integrator_DSTATE;
```

Nonvirtual Subsystem Modular Function Code Limitations

The nonvirtual subsystem option **Function with separate data** has the following limitations:

- The **Function with separate data** option is available only in ERT-based Simulink models (requires a Embedded Coder license).
- The nonvirtual subsystem to which the option is applied cannot have multiple sample times or continuous sample times; that is, the subsystem must be single-rate with a discrete sample time.
- The nonvirtual subsystem cannot contain continuous states.
- The nonvirtual subsystem cannot output function call signals.
- The nonvirtual subsystem cannot contain noninlined S-functions.
- The generated files for the nonvirtual subsystem will reference model-wide header files, such as *`model`*`.h` and *`model`*`_private.h`.
- The **Function with separate data** option is incompatible with the **Classic call interface** option, located on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box. Selecting both generates an error.
- The **Function with separate data** option is incompatible with setting **Code interface packaging** to `Reusable function` (**Code Generation** > **Interface** pane). Selecting both generates an error.

More About

- "Design Models for Generated Embedded Code Deployment" on page 1-2

Configure Simulink Function Code Interface

With Embedded Coder, you can customize the generated C/C++ function interfaces for Simulink Function and Function Caller blocks. Function code interface configuration supports easier integration of generated code with functions or function calls in external code, and customizations for coding standards or design requirements.

By opening a dialog box from a selected Simulink Function or Function Caller block, you can customize the C/C++ function prototype generated for that block. Your changes for the selected block also update other corresponding Simulink Function and Function Caller blocks in the model. You can change the generated C/C++ function name, and the names, type qualifiers, and order of function arguments. Your changes do not graphically alter the model and do not affect the Simulink function prototype defined in the block.

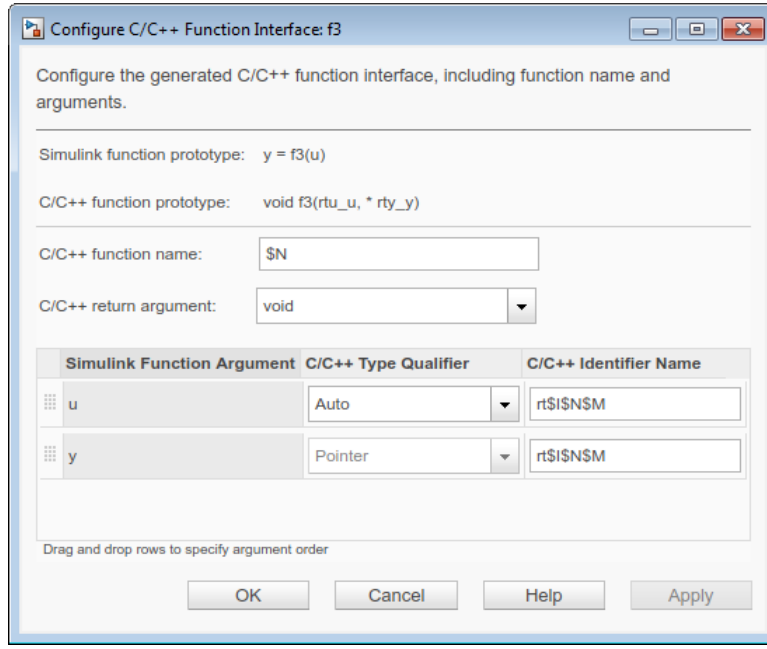
Embedded Coder supports Simulink function code interface configuration for ERT and ERT-derived targets, except for the AUTOSAR target. Function code interface configuration applies to global Simulink functions, and does not apply to private Simulink functions.

Customize Generated C/C++ Function Interface for Simulink Function Block

In this example, you modify the generated C/C++ function interface for a Simulink Function block, and generate C code with the specified changes.

1. Open the example model `rtwdemo_functions`. Save it to a writable work area.
2. Right-click the Simulink Function block `f3`. In the right-click context menu, select **C/C++ Code** > **Configure C/C++ Function Interface**. The Configure C/C++ Function Interface dialog box opens.

   The dialog box displays the Simulink function prototype defined in the block, `y = f3(u)`, and the initial default C/C++ function prototype, `void f3(rtu_u, *rty_y)`.



3 Examine the dialog box settings for the C/C++ function name and the C/C++ argument identifier names — `$N` and `rt$I$N$M`.

In the Configuration Parameters dialog box, **Code Generation** > **Symbols** pane, the **Subsystem method arguments** parameter defines the default identifier format for Simulink Function arguments.

`rt` is a text prefix. `$I`, `$N`, and `$M` are identifier format macros. For more information, see "Subsystem method arguments" (Simulink Coder).

4 In the Configure C/C++ Function Interface dialog box, modify the function and argument identifier names. Changes that you make in the dialog box override model configuration parameter defaults.

In the **C/C++ function name** field, and in the **C/C++ Identifier Name** field for each function argument, enter a custom name or identifier format. Specify valid C-

identifier characters, identifier format macros, or a combination. This example uses function name `function3` and, for both arguments, identifier format `$N$M`.

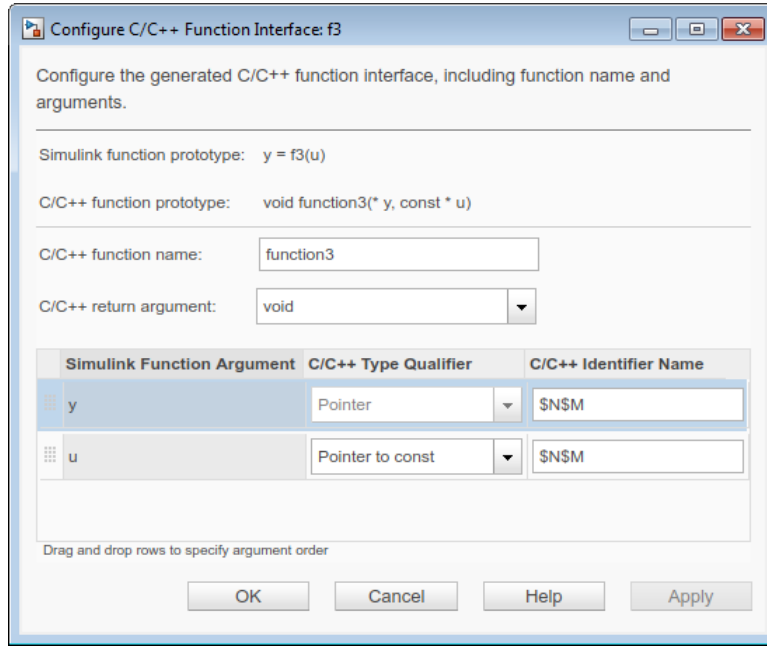
To see tips about available macros, hover over the **C/C++ function name** and **C/C++ Identifier Name** fields. For more information about the identifier format macros, see "Identifier Format Control" on page 36-22.

5 For the `u` argument, change the **C/C++ Type Qualifier** field from `Auto` to `Pointer to const`.

6 To reorder the generated arguments, drag the `y` argument row above the `u` argument row, and drop.

7 Click **Apply** and examine the updated C/C++ function prototype: `void function3(* y, const * u)`.

Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.



Optionally, you could change **C/C++ return argument** from `void` to `y`. The resulting C/C++ function prototype is `y = function3(const * u)`.

8 Save the model changes and generate code for `rtwdemo_functions`.

9 Open the generated file `rtwdemo_functions.c` and search for `function3`. The generated function code reflects the changes to the generated C/C++ function prototype.

```
/* Output and update for Simulink Function: '<Root>/f3' */
void function3(real_T *y, const real_T *u)
{
...
  adder_h(rtB.Subtract, rtU.U2, *u, &rtB.FunctionCaller);
  ...
  *y = rtB.FunctionCaller;
}
```

Simulink Function Code Interface Limitations

- Simulink function code interface configuration is incompatible with C++ class interface control, in which you configure C++ class interfaces for model entry point functions.
- Simulink function code interface configuration does not support Simulink functions and function callers in Stateflow.

Memory Sections in Embedded Coder

Control Data and Function Placement in Memory by Inserting Pragmas

In this section...

Some hardware targets run code more efficiently if different kinds of data and functions are stored in specific locations in computer memory. A *memory section* is a named collection of properties related to placement of an object in memory; for example, in RAM, ROM, or flash memory. Memory section properties let you specify storage directives for model signals, block parameters, and states. For example, you can specify `const` declarations, or compiler-specific `#pragma` statements for allocation of storage in ROM or flash memory sections.

The Embedded Coder software provides a memory section capability that allows you to insert comments and pragmas and to qualify constants as `volatile` in the generated code for:

- Data in custom storage classes
- Model-level functions
- Model-level internal data
- Subsystem functions
- Subsystem internal data

Pragmas inserted into the generated code can surround:

- A contiguous block of function or data definitions
- Each function or data definition separately

When pragmas surround each function or data definition separately, the text of each pragma can contain the name of the definition to which it applies.

To apply a memory section to groups of data or to model functions such as `initialize` and `step`, you use the Configuration Parameters dialog box. To apply a memory section to individual signals and parameters, you must associate the memory section with a custom storage class. For more information about custom storage classes, see "Introduction to Custom Storage Classes" on page 23-2.

Define Memory Sections

To define memory sections, you must create a data class package using MATLAB class syntax. For more information about creating a data class package, see "Define Data Classes" (Simulink).

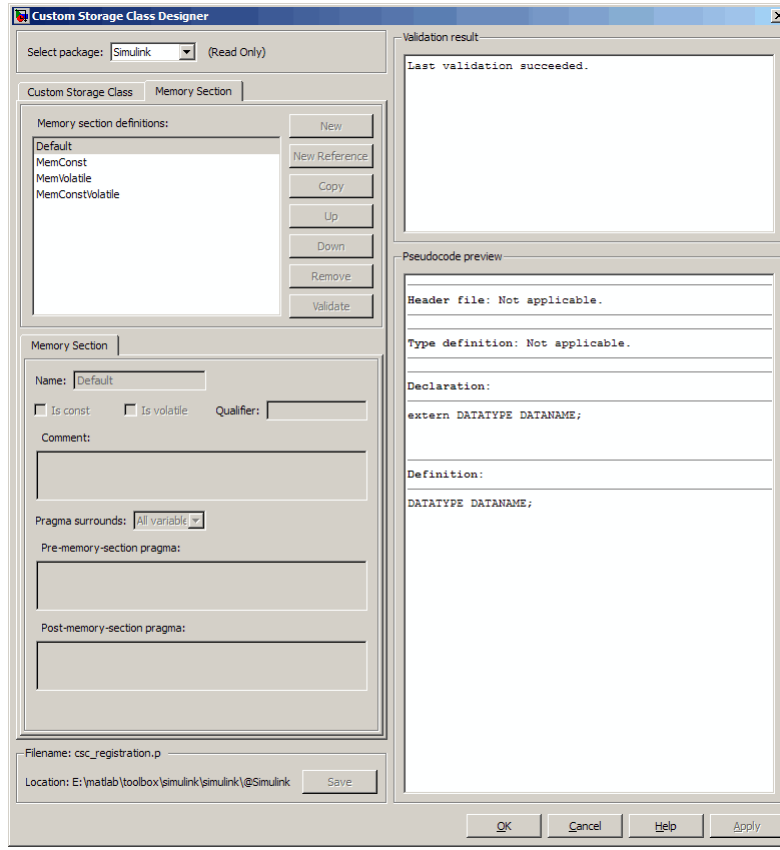
Edit Memory Section Properties

To create new memory sections or specify memory section properties:

1. Choose **View > Model Explorer** in the model window.

   The Model Explorer appears.
2. Choose **Tools > Custom Storage Class Designer** in the Model Explorer window.

   A notification box appears that states **Please Wait ... Finding Packages**. After a brief pause, the notification box closes and the Custom Storage Class Designer appears.
3. Click the **Memory Section** tab of the Custom Storage Class Designer. The **Memory Section** pane initially looks like this:



4 If you intend to create or change memory section definitions, use the **Select package** field to select a writable package.

For more detailed information about the controls on the **Memory Section** pane, see "Design Custom Storage Classes and Memory Sections" on page 23-34.

Specify the Memory Section Name

To specify the name of a memory section, use the **Name** field. A memory section name must be a legal MATLAB identifier.

Specify Comment and Pragma Text

To specify a comment, prepragma, or postpragma for a memory section, enter the comment in the text boxes on the left side of the Custom Storage Class Designer. In the text boxes, you can type multiple lines separated by ordinary Returns.

Surround Individual Definitions with Pragmas

If the **Pragma surrounds** field for a memory section specifies `Each variable`, the code generator will surround each definition in a contiguous block of definitions with the comment, prepragma, and postpragma defined for the section.

If the **Pragma surrounds** field for a memory section specifies **All variables**, the code generator will insert the comment and prepragma for the section before the first definition in a contiguous block of custom storage class data definitions, and the postpragma after the last definition in the block.

Note: Specifying **All variables** affects only custom storage class data definitions. For other definition categories, the code generator surrounds each definition separately regardless of the value of **Pragma surrounds**.

Include Identifier Names in Pragmas

When pragmas surround each separate definition in a contiguous block, you can include the character vector `%<identifier>` in a pragma. The character vector must appear without surrounding quotes.

- When `%<identifier>` appears in a prepragma, the code generator will substitute the identifier from the subsequent function or data definition.
- When `%<identifier>` appears in a postpragma, the code generator will substitute the identifier from the previous function or data definition.

You can use `%<identifier>` with pragmas *only* when pragmas to surround each variable. The `Validate` phase will report an error if you violate this rule.

Note: Although `%<identifier>` looks like a TLC variable, it is not: it is just a keyword that directs the code generator to substitute the applicable data definition identifier when it outputs a pragma. TLC variables cannot appear in pragma specifications in the **Memory Section** pane.

Specify a Qualifier for Custom Storage Class Data Definitions

To specify a qualifier for custom storage class data definitions in a memory section, enter the components of the qualifier below the **Name** field.

- To specify `const`, check **Is const**.
- To specify `volatile`, check **Is volatile**.
- To specify anything else (e.g., `static`), enter the text in the **Qualifier** field.

The qualifier will appear in generated code with its components in the same left-to-right order in which their definitions appear in the dialog box. A preview appears in the **Pseudocode preview** subpane on the lower right.

Note: Specifying a qualifier affects only custom storage class data definitions. The code generator omits the qualifier from other definition categories.

Apply Memory Sections

Assign Memory Sections to Custom Storage Classes

To assign a memory section to a custom storage class,

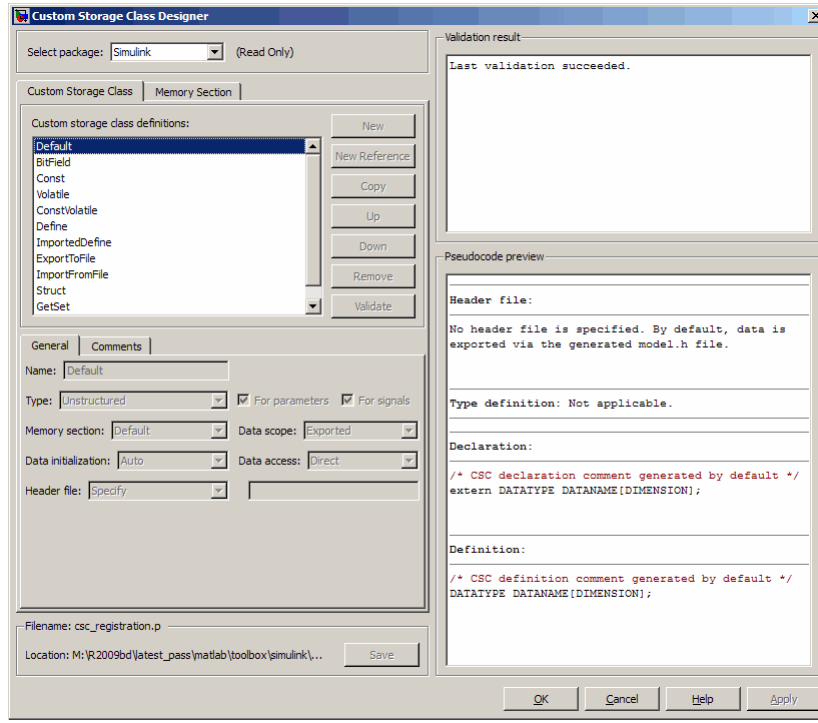
1. Choose **View > Model Explorer** in the model window.

   The Model Explorer appears.

2. Choose **Tools > Custom Storage Class Designer** in the Model Explorer window.

   A notification box appears that states **Please Wait ... Finding Packages**. After a brief pause, the notification box closes and the Custom Storage Class Designer appears.

3. Select the **Custom Storage Class** tab. The **Custom Storage Class** pane initially looks like this:



4. Use the **Select package** field to select a writable package. The rest of this section assumes that you have selected a writable package.
5. Select the desired custom storage class in the **Custom storage class definitions** pane.
6. Select the desired memory section from the **Memory section** pull-down.
7. Click **Apply** to apply changes to the open copy of the model; **Save** to apply changes and save them to disk; or **OK** to apply changes, save changes, and close the Custom Storage Class Designer.

Generated code for data definitions in the specified custom storage class are enclosed in the pragmas of the specified memory section. The pragmas can surround contiguous blocks of definitions or each definition separately, as described in “Surround Individual Definitions with Pragmas” on page 27-5. For more information, see “Design Custom Storage Classes and Memory Sections” on page 23-34.

Note: The code generator does not generate a `pragma` around definitions or declarations for data that has the following built-in storage classes:

- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`

The code generator treats data with these built-in storage classes like custom storage classes without a specified memory section.

Apply Memory Sections to Model-Level Functions and Internal Data

The table shows the categories of model-level functions to which you can apply memory sections.

Function Category	Functions Included in Memory Section
Initialize/Terminate functions	Initialize/Start
	Terminate
Execution functions	Step functions
	Run-time initialization
	Derivative
	Enable
	Disable
Shared utility functions	• Shared utility functions, such as those generated for model references. • Subfunctions, such as those generated by Simulink Coder for intrinsic math utilities, Stateflow graphical functions, and MATLAB subfunctions.

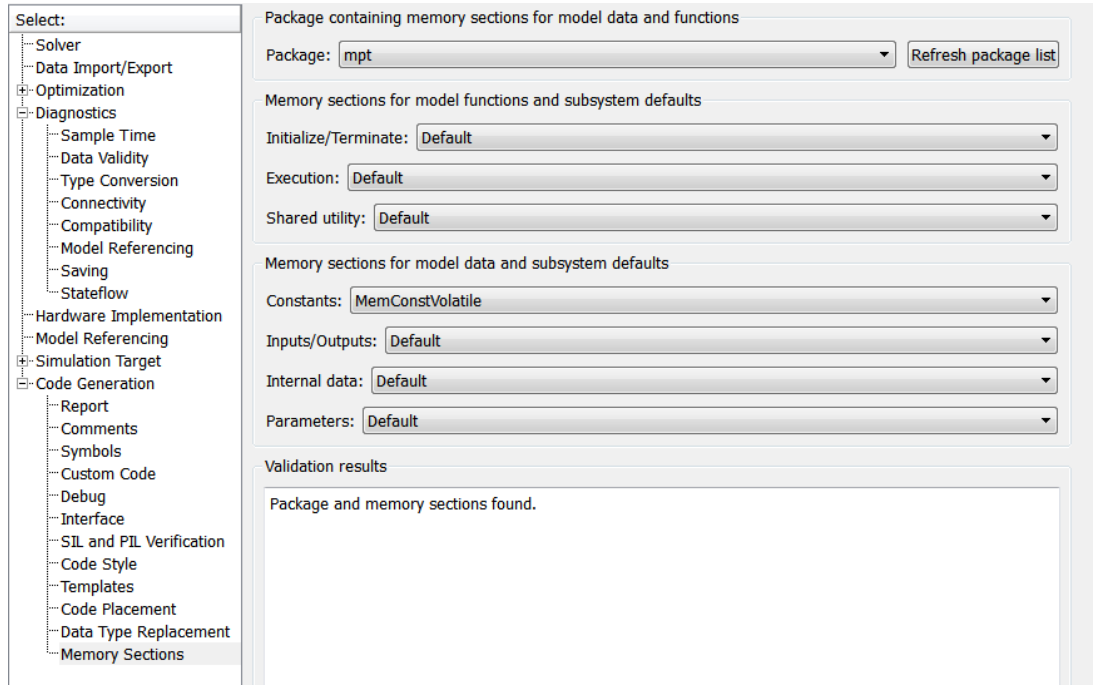
The table shows the categories of internal data to which you can apply memory sections. The specified memory section applies to the corresponding global data structures in the generated code. For basic information about the global data structures, see "Default Data Structures in the Generated Code" (Simulink Coder).

Data Category	Data Included in Memory Section
Constants	Constant block parameters
	Block inputs and outputs that have constant values
Input/Output	Root inputs
	Root outputs
Internal data	Block input and output signals
	DWork vectors
	Zero-crossings
Parameters	Block parameters

Memory section specifications for model-level functions and internal data apply to the top level of the model and to its subsystems. However, these specifications are not applicable to atomic subsystems that contain overriding memory section specifications, as described in “Apply Memory Sections to Atomic Subsystems” on page 27-10.

To specify memory sections for model-level functions or internal data,

1. Open the Configuration Parameters dialog box and select **Code Generation** > **General**.
2. Specify the **System target file** as an ERT target, such as `ert.tlc` .
3. Select **Memory Sections**. The **Memory Sections** pane looks like this:



4 Initially, the **Package** field specifies `---None---` and the pull-down lists only built-in packages. If you have defined packages of your own, click **Refresh package list**. This action adds user-defined packages on your search path to the package list.

5 In the **Package** pull-down, select the package that contains the memory sections that you want to apply.

6 In the pull-down for each category of internal data and model-level function, specify the memory section that you want to apply to that category. Accepting or specifying `Default` omits specifying memory section for that category.

7 Click **Apply** to save changes to the package and memory section selections.

Apply Memory Sections to Atomic Subsystems

For atomic subsystem whose **Function packaging** is **Nonreusable function** or **Reusable function**, you can specify memory sections for functions and internal data that exist in that code interface packaging. Such specifications override model-level memory section specifications. Such overrides apply only to the atomic subsystem itself,

not to subsystems within it. Subsystems of an atomic subsystem inherit memory section specifications from the containing model, *not* from the containing atomic subsystem.

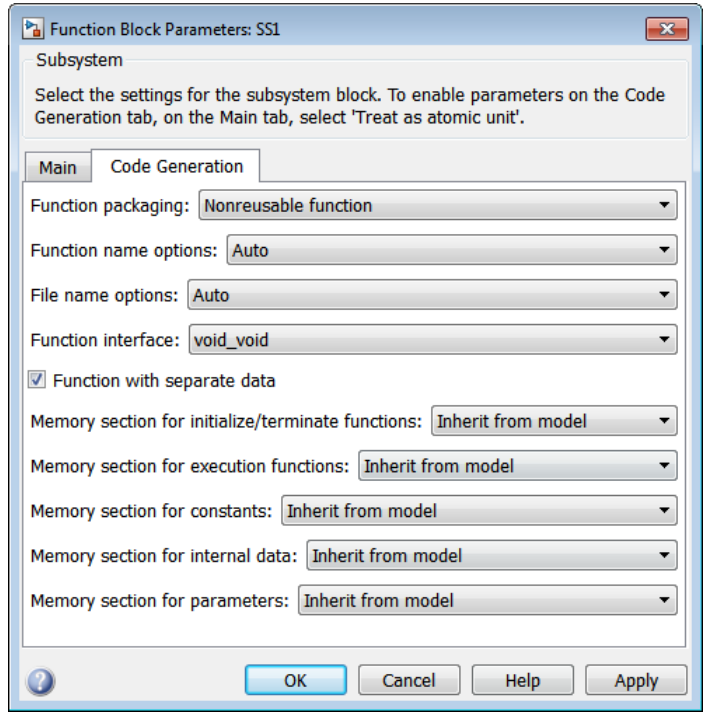
The memory section that you specify for internal data applies to the corresponding global data structures in the generated code. For basic information about the global data structures generated for atomic subsystems, see "Default Data Structures in the Generated Code" (Simulink Coder).

To specify memory sections for an atomic subsystem,

1. Right-click the subsystem in the model window.
2. Choose **Subsystem Parameters** from the context menu. The Function Block Parameters: *`Subsystem`* dialog box appears.
3. Select the **Treat as atomic unit** checkbox. If it is not selected, you cannot specify memory sections for the subsystem.

   For an atomic system, on the **Code Generation** tab, you can use the **Function packaging** field to control the format of the generated code.
4. Specify **Function packaging** as `Nonreusable function` or `Reusable function`. Otherwise, you cannot specify memory sections for the subsystem.
5. If the **Function packaging** is `Reusable function` and you want separate data, check **Function with separate data**.

   The **Code Generation** tab now shows applicable memory section options. The available options depend on the values of **Function packaging** and the **Function with separate data** check box. When the former is `Nonreusable function` and the latter is checked, the pane looks like this:



6 In the pull-down for each available definition category, specify the memory section that you want to apply to that category.

- Selecting `Inherit from model` inherits the corresponding selection from the model level (not parent subsystem).
- Selecting `Default` specifies that the category does not have an associated memory section, overriding model-level specifications for that category.

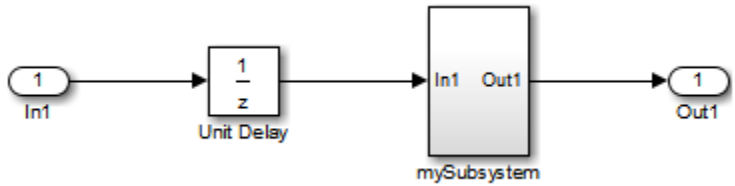
7 Click **Apply** to save changes, or **OK** to save changes and close the dialog box.

Caution: If you use **Build This Subsystem** or **Build Selected Subsystem** to generate code for an atomic subsystem that specifies memory sections, the code generator ignores the subsystem-level specifications and uses the model-level specifications instead. The generated code is the same as if the atomic subsystem specified `Inherit from model` for every category of definition. For information about building subsystems, see "Generate Code and Executables for Individual Subsystem" (Simulink Coder).

It is not possible to specify the memory section for a subsystem in a library. However, you can specify the memory section for the subsystem after you have copied it into a Simulink model. This is because in the library it is unknown what code generation target will be used. You can copy a library block into many different models with different code generation targets and different memory sections available.

Generated Code with Memory Sections

The next figures show an ERT-based Simulink model that defines one subsystem, `mySubsystem`, and then the contents of that subsystem.



Assume that the subsystem is atomic. On the **Code Generation** tab, the **Function packaging** parameter is `Reusable function`. Memory sections have been created and assigned as shown in the next two tables; here, data memory sections specify **Pragma surrounds** to be `Each variable`.

Model-Level Memory Section Assignments and Definitions

Section Assignment	Section Name	Field Name	Field Value
Input/Output	`MemSect1`	Prepragma	`#pragma IO-begin`
		Postpragma	`#pragma IO-end`
Internal data	`MemSect2`	Prepragma	`#pragma InData-begin(%<identifier>)`
		Postpragma	`#pragma InData-end`
Parameters	`MemSect3`	Prepragma	`#pragma Parameters-begin`
		Postpragma	`#pragma Parameters-end`

Section Assignment	Section Name	Field Name	Field Value
Initialize/ Terminate	MemSect4	Prepragma	#pragma InitTerminate-begin
		Postpragma	#pragma InitTerminate-end
Execution functions	MemSect5	Prepragma	#pragma ExecFunc-begin(%<identifier>)
		Postpragma	#pragma ExecFunc-end(%<identifier>)

Subsystem-Level Memory Section Assignments and Definitions

Section Assignment	Section Name	Field Name	Field Value
Execution functions	MemSect6	Prepragma	#pragma DATA_SEC(%<identifier>, "FAST_RAM")
		Postpragma	

Given the preceding specifications and definitions, the code generator would create the following code, with minor variations depending on the current version of the Target Language Compiler.

Model-Level Data Structures

```
#pragma IO-begin
ExternalInputs_mySample mySample_U;
#pragma IO-end

#pragma IO-begin
ExternalOutputs_mySample mySample_Y;
#pragma IO-end

#pragma InData-begin(mySample_B)
BlockIO_mySample mySample_B;
#pragma InData-end

#pragma InData-begin(mySample_DWork)
D_Work_mySample mySample_DWork;
#pragma InData-end

#pragma InData-begin(mySample_M_)
RT_MODEL_mySample mySample_M_;
#pragma InData-end

#pragma Parameters-begin
```

```
Parameters_mySample mySample_P = {
  1.0 , {2.3}
};
#pragma Parameters-end
```

Model-Level Functions

```
#pragma ExecFunc-begin(mySample_step)
void mySample_step(void)
{
 mySample_B.UnitDelay = mySample_DWork.UnitDelay_DSTATE;
 mySample_mySubsystem();
 mySample_DWork.UnitDelay_DSTATE = mySample_U.In1;
}
#pragma ExecFunc-end(mySample_step)

#pragma InitTerminate-begin
void mySample_initialize(void)
{
  mySample_U.In1 = 0.0;
  mySample_Y.Out1 = 0.0;
  mySample_DWork.UnitDelay_DSTATE = mySample_P.UnitDelay_InitialCondition;
}
#pragma InitTerminate-end
```

Subsystem Function

Because the subsystem specifies a memory section for execution functions that overrides that of the parent model, subsystem code looks like this:

```
#pragma DATA_SEC(mySample_mySubsystem, “FAST_RAM”)
void mySample_mySubsystem(void)
{
 mySample_Y.Out1 = mySample_P.Gain_Gain * mySample_B.UnitDelay;
}
```

If the subsystem had not defined its own memory section for execution functions, but inherited that of the parent model, the subsystem code would have looked like this:

```
#pragma ExecFunc-begin(mySample_mySubsystem)
void mySample_mySubsystem(void)
{
 mySample_Y.Out1 = mySample_P.Gain_Gain * mySample_B.UnitDelay;
}
```

```
#pragma ExecFunc-end(mySubsystem)
```

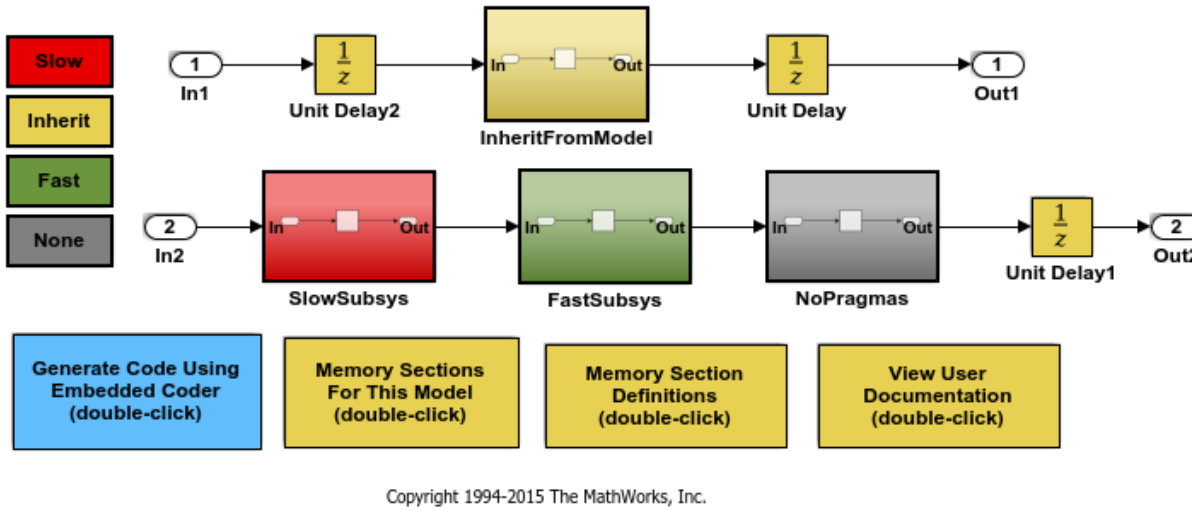
Insert Pragmas for Functions and Data in Generated Code

This model shows how to insert pragmas for functions and data in generated code.

Explore Example Model

Open the example model.

```
open_system('rtwdemo_memsec')
```



Instructions

1. Learn about memory sections by clicking the documentation link in the model.
2. View the memory sections in the ECoderDemos package by clicking the button in the model and then selecting the **Memory Sections** tab.
3. View the memory sections selected for this model by clicking the button in the model. The model-level settings are also the default settings for atomic subsystems.
4. Open the SubSystem Parameters dialog for the subsystems to see the memory section settings for each of the atomic subsystems in the model.

5 Generate code by clicking the button in the model. An HTML report is displayed automatically. Inspect the data and function definitions in the `.c` files and observe how the generated pragmas correspond to the specified memory sections.

Documenting Use of Pragmas with Simulink Report Generator

If you need to report on the use of pragmas to define memory sections, for example to satisfy the modeling guideline "hisl_0402: Use of custom #pragma to improve MISRA C:2012 compliance" (Simulink), you can customize the Simulink Report Generator report to include this information.

To add pragma information to your Simulink Report Generator report:

1 Open your Simulink Report Generator report. For more information on these reports, see "Getting Started with Simulink Report Generator" (Simulink Report Generator).

2 In the Library pane, under the **MATLAB** category, add the **Evaluate MATLAB Expression** component to your report.

3 Add code, similar to the following, to the **Expression to evaluate in the base workspace** text box. This code extracts pragma information from the model.

```
% Find data objects with PRAGMA information
% Note: only objects that are used should be returned

clear pragma;
pragma{1,1}  = {'Pragma Name'};
pragma{1,2}  = {'Pragma Type'};

% Data classes with PRAGMA Information
PragTypes = {'PragmaDemo.PragmaDef','OtherPragma.PragmaDef'};

allData = who;

for inx = 1 : length(allData)
   isPragma = strcmp(eval(['class(',allData{inx},')']),PragTypes);
   if ~isempty(find(isPragma))
      pragma{end+1,1} = allData{inx};
      pragma{end,2}   = PragTypes{isPragma};
   end
end
```

4 Select the **Evaluate this expression if there is an error** check box.

5 In the field under the check box, add code similar to the following:

```
% The exception generated above can be referenced by evalException
% See the default code below for an example
warningMessageLevel = 2;
displayWarningMessage = true;
failGenerationWithException = false;
failGenerationWithoutException = false;

if (displayWarningMessage)
    rptgen.displayMessage(sprintf('%s : %s',...
    'Exception during eval', evalException.message),...
    warningMessageLevel);
end

if (failGenerationWithException)
    rptgen.displayMessage('Failed to evaluate', warningMessageLevel);
    rethrow(evalException);

elseif (failGenerationWithoutException)
    rptgen.displayMessage(sprintf('%s\n%s','Failed to evaluate', ...
    'Halting generation'), warningMessageLevel, false);
    rptgen.haltGenerate;
end
```

6 Click **File** > **Save** to save the report setup file.

For more information on adding a component that evaluates MATLAB commands, see "Add Report Content with Components" (Simulink Report Generator).

- "Default Data Structures in the Generated Code" (Simulink Coder)

Declare Constant Data as Volatile Using Memory Sections

In the C language, the value of data declared with the storage type qualifier, `volatile`, can be read from memory and written back to memory when changed without compiler control or detection. Examples of use include variables for initialization at system power-up or for system clock updates.

You can add the `volatile` qualifier to type definitions generated in code for model constant block I/O, constant parameters, and ground data (zero representation). Note that if the input to a reusable subsystem is volatile data, the code generator casts away the `volatile` qualifier. The subsystem argument is the address of the volatile data.

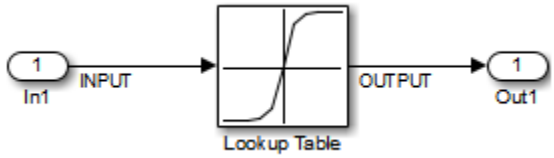
To add the `volatile` qualifier to type definitions, you must configure your model as follows:

- Specify an ERT target
- Set the memory section for constant data to `MemVolatile` or `MemConstVolatile`

If you choose to add the `volatile` qualifier to type definitions in your generated code, note the following:

- If constant data that is qualified with `volatile` is passed by pointer, the code generator casts away the volatility. This occurs because generated functions assume that data values do not change during execution and, therefore, pass their arguments as `const *` (not `const volatile *`).
- If a variable must be declared `const` and you specify `MemVolatile`, the code generator declares the variable with the `const` and `volatile` qualifiers.
- If you set **Constants** to `MemConst` or `MemConstVolatile`, and a variable cannot be declared as constant data, a TLC warning appears and the code generator does not qualify the variable with `const`.

Consider the following simple lookup table model.



1. On the Configuration Parameters dialog box, In the **Code Generation** pane, set **System target file** to `ert.tlc`.
2. In the **Code Generation** > **Memory Sections** pane, set **Package** to `Simulink`, and **Constants** to `MemConstVolatile`.
3. Open the Signal Properties dialog box for signal `INPUT`. On the **Code Generation** tab, set **Storage class** to `ExportedGlobal` for storing state in a global variable.
4. Generate code. You should see the `volatile` qualifier in the generated files *`model`*`_data.c` and *`model`*`.h`.

   `model``_data.c`

```
/* Constant parameters (auto storage) */
/* ConstVolatile memory section */
const volatile ConstParam_simple_lookup simple_lookup_ConstP = {
  /* Expression: [-5:5]
   * Referenced by: '<Root>/Lookup Table'
   */
  { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

  /* Expression: tanh([-5:5])
   * Referenced by: '<Root>/Lookup Table'
   */
  { -0.99990920426259511, -0.999329299739067,
    -0.99505475368673046, -0.9640275800758169,
    -0.76159415595576485, 0.0, 0.76159415595576485,
    0.9640275800758169, 0.99505475368673046,
    0.999329299739067, 0.99990920426259511 }
};
```

   `model``.h`

```
/* Real-time Model Data Structure */
struct RT_MODEL_simple_lookup {
  const char_T * volatile errorStatus;
};

/* Constant parameters (auto storage) */
extern const volatile ConstParam_simple_lookup simple_lookup_ConstP;
```

   Also note in the *`model`*`.c` file that a typecast is inserted in the `rt_Lookup` function call, removing the `volatile` qualifier.

```
/* Lookup: '<Root>/Lookup Table' incorporates:
```

```
 *  Inport: '<Root>/In1'
 */
OUTPUT = rt_Lookup(((const real_T*)
  &simple_lookup_ConstP.LookupTable_XData[0]), 11, INPUT, ((
  const real_T*) &simple_lookup_ConstP.LookupTable_YData[0]));
```

Code Generation

Configuration for Simulink Coder

Code Generation Configuration

When you are ready to generate code for a model, you can modify the model configuration parameters specific to code generation. The code generation parameters determine how the code generator produces code and builds an executable program from your model.

The model configuration parameters for code generation are in the **Code Generation** and **Optimization** panes in the Configuration Parameters dialog box. The content of the **Code Generation** pane and its subpanes can change depending on the target that you specify. Some configuration options are available only with the Embedded Coder product. The **Optimization** pane includes code generation parameters that help to improve the performance of the generated code.

Your application objectives can include a combination of these code generation objectives: debugging, traceability, execution efficiency, and safety precaution. There are tradeoffs associated with these configuration choices, such as execution speed and memory usage. To help configure a model to achieve your application objectives, use the Model Advisor and the Code Generation Advisor.

Open the Model Configuration for Code Generation

To modify the model configuration parameters for code generation, open the **Code Generation** pane. There are several different ways to open the **Code Generation** pane from the Simulink editor:

- To open the Configuration Parameters dialog box, click the model configuration parameters icon.

  

  Then click **Code Generation** in the **Select** (left) pane.
- From the **Simulation** menu, select **Model Configuration Parameters**. When the Configuration Parameters dialog box opens, click **Code Generation** in the **Select** (left) pane.
- From the **Code** menu, select **C/C++ Code** > **Code Generation Options**.
- From the **View** menu in the model window, select **Model Explorer**, or from the MATLAB command line, type `daexplr` and press **Enter**. In the Model Explorer,

expand the node for the current model in the left pane and click `Configuration (active)`. Click elements in the middle pane to display the corresponding parameters in the right pane.

Note In a Configuration Parameters dialog box, when you change the value of a check box, menu selection, or edit field, the white background of the element changes color to indicate that you made an unsaved change. When you click **OK**, **Cancel**, or **Apply**, the background resets to white.

Configuration Tools

To help you configure your model for code generation and to check your configuration against your code generation objectives, Simulink Coder and Embedded Coder provide several tools.

Goal	Approach	More Information
Automate configuration.	At the MATLAB command line, use the `set_param` function	"Configure Code Generation Parameters for Model Programmatically" on page 28-5
Configure your model for code generation quickly and easily (Embedded Coder).	Embedded Coder Quick Start tool	"Generate Code with the Quick Start Tool" on page 34-10
Use a template to create a model configured for code generation, ready for you to add your own blocks.	Code generation templates	• "Generate Code and Simulate Models in a Simulink Project" (Simulink Coder) • "Generate Code and Simulate Models in a Simulink Project"
To configure your model for code generation, use Simulink blocks and predefined or custom MATLAB scripts.	Code Generation Wizards blocks	"Configure and Optimize Model with Configuration Wizard Blocks" on page 29-21

Goal	Approach	More Information
Verify that your model meets standards and guidelines.	Model Advisor	"Select and Run Model Advisor Checks" (Simulink)
Verify that your model meets your application objectives.	Code Generation Advisor	"Application Objectives Using Code Generation Advisor" on page 28-9

Related Examples

- "Configuration Reuse" (Simulink)
- "Configure Code Generation Parameters for Model Programmatically" (Simulink Coder)
- "Application Objectives Using Code Generation Advisor" on page 28-9

Configure Code Generation Parameters for Model Programmatically

You can modify code generation parameters for the active configuration set in the Configuration Parameters dialog box or from the MATLAB command line. Use the command-line approach for creating a script that automates setting parameters for an established model configuration. The Configuration Parameters **All Parameters** tab provides parameter command-line names to use in scripts.

Modify Parameters to Support `Execution efficiency`

In this example, you modify the configuration parameters to support the Code Generation Advisor application objective, `Execution efficiency`.

Step 1. Open a model.

```
slexAircraftExample
```

Step 2. Get the active configuration set.

```
cs = getActiveConfigSet(model);
```

Step 3. Select the Generic Real-Time (GRT) target.

```
switchTarget(cs,'grt.tlc',[]);
```

Step 4. To optimize execution speed, modify parameters.

If your application objective is `Execution efficiency`, use `set_param` to modify these parameters:

```
set_param(cs,'MatFileLogging','off');
set_param(cs,'SupportNonFinite','off');
set_param(cs,'RTWCompilerOptimization','on');
set_param(cs,'OptimizeBlockIOStorage','on');
set_param(cs,'EnhancedBackFolding','on');
set_param(cs,'ConditionallyExecuteInputs','on')
set_param(cs,'DefaultParameterBehavior','Inlined');
set_param(cs,'BooleanDataType','on');
set_param(cs,'BlockReduction','on');
set_param(cs,'ExpressionFolding','on');
set_param(cs,'LocalBlockOutputs','on');
```

```
set_param(cs,'EfficientFloat2IntCast','on');
set_param(cs,'BufferReuse','on');
```

Step 5. Save the model configuration to a file.

Save the model configuration to a file, `'Exec_efficiency_cs.m'`, and view the parameter settings.

```
saveAs(cs,'Exec_Efficiency_cs');
dbtype Exec_Efficiency_cs 1:50
```

Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	"Run Model Checks" (Simulink)
Code Generation Advisor	"Application Objectives Using Code Generation Advisor" (Simulink Coder)
Checks available with Simulink Coder	"Simulink Coder Checks" (Simulink Coder)
Checks available with Embedded Coder	"Embedded Coder Checks"

Check Mode for Code Efficiency with Model Advisor

To check model `rtwdemo_throttlecntrl` for code efficiency, use the Model Advisor.

1. Open `rtwdemo_throttlecntrl`. Save a copy as `throttlecntrl` in a writable location on your MATLAB path.
2. To start the Model Advisor, select **Analysis > Model Advisor > Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder . By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
5. In the left pane, select the remaining checks, and then select **Code Generation Efficiency**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see "View Model Advisor Reports" (Simulink).

Check Model During Code Generation with Code Generation Advisor

To review a model as part of the code generation process, use the Code Generation Advisor.

1. To specify your code generation objectives, on the **Configuration Parameters > Code Generation** pane, choose a value for the **Select objective** parameter.
2. On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
   - `On (proceed with warnings)`
   - `On (stop for warnings)`
3. If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
4. Apply your changes, and then click **Generate Code/Build**. The Code Generation Advisor starts and reviews the top model and subsystems.

   If the Code Generation Advisor issues failures or warnings, and you specified:

   - `On (proceed with warnings)` — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
   - `On (stop for warnings)` — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
5. In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.
6. After reviewing the check results, you can choose to fix warnings and failures as described in "Fix a Model Check Warning or Failure" (Simulink).

Note: When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see "Set Objectives — Code Generation Advisor Dialog Box" (Simulink Coder)

Application Objectives Using Code Generation Advisor

In this section...

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation options in a model configuration set. Parameters that you set in the **Solver**, **Data Import/Export**, **Diagnostics**, and **Code Generation** panes in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model . When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in "Recommended Settings Summary for Model Configuration Parameters" to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.

High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability might be more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

Configure Model for Code Generation Objectives Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

1. On the menu bar, select **Code** > **C/C++ Code** > **Code Generation Advisor**.
2. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
3. In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives from the drop-down list (GRT-based targets). As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it will run on your model. If your model is configured with an ERT-based target, more objectives are available.
4. Click **Run Selected Checks** to run the checks listed in the left pane of the Code Generation Advisor.
5. In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

   Check model configuration settings against code generation objectives triggers a warning for these issues:

   - Parameters are set to values other than the value recommended for the specified code generation objectives.
   - Selected code generation objectives differ from the objectives set in the model.

   Click **Modify Parameters** to set:

   - Parameters to the value recommended for the specified code generation objectives.
   - Code generation objectives in the model to the objectives specified in the Code Generation Advisor.
6. In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.
7. After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to check and configure the code generation objectives in the Configuration Parameters dialog box:

1. Open the Configuration Parameters dialog box and select **Code Generation**.
2. Select or confirm selection of a System target file.
3. Specify the objectives using the **Select objectives** drop down list (GRT-based targets) or clicking **Set Objectives** button (ERT-based targets). Clicking **Set Objectives** opens the "Set Objectives — Code Generation Advisor Dialog Box" (Simulink Coder) dialog box.
4. Click **Check Model** to run the model checks. The Code Generation Advisor dialog box opens. The Code Generation Advisor uses the code generation objectives to determine which model checks to run.
5. On the left pane, the Code Generation Advisor lists the checks run on the model and the results. Click each warning to see the suggestions for changes that you can make to your model to pass the check.
6. Determine which changes to make to your model. On the right pane of the Code Generation Advisor, follow the instructions listed for each check to modify the model.

Simulink Coder Model Advisor Checks for Standards and Code Efficiency

To check that your model meets standards and is ready to generate code, you can use the Model Advisor checks available with Simulink Coder.

- To start the Model Advisor, in the model window, select **Analysis** > **Model Advisor** > **Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see "Run Model Checks" (Simulink).

The table summarizes the Simulink Coder Model Advisor checks that are available in the **By Task** folders.

By Task folder	Model Advisor checks
Code Generation Efficiency	"Identify blocks using one-based indexing" (Simulink Coder)
Modeling Standards for DO-178C/ DO-331	"Check solver for code generation" (Simulink Coder) "Check for blocks that have constraints on tunable parameters" (Simulink Coder) "Check sample times and tasking mode" (Simulink Coder)
Model Referencing	"Check for model reference configuration mismatch" (Simulink Coder) "Check for code generation identifier formats used for model reference" (Simulink Coder)

Related Examples

- "Select and Run Model Advisor Checks" (Simulink)
- "Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency" on page 29-12
- "Modeling Guidelines for Model Configuration" (Simulink Coder)

Configure Code Comments

Configure how the code generator inserts comments into generated code by modifying parameters on the **Code Generation > Comments** pane.

To...	Select...
Include comments in generated code	**Include comments** (Simulink Coder). Selecting this parameter allows you to select one or more auto generated comment types to be placed in the code.
Include comments that describe a block's code	**Simulink block / Stateflow object comments** (Simulink Coder). Selecting this parameter includes the comments before the block's code in the generating file.
Include MATLAB source code as comments	**MATLAB source code as comments** (Simulink Coder). Selecting this parameter inserts these comments preceding the associated generated code. The function signature is included in the function banner.
Include comments for eliminated blocks	**Show eliminated blocks** (Simulink Coder). Selecting this parameter includes comments for blocks that were eliminated as the result of optimizations, such as inlining parameters.
Include parameter comments regardless of the number of parameters	**Verbose comments for SimulinkGlobal storage class** (Simulink Coder). Selecting this parameter includes comments for parameter variable names and names of source blocks in the model parameter structure declaration in *`model`*`_prm.h`. If you do not select this parameter, parameter comments are generated if less than 1000 parameters are declared. This reduces the size of the generated file for models with a large number of parameters.

Note When you configure the code generator to produce code that includes comments, the code generator includes text for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ア with the escape sequence `&#x30A2;`. For more information, see "Internationalization and Code Generation" (Simulink Coder).

Construction of Generated Identifiers

For GRT and RSim targets, the code generator automatically constructs identifiers for variables and functions in the generated code. These identifiers represent:

- Signals and parameters that have `Auto` storage class
- Subsystem function names that are not user defined
- Stateflow names

The components of a generated identifier include

- The root model name, followed by
- The name of the generating object (signal, parameter, state, and so on), followed by
- Unique *name-mangling* text

The code generator conditionally generates the name-mangling text to resolve potential conflicts with other generated identifiers.

To configure how the code generator names identifiers and objects, see:

- "Specify Identifier Length to Avoid Naming Collisions" on page 28-17
- "Specify Reserved Names for Generated Identifiers" on page 28-18

The code generator reserves certain words for its own use as keywords of the generated code language. For more information, see "Reserved Keywords" on page 28-19.

With an Embedded Coder license, you can specify parameters to control identifier formats, mangle length, scalar inlined parameters, and Simulink data object naming rules. For more information, see "Customize Generated Identifier Naming Rules" on page 36-15.

Identifier Name Collisions and Mangling

In identifier generation, a circumstance that would cause generation of two or more identical identifiers is called a *name collision*. When a potential name collision exists, unique *name-mangling* text is generated and inserted into each of the potentially conflicting identifiers. Each set of name-mangling characters is unique for each generated identifier.

Identifier Name Collisions with Referenced Models

Referenced models can introduce additional naming constraints. Within a model that uses referenced models, collisions between the names of the models cannot exist. When you generate code from a model that includes referenced models, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and name-mangling text. A code generation error occurs if **Maximum identifier length** is too small.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

For more information on referenced models, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

Specify Identifier Length to Avoid Naming Collisions

The length of a generated identifier is limited by the **Maximum identifier length** parameter specified on the **Symbols** pane of the Configuration Parameters dialog box. The **Maximum identifier length** field allows you to limit the number of characters in function, type definition, and variable names. The default is 31 characters. This is also the minimum length you can specify. The maximum is 256 characters.

When there is a potential name collision between two identifiers, name-mangling text is generated. The text has the minimum number of characters required to avoid the collision. The other symbol components are then inserted. If **Maximum identifier length** is not large enough to accommodate full expansions of the other components, they are truncated. To avoid this outcome, it is good practice to:

- Avoid name collisions by not using default block names (for example, `Gain1`, `Gain2...`) when the model includes multiple blocks of the same type.
- For subsystems, make them atomic and reusable.
- Increase the **Maximum identifier length** parameter to accommodate the length of the identifier you expect to generate.

Specify Reserved Names for Generated Identifiers

You can specify a set of reserved keywords that the code generation process should not use, facilitating code integration where functions and variables from external environments are unknown in the Simulink model. To create a list of reserved names, open the Configuration Parameters dialog box. On the **Code Generation > Symbols** pane, enter the keywords in the “Reserved names” (Simulink Coder) field.

If your model contains MATLAB Function or Stateflow blocks, the code generation process can use the reserved names specified for those blocks if you select **Use the same reserved names as Simulation Target** (Simulink Coder) on the **Code Generation > Symbols** pane.

Reserved Keywords

In this section...

Generator keywords are reserved for internal use. Do not use them in models as identifiers or function names. Also avoid using C reserved keywords in models as identifiers or function names. If your model contains reserved keywords, code generation does not complete and an error message appears. To address the error, modify your model to use identifiers or names that are not reserved.

If you use the code generator to produce C++ code, your model must not contain the “Reserved Keywords for Code Generation” on page 28-20 nor the “C++ Reserved Keywords” on page 28-20.

Note: You can register additional reserved identifiers in the Simulink environment. For more information, see “Specify Reserved Names for Generated Identifiers” on page 28-18.

C Reserved Keywords

`auto`	`double`	`int`	`struct`
`break`	`else`	`long`	`switch`
`case`	`enum`	`register`	`typedef`
`char`	`extern`	`return`	`union`
`const`	`float`	`short`	`unsigned`
`continue`	`for`	`signed`	`void`
`default`	`goto`	`sizeof`	`volatile`
`do`	`if`	`static`	`while`

Code Generation Code Replacement Library Keywords

The list of code replacement library reserved keywords for your development environment varies depending on which libraries are registered. The list of available code replacement libraries varies depending on other installed products (for example, a target product), or if you used Embedded Coder to create and register custom code replacement libraries.

To generate a list of reserved keywords for libraries currently registered in your environment, use the following MATLAB function:

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers()
```

This function returns an array of library keywords. Specifying the input argument is optional.

Note: To list the libraries currently registered in your environment, use the MATLAB command `crviewer`.

To generate a list of reserved keywords for a specific library that you are using to generate code, call the function passing the name of the library as displayed in the **Code replacement library** menu on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. For example,

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')
```

Here is a partial example of the function output:

```
>> lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')

lib_ids =

    'exp10'
    'exp10f'
    'acosf'
    'acoshf'
```

```
    'asinf'
    'asinhf'
    'atanf'
    'atanhf'
...
    'rt_lu_cplx'
    'rt_lu_cplx_sgl'
    'rt_lu_real'
    'rt_lu_real_sgl'
    'rt_mod_boolean'
    'rt_rem_boolean'
    'strcpy'
    'utAssert'
```

Note: Some of the returned keywords appear with the suffix `$N`, for example, `'rt_atan2$N'`. `$N` expands into the suffix `_snf` only if nonfinite numbers are supported. For example, `'rt_atan2$N'` represents `'rt_atan2_snf'` if nonfinite numbers are supported and `'rt_atan2'` if nonfinite numbers are not supported. As a precaution, you should treat both forms of the keyword as reserved.

Debug

In the Configuration Parameters dialog box, use parameters on the **Diagnostics** pane and debugging parameters on the **All Parameters** tab to configure a model such that the generated code and the build process are set for debugging. You can set parameters that apply to the model compilation phase, the target language code generation phase, or both.

Parameters in the following table will be helpful if you are writing TLC code for customizing targets, integrating legacy code, or developing new blocks.

To...	Select...
Display progress information during code generation in the MATLAB Command Window	"Verbose build" (Simulink Coder).Compiler output also displays.
Prevent the build process from deleting the *model*`.rtw` file from the build folder at the end of the build	"Retain .rtw file" (Simulink Coder). This parameter is useful if you are modifying the target files, in which case you need to look at the *model*`.rtw` file.
Instruct the TLC profiler to analyze the performance of TLC code executed during code generation and generate a report	"Profile TLC" (Simulink Coder). The report is in HTML format and can be read in your Web browser.
Start the TLC debugger during code generation	"Start TLC debugger when generating code" (Simulink Coder). Alternatively, enter the argument `-dc` for the "System target file" (Simulink Coder) parameter on the **Code Generation** pane. To start the debugger and run a debugger script, enter `-df filename` for **System target file**.
Generate a report containing statistics indicating how many times the code generator reads each	"Start TLC coverage when generating code" (Simulink Coder). Alternatively, enter the argument `-dg` for the **System Target File** parameter on the **Code Generation** pane.

To...	Select...
line of TLC code during code generation	

Halt a build if a user-supplied TLC file contains an `%assert` directive that evaluates to `FALSE`	"Enable TLC assertion" (Simulink Coder). Alternatively, you can use MATLAB commands to control TLC assertion handling.
	
	To set the flag on or off, use the `set_param` command. The default is off.
	
	`set_param(model, 'TLCAssertion', 'on|off')`
	
	To check the current setting, use `get_param`.
	
	`get_param(model, 'TLCAssertion')`

Detect loss of tunability	"Detect loss of tunability" (Simulink) on the **Diagnostics** > **Data Validity** pane. You can use this parameter to report loss of tunability when an expression is reduced to a numeric expression. This can occur if a tunable workspace variable is modified by Mask Initialization code, or is used in an arithmetic expression with unsupported operators or functions. Possible values are: • `none` — Loss of tunability can occur without notification. • `warning` — Loss of tunability generates a warning (default). • `error` — Loss of tunability generates an error. For a list of supported operators and functions, see "Tunable Expression Limitations" (Simulink Coder)

To...	Select...

Enable model verification (assertion) blocks	"Model Verification block enabling" (Simulink) on the **All Parameters**. Use this parameter to enable or disable model verification blocks such as Assert, Check Static Gap, and related range check blocks. The diagnostic applies to generated code as well as simulation behavior. For example, simulation and code generation ignore this parameter when model verification blocks are inside an S-function. Possible values are:
	• `User local settings`
	• `Enable All`
	• `Disable All`
	For Assertion blocks not disabled, generated code for a model includes one of the following statements, depending on the blocks input signal type (Boolean, real, or integer, respectively).
	`utAssert(input_signal);`
	`utAssert(input_signal != 0.0);`
	`utAssert(input_signal != 0);`
	By default, `utAssert` does not change generated code. For assertions to abort execution, you must enable them by specifying the following `make_rtw` command for **Code Generation >** "Make command" (Simulink Coder) parameter:
	`make_rtw OPTS="-DDOASSERTS"`
	Use the following variant if you want triggered assertions to print the assertion statement instead of aborting execution:
	`make_rtw OPTS="-DDOASSERTS -DPRINT_ASSERTS"`
	utAssert is defined as `#define utAssert(exp) assert(exp)`.
	To customize assertion behavior, provide your own definition of `utAssert` in a handwritten header file that overrides the default `utAssert.h`. For details on how to include a customized header file in generated code, see "Integrate

To...	Select...
	External Code by Using Model Configuration Parameters" (Simulink Coder). When running a model in accelerator mode, the Simulink engine calls back to itself to execute assertion blocks instead of using generated code. Thus, user-defined callbacks are still called when assertions fail.

For more information about the TLC debugging options, see Debugging on "Target Language Compiler" (Simulink Coder). Also, consider using the Model Advisor as a tool for troubleshooting model builds.

Configuration in Embedded Coder

Configure Model for Code Generation Objectives by Using Code Generation Advisor

In this section...

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation parameters in a model configuration set. Parameters that you set in the **Solver**, **Data Import/Export**, **Diagnostics**, and **Code Generation** panes in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in "Recommended Settings Summary for Model Configuration Parameters" to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks that the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. but the Code Generation Advisor cannot modify the configuration parameter settings.

High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability are more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

Specify Objectives in Referenced Models

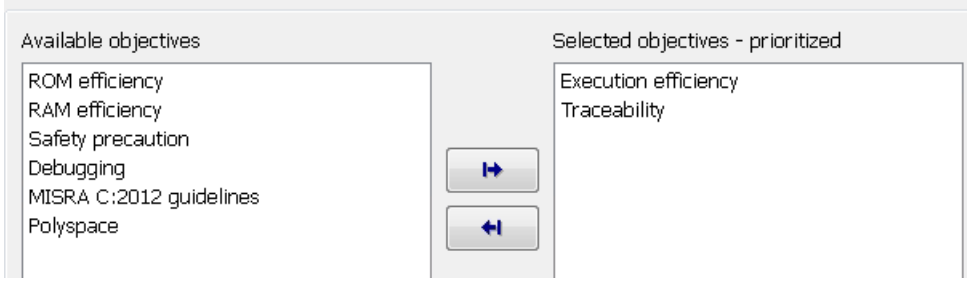
When you check a model during the code generation process, you must specify the same objectives in the top model and referenced models. If you specify different objectives for the top model and referenced model, the build process generates an error.

To specify different objectives for the top model and each referenced model, review the models separately without generating code.

Configure Model Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

1. On the menu bar, select **Code > C/C++ Code > Code Generation Advisor**.
2. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
3. In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. If your model is configured with an ERT-based target, more objectives are available. For this example, the model is configured with an ERT-based target. If your objectives are execution efficiency and traceability, in that priority, do the following:
   a. In **Available objectives**, double-click `Execution efficiency`. `Execution efficiency` is added to **Selected objectives - prioritized**.
   b. In **Available objectives**, double-click `Traceability`. `Traceability` is added to **Selected objectives - prioritized** under `Execution efficiency`.



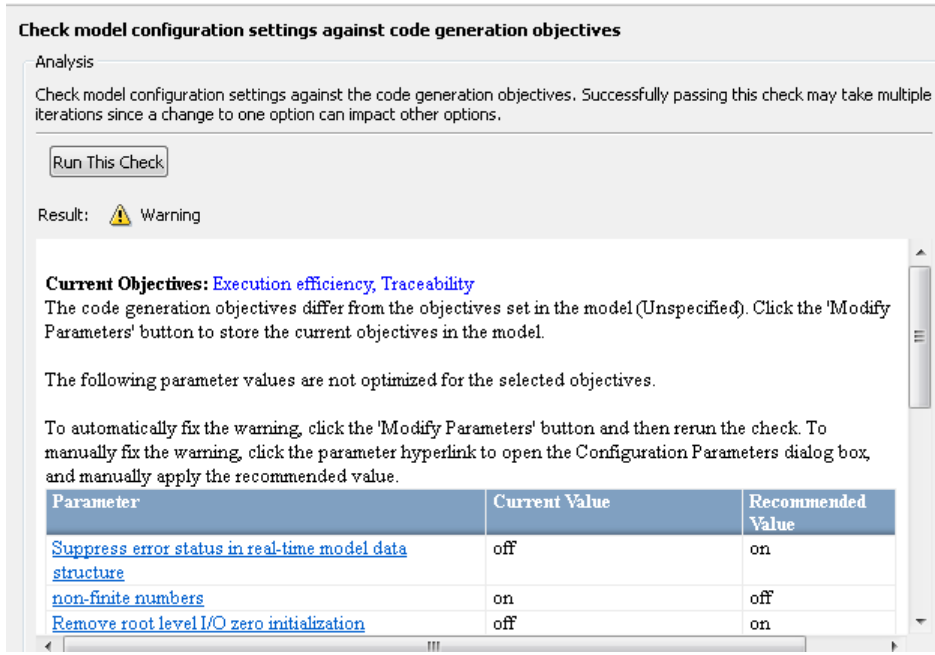
4. To run the checks listed in the left pane of the Code Generation Advisor, click **Run Selected Checks**.
5. In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

Check model configuration settings against code generation objectives triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
- Code generation objectives in the model to the objectives specified in the Code Generation Advisor.



6 In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.

7 After reviewing the check results, you can choose to fix warnings and failures, as described in "Fix a Model Check Warning or Failure" (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to configure and check your model to meet code generation objectives via the Configuration Parameters dialog box:

1 Open the Configuration Parameters dialog box. Select **Code Generation**.

2 Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, choose an ERT-based target such as `ert.tlc`.

3 Click **Set Objectives**.

4 In the "Set Objectives — Code Generation Advisor Dialog Box" (Simulink Coder), specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, do the following:

   a In **Available objectives**, double-click `Execution efficiency`. `Execution efficiency` is added to **Selected objectives - prioritized**.

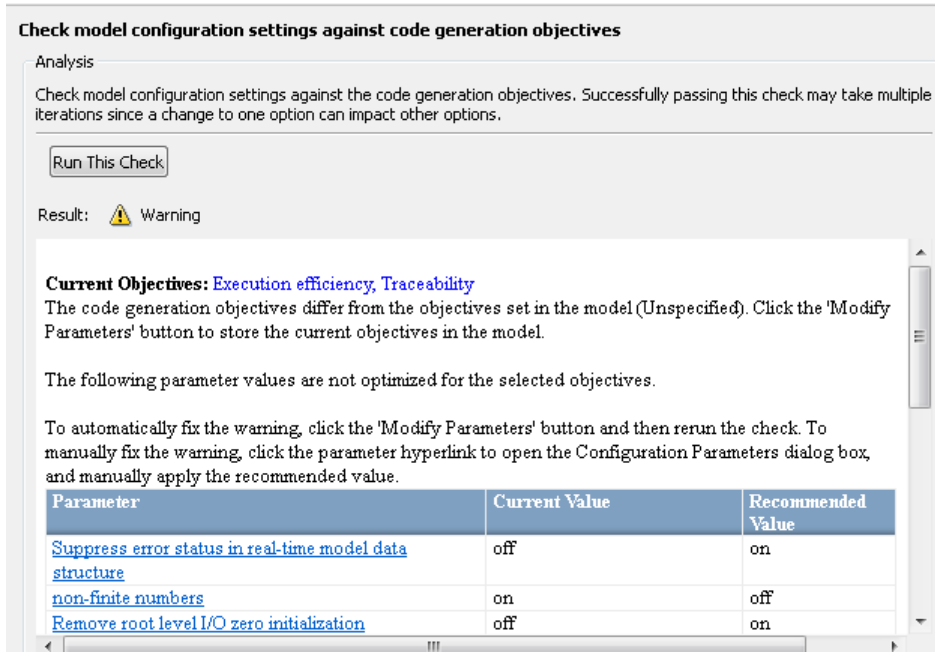
   b In **Available objectives**, double-click `Traceability`. `Traceability` is added to **Selected objectives - prioritized** under `Execution efficiency`.

   c To accept the objectives, click **OK**. In the Configuration Parameters dialog box, **Code Generation** > **General** > **Prioritized objectives** is updated.

5 On the **Configuration Parameters** > **Code Generation** > **General** pane, click **Check Model**.

6 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**. The Code Generation Advisor opens and reviews the model or subsystem that you specified.

7 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.



8 After reviewing the check results, you can choose to fix warnings and failures, as described in "Fix a Model Check Warning or Failure" (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see "Set Objectives — Code Generation Advisor Dialog Box" (Simulink Coder)

Configure Code Generation Objectives Programmatically

This example shows how to configure code generation objectives by writing a MATLAB script or entering commands at the command line.

1. Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, specify `ert.tlc`. *`model_name`* is the name or handle to the model.

   ```
   set_param(model_name, 'SystemTargetFile', 'ert.tlc');
   ```

2. Specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, enter:

   ```
   set_param(model_name, 'ObjectivePriorities',...
   {'Execution efficiency', 'Traceability'});
   ```

3. Execute the Code Generation Advisor, by using either the Code Generation Advisor or in the Configuration Parameters dialog box. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 29-2.

When you specify a GRT-based system target file, you can specify an objective at the command line. If you specify `ROM efficiency`, `RAM efficiency`, `Traceability`, `MISRA C:2012 guidelines`, `Polyspace`, or `Safety precaution`, the build process changes the objective to `Unspecified` because you have specified a value that is invalid when using a GRT-based target.

Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	"Run Model Checks" (Simulink)
Code Generation Advisor	"Configure Model for Code Generation Objectives by Using Code Generation Advisor" on page 29-2
Checks available with Simulink Coder	"Simulink Coder Checks" (Simulink Coder)
Checks available with Embedded Coder	"Embedded Coder Checks"

To check model `rtwdemo_throttlecntrl` for code efficiency, use the Model Advisor.

1. Open `rtwdemo_throttlecntrl`. Save a copy as `throttlecntrl` in a writable location on your MATLAB path.
2. To start the Model Advisor, select **Analysis** > **Model Advisor** > **Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Task** > **Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
5. In the left pane, select the remaining checks, and then select **Code Generation Efficiency**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see "View Model Advisor Reports" (Simulink).

Check Model During Code Generation

To review a model as part of the code generation process, use the Code Generation Advisor .

1. To select and prioritize your code generation objectives, on the **Configuration Parameters > Code Generation** pane, click **Set Objectives**.
2. On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
   - `On (proceed with warnings)`
   - `On (stop for warnings)`
3. If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
4. Apply your changes. In the model window, press **Ctrl+B** to generate code or build the model.

   If the Code Generation Advisor issues failures or warnings, and you specified:

   - `On (proceed with warnings)` — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
   - `On (stop for warnings)` — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
5. In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.
6. After reviewing the check results, you can choose to fix warnings and failures as described in "Fix a Model Check Warning or Failure" (Simulink).

Note: When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see "Set Objectives — Code Generation Advisor Dialog Box" (Simulink Coder)

Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency

To check that your model meets guidelines, standards, and is ready to generate code, you can use the Model Advisor checks available with Embedded Coder.

- To start the Model Advisor, in the model window, select **Analysis** > **Model Advisor** > **Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see "Run Model Checks" (Simulink).

The table summarizes the Embedded Coder Model Advisor checks that are available in the **By Task** folders.

By Task folder	Model Advisor checks
Modeling Standards for • **IEC 61508, IEC 62304, ISO 26262, and EN 50128** • **Modeling Standards for MAAB**	"Check for blocks not recommended for C/C++ production code deployment"
Code Generation Efficiency	"Identify lookup table blocks that generate expensive out-of-range checking code" "Check output types of logic blocks" "Identify questionable software environment specifications" "Identify questionable code instrumentation (data I/O)" "Identify blocks that generate expensive fixed-point and saturation code" "Identify blocks that generate expensive rounding code"

By Task folder	Model Advisor checks
	"Identify questionable fixed-point operations"
Modeling Standards for DO-178C/DO-331	"Check for blocks not recommended for C/C++ production code deployment" "Check the hardware implementation" "Identify questionable subsystem settings"
Modeling Guidelines for MISRA C:2012	"Check configuration parameters for MISRA C:2012" "Check for blocks not recommended for MISRA C:2012" "Check for unsupported block names" "Check usage of Assignment blocks" "Check for bitwise operations on signed integers" "Check for recursive function calls" "Check for switch case expressions without a default case" "Check for equality and inequality operations on floating-point values"

Create Custom Code Generation Objectives

In this section...

The Code Generation Advisor reviews your model based on objectives that you specify. If the predefined efficiency, traceability, Safety precaution, and debugging objectives do not meet your requirements, you can create custom objectives.

To create custom objectives:

- Create an objective and add parameters and checks to this new objective.
- Create an objective based on an existing objective, then add, modify, and remove the parameters and checks within that new objective.

Specify Parameters in Custom Objectives

When you create a custom objective, you specify the values of configuration parameters that the Code Generation Advisor reviews. You can use the following methods:

- addParam — Add parameters and specify the values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- modifyInheritedParam — Modify inherited parameter values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- removeInheritedParam — Remove inherited parameters from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this parameter, the Code Generation Advisor reviews the parameter value in **Check model configuration settings against code generation objectives**.

Specify Checks in Custom Objectives

Objectives include the **Check model configuration settings against code generation objectives** check by default. When you create a custom objective, you specify the list of additional checks that are associated with the custom objective. You can use the following methods:

- addCheck — Add checks to the Code Generation Advisor. When you select the custom objective, the Code Generation Advisor displays the check, unless you specify an additional objective with a higher priority that excludes the check.

  For example, add a check to the Code Generation Advisor to include a custom check in the automatic model checking process.
- excludeCheck — Exclude checks from the Code Generation Advisor. When you select multiple objectives, if you specify an additional objective that includes this check as a higher priority objective, the Code Generation Advisor displays this check.

  For example, exclude a check from the Code Generation Advisor when a check takes a long time to process.
- removeInheritedCheck — Remove inherited checks from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this check, the Code Generation Advisor displays the check.

  For example, remove an inherited check, rather than exclude the check, when the check takes a long time to process, but the check is important for another objective.

Determine Checks and Parameters in Existing Objectives

When you base a new objective on an existing objective, you can determine what checks and parameters the existing objective contains. The Code Generation Advisor contains the list of checks in each objective.

For example, the `Efficiency` objective includes checks that you can see in the Code Generation Advisor.

1. Open the rtwdemo_rtwecintro model.
2. Specify an ERT-based target.
3. On the model toolbar, select **Code > C/C++ Code > Code Generation Advisor**.
4. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.

5 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. For this example, select `Execution efficiency`. In **Available objectives**, double-click `Execution efficiency`. `Execution efficiency` is added to **Selected objectives - prioritized**.

In the left pane, the Code Generation Advisor lists the checks for the `Execution efficiency` objective. The first check, **Check model configuration settings against code generation objectives**, lists parameters and values specified by the objective. For example, the Code Generation Advisor displays the list of parameters and the recommended values in the `Execution efficiency` objective. To see the list of parameters and values:

1 Run **Check model configuration settings against code generation objectives**.

2 Click **Modify Parameters**.

3 Rerun the check.

In the check results, the Code Generation Advisor displays the list of parameters and recommended values for the `Execution efficiency` objective.

Passed
Current Objectives: Execution efficiency

The following parameters have been checked and confirmed with the recommended value

Parameter	Value
non-inlined S-functions	off
Suppress error status in real-time model data structure	on
MAT-file logging	off
Classic call interface	off
continuous time	off
non-finite numbers	off
Single output/update function	on
Minimize algebraic loop occurrences	off

Steps to Create Custom Objectives

To create a custom objective:

1 Create an `sl_customization.m` file.

- Specify custom objectives in a single `sl_customization.m` file only or the software generates an error. This issue is true even if you have more than one `sl_customization.m` file on your MATLAB path.

- Except for the *matlabroot*`/work` folder, do not place an `sl_customization.m` file in your root MATLAB folder or its subfolders. Otherwise, the software ignores the customizations that the file specifies.

2 Create an `sl_customization` function that takes a single argument. When the software invokes the function, the value of this argument is the Simulink customization manager. In the function:

- To create a handle to the code generation objective, use the `ObjectiveCustomizer` constructor.
- To register a callback function for the custom objectives, use the `ObjectiveCustomizer.addCallbackObjFcn` method.
- To add a call to execute the callback function, use the `ObjectiveCustomizer.callbackFcn` method.

For example:

```
function sl_customization(cm)
%SL_CUSTOMIZATION objective customization callback

objCustomizer = cm.ObjectiveCustomizer;
index = objCustomizer.addCallbackObjFcn(@addObjectives);
objCustomizer.callbackFcn{index}();

end
```

3 Create a MATLAB callback function that:

- Creates code generation objective objects by using the rtw.codegenObjectives.Objective constructor.
- Adds, modifies, and removes configuration parameters for each objective by using the addParam, modifyInheritedParam, and removeInheritedParam methods.
- Includes and excludes checks for each objective by using the addCheck, excludeCheck, and removeInheritedCheck methods.
- Registers objectives by using the register method.

The following example shows how to create an objective `Reduce RAM Example`. `Reduce RAM Example` includes five parameters and three checks that the Code Generation Advisor reviews.

```
function addObjectives

% Create the custom objective
obj = rtw.codegenObjectives.Objective('ex_ram_1');
```

```
setObjectiveName(obj, 'Reduce RAM Example');

% Add parameters to the objective
addParam(obj, 'DefaultParameterBehavior', 'Inlined');
addParam(obj, 'BooleanDataType', 'on');
addParam(obj, 'OptimizeBlockIOStorage', 'on');
addParam(obj, 'EnhancedBackFolding', 'on');
addParam(obj, 'BooleansAsBitfields', 'on');

% Add additional checks to the objective
% The Code Generation Advisor automatically includes 'Check model
% configuration settings against code generation objectives' in every
% objective.
addCheck(obj, 'mathworks.design.UnconnectedLinesPorts');
addCheck(obj, 'mathworks.design.Update');

%Register the objective
register(obj);

end
```

The following example shows you how to create an objective `My Traceability Example` based on the existing Traceability objective. The custom objective modifies, removes, and adds parameters that the Code Generation Advisor reviews. It also adds and removes checks from the Code Generation Advisor.

```
function addObjectives

% Create the custom objective from an existing objective
obj = rtw.codegenObjectives.Objective('ex_my_trace_1', 'Traceability');
setObjectiveName(obj, 'My Traceability Example');

% Modify parameters in the objective
modifyInheritedParam(obj, 'GenerateTraceReportSf', 'Off');
removeInheritedParam(obj, 'ConditionallyExecuteInputs');
addParam(obj, 'MatFileLogging', 'On');

% Modify checks in the objective
addCheck(obj, 'mathworks.codegen.SWEnvironmentSpec');
removeInheritedCheck(obj, 'mathworks.codegen.CodeInstrumentation');

%Register the objective
register(obj);

end
```

4. If you previously opened the Code Generation Advisor, close the model from which you opened the Code Generation Advisor.
5. Refresh the customization manager. At the MATLAB command line, enter `sl_refresh_customizations`.
6. Open your model and review the new objectives.

- "Code Generation Advisor Checks" (Simulink Coder)

Configuration Variations

Every model contains one or more named configuration sets that specify model parameters such as solver options, code generation options, and other choices. A model can contain multiple configuration sets, but only one configuration set is active at a time. For more information on configuration sets and how to view and edit them in the Configuration Parameters dialog box, see “About Model Configurations” (Simulink).

A configuration set includes parameters that specify code generation in general. For more information, see “Configure a Model for Code Generation” (Simulink Coder). With Embedded Coder and an ERT system target file, more parameters are available for fine-tuning to optimize and customize the appearance of the generated code.

Multiple configuration sets can be useful in embedded systems development. By defining multiple configuration sets in a model, you can easily retarget code generation from that model. For example, one configuration set can specify the default ERT target with external mode support enabled for rapid prototyping. Another configuration set can specify the ERT-based target for Visual C++® to generate production code for deployment of the application. Activation of either configuration set fully reconfigures the model for that type of code generation.

Configure and Optimize Model with Configuration Wizard Blocks

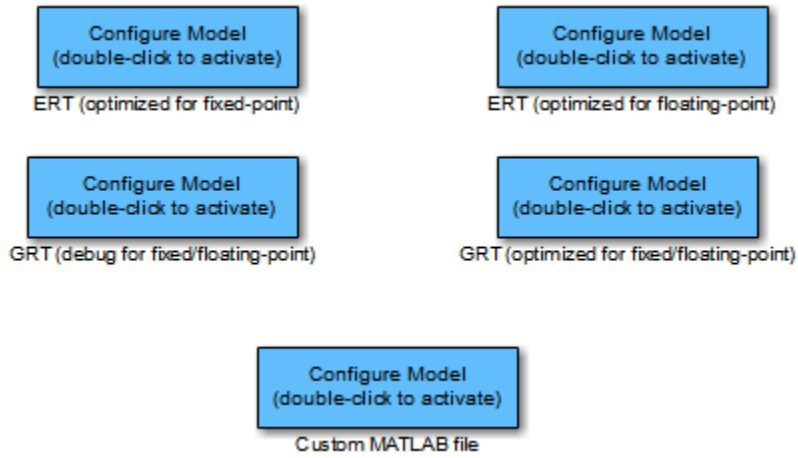
The Embedded Coder software provides a library of Configuration Wizard blocks and scripts to help you configure and optimize code generation from your models.

In this section...

Configuration Wizard Block Library

The library provides a Configuration Wizard block that you can customize. It also provides four preset Configuration Wizard blocks that update the active configuration parameters for a specified goal.

Block	Description
Custom MATLAB file	Update active configuration parameters of parent model by using a custom file
ERT (optimized for fixed-point)	Update active configuration parameters of parent model for ERT fixed-point code generation
ERT (optimized for floating-point)	Update active configuration parameters of parent model for ERT floating-point code generation
GRT (debug for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation with debugging enabled
GRT (optimized for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation



When you add one of the preset Configuration Wizard blocks to your model and double-click it, a predefined MATLAB file script configures parameters of the active configuration set without manual intervention. The preset blocks optimally configure the parameters for one of the following cases:

- Fixed-point code generation with the ERT target
- Floating-point code generation with the ERT target
- Fixed-point or floating-point code generation with TLC debugging parameters enabled, with the GRT target.
- Fixed-point or floating-point code generation with the GRT target

The Custom block provides an example MATLAB file script that you can adapt to your requirements.

You can also set up the Configuration Wizard blocks to invoke the build process after configuring the model.

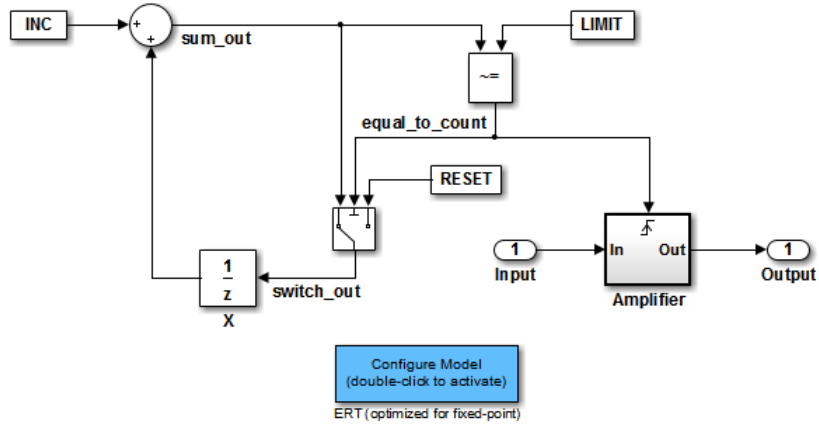
Add a Configuration Wizard Block

The Configuration Wizard blocks are available in the Embedded Coder block library. To use a Configuration Wizard block:

1. Open the model that you want to configure.
2. Open the Embedded Coder block library by typing the command `rtweclib`.

3 Double-click the Configuration Wizards icon. The Configuration Wizards sublibrary opens.

4 Select the Configuration Wizard block that you want to use and drag it into your model. This model contains the `ERT (optimized for fixed-point)` Configuration Wizard block.



5 If you want the Configuration Wizard block to invoke the build process after configuration, right-click the Configuration Wizard block in your model, and select **Mask > Mask Parameters** from the context menu. Then, select the **Invoke build process after configuration** parameter. Do not change the **Configure the model for** block parameter, unless you want to create a custom block and script. In that case, see "Create a Custom Configuration Wizard Block" on page 29-24.

6 Click **Apply** and close the Mask Parameters dialog box.

7 Save the model.

Use Configuration Wizard Blocks to Configure Your Model

After you add a Configuration Wizard block to your model, to configure your model, double-click the block. The script associated with the block sets parameters of the active configuration set that are relevant to code generation (including selection of the target). You can see that the parameters have changed by opening the Configuration Parameters dialog box and examining the parameter settings.

If you selected the **Invoke build process after configuration** block parameter, the script also initiates the code generation and build process.

Note: To provide a quick way to switch between configurations, you can add more than one Configuration Wizard block to your model.

Create a Custom Configuration Wizard Block

The Custom Configuration Wizard block and the associated MATLAB file script, *matlabroot*/toolbox/rtw/rtw/rtwsampleconfig.m, provide a starting point for customization.

Set Up a Configuration Wizard Block

Set up a custom Configuration Wizard block and link it to a script. If you want to use the block in more than one mode, it is advisable to create a Simulink library to contain the block.

To begin, make a copy of the example script for later customization:

1. To store your custom script, create a folder. This folder must not be anywhere inside the MATLAB folder structure (that is, it must not be under *matlabroot*).

   The example refers to this folder as /my_wizards.
2. Add the folder to the MATLAB path. Save the path for future sessions.
3. Copy the example script rtwsampleconfig.m in the folder *matlabroot*/toolbox/rtw/rtw (open) to the /my_wizards folder that you created. Then, rename the script. This example uses the name my_configscript.m.
4. Open the example script into the MATLAB editor. Scroll to the end of the file and enter the following line of code:

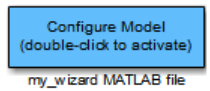
   ```
   disp('Custom Configuration Wizard Script completed.');
   ```

   This statement is used later as a test to see that your custom block has executed the script.
5. Save your script and close the MATLAB editor.

The next task is to create a Simulink library and add a custom block to it.

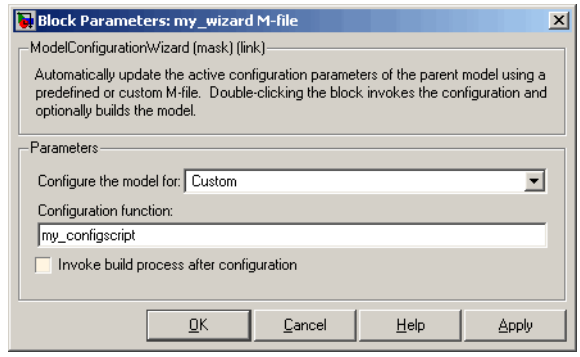
1. Open the Embedded Coder block library and the Configuration Wizards sublibrary, as described in “Add a Configuration Wizard Block” on page 29-22.
2. Select **New > Library** from the **File** menu of the Configuration Wizards sublibrary window. An empty library window opens.

3. Select the Custom MATLAB file block from the Configuration Wizards sublibrary and drag it into the empty library window.
4. To distinguish your custom block from the original, edit the Custom MATLAB file label under the block.
5. Select **Save as** from the **File** menu of the new library window. Save the library to the `/my_wizards` folder, under your library name of choice. In this figure, the library is saved as `ex_custom_button` and the block is labeled `my_wizard MATLAB-file`.



The next task is to link the custom block to the custom script:

1. Right-click the block in your model and select **Mask > Mask Parameters** from the context menu. The **Configure the model for** menu is set to `Custom`. When `Custom` is selected, the **Configuration function** edit field is enabled so that you can enter the name of a custom script.
2. In the **Configuration function** field, enter the name of your custom script . (Do not enter the `.m` file name extension, which is implicit.)



3. By default, the **Invoke build process after configuration** parameter is cleared. You can change the default for your custom block by selecting this option. For now, leave this parameter cleared.
4. Click **Apply** and close the Mask Parameters dialog box.
5. Save the library.

6 Close the Embedded Coder block library and the Configuration Wizards sublibrary. Leave your custom library open for use in the next task.

Test your block and script in a model.

1 Open the `vdp` model by typing the command:

```
vdp
```

2 Open the Configuration Parameters dialog box and view the parameters by clicking **Code Generation** in the list in the left pane of the dialog box.

3 Observe that `vdp` is configured, by default, for the GRT target. Close the Configuration Parameters dialog box.

4 Select your custom block from your custom library. Drag the block into the `vdp` model.

5 In the `vdp` model, double-click your custom block.

6 In the MATLAB window, you see the test message that you previously added to your script:

```
Custom Configuration Wizard Script completed.
```

The test message indicates that the custom block executed the script.

7 Reopen the Configuration Parameters dialog box and view the **Code Generation** pane again. The model is now configured for the ERT target.

Before applying further edits to your custom script, proceed to the next section to learn about the operation and conventions of Configuration Wizard scripts.

Create a Configuration Wizard Script

Create your custom Configuration Wizard script by copying and modifying the example script, `rtwsampleconfig.m`.

The Configuration Function

The example script implements a single function without a return value. The function takes a single argument `cs`:

```
function rtwsampleconfig(cs)
```

The argument `cs` is a handle to a proprietary object that contains information about the active configuration set. The Simulink software obtains this handle and passes it in to the configuration function when you double-click a Configuration Wizard block.

Your custom script must conform to this prototype. Your code must use `cs` as a "black-box" object that transmits information to and from the active configuration set.

Access Configuration Set Parameters

To set parameters or obtain parameter values, use the Simulink `set_param` and `get_param` functions.

Option names are passed in to `set_param` and `get_param` as character vectors specifying an *internal option name*. The internal option name can be different from the option label on the UI (for example, the Configuration Parameters dialog box). The example configuration accompanies each `set_param` and `get_param` call with a comment that correlates internal option names to UI option labels. For example:

```
set_param(cs,'LifeSpan','1'); % Application lifespan (days)
```

To obtain the current setting of an option in the active configuration set, call `get_param`. Pass in the `cs` object as the first argument, followed by the internal option name. For example, the following code excerpt tests the setting of the **Create code generation report** option:

```
if strcmp(get_param(cs, 'GenerateReport'), 'on')
    ...
```

To set an option in the active configuration set, call `set_param`. Pass in the `cs` object as the first argument, followed by one or more parameter/value pairs that specify the internal option name and its value. For example, the following code excerpt turns off the **Support absolute time** option:

```
set_param(cs,'SupportAbsoluteTime','off');
```

Select a Target

A Configuration Wizard script must select a target configuration. The example script uses the ERT target as a default. The script first stores character vector variables that correspond to the required **System target file**, **Template makefile**, and **Make command** settings:

```
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc  = 'make_rtw';
```

You select the system target file by passing the `cs` object and the `stf` character vector to the `switchTarget` function:

```
switchTarget(cs,stf,[]);
```

Set the template makefile and make command options by using `set_param` calls:

```
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

To select a target, your custom script must set up the character vector variables `stf`, `tmf`, and `mc` and pass them to the calls.

Obtain Target and Configuration Set Information

The following utility functions and properties are provided so that your code can obtain information about the current target and configuration set with the `cs` object:

- `isValidParam(cs, 'option')`: The `option` argument is an internal option name. `isValidParam` returns true if `option` is a valid option in the context of the active configuration set.
- `getPropEnabled(cs, 'option')`: The `option` argument is an internal option name. Returns true if this `option` is enabled (that is, writable).
- `IsERTTarget` property: Your code can detect whether the currently selected target is derived from the ERT target by checking the `IsERTTarget` property, as follows:

  ```
  isERT = strcmp(get_param(cs,'IsERTTarget'),'on');
  ```

You can use this information to determine whether the script must configure ERT-specific parameters, for example:

```
if isERT
  set_param(cs,'ZeroExternalMemoryAtStartup','off');
  set_param(cs,'ZeroInternalMemoryAtStartup','off');
  set_param(cs,'InitFltsAndDblsToZero','off');
  set_param(cs,'InlinedParameterPlacement',...
                'NonHierarchical');
     set_param(cs,'NoFixptDivByZeroProtection','on')
end
```

Invoke a Configuration Wizard Script from the Command Line

Configuration Wizard scripts can be run from the MATLAB command line.

Before invoking the script, you must open a model and instantiate a `cs` object to pass in as an argument to the script. After running the script, you can invoke the build process with the `rtwbuild` command. The following example opens, configures, and builds a model.

```
open my_model;
cs = getActiveConfigSet ('my_model');
rtwsampleconfig(cs);
rtwbuild('my_model');
```

Create a Model Configured for Code Generation Using Model Templates

Model templates provide you with a starting point for quickly developing models for code generation. Embedded Coder templates provide starting models for the following applications:

- Code Generation System. Create a model to get started with code generation.
- Exported functions. Create a model for generating code from function-call subsystems.
- Fixed-step, multirate. Create a fixed-step model with multiple rates for production code generation.
- Fixed-step, single-rate. Create a fixed-step model with a single rate for production code generation.

In the templates, traceability and reporting are turned on so that you can easily evaluate your generated code. The model has **System target file** set to `ert.tlc` and is configured to meet code generation objectives prioritized in the following order:

1. Execution efficiency
2. Traceability

To create a model using a model template:

1. On the MATLAB home tab, click **Simulink**.
2. In the Simulink start page, expand **Embedded Coder**.
3. Select a template.
4. Click **Create**. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see "Create a Template from a Model" (Simulink).

System Target File Configuration

Select a System Target File

To configure a model for code generation, follow the steps in "Select a Solver That Supports Code Generation" (Simulink Coder) and "Select a System Target File from STF Browser" (Simulink Coder). When you select a system target file, other model configuration parameters change to serve requirements of the execution environment. For example:

- Code interface parameters
- Build process parameters, such as the toolchain or template makefile
- Target hardware parameters, such as word size and byte ordering

After selecting a system target file, you can modify model configuration parameter settings.

You can switch between different system target files in a single workflow for different code generation purposes (for example, rapid prototyping versus product code deployment). To switch, set up different configuration sets for the same model and switch the active configuration set for the current operation. For more information on how to set up configuration sets and change the active configuration set, see "Manage a Configuration Set" (Simulink).

In this section...

Select a Solver That Supports Code Generation

To build a model, the model configuration must select a solver that is compatible with code generation for the system target file. Few system target files support code generation with variable-step solvers or for models with a nonzero start time.

- Use **Configuration Parameters** > **Solver** > **Type** and select `Fixed-step` for GRT, ERT, and ERT-based system target files.
- Use **Configuration Parameters** > **Solver** > **Type** and select `Fixed-step` or `Variable-step` for Rapid Simulation (Rsim) or S-Function (rtwsfcn) system target files.

For more information, see “Time-Based Scheduling and Code Generation” on page 16-2.

When you try to build models with a nonzero start time using a system target file does not support a nonzero start time, the code generator does not produce code. The build process displays an error message. The Rapid Simulation (RSim) system target file supports a nonzero start time when **Configuration Parameters > RSim Target > Solver selection** is set to `Use Simulink solver module`. Other system target files do not support a nonzero start time.

Select a System Target File from STF Browser

After you follow the steps in “Select a Solver That Supports Code Generation” (Simulink Coder), use **Configuration Parameters > Code Generation > System target file** and click the **Browse** button to open the System Target File Browser. Select a system target file from the list. Your selection appears in the **System target file** field (*`target`*`.tlc`).

If you use a system target file that does not appear in the System Target File Browser, enter the name of your system target file in the **System target file** field.

You also can select a system target file programmatically from MATLAB code, as described in “Select a System Target File Programmatically” on page 30-4.

After selecting a system target file, you can modify model configuration parameter settings. Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Choose and Configure Build Process” on page 40-14.

If you want to switch between different system target files in a single workflow for different code generation purposes, set up different configuration sets for the same model. Switch the active configuration set for the current operation. This approach is useful for switching between rapid prototyping and product code deployment. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).

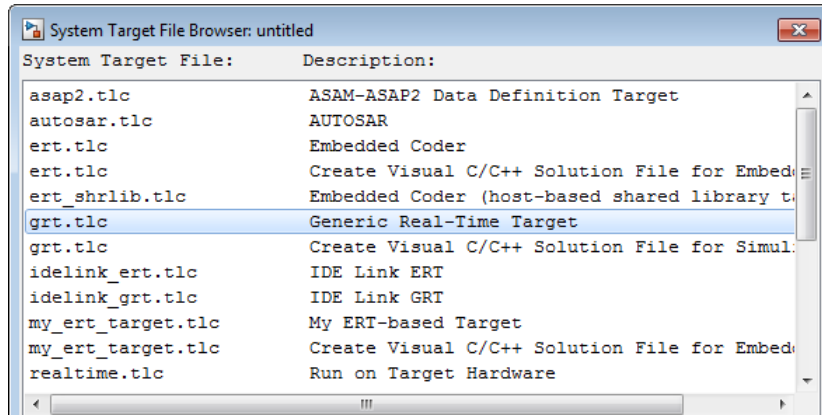
To select a system target file using the System Target File Browser,

1. Open the **Code Generation** pane of the Configuration Parameters dialog box.
2. Click the **Browse** button next to the **System target file** field. This button opens the System Target File Browser. The browser displays a list of currently available

system target files, including customizations. When you select a system target file, the code generator automatically chooses the system target file, toolchain or template makefile, and/or `make` command for that configuration.

The next step shows the System Target File Browser with the GRT system target file selected.

3 Click the desired entry in the list of available configurations. The background of the list box turns yellow to indicate that an unapplied choice has been made. To apply it, click **Apply** or **OK**.



System Target File Browser

When you choose a system target file, the code generator selects the toolchain or template makefile and/or `make` command for that configuration and displays them in the **System target file** field. The description of the system target file from the browser is placed below its name in the **Code Generation** pane. For information each system target file, see “Compare System Target File Support” on page 30-21.

Select a System Target File Programmatically

Simulink models store model-wide parameters and system target file-specific data in *configuration sets*. Every configuration set contains a component that defines the structure of a particular system target file and the current values of relevant options. Simulink loads some of this information from the system target file that you specify. You can configure models to generate alternative code by copying and modifying old or adding

new configuration sets and browsing to select a new system target file. Then, you can interactively select an active configuration from among these sets (only one configuration set can be active at a given time).

Scripts that automate system target file selection must emulate this process.

To program system target file selection:

1. Obtain a handle to the active configuration set with a call to the `getActiveConfigSet` function.
2. Define character vector variables that correspond to the required system target file, toolchain or template makefile, and/or `make` command settings. For example, for the ERT system target file, you would define variables for the character vectors `'ert.tlc'`, `'ert_default_tmf'`, and `'make_rtw'`.
3. Select the system target file with a call to the `switchTarget` function. In the function call, specify the handle for the active configuration set and the system target file.
4. Set the `TemplateMakefile` and `MakeCommand` configuration parameters to the corresponding variables created in step 2.

For example:

```
cs = getActiveConfigSet(model);
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc  = 'make_rtw';
switchTarget(cs,stf,[]);
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

For more information about selecting system target files programmatically, see `switchTarget`.

Develop Custom System Target Files

You can create your own system target files that interface with external code or operating environments.

For more information on how to make custom system target files appear in the System Target File Browser and display relevant controls, see “About Embedded Target Development” (Simulink Coder) and the topics it references.

- “Configure STF-Related Code Generation Parameters” on page 30-7
- “Configure a Code Replacement Library” on page 30-17
- “Configure Standard Math Library for Target System” on page 30-18
- “Compare System Target File Support” on page 30-21
- “About Embedded Target Development” (Simulink Coder)

Configure STF-Related Code Generation Parameters

Many model configuration parameters for code generation are specific to GRT, ERT, or ERT-based system target files. For more information, see the following topics.

In this section...

Specify Generated Code Interfaces

Use interface model configuration parameters to control which libraries to use when generating code, whether to include support for an API in generated code, and other interface options.

To...	Select or Enter...
Specify the standard math library that the code generator uses when generating code.	Select `C89/C90 (ANSI)`, `C99 (ISO)`, or `C++03 (ISO)` for the **Standard math library** parameter on the **All Parameters** tab. Selecting `C89/C90 (ANSI)` provides the ANSI[a] C set of library functions. For example, selecting `C89/C90 (ANSI)` results in generated code that calls `sin()` whether the input argument is double precision or single precision. However, if you select `C99 (ISO)`, the generated code calls the function `sinf()` when the input argument is single precision. If your compiler supports the ISO®[b] C math extensions, selecting the ISO C library can result in more efficient code. For more information, see "Standard math library" (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.

To...	Select or Enter...
Specify an application-specific library that the code generator uses when generating code.	If you generate application-specific C or C++ code for math functions or operations, select a value for **Code replacement library**. Otherwise, specify `None`. For more information about code replacement libraries, see "Choose a Code Replacement Library" on page 37-9 and "Code replacement library" (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.
Direct where the code generator places fixed-point and other utility code.	Select `Auto` or `Shared location` for **Shared code placement**. The shared location directs code for utilities to be placed within the `slprj` folder in your working folder, which is used for building referenced models. If you select `Auto`, • When the model contains Model blocks, places utility code within the `slprj/`*`target`*`/_sharedutils` folder. • When the model does not contain Model blocks, places utility code in the build folder (generally, in *`model`*`.c` or *`model`*`.cpp`).
Specify text to be added to the variable names used when logging data to MAT-files and to distinguish logging data from code generation and simulation applications.	Enter a prefix or suffix, such as `rt_` or `_rt`, for the **MAT-file variable name modifier** parameter on the **All Parameters** tab. The code generator prefixes or appends the text to the variable names for system outputs, states, and simulation time specified in the **Data Import/Export** pane. See "Log Program Execution Results" on page 42-2 for information on MAT-file data logging.

To...	Select or Enter...
Specify data exchange APIs to be included in generated code.	Select one or more **C API** options, the **ASAP2 interface** option, or the **External mode** option. When you select **External mode**, other options appear. The data exchange APIs are independent, and you can select combinations of these APIs. For example, you could choose C API and external mode. For more information on working with these interfaces, see "Exchange Data Between Generated and External Code Using C API" on page 43-2, "Export ASAP2 File for Data Measurement and Calibration" on page 44-2, and "What You Can Do with a Host/ Target Communication Channel" on page 41-2. The options for this parameter have dependencies. See Interface Dependencies.

a. ANSI is a registered trademark of the American National Standards Institute, Inc.
b. ISO is a registered trademark of the International Organization for Standardization.

Note: Before setting **Standard math library** or **Code replacement library**, verify that your compiler supports the library you want to use. If you select a parameter value that your toolchain does not support, compiler errors can occur. For example, if you select standard math library `C99 (ISO)` and your compiler does not support the ISO C math extensions, compile-time errors could occur.

When the Embedded Coder product is installed on your system, the **Code Generation** > **Interface** pane expands to include several additional options. For descriptions of **Code Generation** > **Interface** pane parameters, see "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

Several interface parameters have dependencies on settings of other parameters. The following table summarizes the dependencies.

Interface Dependencies

Parameter	Dependencies?	Dependency Details
Standard math library	Yes	Available values depend on **Language** selection.

Parameter	Dependencies?	Dependency Details
Code replacement library	Yes	Available values depend on product licensing and other parameters. For more information, see "Code replacement library" (Simulink Coder).
Shared code placement	No	
Support: floating-point numbers (ERT system target files only)	No	
Support: non-finite numbers	Yes (ERT) No (GRT)	For ERT system target files, enabled by **Support floating-point numbers**
Support: complex numbers (ERT system target files only)	No	
Support: absolute time (ERT system target files only)	No	
Support: continuous time (ERT system target files only)	Yes	Requires that you disable **Remove error status field in real-time model data structure**.
Support: non-inlined S-functions (ERT system target files only)	Yes	Requires that you enable **Support floating-point numbers** and **Support non-finite numbers**
Classic call interface	Yes	Requires that you disable **Single output/update function**. For ERT system target files, requires that you enable **Support floating-point numbers**.
Single output/update function	Yes	Disable for **Classic call interface**
Terminate function required (ERT system target files only)	Yes	
Code interface packaging	Yes	Available values depend on **Language** selection.
Multi-instance code error diagnostic	Yes	Set **Code interface packaging** to `Reusable function` or `C++ class`

Parameter	Dependencies?	Dependency Details
Pass root-level I/O as (ERT system target files only)	Yes	Set **Code interface packaging** to `Reusable function`
Use dynamic memory allocation for model initialization (ERT system target files only)	Yes	Set **Code interface packaging** to `Reusable function`
MAT-file logging	Yes	For GRT system target files, requires that you enable **Support non-finite numbers**; for ERT system target files, requires that you enable **Support floating-point numbers**, **Support non-finite numbers**, and **Terminate function required**
MAT-file file variable name modifier	Yes	Enabled by **MAT-file logging**
Remove error status field in real-time model data structure (ERT system target files only)	Yes	Requires that you disable **Support: continuous time**.
Generate C API for: signals	No	
Generate C API for: parameters	No	
Generate C API for: states	No	
Generate C API for: root-level I/O	No	
ASAP2 interface	No	
External mode	No	
Transport layer	Yes	Enable **External mode**
MEX-file arguments	Yes	Enable **External mode**
Static memory allocation	Yes	Enable **External mode**
Static memory buffer size	Yes	Enable **Static memory allocation**

Configure Numeric Data Support

By default, ERT system target files support code generation for integer, floating-point, nonfinite, and complex numbers.

To Generate Code That Supports...	Do...
Integer data only	Clear **Support floating-point numbers**. If noninteger data or expressions are encountered during code generation, an error message reports the offending blocks and parameters.
Floating-point data	Select **Support floating-point numbers**.
Nonfinite values (for example, `NaN`, `Inf`)	Select **Support floating-point numbers** and **Support non-finite numbers**.
Complex data	Select **Support complex numbers**.

For more information, see "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

Configure Time Value Support

Certain blocks require the value of absolute time, elapsed time, or continuous time. Absolute time is the time from the start of program execution to the present time. Elapsed time is the time elapsed between two trigger events. Depending on the blocks used, your model could require adjustment of the configuration settings for supported time values.

To...	Select...
Generate code that creates and maintains integer counters for blocks that use absolute or elapsed time values (default).	**Support absolute time**. For further information on the allocation and operation of absolute and elapsed timers, see "Absolute and Elapsed Time Computation" (Simulink Coder). If you do not select this parameter and the model includes a block that uses absolute or elapsed time values, the build process generates an error.
Generate code for blocks that rely on continuous time.	**Support continuous time**. If you do not select this parameter and the model includes continuous-time blocks, the build process generates an error.

For more information, see "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

Configure Noninlined S-Function Support

To generate code for noninlined S-Functions in a model, select **Support noninlined S-functions**. The generation of noninlined S-functions requires floating-point and nonfinite numbers. Thus, when you select **Support non-inlined S-functions**, the ERT system target file selects **Support floating-point numbers** and **Support non-finite numbers**.

When you select **Support non-finite numbers** and the model includes a C MEX S-function that does not have a corresponding TLC implementation (for inlining code generation), the build process generates an error.

Inlining S-functions is highly advantageous in production code generation, for example in implementing device drivers. To enforce the use of inlined S-functions for code generation, clear **Support non-inlined S-functions**.

When generating code for a model that contains noninlined S-functions with an ERT system target file, there could be a mismatch between the simulation and code generation results when either of the following is true:

- Model configuration parameter `GenCodeOnly` is set to `off` or **Configuration Parameters** > **Code Generation** > **Generate code only** is cleared.
- Model configuration parameter `ProdEqTarget` is set to `off`.

To avoid such a mismatch, set `ProdEqTarget` to `on` or select **Configuration Parameters** > **Code Generation** > **Generate code only** (or set `GenCodeOnly` to `on`).

Configure Model Function Generation and Argument Passing

For ERT system target files, you can configure model for how functions are generated and how arguments are passed to the functions.

To...	Do...
Generate model function calls that are compatible with the main program module of the pre-R2012a GRT system target file (`grt_main.c` or `.cpp`).	Select **Classic call interface** and **MAT-file logging**. In addition, clearing **Remove error status field in real-time model data structure**. **Classic call interface** provides a quick way to use code generated in R2012a or higher with a pre-R2012a GRT-based custom system target file by generating wrapper function calls that interface to the generated code.

To...	Do...
Reduce overhead and use more local variables by combining the output and update functions in a single *model*_step function.	Select **Single output/update function** Errors or unexpected behavior can occur if a Model block is part of a cycle and the model configuration enables "Single output/update function" (Simulink Coder) (the default). See "Model Blocks and Direct Feed through" (Simulink).
Generate a *model*_terminate function for a model not designed to run indefinitely.	Select **Terminate function required** (Simulink Coder). For more information, see the description of model_terminate.
Generate reusable, reentrant code from a model or subsystem.	Select **Generate reusable code**. See "Configure Code Reuse Support" on page 30-15 for details.
Statically allocate model data structures and access them directly in the model code.	Clear **Generate reusable code**. The generated code is not reusable or reentrant. See "Entry-Point Functions and Scheduling" (Simulink Coder) for information on the calling interface generated for model functions in this case.
Suppress the generation of an error status field in the real-time model data structure, rtModel, for example, if you do not require to log or monitor error messages.	Select **Remove error status field in real-time model data structure**. Selecting this parameter can also cause the code generator to omit the rtModel structure from the generated code. When generating code for multiple integrated models, set this parameter the same for all of the models. Otherwise, the integrated application could exhibit unexpected behavior. For example, if you select the option in one model but not in another, it is possible that the integrated application could not register the error status. Do not select this parameter if you select the **MAT-file logging** option. The two options are incompatible.

To...	Do...
Open the Model Step Functions dialog box preview and modify the *model*_step function prototype (see "Entry-Point Functions and Scheduling" (Simulink Coder)).	Click **Configure Step Function**. Based on the **Function specification** value you select for your *model*_step function (supported values include `Default model-step function` and `Model specific C prototype`), you can preview and modify the function prototype. Once you validate and apply your changes, you can generate code based on your function prototype modifications. For more information about using the **Configure Step Function** button and the Model Step Functions dialog box, see "Control Generation of Function Prototypes" on page 26-2.

For more information, see "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

Configure Code Reuse Support

For GRT, ERT, GRT-based, and ERT-based system target files, you can configure how a model reuses code by setting the **Configuration Parameters** > **Code Generation** > **Code interface packaging** parameter value to `Reusable function`.

The **Configuration Parameters** > **Code Generation** > **Pass root-level I/O as** parameter provides options that control how model inputs and outputs at the root level of the model are passed to the *model*_step function.

To...	Select...
Pass each root-level model input and output argument to the *model*_step function individually (the default)	**Code interface packaging** > `Reusable function` and **Pass root-level I/O as** > `Individual arguments`.
Pack root-level input arguments and root-level output arguments into separate structures that are then passed to the *model*_step function	**Code interface packaging** > `Reusable function` and **Pass root-level I/O as** > `Structure reference`.
Pack root-level input arguments and root-level output arguments into the model data structure to support reentrant multi-instance code from a model for ERT system target file	**Code interface packaging** > `Reusable function` and **Pass root-level I/O as** > `Part of model data structure`.

If using the **Code interface packaging** > `Reusable function` selection, consider using the **Use dynamic memory allocation for model initialization** option to control

whether an allocation function is generated. This option applies for ERT system target files.

Sometimes, selecting **Code interface packaging** as `Reusable function` can generate code that compiles but is not reentrant. For example, if a signal, `DWork` structure, or parameter data has a storage class other than `Auto`, global data structures are generated. To handle such cases, use the **Multi-instance code error diagnostic** parameter to choose the severity levels for diagnostics.

Sometimes, the code generator is unable to generate valid and compilable code. For example, if the model contains one of the following, the generated code is invalid.

- An S-function that is not code-reuse compliant
- A subsystem triggered by a wide function-call trigger

In these cases, the build terminates after reporting the problem.

For more information, see "Generate Reentrant Code from Top-Level Models" on page 34-20 and "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

More About

- "Select a System Target File" on page 30-2
- "Configure a Code Replacement Library" on page 30-17
- "Configure Standard Math Library for Target System" on page 30-18
- "Compare System Target File Support" on page 30-21

Configure a Code Replacement Library

You can configure the code generator to change the code that it generates for functions and operators such that the code meets application requirements. Configure the code generator to apply a code replacement library (CRL) during code generation. If you have Embedded Coder, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see "What Is Code Replacement?" on page 38-2 and "Code Replacement Libraries" (Simulink Coder). For information about developing code replacement libraries, see "What Is Code Replacement Customization?" on page 51-3.

- "Configure Standard Math Library for Target System" on page 30-18
- "Compare System Target File Support" on page 30-21
- "Specify Generated Code Interfaces" on page 30-7

Configure Standard Math Library for Target System

Specify standard library extensions that the code generator uses for math operations. When you generate code for a new model or with a new configuration set object, the code generator uses the ISO®/IEC 9899:1999 C (C99 (ISO)) library by default. For preexisting models and configuration set objects, the code generator uses the library specified by the **Standard math library** parameter.

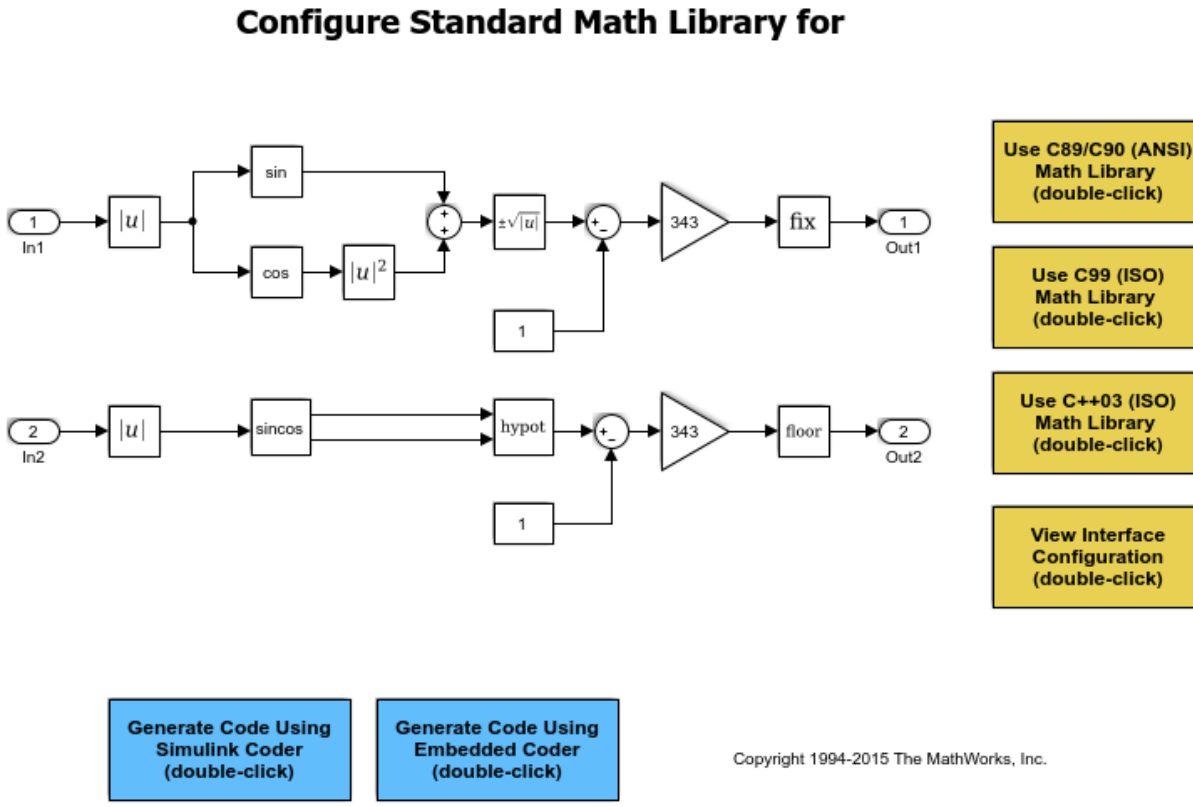
If your compiler supports the ISO®/IEC 9899:1990 (C89/C90 (ANSI)) or ISO/IEC 14882:2003(C++03 (ISO)) math library extensions, you can change the standard math library setting. The C++03 (ISO) library is an option when you select C++ for the programming language.

The C99 library leverages the performance that a compiler offers over standard ANSI C. When using the C99 library, the code generator produces calls to ISO C functions when possible. For example, the generated code calls the function `sqrtf()`, which operates on single-precision data, instead of `sqrt()`.

To change the library setting, use the **Configuration Parameters>All Parameters>Standard math library** parameter. The command-line equivalent is `TargetLangStandard`.

Generate and Inspect ANSI C Code

1. Open the example model `rtwdemo_clibsup`.



2. Generate code.

```
### Starting build procedure for model: rtwdemo_clibsup
### Successful completion of code generation for model: rtwdemo_clibsup
```

3. Examine the code in the generated file `rtwdemo_clibsup.c`. Note that the code calls the `sqrt` function.

```
if (rtb_Abs2 < 0.0F) {
  rtb_Abs2 = -(real32_T)sqrt((real32_T)fabs(rtb_Abs2));
} else {
  rtb_Abs2 = (real32_T)sqrt(rtb_Abs2);
}
```

Generate and Inspect ISO C Code

1. Change the setting of **All Parameters>Standard math library** to `C99 (ISO)`. Alternatively, at the command line, set `TargetLangStandard` to `C99 (ISO)`.

2. Regenerate the code.

```
### Starting build procedure for model: rtwdemo_clibsup
### Successful completion of code generation for model: rtwdemo_clibsup
```

3. Rexamine the code in the generated file `rtwdemo_clibsup.c`. Now the generated code calls the function `sqrtf` instead of `sqrt`.

```
if (rtb_Abs2 < 0.0F) {
  rtb_Abs2 = -sqrtf(fabsf(rtb_Abs2));
} else {
  rtb_Abs2 = sqrtf(rtb_Abs2);
}
```

Compare System Target File Support

A system target file (such as `grt.tlc`) defines a run-time environment. The code generator uses the system target file to produce code intended for execution on certain target hardware or operating system. The system target file invokes other run-time environment-specific files. For more information on configuring model code generation parameters for target hardware, see "Configure Run-Time Environment Options" (Simulink Coder).

Different types of system target files support a selection of generated code features. In the system target file, the value of the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value identify the system target file type and generated code features. These selections control decisions made at several points in the code generation process. These decisions include whether and how the model build generates:

- Certain data structures (for example, `SimStruct` or `rtModel`)
- Static or dynamic memory allocation code
- Calling interface for generated model functions

For custom system target file development, follow these guidelines:

- If the system target file does not include a value for the `CodeFormat` TLC variable, the default value is `RealTime` for generic real-time target (GRT). The corresponding `rtwgensettings.DerivedFrom` field value is `grt.tlc` (default value).
- If you are developing a custom system target file and you have a license for Embedded Coder software, consider setting the `CodeFormat` TLC variable value to `Embedded-C` for embedded real-time target (ERT). The corresponding `rtwgensettings.DerivedFrom` field value is `ert.tlc`. The ERT system target file supports more generated code features than the GRT system target file.

The following example shows how the value for the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value are set in `ert.tlc`.

```
%assign CodeFormat = "Embedded-C"

/%
  BEGIN_RTW_OPTIONS
  rtwgensettings.DerivedFrom = 'ert.tlc';
  END_RTW_OPTIONS
%/
```

Warning: You must use the value for the `CodeFormat` TLC variable with its corresponding `rtwgensettings.DerivedFrom` field value to generated code for the model. If none are explicitly selected, the default values correspond. For more information, see "System Target File Structure" (Simulink Coder).

For a description of the optimized call interface generated by default for both the GRT and ERT system target files, see "Entry-Point Functions and Scheduling" (Simulink Coder).

The real-time model data structure (`rtModel`) encapsulates model-specific information in a much more compact form than the `SimStruct`. Many efficiencies related to generated code depend on generation of `rtModel` rather than `SimStruct`, including:

- Integer absolute and elapsed timing services
- Independent timers for asynchronous tasks
- Generation of improved C API code for signal, state, and parameter monitoring
- Pruning the data structure to minimize its size (ERT-derived system target files only)

For a description of the `rtModel`data structure, see "Use the Real-Time Model Data Structure" (Simulink Coder).

The following topics provide more information about generated code features:

In this section...
"Evaluate Product System Target Files" on page 30-22

"Compare Generated Code Features by Product" on page 30-26
"Compare Generated Code Features by STF" on page 30-29

Evaluate Product System Target Files

The following table lists supported system target files.

Note You can select from a range of system target files by using the System Target File Browser. This selection lets you experiment with configuration options and save your model with different configurations. However, you cannot build or generate code for

non-GRT system target files, unless you have the required license on your system. For example, you require Embedded Coder for ERT system target files, require Simulink Desktop Real-Time for SLDRT system target files, and so on.

Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Choose and Configure Build Process” on page 40-14.

a. UNIX is a registered trademark of The Open Group in the United States and other countries.
b. Visual C++ is a registered trademark of Microsoft Corporation.
c. Set RTW.MSVCBuild in the "Template makefile" (Simulink Coder) field. This creates and builds Visual C++ Solution (.sln) file with Debug configuration.

Compare Code Styles and STF Support

The code generator produces two styles of code. One code style is suitable for rapid prototyping (and simulation by using code generation). The other style is suitable for embedded applications. The following table maps system target files to corresponding code styles.

Code Styles Listed by System Target File

System Target File	Code Style	Purpose
Embedded Coder embedded real-time (ERT)	Embedded	A starting point for embedded application development of C/C++ generated code
Simulink Coder generic real-time (GRT)	Rapid prototyping	A starting point for creating a rapid prototyping target hardware that does not use real-time operating system tasking primitives and for verifying the generated C/C++ code on your desktop computer
Rapid simulation (RSim)	Rapid prototyping	Provides non-real-time simulation on your desktop computer and a high-speed or batch simulation tool
S-function	Rapid prototyping	Creates a C MEX S-function for simulation within another Simulink model
Simulink Desktop Real-Time	Rapid prototyping	Runs model in real time at interrupt level while your desktop computer runs Microsoft Windows in the background
Simulink Real-Time	Rapid prototyping	Runs model in real time on a desktop computer running the Simulink Real-Time kernel

Third-party vendors supply additional system target files for the code generator. For more information about third-party products, see the MathWorks Connections program web page: http://www.mathworks.com/products/connections.

Compare Generated Code Features by Product

The code generation process for real-time system target files (such as GRT) provides many embedded code optimizations. GRT and ERT system target files have many common features. But, selecting an ERT-based system target file offers more extensive features. The system target file selection determines the available features for the code generation product. The following table compares code features available with Simulink Coder and features available with Embedded Coder.

Compare Code Generation Features for Simulink Coder Versus Embedded Coder

Feature	Simulink Coder	Embedded Coder
`rtModel` data structure	• Full `rtModel` structure generated • GRT variable declaration: `rtModel_model model_M_;`	• `rtModel` is optimized for the model • Optional suppression of error status field and data logging fields • ERT variable declaration: `RT_MODEL_model model_M_;`
Custom storage classes (CSCs)	Code generation ignores CSCs; objects are assigned a CSC default to `Auto` storage class	Code generation with CSCs is supported
HTML code generation report	Basic HTML code generation report	Enhanced report with additional detail and hyperlinks to the model
Symbol formatting	Symbols (for signals, parameters, and so on) are generated in accordance with hard-coded default	Detailed control over generated symbols.
User-defined maximum identifier length for generated symbols	Supported	Supported
Generation of terminate function	Generated	Option to suppress the terminate function
Combined output/ update function	Separate output/update functions are generated	Option to generate combined output/ update function
Optimized data initialization	Not available	Options to suppress generation of unnecessary initialization code for zero-valued memory, I/O ports, and so on
Comments generation	Basic options to include or suppress comment generation	Options to include Simulink block descriptions, Stateflow object descriptions, and Simulink data object descriptions in comments
Module Packaging Features (MPF)	Not supported	Extensive code customization features (See “What Are User-

Feature	Simulink Coder	Embedded Coder
		Defined Data Types?" on page 21-2 and "Custom Storage Classes".)
System target file-optimized data types header file	Requires full `tmwtypes.h` header file	Generates optimized `rtwtypes.h` header file, including definitions required by the system target file
User-defined types	User-defined types default to base types in code generation	User-defined data type aliases are supported in code generation
Rate grouping	Not supported	Supported
Auto-generation of main program module	Not supported; static main program module is provided.	Automated and customizable generation of main program module is supported (static main program also available)
Reusable (multi-instance) code generation	Option to generate reusable code with dynamic memory allocation	Option to generate reusable code with static or dynamic memory allocation
Software constraint options	Support for floating point, complex, and nonfinite numbers is enabled	Options to enable or disable support for floating-point, complex, and nonfinite numbers
Application life span	Defaults to `inf`	User-specified; determines most efficient word size for integer timers
Software-in-the-loop (SIL) testing	Model reference simulation target can be used for SIL testing	Additional SIL testing support by using auto-generation of SIL block
ANSI[a]-C/C++ code generation	Supported	Supported
ISO[b]-C/C++ code generation	Supported	Supported
GNU®[c]-C/C++ code generation	Supported	Supported
Generate scalar inlined parameters as `#DEFINE` statements	Not supported	Supported
MAT-file variable name modifier	Supported	Supported

Feature	Simulink Coder	Embedded Coder
Data exchange: C API, ASAP2, external mode	Supported	Supported

a. ANSI is a registered trademark of the American National Standards Institute, Inc.
b. ISO is a registered trademark of the International Organization for Standardization.
c. GNU is a registered trademark of the Free Software Foundation.

Compare Generated Code Features by STF

The code generator supports a selection of generated code features for different types of system target files. In each system target file, the value of the `CodeFormat` TLC variable identifies the set of features.

The following table summarizes how different system target files support applications:

Application	System Target File (STF)
Fixed- or variable-step acceleration	RSIM, S-Function, Model Reference
Fixed-step real-time deployment	GRT, ERT, Simulink Real-Time, Simulink Desktop Real-Time, ...

The following table summarizes the various options available for each **System target file** selection, with the exceptions noted.

Features Supported in Code Generated for System Target Files (STF)

	System Target Files (STF)							
Feature	**grt.tlc**[1]	**ert.tlc**[1]	**ert_shrlib.tlc**[1]	**rtwsfcn.tlc**[1]	**rsim.tlc**[1]	**sldrt.tlc**[1]	**slrt.tlc**[1]	**Other**[1]
Static memory allocation	X	X				X	X	X
Dynamic memory allocation	X[4, 5]	X[4, 5]		X	X		X	
Continuous time	X	X		X	X	X	X	
C/C++ MEX S-functions	X	X		X	X	X	X	

	System Target Files (STF)							
Feature	**grt.tlc**[1]	**ert.tlc**[1]	**ert_shrlib.tlc**[1]	**rtwsfcn.tlc**[1]	**rsim.tlc**[1]	**sldrt.tlc**[1]	**slrt.tlc**[1]	**Other**[1]
(noninlined)								
S-function (inlined)	X	X		X	X	X	X	X
Minimize RAM/ROM usage		X					X[2]	X
Supports external mode	X	X			X	X	X	
Rapid prototyping	X					X	X	X
Production code		X					X[2]	X[3]
Batch parameter tuning and Monte Carlo methods			X		X			
System-level Simulator			X					
Executes in hard real time	X[3]	X[3]				X	X	X[5]
Non-real-time executable included	X	X			X			
Multiple instances of model	X[4, 5]	X[4, 5]		X[4]			X[4, 5]	X[4, 5]

	System Target Files (STF)							
Feature	**grt.tlc**[1]	**ert.tlc**[1]	**ert_shrlib.tlc**[1]	**rtwsfcn.tlc**[1]	**rsim.tlc**[1]	**sldrt.tlc**[1]	**slrt.tlc**[1]	**Other**[1]
Supports variable-step solvers				X	X			
Supports SIL/PIL		X						X

[1] System Target Files: **grt.tlc** - generic real-time target, **ert.tlc** - embedded real-time target, **ert_shrlib.tlc** - embedded real-time target shared library), **rtwsfcn.tlc** - S-Function, **rsim.tlc** - rapid simulation, **sldrt.tlc** - Simulink Desktop Real-Time, **slrt.tlc** - Simulink Real-Time, and **Other** - The embedded real-time capabilities in Simulink Coder support other system target files.

[2]Does not apply to GRT-based system target files. Applies only to an ERT-based system target files.

[3]The default GRT and ERT `rt_main` files emulate execution of hard real time, and when explicitly connected to a real-time clock execute in hard real time.

[4]You can generate code for multiple instances of a Stateflow chart or subsystem containing a chart, except when the chart contains exported graphical functions or the Stateflow model contains machine parented events.

[5]You must select the value **Reusable function** for **Code interface packaging** (Simulink Coder) in the **Code Generation > Interface** pane of the Configuration Parameters dialog box.

Internationalization Support in Simulink Coder

Internationalization and Code Generation

Internationalization support in software development tooling is vital for enabling efficient globalization. If there is any possibility of future collaboration with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

In this section...

Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode® codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see "Internationalization" (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check "Check model for foreign characters" (Simulink).

Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

- Generated code comments
- Code generation reports
- Block paths logged to MAT-files
- Block paths logged to C API files *`model`*`_capi.c` (or `.cpp`) and *`model`*`_capi.h`

Generate and Review Code with Mixed Languages and Mixed Locales

This example shows how to use the code generator to generate and review code for use in mixed languages and mixed locales.

Before using this example, see “Internationalization and Code Generation” (Simulink Coder) or “Internationalization and Code Generation”.

The `rtwdemo_unicode` model configuration uses the Embedded Coder (R) `ert.tlc` system target file. To see internationalization and localization support with Simulink Coder®, configure the model to use the `grt.tlc` system target file. The example indicates the support that is specific to Embedded Coder® (for example, code generation templates).

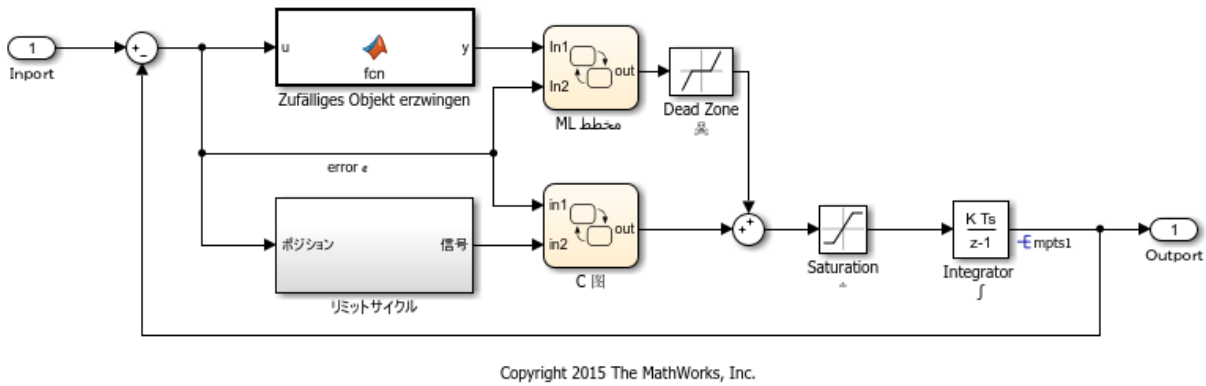
The model configuration specifies files and settings that control how the code generator handles localization for:

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder®)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

Open the example model `rtwdemo_unicode`.

Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```
model = 'rtwdemo_unicode';
open_system(model);
```



Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Windows Platforms” (MATLAB)
- “Set Locale on Linux Platforms” (MATLAB)
- “Set Locale on Mac Platforms” (MATLAB)

Verify Model for Use of Foreign Characters

to verify the model for characters that the code generator cannot represent in the model's current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters**.

1. Open the Model Advisor in Simulink®. Select **Analysis** > **Model Advisor** > **Model Advisor**. Or, in the Command Window, type:

```
modeladvisor('rtwdemo_unicode')
```

```
Loading Model Advisor cache…
Warning: Cannot load an object of class
'SDRSLHDLWAPlugin':
Its class cannot be found.
Warning: Cannot load an object of class
'SDRSLHDLWAPlugin':
Its class cannot be found.
Model Advisor cache loaded. For new customizations, to update the cache, use the Adviso
Updating Model Advisor cache…
Model Advisor cache updated. For new customizations, to update the cache, use the Advis
```

2. Expand **By Product**.

3. Expand **Simulink**.

4. Select **Check model for foreign characters**

5. Click **Run This Check**.

6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.

7. Close the Model Advisor.

Code Generation Template Files

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the `.cgt` file, enable replacements by specifying:

```
<encodingIn = "encoding-name">
```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

```
edit rtwdemo_unicode.cgt
```

4. Find the line of code that enables escape sequence replacements for the character set encoding `UTF-8`.

```
<encodingIn = "UTF-8">
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

Generated File Customization Template

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file `example_file_process.tlc`. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

```
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```
%% %assign ERTCustomFileTest = TLC_TRUE%
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

Generate C Code

Generate C code and a code generation report.

```
evalc('rtwbuild(''rtwdemo_unicode'')');
```

Review the Generated Code

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:

```
coder.report.open('rtwdemo_unicode')
```

2. Review the generated code in `rtwdemo_unicode.c` and `rtwdemo_unicode.h`. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (`State 'Selection' <S2>:23`). The report view changes to show the corresponding code in `rtwdemo_unicode.c`.

5. In the code comment, click the `<S2>:23` link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. Select **C/C++ Code > Navigate to C/C++ Code**. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

Generate C++ Code

Generate C++ code and a code generation report.

1. Open the model.

```
model = 'rtwdemo_unicode';
```

```
open_system(model);
```

2. Change **Configuration Parameters** > **Code Generation** > **Language** to `C++`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Change **Configuration Parameters** > **Code Generation** > **Interface** > **Code interface packaging** to `C++ class`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

Internationalization Support in Embedded Coder

Internationalization and Code Generation

Internationalization support in software development tooling is vital to enabling efficient globalization. If there is a remote possibility that you could collaborate in the future with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

In this section...

Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see "Internationalization" (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check "Check model for foreign characters" (Simulink).

Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

- Generated code comments
- Code generation reports
- Block paths logged to MAT-files
- Block paths logged to C API files *`model`*`_capi.c` (or `.cpp`) and *`model`*`_capi.h`

CGT Files and XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding for a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in Comments in code generation template (CGT) files.

By default, code generation template files do not contain character set encoding information. The operating system reads the files, using its current encoding, regardless of the encoding that you use to write the file. You can enable escape sequence replacements by adding the following token at the top of the template file:

```
<encodingIn = "encoding">
```

Replace *encoding* with a string that names a standard character encoding scheme, such as `UTF-8`, `ISO-8859–1`, or `windows-1251`.

This example shows content from the file rtwdemo_unicode.cgt in a MATLAB session for `windows-1251`. The example uses the `encodingIn` token to set the encoding to `UTF–8`, which is the correct value for code generation.

```
17  <encodingIn = "UTF-8">
18  <FileBanner style = "box">
19  File: %<FileName>
20
21  Code generated for Simulink model '%<ModelName>'.
22
23  Model version                  : %<ModelVersion>
24  Simulink Coder version         : %<RTWFileVersion>
25  TLC version                    : %<TLCVersion>
26  C/C++ source code generated on : %<SourceGeneratedOn>
27
28  You can customize this banner by specifying a different template.
29   Unicode characters written in cgt file:
30   ï¼³ï¼●ï¼‰ï¼": â™  â™¡ â™¢ â™£ â™¤ â™¥ â™¦
31   Greek Symbols: â™ƒ â™„ â™… â™† â™‡ â™ˆ â™‰ â™Š â™‹ â™Œ â™ â™Ž â™ â™ â™‘ â™’ â™“
```

Generate and Review Code with Mixed Languages and Mixed Locales

This example shows how to use the code generator to generate and review code for use in mixed languages and mixed locales.

Before using this example, see “Internationalization and Code Generation” (Simulink Coder) or “Internationalization and Code Generation”.

The `rtwdemo_unicode` model configuration uses the Embedded Coder (R) `ert.tlc` system target file. To see internationalization and localization support with Simulink Coder®, configure the model to use the `grt.tlc` system target file. The example indicates the support that is specific to Embedded Coder® (for example, code generation templates).

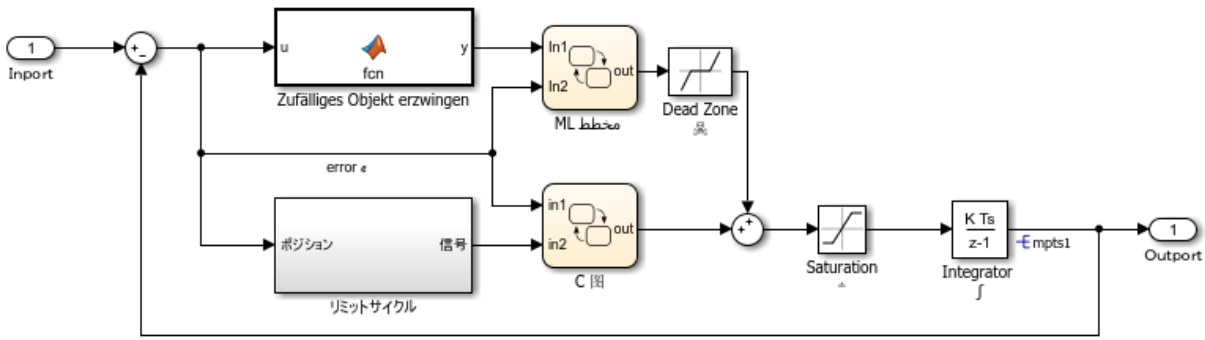
The model configuration specifies files and settings that control how the code generator handles localization for:

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder®)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

Open the example model `rtwdemo_unicode`.

Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```
model = 'rtwdemo_unicode';
open_system(model);
```



Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Windows Platforms” (MATLAB)
- “Set Locale on Linux Platforms” (MATLAB)
- “Set Locale on Mac Platforms” (MATLAB)

Verify Model for Use of Foreign Characters

to verify the model for characters that the code generator cannot represent in the model's current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters**.

1. Open the Model Advisor in Simulink®. Select **Analysis** > **Model Advisor** > **Model Advisor**. Or, in the Command Window, type:

```
modeladvisor('rtwdemo_unicode')
```

```
Loading Model Advisor cache…
Warning: Cannot load an object of class
'SDRSLHDLWAPlugin':
Its class cannot be found.
Warning: Cannot load an object of class
'SDRSLHDLWAPlugin':
Its class cannot be found.
Model Advisor cache loaded. For new customizations, to update the cache, use the Adviso
Updating Model Advisor cache…
Model Advisor cache updated. For new customizations, to update the cache, use the Advis
```

2. Expand **By Product**.

3. Expand **Simulink**.

4. Select **Check model for foreign characters**

5. Click **Run This Check**.

6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.

7. Close the Model Advisor.

Code Generation Template Files

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the `.cgt` file, enable replacements by specifying:

```
<encodingIn = "encoding-name">
```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

```
edit rtwdemo_unicode.cgt
```

4. Find the line of code that enables escape sequence replacements for the character set encoding `UTF-8`.

```
<encodingIn = "UTF-8">
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

Generated File Customization Template

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file `example_file_process.tlc`. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

```
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```
%% %assign ERTCustomFileTest = TLC_TRUE%
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

Generate C Code

Generate C code and a code generation report.

```
evalc('rtwbuild(''rtwdemo_unicode'')');
```

Review the Generated Code

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:

```
coder.report.open('rtwdemo_unicode')
```

2. Review the generated code in `rtwdemo_unicode.c` and `rtwdemo_unicode.h`. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (`State 'Selection' <S2>:23`). The report view changes to show the corresponding code in `rtwdemo_unicode.c`.

5. In the code comment, click the `<S2>:23` link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. Select **C/C++ Code > Navigate to C/C++ Code**. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

Generate C++ Code

Generate C++ code and a code generation report.

1. Open the model.

```
model = 'rtwdemo_unicode';
```

```
open_system(model);
```

2. Change **Configuration Parameters** > **Code Generation** > **Language** to `C++`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Change **Configuration Parameters** > **Code Generation** > **Interface** > **Code interface packaging** to `C++ class`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

More About

- "Locale Settings for MATLAB Process" (MATLAB)

Source Code Generation in Simulink Coder

Configure Model, Generate Code, and Simulate

In this section...

About This Example

Learning Objectives

- Learn about the functional behavior of the example model.
- Learn about the role of the example test harness and its components.
- Run simulation tests on a model.

Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Understand subsystems and how to view subsystem details.
- Understand referenced models and how to view referenced model details.
- Ability to set model configuration parameters.

Required Files

Before you use each example model file, place a copy in a writable location and add it to your MATLAB path.

- `rtwdemo_throttlecntrl` model file
- `rtwdemo_throttlecntrl_testharness` model file

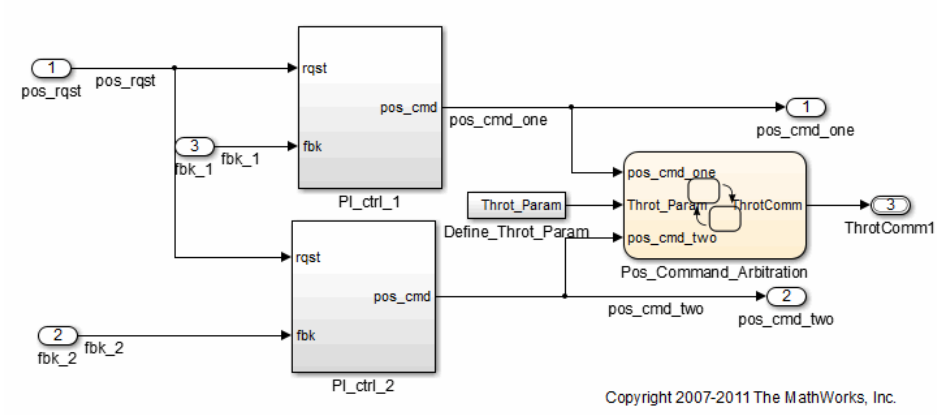
Functional Design of the Model

This example uses a simple, but functionally complete, example model of a throttle controller. The model features redundant control algorithms. The model highlights a standard model structure and a set of basic blocks in algorithm design.

View the Top Model

Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

Note: This model uses Stateflow software.



The top level of the model consists of the following elements:

Subsystems	`PI_ctrl_1`
	`PI_ctrl_2`
	`Define_Throt_Param`
	`Pos_Command_Arbitration`

Top-level input	`pos_rqst`
	`fbk_1`
	`fbk_2`

Top-level output	`pos_cmd_one`
	`pos_cmd_two`
	`ThrotComm1`

Signal routing	
Omit blocks that change the value of a signal, such as Sum and Integrator	

The layout uses a basic architectural style for models:

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

You can apply this style to a wide range of models.

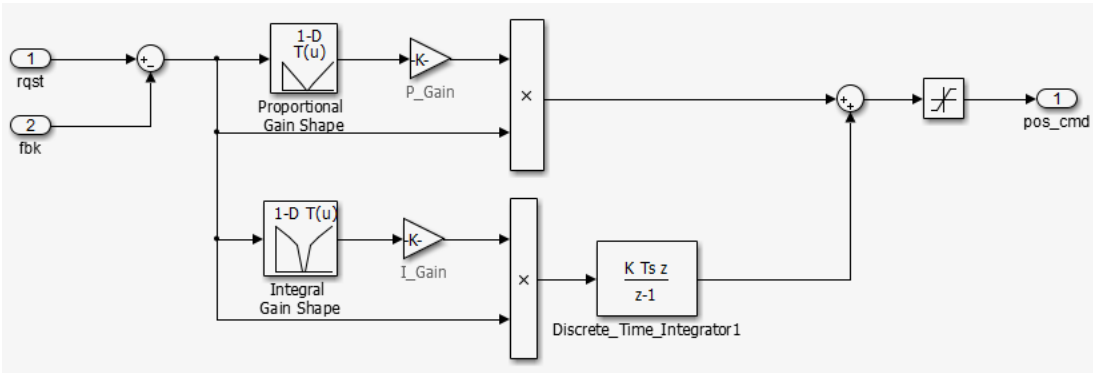
View the Subsystems

Explore two of the subsystems in the top model.

1. If not already open, open `throttlecntrl`.

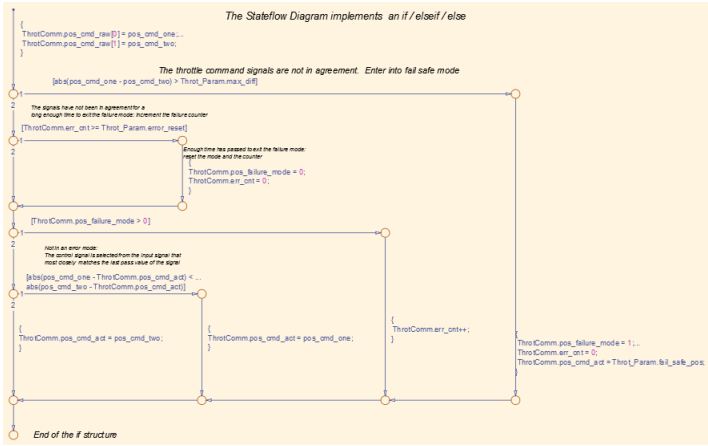
   Two subsystems in the top model represent proportional-integral (PI) controllers, `PI_ctrl_1` and `PI_ctrl_2`. At this stage, these identical subsystems, use identical data. If you have Embedded Coder, you can use these subsystems in an example that shows how to "Customize Function Interface and File Packaging".

2. Open the `PI_ctrl_1` subsystem.



The PI controllers in the model are from a *library*, a group of related blocks or models for reuse. Libraries provide one of two methods for including and reusing models. The second method, model referencing, is described in "Simulation Test Environment" on page 33-5. You cannot edit a block that you add to a model from a library. Edit the block in the library so that instances of the block in different models remain consistent.

3 Open the `Pos_Command_Arbitration` subsystem. This Stateflow chart performs basic error checking on the two command signals. If the command signals are too far apart, the Stateflow diagram sets the output to a `fail_safe` position.



4 Close `throttlecntrl`.

Simulation Test Environment

To test the throttle controller algorithm, incorporate it into a *test harness*. A test harness is a model that evaluates the control algorithm and offers the following benefits:

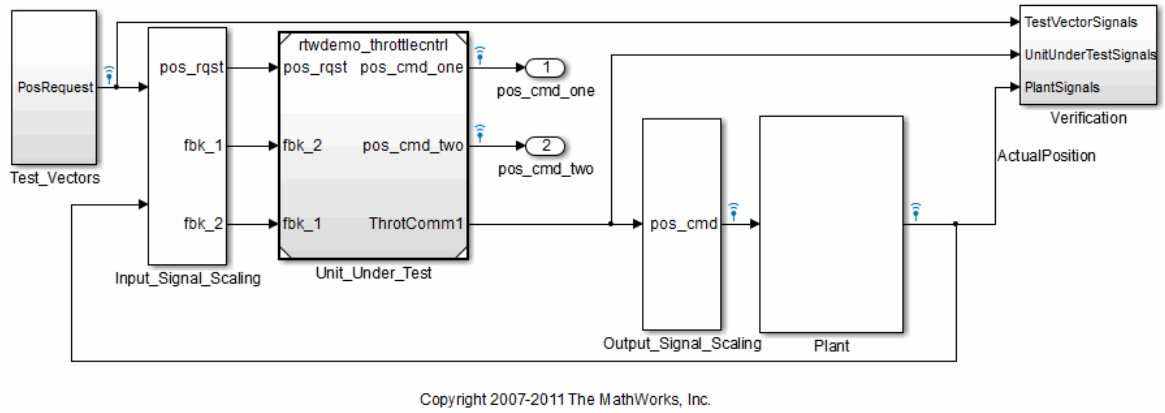
- Separates test data from the control algorithm.
- Separates the plant or feedback model from the control algorithm.
- Provides a reusable environment for multiple versions of the control algorithm.

The test harness model for this example implements a common simulation testing environment consisting of the following parts:

- Unit under test
- Test vector source
- Evaluation and logging
- Plant or feedback system
- Input and output scaling

Explore the simulation testing environment.

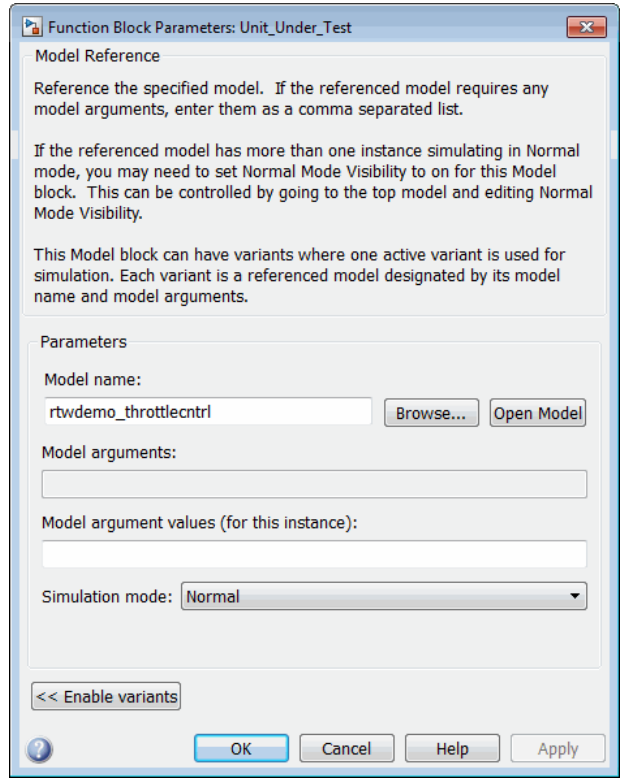
1 Open the test harness model `rtwdemo_throttlecntrl_testharness` and save a copy as `throttlecntrl_testharness` in a writable location on your MATLAB path.



2 Set up your `throttlecntrl` model as the control algorithm of the test harness.

a Open the `Unit_Under_Test` block and view the control algorithm.

b View the model reference parameters by right-clicking the `Unit_Under_Test` block and selecting **Block Parameters (ModelReference)**.



`rtwdemo_throttlecntrl` appears as the name of the referenced model.

c Change the value of **Model name** to `throttlecntrl`.

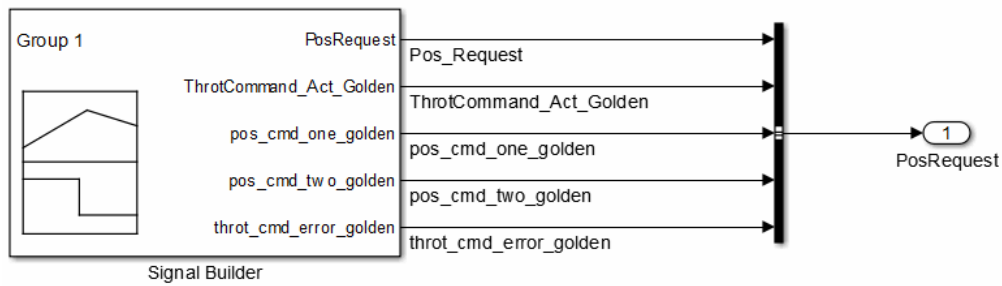
d Update the test harness model diagram by clicking **Simulation** > **Update Diagram**.

The control algorithm is the *unit under test*, as indicated by the name of the Model block, `Unit_Under_Test`.

The Model block provides a method for reusing components. From the top model, it allows you to reference other models (directly or indirectly) as *compiled functions*. By default, Simulink software recompiles the model when the referenced models change. Compiled functions have the following advantages over libraries:

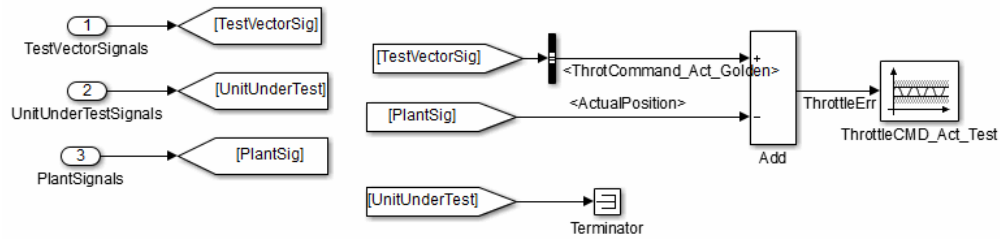
- Simulation time is faster for large models.
- You can directly simulate compiled functions.
- Simulation requires less memory. Only one copy of the compiled model is in memory, even when the model is referenced multiple times.

3 Open the *test vector source*, implemented in this test harness as the `Test_Vectors` subsystem.



The subsystem uses a Signal Builder block for the test vector source. The block has data that drives the simulation (`PosRequest`) and provides the expected results used by the `Verification` subsystem. This example test harness uses only one set of test data. Typically, create a test suite that fully exercises the system.

4 Open the *evaluation and logging* subsystem, implemented in this test harness as subsystem `Verification`.

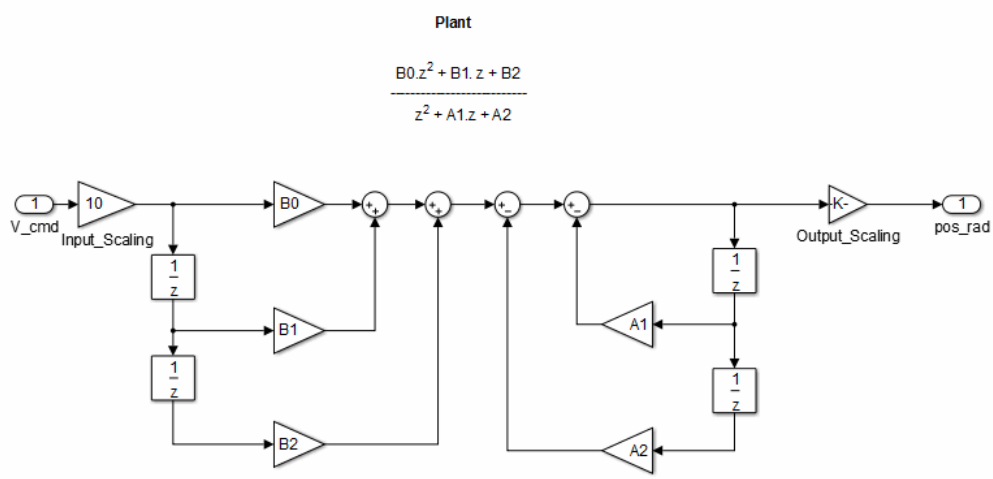


A test harness compares control algorithm simulation results against *golden data* — test results that exhibit the desired behavior for the control algorithm as certified by an expert. In the `Verification` subsystem, an Assertion block compares the simulated throttle value position from the plant against the golden value from the

test harness. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.

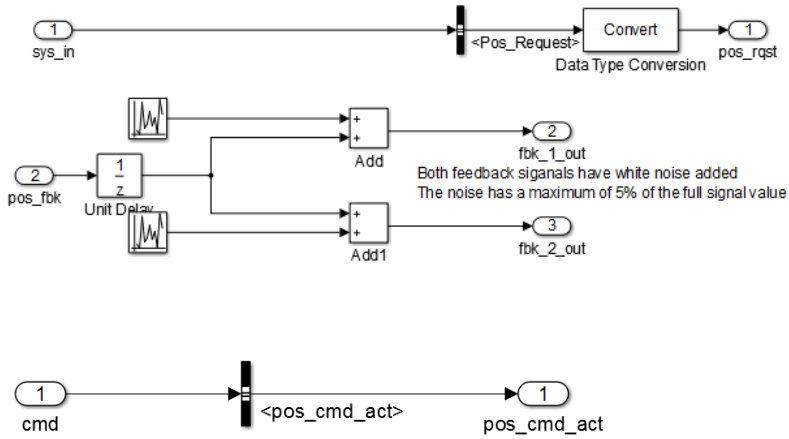
Alternatively, you can evaluate the simulation data after the simulation completes execution. Perform the evaluation with either MATLAB scripts or third-party tools. Post-execution evaluation provides greater flexibility in the analysis of data. However, it requires waiting until execution is complete. Combining the two methods can provide a highly flexible and efficient test environment.

5 Open the *plant or feedback system*, implemented in this test harness as the `Plant` subsystem.



The `Plant` subsystem models the throttle dynamics with a transfer function in canonical form. You can create plant models to varying levels of fidelity. It is common to use different plant models at different stages of testing.

6 Open the *input and output scaling* subsystems, implemented in this test harness as `Input_Signal_Scaling` and `Output_Signal_Scaling`.



The subsystems that scale input and output perform the following primary functions:

- Select input signals to route to the unit under test.
- Select output signals to route to the plant.
- Rescale signals between engineering units and units that are writable for the unit under test.
- Handle rate transitions between the plant and the unit under test.

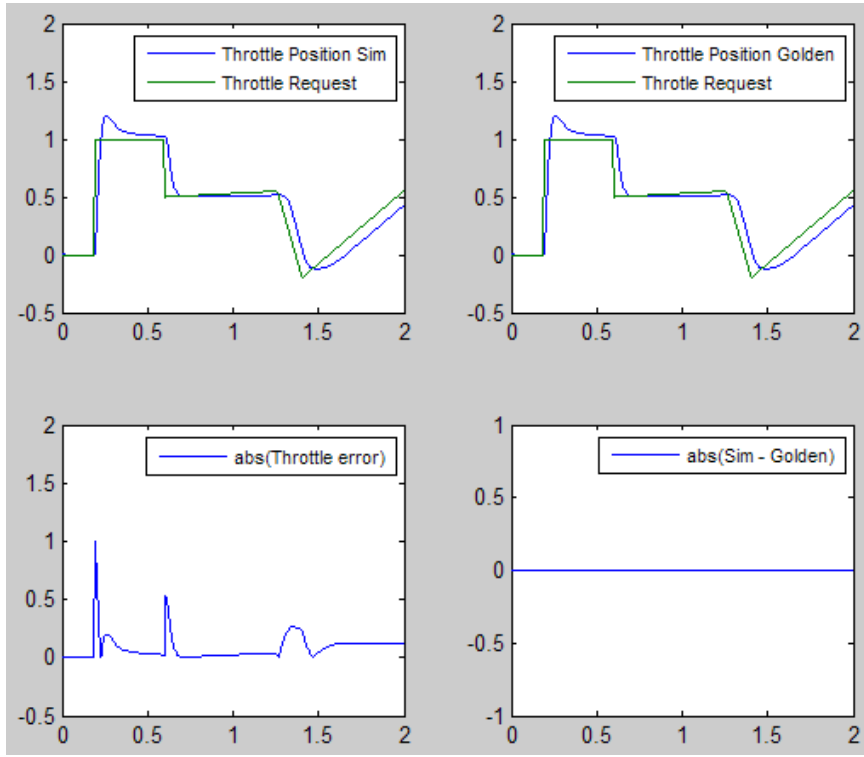
7 Save and close `throttlecntrl_testharness`.

Run Simulation Tests

1 Check that your working folder is set to a writable folder, such as the folder into which you placed copies of the example model files.

2 Open your copy of the test harness model, `throttlecntrl_testharness`.

3 Start a test harness model simulation. When the simulation is complete, the following results appear.



The lower-right hand plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculates. If the difference between the two values is greater than ±0.05, the simulation stops.

4 Save and close throttle controller and test harness models.

Key Points

- A basic model architecture separates calculations from signal routing and partitions the model into subsystems
- Two options for model reuse include block libraries and model referencing.
- If you represent your control algorithm in a test harness as a Model block, specify the name of the control algorithm model in the Model Reference Parameters dialog box.

- A test harness is a model that evaluates a control algorithm. Typically, a harness consists of a unit under test, a test vector source, evaluation and logging, a plant or feedback system, and input and output scaling components.
- The unit under test is the control algorithm being tested.
- The test vector source provides the data that drives the simulation which generates results used for verification.
- During verification, the test harness compares control algorithm simulation results against golden data and logs the results.
- The plant or feedback component of a test harness models the environment that is being controlled.
- When developing a test harness,
  - Scale input and output components.
  - Select input signals to route to the unit under test.
  - Select output signals to route to the plant.
  - Rescale signals between engineering units and units that are writable for the unit under test.
  - Handle rate transitions between the plant and the unit under test.
- Before running simulation or completing verification, consider checking a model with the Model Advisor.

Configure Model and Generate Code

In this section...

About This Example

Learning Objectives

- Configure a model for code generation.
- Apply model checking tools to discover conditions and configuration settings resulting in generation of inaccurate or inefficient code.
- Generate code from a model.
- Locate and identify generated code files.
- Review generated code.

Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to use the Simulink Model Advisor.
- Ability to read C code.
- An installed, supported C compiler.

Required Files

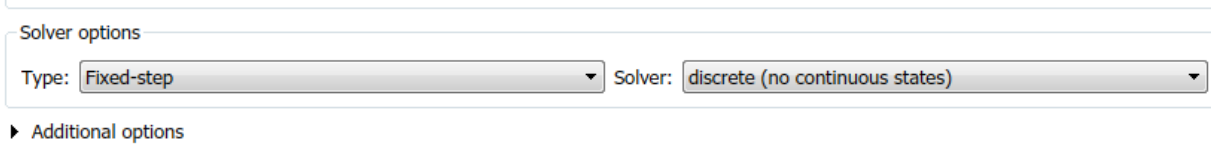
`rtwdemo_throttlecntrl` model file

Configure the Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

1. Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.
2. Open the Configuration Parameters dialog box, **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. The following table shows the solver configuration for this example.

Parameter	Setting	Effect on Generated Code
Type	`Fixed-step`	Maintains a constant (fixed) step size, which is required for code generation
Solver	`discrete (no continuous states)`	Applies a fixed-step integration technique for computing the state derivative of the model
Fixed-step size	`.001`	Sets the base rate; must be the lowest common multiple of the rates in the system



3. Open the **Code Generation** > **General** pane and note that the **System target file** is set to `grt.tlc`.

Note: The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file (STF) defines an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a system target file is the value for the `CodeFormat` TLC variable. The GRT configuration requires a fixed step solver and the rsim.tlc supports variable step code generation.

4 Open the **Code Generation** > **Custom Code** pane and under **Include list of additional**, select **Include directories**. The following path appears in the text field:

```
"$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
```

This folder includes files that are required to build an executable for the model.

5 Close the dialog box.

Save Your Model Configuration as a MATLAB Function

You can save the settings of model configuration parameters as a MATLAB function by using the `getActiveConfigSet` function. In the MATLAB Command Window, enter:

```
thcntrlAcs = getActiveConfigSet('throttlecntrl');
thcntrlAcs.saveAs('throttlecntrlModelConfig');
```

You can then use the resulting function (for example, `throttlecntrlModelConfig`) to:

- Archive the model configuration.
- Compare different model configurations by using differencing tools.
- Set the configuration of other models.

For example, you can set the configuration of model `myModel` to match the configuration of the throttle controller model by opening `myModel` and entering:

```
myModelAcs = throttlecntrlModelConfig;
attachConfigSet('myModel', myModelAcs, true);
setActiveConfigSet('myModel', myModelAcs.Name);
```

For more information, see “Save a Configuration Set” (Simulink) and “Load a Saved Configuration Set” (Simulink).

Check Model Conditions and Configuration Settings

Before generating code for a model, use the Simulink Model Advisor to check the model for conditions and configuration settings. This check finds issues that can result in inaccurate or inefficient code.

1. Open `throttlecntrl`.
2. Start the Model Advisor by selecting **Analysis** > **Model Advisor** > **Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Product** and **Embedded Coder**. By default, checks that do not trigger an Update Diagram, with one exception, are selected.
5. In the left pane, select the remaining checks and select **Embedded Coder**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues for embedded systems. At this point, you can ignore them. For more information about reports, see "View Model Advisor Reports" (Simulink).

Generate Code for the Model

1. Open `throttlecntrl`.
2. In the Configuration Parameters dialog box, select **Code Generation** > **Generate code only** and click **Apply**.
3. On the **Code Generation** > **Report** pane, select **Create code generation report** and click **Apply**.
4. With the model open, initiate code generation and the build process for the model by using any of the following options:

   - Click the **Build Model** button.
   - Press **Ctrl+B**.
   - Select **Code** > **C/C++ Code** > **Build Model**.
   - Invoke the `rtwbuild` command from the MATLAB command line.
   - Invoke the `slbuild` command from the MATLAB command line.

Watch the messages that appear in the MATLAB Command Window. The code generator produces standard C and header files, and an HTML code generation report. The code generator places the files in a *build folder*, a subfolder named `throttlecntrl_grt_rtw` under your current working folder.

Review the Generated Code

1. Open Model Explorer, and in the **Model Hierarchy** pane, expand the node for the `throttlecntrl` model, and select the **Code for** node.
2. In the **Contents** pane, select **HTML Report**. Model Explorer displays the HTML code generation report for the throttle controller model.
3. In the HTML report, click the link for the generated C model file and review the generated code. Look for these items in the report:
   - Identification, version, timestamp, and configuration comments.
   - Links to help you navigate within and between files
   - Data definitions
   - Scheduler code
   - Controller code
   - Model initialization and termination functions
   - Call interface for the GRT system target file — output, update, initialization, start, and terminate
4. Save and close `throttlecntrl`.

Consider examining the following files. In the HTML report **Contents** pane, click the links. Or, in your working folder, explore the generated code subfolder.

File	Description
`throttlecntrl.c`	C file that contains the scheduler, controller, initialization, and interface code
`throttlecntrl_data.c`	C file that assigns values to generated data structures
`throttlecntrl.h`	Header file that defines data structures
`throttlecntrl_private.h`	Header file that defines data used only by the generated code

File	Description
`throttlecntrl_types.h`	Header file that defines the model data structure

For more information, see "Manage Build Process File Dependencies" (Simulink Coder).

At this point, consider logging data to a MAT-file. For an example, see "Log Data for Analysis" (Simulink Coder).

Generate an Executable

1. Open `throttlecntrl`.
2. In the Configuration Parameters dialog box, clear the **Code Generation** > **Generate code only** check box and click **Apply**.
3. Press **Ctrl+B**. Watch the messages in the MATLAB Command Window. The code generator uses a template make file associated with your system target file selection to create an executable file. You can run this program on your workstation, independent of external timing and events.
4. Check your working folder for the file`throttlecntrl.exe`.
5. Run the executable. In the Command Window, enter `!throttlecntrl`. The ! character passes the command that follows it to the operating system, which runs the standalone program.

   The program produces one line of output in the Command Window:

   ```
   ** starting the model **
   ```

   At this point, consider logging data to a MAT-file. For an example, see "Log Data for Analysis" (Simulink Coder).

Tip: For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Key Points

- To generate code, change the model configuration to specify a fixed-step solver then select a system target file. Using the `grt.tlc` file requires a fixed-step solver. If the model contains continuous time blocks, you can use a variable-step solver with the `rsim.tlc` system target file.
- After debugging a model, consider configuring a model with parameter inlining enabled.
- Use the `getActiveConfigSet` function to save a model configuration for future use or to apply it to another model.
- Before generating code, consider checking a model with the Model Advisor.
- The code generator places generated files in a subfolder (*model*`_grt_rtw`) of your working folder.

- "Run Model Checks" (Simulink)

Configure Data Interface

About This Example

Learning Objectives

- Configure the data interface for code generated for a model.
- Control the name, data type, and data storage class of signals and parameters in generated code.

Prerequisites

- Understanding ways to represent and use data and signals in models.
- Familiarity with representing data constructs as data objects.
- Ability to read C code.

Required File

`rtwdemo_throttlecntrl_datainterface` model file

Declare Data

Most programming languages require that you *declare* data before using it. The declaration specifies the following information:

Data Attribute	Description
Scope	The region of the program that has access to the data
Duration	The period during which the data is resident in memory
Data type	The amount of memory allocated for the data
Initialization	An initial value, a pointer to memory, or NULL. If you do not provide an initial value, most compilers assign a zero value or a null pointer.

The following data types are supported for code generation.

Supported Data Types

Name	Description
`double`	Double-precision floating point
`single`	Single-precision floating point
`int8`	Signed 8-bit integer
`uint8`	Unsigned 8-bit integer
`int16`	Signed 16-bit integer
`uint16`	Unsigned 16-bit integer
`int32`	Signed 32-bit integer
`uint32`	Unsigned 32-bit integer
Fixed-point data types	8-, 16-, 32-bit word lengths

A *storage class* is the scope and duration of a data item. For more information about storage classes, see

- "Override Default Parameter Behavior by Creating Global Variables in the Generated Code" (Simulink Coder)
- "Signal Storage Class" (Simulink Coder)
- "Storage Classes for Block States" (Simulink Coder)

Use Data Objects

In Simulink models and Stateflow charts, the following methods are available for declaring data: *data objects* and *direct specification*. This example uses the data object method. Both methods allow full control over the data type and storage class. You can mix the two methods in a single model.

In the MATLAB and Simulink environment, you can use data objects in various ways. This example focuses on the following types of data objects:

- Signal
- Parameter
- Bus

To configure the data interface for your model using the data object method, in the MATLAB base workspace, you define data objects. Then, associate them with your

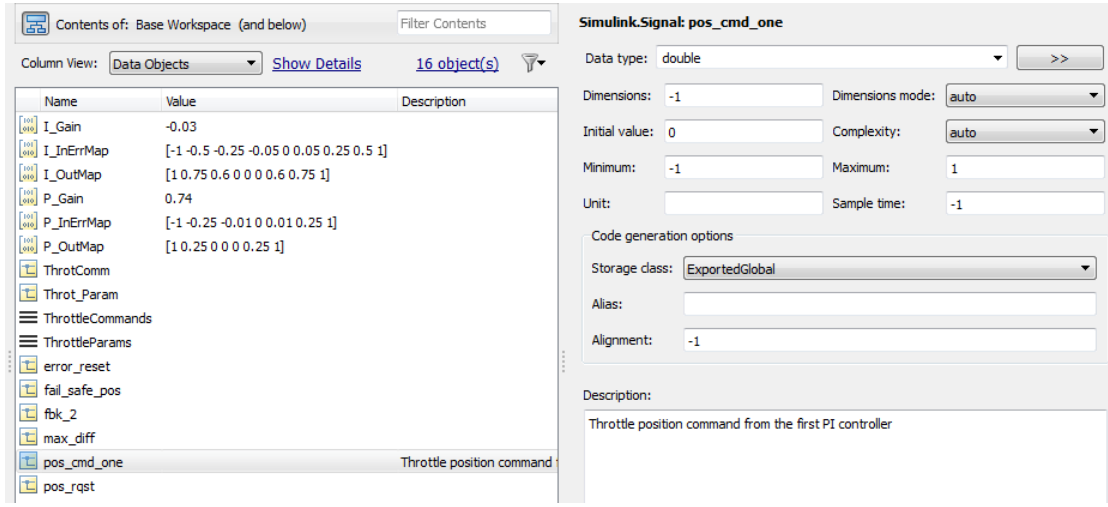
Simulink model or embedded Stateflow chart. When you build your model, the build process uses the associated base workspace data objects in the generated code.

You can set the values of the data object properties, which include:

- Data type
- Storage class
- Value (parameters)
- Initial value (signals)
- Alias (define a different name in the generated code)
- Dimension (typically inherited for parameters)
- Complexity (inherited for parameters)
- Unit (physical measurement unit)
- Minimum value
- Maximum value
- Description (used to document your data objects — does not affect simulation or code generation)

You can create and inspect base workspace data objects by entering commands in the MATLAB Command Window or by using Model Explorer. To explore base workspace signal data objects, use these steps:

1. Open `rtwdemo_throttlecntrl_datainterface` and save a copy as `throttlecntrl_datainterface` in a writable location on your MATLAB path.
2. Open Model Explorer.
3. Select **Base Workspace**.
4. Select the `pos_cmd_one` signal object for viewing.



You can also view the definition of a signal object. In the MATLAB Command Window, enter `pos_cmd_one`:

```
pos_cmd_one =

Signal with properties:

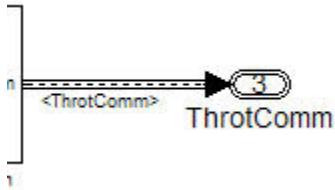
       CoderInfo: [1x1 Simulink.CoderInfo]
     Description: 'Throttle position command from the first PI controller'
        DataType: 'double'
             Min: -1
             Max: 1
            Unit: ''
      Dimensions: -1
  DimensionsMode: 'auto'
      Complexity: 'auto'
      SampleTime: -1
    InitialValue: '0'
```

5 To view other signal objects, in Model Explorer, click the object name or in the MATLAB Command Window, enter the object name. The following table summarizes object characteristics for some of the data objects in this model.

Object Characteristics	pos_cmd_one	pos_rqst	P_InErrMap	ThrotComm*	ThrottleCommands*
Description	Top-level output	Top-level input	Calibration parameter	Top-level output structure	Bus definition
Data type	Double	Double	Auto	Auto	Structure
Storage class	Exported global	Imported extern pointer	Constant	Exported global	None

* `ThrottleCommands` defines a Bus object; `ThrotComm` is an instantiation of the bus. If the bus is a nonvirtual bus, the signal generates a structure in the C code.

You can use a bus definition (`ThrottleCommands`) to instantiate multiple instances of the structure. In a model diagram, a bus object appears as a wide line with central dashes, as shown.



Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

To find constructs for which you can create data objects, use the Data Object Wizard. This tool finds the constructs and then creates the objects for you. The model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

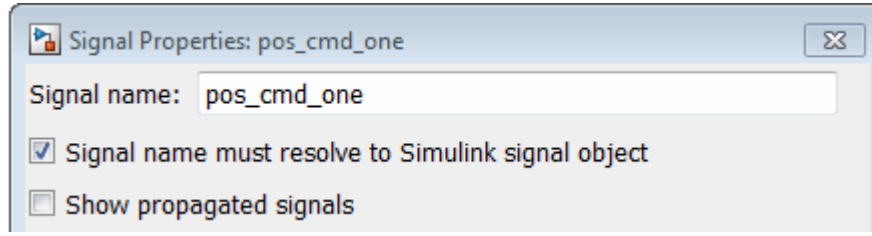
To find the signals and create data objects for them:

1 In the model window, select **Code > Data Objects > Data Object Wizard**. The Data Object Wizard dialog box opens.

2. To find candidate constructs, click **Find**. Constructs `fbk_1` and `pos_cmd_two` appear in the dialog box.
3. To select both constructs, click **Select All**.
4. In the table, under **Class**, make sure that each proposed data object uses the class `Simulink.Signal`. To change the class of the objects, click **Change Class**.
5. To create the data objects, click **Create**. Constructs `fbk_1` and `pos_cmd_two` are removed from the dialog box.
6. Close the Data Object Wizard.
7. In the **Contents** pane of the Model Explorer, find the newly created objects `fbk_1` and `pos_cmd_two`.

Enable Data Objects for Generated Code

1. Enable a signal to appear in generated code.
   a. In the model window, right-click the `pos_cmd_one` signal line and select **Properties**. A Signal Properties dialog box opens.
   b. Make sure that you select the **Signal name must resolve to Simulink signal object** parameter.



2. Enable signal object resolution for the signals in the model. In the MATLAB Command Window, enter:

```
disableimplicitsignalresolution('throttlecntrl_datainterface')
```

3. Save and close `throttlecntrl_datainterface`.

Effects of Simulation on Data Typing

In the throttle controller model, the data types are set to `double`. Because Simulink software uses the `double` data type for simulation, do not expect changes in the model

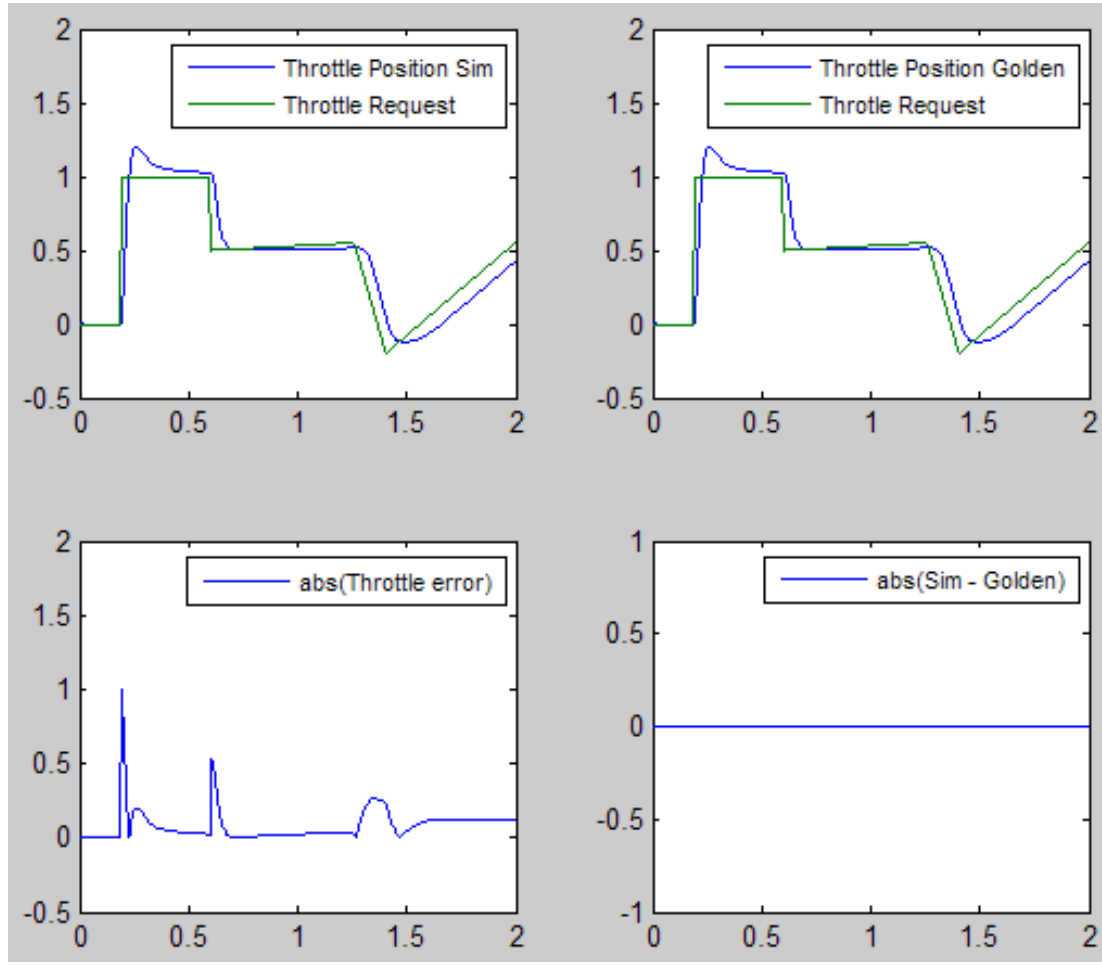
behavior when you run the generated code. You verify this effect by running the test harness.

Before you run your test harness, update it to include the `throttlecntrl_datainterface` model.

Note: The following procedure requires a Stateflow license.

1. Open `throttlecntrl_datainterface`.
2. Open your copy of test harness, `throttlecntrl_testharness`.
3. Right-click the `Unit_Under_Test` Model block and select **Block Parameters (ModelReference)**.
4. Set **Model name** to `throttlecntrl_datainterface`. Click **OK**.
5. Update the test harness model diagram.
6. Simulate the test harness.

   The resulting plot shows that the difference between the golden and simulated versions of the model remains zero.



7 Save and close `throttlecntrl_testharness`.

Manage Data

Data objects exist in a separate file from the model in the base workspace. To save the data manually, in the MATLAB Command Window, enter `save`.

The separation of data from the model provides the following benefits:

- One model, multiple data sets:
  - Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)
  - Use of different data types to change targeted hardware (for example, for floating-point and fixed-point targeted hardware)
- Multiple models, one data set:
  - Sharing data between models in a system
  - Sharing data between projects (for example, transmission, engine, and wheel controllers can use the same CAN message data set)

Key Points

- You can declare data in Simulink models and Stateflow charts by using data objects or direct specification.
- From the Model Explorer or from the command line in the MATLAB Command Window, manage (create, view, configure, and so on) base workspace data.
- The Data Object Wizard provides a quick way to create data objects for constructs such as signals, buses, and parameters.
- Configure data objects explicitly to appear by name in generated code.
- Separation of data from model provides several benefits.

Call External C Functions

In this section...

About This Example

Learning Objectives

- Evaluate a C function as part of a model simulation.
- Call an external C function from generated code.

Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to read C code.
- An installed, supported C compiler.

Required Files

- `rtwdemo_throttlecntrl_extfunccall` model file
- `rtwdemo_ValidateLegacyCodeVrsSim` model file
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.c`
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.h`

Include External C Functions in a Model

Simulink models are one part of Model-Based Design. For many applications, a design also includes a set of pre-existing C functions created, tested (verified), and validated outside of a MATLAB and Simulink environment. You can integrate these functions easily into a model and the generated code. You can use external C code in the generated code to access hardware devices and external data files during rapid simulation runs.

This example shows you how to create a custom block that calls an external C function. When the block is part of the model, you can take advantage of the simulation environment to test the system further.

Create a Block That Calls a C Function

To specify a call to an external C function, use an S-Function block. You can automate the process of creating the S-Function block by using the Simulink Legacy Code Tool. Using this tool, specify an interface for your external C function. The tool then uses that interface to automate creation of an S-Function block.

1. Make copies of the files `SimpleTable.c` and `SimpleTable.h`, located in the folder *`matlabroot`*`/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files` (open). Put the copies in your working folder.
2. Create an S-Function block that calls the specified function at each time step during simulation:

   a. In the MATLAB Command Window, create a function interface definition structure:

   ```
   def=legacy_code('initialize')
   ```

   The data structure `def` defines the function interface to the external C code.

   ```
   def =

                       SFunctionName: ''
       InitializeConditionsFcnSpec: ''
                      OutputFcnSpec: ''
                       StartFcnSpec: ''
                  TerminateFcnSpec: ''
                        HeaderFiles: {}
                        SourceFiles: {}
   ```

```
  HostLibFiles: {}
TargetLibFiles: {}
      IncPaths: {}
      SrcPaths: {}
      LibPaths: {}
    SampleTime: 'inherited'
       Options: [1x1 struct]
```

b Populate the function interface definition structure by entering the following commands:

```
def.OutputFcnSpec=['double y1 = SimpleTable(double u1,',...
   'double p1[], double p2[], int16 p3)'];
def.HeaderFiles = {'SimpleTable.h'};
def.SourceFiles = {'SimpleTable.c'};
def.SFunctionName = 'SimpTableWrap';
```

c Create the S-function:

```
legacy_code('sfcn_cmex_generate', def)
```

d Compile the S-function:

```
legacy_code('compile', def)
```

e Create the S-Function block:

```
legacy_code('slblock_generate', def)
```

A new model window opens that contains the `SimpTableWrap` block.

Tip: Creating the S-Function block is a one-time task. Once the block exists, you can reuse it in multiple models.

---

3 Save the model to your working folder as: `s_func_simptablewrap`.

4 Create a Target Language Compiler (TLC) file for the S-Function block:

```
legacy_code('sfcn_tlc_generate', def)
```

The TLC file is the component of an S-function that specifies how the code generator produces the code for a block.

For more information on using the Legacy Code Tool, see:

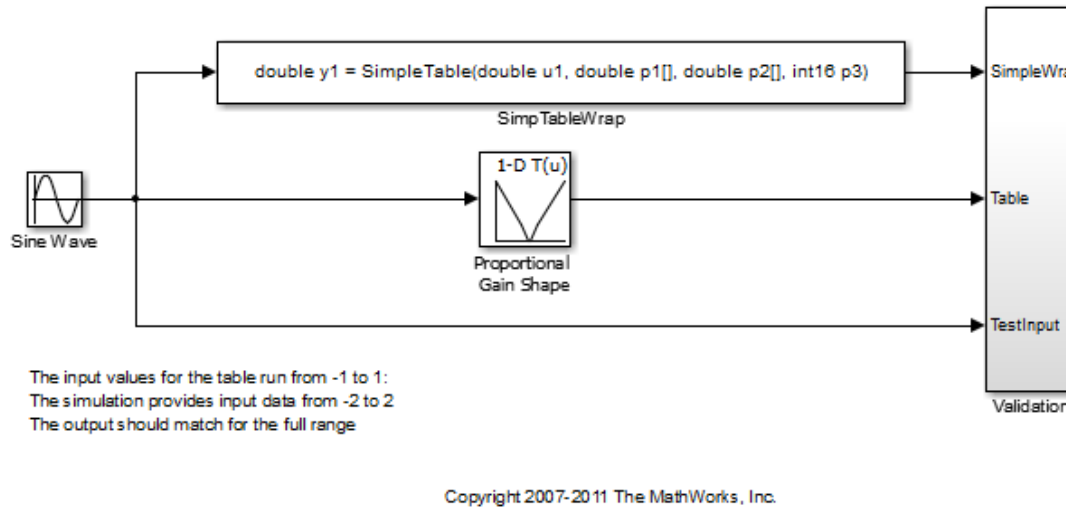
- "Integrate C Functions Using Legacy Code Tool" (Simulink)

- "Import Calls to External Code into Generated Code with Legacy Code Tool" (Simulink Coder)

Validate External Code in the Simulink Environment

When you integrate external C code with a Simulink model, before using the code, validate the functionality of the external C function code as a standalone component.

1 Open the model `rtwdemo_ValidateLegacyCodeVrsSim`. This model validates the S-function block that you created.

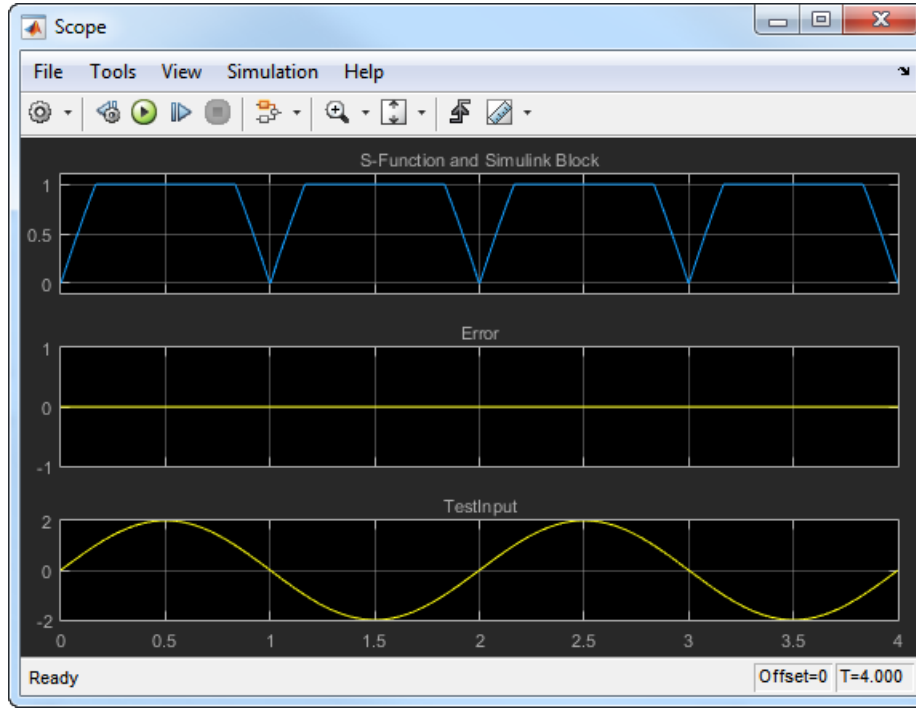


- The Sine Wave block produces output values from [-2 : 2].
- The input range of the lookup table is from [-1 : 1].
- The output from the lookup table is the absolute value of the input.
- The lookup table output clips the output at the input limits.

2 Simulate the model.

3 View the validation results by opening the `Validation` subsystem and, in that subsystem, clicking the Scope block.

The following figure shows the validation results. The external C code and the Simulink Lookup table block provide the same output values.



4 Close the validation model.

Validate C Code as Part of a Model

After you validate the functionality of the external C function code as a standalone component, validate the S-function in the model. Use the test harness model to complete the validation.

Note: The following procedure requires a Stateflow license.

1 Open `rtwdemo_throttlecntrl_extfunccall` and save a copy to `throttlecntrl_extfunccall` in a writable folder on your MATLAB path.

2 Examine the `PI_ctrl_1` and `PI_ctrl_2` subsystems.

a Lookup blocks have been replaced with the block you created using the Legacy Code Tool.

b Note the block parameter settings for `SimpTableWrap` and `SimpTableWrap1`.

c Close the Block Parameter dialog boxes and the PI subsystem windows.

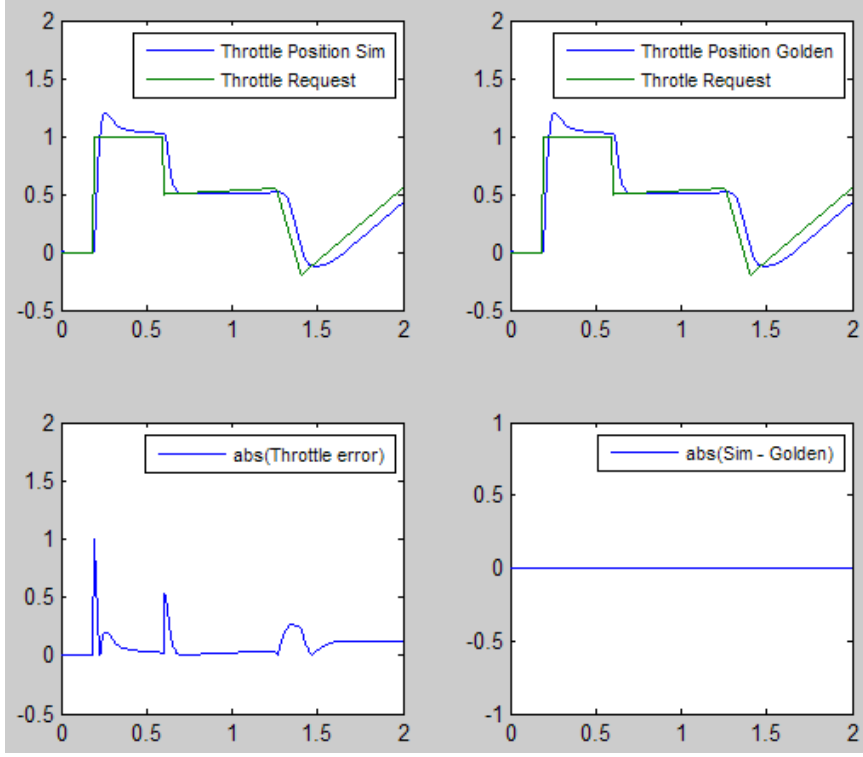
3 Open the test harness model, right-click the `Unit_Under_Test` Model block, and select **Block Parameters (ModelReference)**.

4 Set **Model name** to `throttlecntrl_extfunccall`. Click **OK**.

5 Update the test harness model diagram.

6 Simulate the test harness.

The simulation results match the expected golden values.



7 Save and close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

Call a C Function from Generated Code

The code generator uses a TLC file to process the S-Function block. Calls to C code embedded in an S-Function block:

- Can use data objects.
- Are subject to *expression folding*, an operation that combines multiple computations into a single output calculation.

1 Open `throttlecntrl_extfunccall`.

2 Generate code for the model.

3 Examine the generated code in the file`throttlecntrl_extfunccall.c`.

4 Close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

Key Points

- You can easily integrate external functions into a model and generated code by using the Legacy Code Tool.
- Validate the functionality of external C function code which you integrate into a model as a standalone component.
- After you validate the functionality of external C function code as a standalone component, validate the S-function in the model.

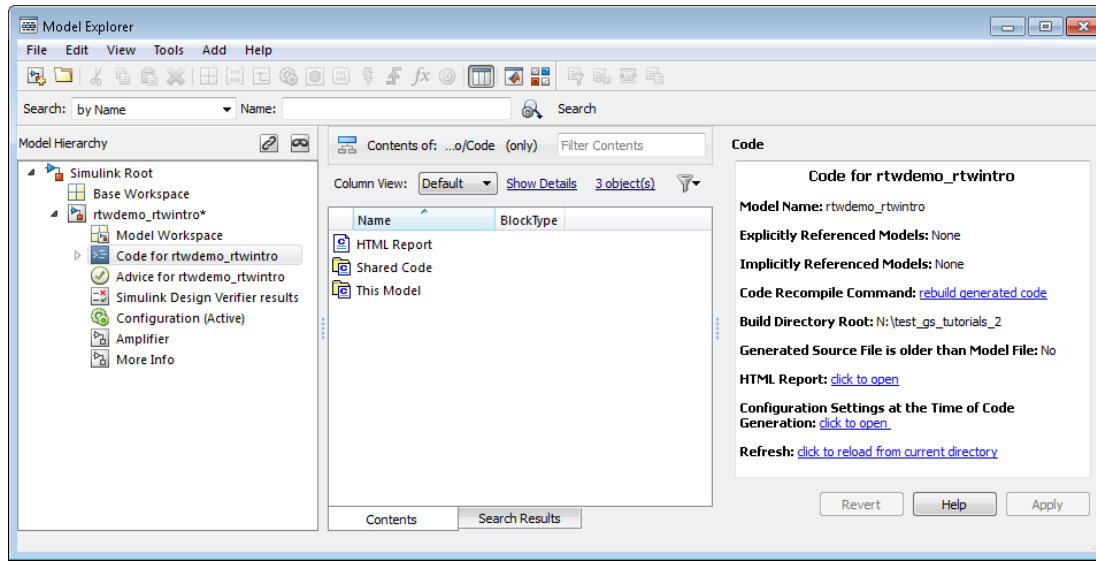
More About

- "Integrate C Functions Using Legacy Code Tool" (Simulink)
- "S-Functions and Code Generation" (Simulink Coder)

Reload Generated Code

You can reload the code generated for a model from the Model Explorer.

1. Click the **Code for *model*** node in the **Model Hierarchy** pane.
2. In the **Code** pane, click the **Refresh** link.



The code generator reloads the code for the model from the build folder.

- "Rebuild a Model" (Simulink Coder)
- "Control Regeneration of Top Model Code" (Simulink Coder)

Manage Build Process Folders

By default, the build process places generated files from Simulink diagram updates and model builds in a hierarchy of folders. The code generation folder is the root folder of this folder hierarchy. The default code generation folder is the current working folder (`pwd`). If you are building models, artifacts used for simulation and code generation files reside in subfolders within that code generation folder. If you are building code for more than one referenced model within the same code generation folder, the model reference files are added to the existing `slprj` folder.

For specifying the folder locations, the software provides:

- MATLAB session parameters `CacheFolder` and `CodeGenFolder`
- Simulink preferences **Simulation cache folder** (Simulink) and **Code generation folder** (Simulink), which, if specified, provide the initial defaults for the MATLAB session parameters
- Function `Simulink.fileGenControl` for directly manipulating the MATLAB session parameters, for example, overriding or restoring the initial default values for the current session

For more information about managing build process folders, see these topics:

In this section...
“Select Simulation Cache Folder” on page 33-40
“Select Code Generation Folder” on page 33-40
“Override Build Folder Settings for Current Session” on page 33-41

For more information on organizing your files regarding code generation folders for referenced models, see “Generate Code for Referenced Models” (Simulink Coder).

The table lists folders where the build process places output files. The build folder contains the generated code modules *`model`*`.c`, *`model`*`.h`, and the generated makefile *`model`*`.mk`. In the paths in the table, *`model`* is the name of the model being used as a referenced model. And, *`target`* is the system target file acronym (for example, `grt`, `ert`, and `rsim`).

Folders	Description
“Code generation folder” (Simulink)	The default folder for code generation is the current working folder, `pwd`.

Folders	Description
	If you choose to generate an executable program file, the code generator writes the file *model*`.exe` (Windows) or *model* (UNIX) to your code generation folder. To choose a folder other than `pwd`, use Simulink preferences. See "Select Code Generation Folder" on page 33-40. When your default folder is set to the root folder of a drive, such as C:\, the code generator cannot generate code for your model.
"Simulation cache folder" (Simulink)	The default folder for simulation cache is the current working folder, `pwd`. If you choose to generate code for simulation, the code generator writes any model build artifacts for simulation to the simulation cache folder. To choose a folder other than `pwd`, use Simulink preferences. See "Select Simulation Cache Folder" on page 33-40.
model_target`_rtw`	The build folder — *model_target*`_rtw` A subfolder within your code generation folder. *model_target*`_rtw` is the name of the build folder. *model* is the name of the source model. The default for *target* is name of the selected system target file (for example, `grt` for the generic real-time system target file). You can change the *target* with the `rtwgensettings.BuildDirSuffix` field in the system target file. The build folder stores generated source code and other files created during the build process (except the executable program file).
model_target`_rtw/html`	The code generation report folder — *model_target*`_rtw/html` A subfolder within your build folder. *model_target*`_rtw/html` is the name of the code generation report folder. The report folder stores code generation report files created during the build process.

Folders	Description
`slprj`	Reference model code and shared utilities folder — `slprj` A subfolder within your "Code generation folder" (Simulink). When referenced models (model blocks) are built for simulation or code generation, the code generator places files in `slprj`. Subfolders in `slprj` provide separate places for simulation code, some generated code, utility code shared between models, and other files.
`slprj/sim/`*`model`*	Simulation target files for referenced models.
`slprj/sim/`*`model`*`/tmwinternal`	MAT-files used during code generation.
`slprj/sim/_sharedutils`	Utility functions for simulation system target files, shared across models.
`slprj/`*`target`*`/`*`model`*`/referenced_model_includes`	Header files from models referenced by this model.
`slprj/`*`target`*`/`*`model`*	Model reference target files.
`slprj/`*`target`*`/`*`model`*`/tmwinternal`	MAT-files used during code generation.
`slprj/`*`target`*`/_sharedutils`	Utility functions for model reference system target files, shared across models.

For an ERT-based system target file, the model configuration has additional shared utility options. For more information, see "Cross-Release Shared Utility Code Reuse" (Simulink Coder) and "Cross-Release Code Integration" (Simulink Coder).

- `UtilityFuncGeneration` parameter places generated shared code in `slprj` without the use of model reference.
- `ExistingSharedCode` parameter specifies the folder that contains previously generated shared code.
- `UseOnlyExistingSharedCode` parameter prohibits the build process from generating new shared code.
- `sharedCodeUpdate` function integrates shared code from multiple source folders into an existing shared code folder.

For more information about using code generation folders, see “Customize Build to Use Shared Utility Code” (Simulink Coder).

Select Simulation Cache Folder

By default, Simulink diagram updates place generated files in a build folder, the root of which is the current working folder (`pwd`). In some situations, you want the generated files to go to a root folder outside the current working folder. For example:

- You want to keep generated files separate from the models and other source materials that generate them.
- You want to reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder.

The Simulink preference **Simulation cache folder** (Simulink) provides control over the output location for files generated by Simulink diagram updates. The preference appears in the **General** pane, under **File generation control**. To specify the root folder location for files generated by Simulink diagram updates, set the preference value by entering or browsing to a folder path. For example, on Windows, you could set the folder to `'C:\Work\mymodelsimcache'`.

The folder path that you specify provides the initial default for the MATLAB session parameter `CacheFolder`. When you initiate a Simulink diagram update, the update places the generated files in a build folder. This folder is at the root location specified by `CacheFolder` (if any), rather than in the current working folder (`pwd`).

You can choose to override the **Simulation cache folder** (Simulink) preference value for the current MATLAB session. See “Override Build Folder Settings for Current Session” on page 33-41.

Select Code Generation Folder

By default, Simulink model builds place generated files in a build folder, the root of which is the current working folder (`pwd`). Model builds potentially generate files for simulation and code generation system target files, and the resulting build folder contains artifacts for simulation and code generation. In some situations, you want the generated files to go to one or more root folders outside the current working folder. For example:

- You want to keep generated files separate from the models and other source materials that generate them.

- You want to separate generated production code from generated simulation artifacts.

The Simulink preference **Code generation folder** (Simulink) provides control over the output location for files that model builds generate for system target files. The preference appears in the **General** pane, under **File generation control**. To specify the root folder location for code generation files generated by model builds, set the preference value by entering or browsing to a folder path. For example, on Windows, you could set the **Code generation folder** (Simulink) to `'C:\test\mymodelgencode'`.

The folder path that you specify provides the initial default for the MATLAB session parameter `CodeGenFolder`. When you initiate a Simulink model build, the build process places the generated files in a build folder. This folder is at the root location specified by `CodeGenFolder` (if any), rather than in the current working folder (`pwd`).

You can choose to override the **Code generation folder** (Simulink) preference value for the current MATLAB session. See "Override Build Folder Settings for Current Session" on page 33-41.

Override Build Folder Settings for Current Session

The Simulink preferences **Simulation cache folder** (Simulink) and **Code generation folder** (Simulink) provide initial defaults for the MATLAB session parameters `CacheFolder` and `CodeGenFolder`. These session parameters determine where Simulink diagram updates and model builds place generated files.

You can override these build folder settings during the current MATLAB session by using the `Simulink.fileGenControl` function. With this function, you can manipulate directly the MATLAB session parameters, for example, overriding or restoring the initial default values. The values that you set by using `Simulink.fileGenControl` expire at the end of the current MATLAB session. For more information and detailed examples, see `Simulink.fileGenControl`.

More About

- "Manage Build Process Files" (Simulink Coder)
- "Manage Build Process File Dependencies" (Simulink Coder)
- "Add Build Process Dependencies" (Simulink Coder)
- "Enable Build Process for Folder Names with Spaces" (Simulink Coder)
- "Build and Run a Program" (Simulink Coder)

Manage Build Process Files

The code generator creates *model*.* files during the code generation and build process. The code generator creates additional folders and dependency files to support shared utilities and model references.

For more information about the folders that the build process creates, see "Manage Build Process Folders" (Simulink Coder).

The source and header files in the table have dependency relationships. For descriptions of other file dependencies, see "Manage Build Process File Dependencies" (Simulink Coder) and "Add Build Process Dependencies" (Simulink Coder).

Depending on model architectures and code generation options, the build process for a GRT-based system target file can produce files that the build process does not generate for an ERT-based system target file. Also, for ERT-based system target files, the build process packages generated files differently than for GRT-based system target files. See "Manage File Packaging of Generated Code Modules" on page 34-14.

The table describes the principal generated files. Within the generated file names shown in the table, the *model* represents the name of the model for which you are generating code. The *subsystem* represents the name of a subsystem within the model. When you select the **Create code generation report** parameter, the code generator produces a set of HTML files. There is one HTML file for each source file plus a *model*_contents.html index file in the html subfolder within your build folder.

File	Description
builtin_typeid_types.h	Defines an enumerated type corresponding to built-in data types. A model build generates this file when one or more of these conditions apply: • Your model contains a Stateflow chart that uses messages. • Your model configuration enables **MAT-file logging**. • Your model configuration enables C API options in **Code Generation** > **Interface**.
modelsources.txt	Lists additional sources to include in the compilation.
model.bat	Contains Windows batch file commands that set the compiler environment and invoke the make utility.

File	Description
	For more information about using this file, see “model.bat” on page 33-48.
model.c *model*.cpp	Corresponds to the model file. The Target Language Compiler generates this C or C++ source code file. The file contains: • Include files *model*.h and *model*_private.h • Data, except data placed in *model*_data.c • Model-specific scheduler code • Model-specific solver code • Model registration code • Algorithm code • Optional GRT wrapper functions
model.exe (Windows platform) *model* (UNIX and Macintosh platforms)	Executable program file. A model build generates this file unless you explicitly specify that the code generator produce code only. The build generates the executable in the current folder (not the build folder) under control of the make utility of your development system.
model.h	Defines model data structures and a public interface to the model entry points and data structures. Provides an interface to the real-time model data structure (*model*_rtM) via access macros. Subsystem .c or .cpp files in the model include *model*.h. This file includes: • Exported Simulink data symbols • Exported Stateflow machine parented data • Model data structures, including rtM • Model entry-point functions For more information, see “model.h” (Simulink Coder).

File	Description
model.mk	Generated makefile that controls compiling and linking the generated code into the final binary file by the `make` utility of your development system. If you set the `MAKEFLAGS` environment variable, do not select options with this variable that conflict with the current `make` utility used by the build process.
model.rtw	Represents the compiled model. By default, the build process deletes this ASCII file when the build process is complete. You can choose to retain the file for inspection.
*model*_capi.h *model*_capi.c	(optional files) Contain data structures that describe the model signals, states, and parameters without using external mode. For more information, see "Exchange Data Between Generated and External Code Using C API" (Simulink Coder).
*model*_data.c	Contains (if conditionally generated) declarations for the parameters data structure and the constant block I/O data structure, and zero representations for structure data types that the model uses. A model build generates this file when the model uses these data structures. The `extern` declarations for structures appear in *model*.h. When present, this file contains: • Constant block I/O parameters • Include files *model*.h and *model*_private.h • Definitions for the zero representations for user-defined structure data types that the model uses • Constant parameters
*model*_dt.h	(optional file) Declares structures that contain data type and data type transition information for generated model data structures for supporting external mode.

File	Description
*model*_private.h	Contains local `define` constants and local data for the model and subsystems. The generated source files from the model build include this file. When you interface external code with generated code from a model, include *model*_private.h. The file contains: • Imported Simulink data symbols • Imported Stateflow machine parented data • Stateflow entry points • Simulink Coder details (various macros, `enum`s, and so forth, that are private to the code) For more information, see "Manage Build Process File Dependencies" (Simulink Coder).
model_reference_types.h	Contains type definitions for timing bridges. A model build generates this file for a referenced model or a model containing model reference blocks.
*model*_targ_data_map.m	(optional file) Contains MATLAB language commands that external mode uses to initialize the external mode connection.
*model*_types.h	Provides forward declarations for the real-time model data structure and the parameters data structure. The generated header files from the model build include this file. Function declarations of reusable functions can use these structures.

File	Description
`multiword_types.h`	Contains type definitions for multiple-word wide data types and their word-size chunks. If your code uses multiword data types, include this header file. A model build generates this file when one or more of these conditions apply: • Your model uses multiword data types. • Your model configuration enables **MAT-file logging**. • Your model configuration enables **Code Generation** > **Interface** > **External mode**.

`rtGetInf.c`
 	
`rtGetInf.h`
 	
`rtGetNaN.c`
 	
`rtGetNaN.h`
 	
`rt_nonfinite.c`
 	
`rt_nonfinite.h`
	Declares and initializes global nonfinite values for `inf`, minus `inf`, and `nan`. Provides nonfinite comparison functions.
	
	A model build generates these files when one or more of these conditions apply:
	
	• The model contains S-functions.
	• The generated code from the model requires nonfinite numbers.
	• Your model configuration enables **MAT-file logging**.
	• Your model configuration selects `grt.tlc` as the **System target file** and enables the **Classic call interface**.

`rtmodel.h`	Contains `#include` directives required by static main program modules such as `rt_main.c`. The build process does not create these modules at code generation time. The modules include `rt_model.h` to access model-specific data structures and entry points. If you create your own main program module, make sure to include `rtmodel.h`.

File	Description
`rtwtypes.h`	Provides the essential type definitions, `#define` statements, and enumerations. For GRT-based system target files, `rtwtypes.h` includes `simstruc_types.h` which, in turn, includes `tmwtypes.h`. For ERT-based system target files that do not generate a GRT interface and do not have noninlined S-functions, `rtwtypes.h` does not include `simstruc_types.h`. For more information, see "rtwtypes.h" (Simulink Coder) and "Manage Build Process File Dependencies" (Simulink Coder).

`rtw_proj.tmw`
 	
`sl_proj.tmw`
	Marker files.
	
	The build process generates these files to help the `make` utility determine when to recompile and link the generated code.

`rt_defines.h`	Contains type definitions for special mathematical constants (such as π and *e*) and defines the `UNUSED_PARAMETER` macro. A model build generates this file when the generated code requires a mathematical constant definition or when the function body does not access a required model function argument.

`rt_sfcn_helper.h`
 	
`rt_sfcn_helper.c`
	(optional files) Provide functions that the noninlined S-functions use in a model.
	
	The noninlined S-functions use functions `rt_CallSys`, `rt_enableSys`, and `rt_DisableSys` to call downstream function-call subsystems.

`subsystem``.c`	(optional file) Contains C source code for each noninlined nonvirtual subsystem or copy the code when the subsystem is configured to place code in a separate file.
`subsystem``.h`	(optional file) Contains exported symbols for noninlined nonvirtual subsystems.

model.bat

This file contains Windows batch file commands that set the compiler environment and invoke the `make` utility.

If you are using the toolchain approach for the build process, you also can use this batch file to extract information from the generated makefile, *model*`.mk`. The information includes macro definitions and values that appear in the makefile, such as `CFLAGS` (C compiler flags) and `CPP_FLAGS` (C++ compiler flags). With the folder containing *model*`.bat` selected as the current working folder, in the Command Window, type:

```
>> system('model.bat info')
```

On UNIX and Macintosh platforms, the code generator does not create the *model*`.bat` file. To extract information for toolchain approach builds from the generated makefile on these systems, in the Command Window, type:

```
>> system('gmake –f model.mk info')
```

model.h

The header file *model*`.h` declares model data structures and a public interface to the model entry points and data structures. This header file also provides an interface to the real-time model data structure (*model*`_M`) by using access macros. If your code interfaces to model functions or model data structures, include *model*`.h`:

- Exported global signals

  ```
  extern int32_T INPUT;    /* '<Root>/In' */
  ```

- Global structure definitions

  ```
  /* Block parameters (auto storage) */
  extern Parameters_mymodel mymodel_P;
  ```

- Real-time model (RTM) macro definitions

  ```
  #ifndef rtmGetSampleTime
  # define rtmGetSampleTime(rtm, idx)
  ((rtm)->Timing.sampleTimes[idx])
  #endif
  ```

- Model entry point functions (ERT example)

  ```
  extern void mymodel_initialize(void);
  ```

```
extern void mymodel_step(void);
extern void mymodel_terminate(void);
```

The `main.c` (or `.cpp`) file includes *`model`*`.h`. If the model build generates the `main.c` (or `.cpp`) file from a TLC script, the TLC source can include *`model`*`.h`.

```
#include "%<CompiledModel.Name>.h"
```

If `main.c` is a static source file, you can use the fixed header file name `rtmodel.h`. This file includes the *`model`*`.h` header file:

```
#include "model.h"     /* If main.c is generated */
```

or

```
#include "rtmodel.h"   /* If static main.c is used */
```

Other external source files can require to include *`model`*`.h` to interface to model data, for example exported global parameters or signals. The *`model`*`.h` file itself can have additional header dependencies due to requirements of generated code. See "System Header Files" (Simulink Coder) and "Code Generator Header Files" (Simulink Coder).

To reduce dependencies and reduce the number of included header files, see "Manage Build Process File Dependencies" (Simulink Coder).

rtwtypes.h

The header file `rtwtypes.h` defines data types, structures, and macros required by the generated code. You include `rtwtypes.h` for GRT and ERT system target files, instead of including `tmwtypes.h` or `simstruc_types.h`.

Often, the generated code requires that integer operations overflow or underflow at specific values. For example, when the code expects a 16-bit integer, the code does not accept an 8-bit or a 32-bit integer type. The C language does not set a standard for the number of bits in types such as `char`, `int`, and others. So, there is no universally accepted data type in C to use for sized-integers.

To accommodate this feature of the C language, the generated code uses sized integer types, such as `int8_T`, `uint32_T`, and others, which are not standard C types. In `rtwtypes.h`, the generated code maps these sized-integer types to the corresponding C keyword base type using information in the **Hardware Implementation** pane of the configuration parameters.

The code generator produces the optimized version of `rtwtypes.h` for ERT-based system target files when these conditions exist:

- The model has a cleared **Classic call interface** option in the **All Parameters** tab of the Configuration Parameters dialog box.
- The model does not contain noninlined S-functions.

Include `rtwtypes.h`. If you include it for GRT system target files, for example, it is easier to use your code with ERT-based system target files.

For GRT and ERT system target files, the location of `rtwtypes.h` depends on whether the build process uses the *shared utilities* location. If it uses a shared location, the code generator places `rtwtypes.h` in `slprj/target/_sharedutils`; otherwise, it places `rtwtypes.h` in the build folder (*`model_target`*`_rtw`). See "Specify Generated Code Interfaces" (Simulink Coder).

Source files include the `rtwtypes.h` header file when the source files use code generator type names or other code generator definitions. A typical example is for files that declare variables by using a code generator data type, for example, `uint32_T myvar`.

A source file that the code generator and an S-function use can use the preprocessor macro `MATLAB_MEX_FILE`. The macro definition comes from the `mex` function:

```
#ifdef  MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
```

A source file for the code generator `main.c` (or `.cpp`) file includes `rtwtypes.h` without preprocessor checks.

```
#include "rtwtypes.h"
```

Custom source files that the Target Language Compiler generates can also emit these `include` statements into their generated file.

See "Control Placement of rtwtypes.h for Shared Utility Code" (Simulink Coder).

Manage Build Process File Dependencies

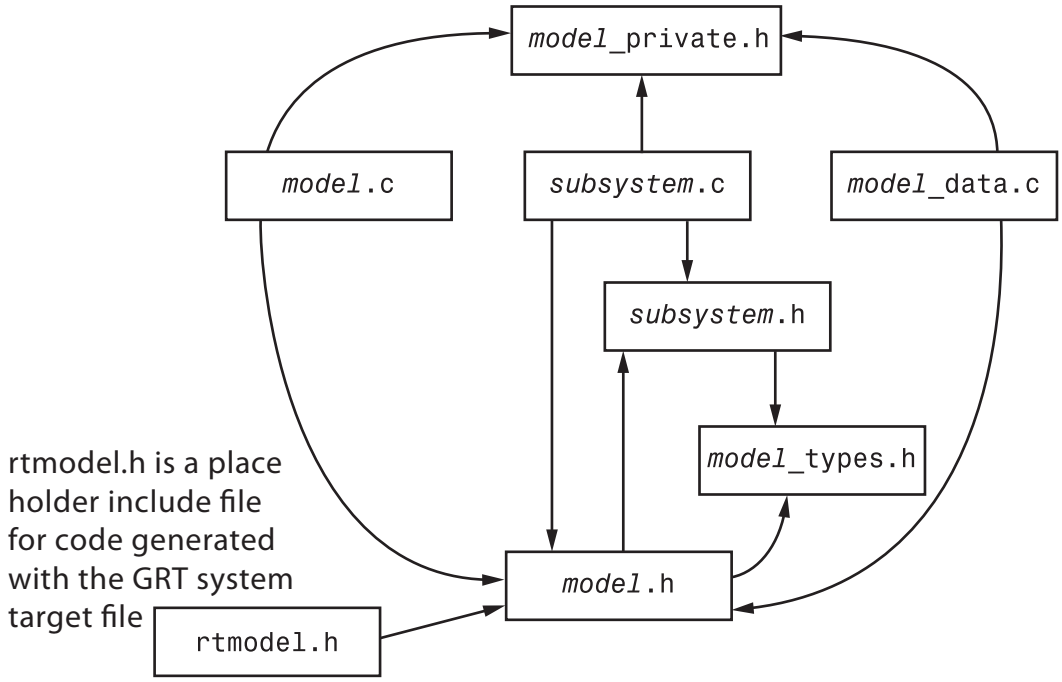
The dependency relationships among generated source and header files appear in the figure. Arrows coming from a file point to files it includes. Other dependencies exist, for example, on Simulink header files `tmwtypes.h` and `simstruc_types.h`, plus C or C ++ library files. The figure maps inclusion relations between only those files that are generated in the build folder. These files can reference utility and model reference code located in a code generation folder. For more information about the folders and files that the build process creates, see "Manage Build Process Folders" (Simulink Coder) and "Manage Build Process Files" (Simulink Coder).

The two tables identify the conditions that control creation of dependency files for GRT and ERT targets. To manage build-related dependencies, consider how these conditions apply to your model and code generation process. Then, configure model parameters and code generation options to manage build process file dependencies.

Due to differences in file packaging options for code generated with ERT-based system target files, the file dependencies differ slightly from file packaging for code generated with GRT-based system target files. See "Manage File Packaging of Generated Code Modules" on page 34-14.

The parent system header files (*`model`*`.h`) include child subsystem header files (*`subsystem`*`.h`). In more layered models, subsystems similarly include their children's header files in the model hierarchy. As a consequence, subsystems are able to view recursively into their descendant subsystems and view into the root system because every *`subsystem`*`.c` or *`subsystem`*`.cpp` includes *`model`*`.h` and *`model`*`_private.h`.

In the figure, files *`model`*`.h`, *`model`*`_private.h`, and *`subsystem`*`.h` depend on the header file `rtwtypes.h`. If you use system target files that are not based on the ERT system target file, the source files that you generate can have additional dependencies on `tmwtypes.h` and `simstruc_types.h`.



For information about file dependencies in header files, see the following:

In this section...
“System Header Files” on page 33-53
“Code Generator Header Files” on page 33-56

System Header Files

The system header files make function declarations, type definitions, and macro definitions available to the legacy or external code. Some code generation scenarios require including header files that are specific to the code generator product.

The code generator includes some system header files for broadly defined cases. For example, generated code includes `<stddef.h>` when the model contains a utility function that requires this header file. This approach helps identify header file dependencies:

1. Set the Shared code placement parameter to `'Shared location'` and build the model. The code generator places the utility functions in `__sharedutils` folder.
2. Use a find-in-file utility (for example, grep utility) to search the `.c` and `.h` files in the `__sharedutils` folder for `#include`. The search results list the utilities with header file dependencies.
3. Use this information to identify utilities to remove from the model and reduce header file dependencies in the generated code.

For more information, see "Generate Shared Utility Code for Fixed-Point Functions" (Simulink Coder).

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`<math.h>`	Defines math constants GRT—Generated code does not include this file. ERT—Generated code includes this file when the code honors your model configuration for solver **Stop time** and either: • Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder). • Your model configuration enables **Code Generation** > **Interface** > **External mode**.
`<float.h>`	Provides floating-point math functions GRT—Generated code includes this file when your model contains a floating-point math function. ERT—Generated code includes this file when your model contains a floating-point math function, unless a code replacement library entry overrides the function. For more information, see "Choose a Code Replacement Library" (Simulink Coder).
`<stddef.h>`	Defines NULL GRT and ERT—Generated code includes this file when your model contains a utility function that requires this file.
`<stdio.h>`	Provides file I/O functions

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
	GRT—Generated code includes this file when your model includes a To File block. ERT—Generated code includes this file when either: • Your model includes a To File block. • Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder).
`<stdlib.h>`	Provides utility functions such as the integer versions of `div()` and `abs()` GRT—Generated code includes this file when either: • Your model includes a Stateflow chart. • Your model includes a math function block configured for `mod()` or `rem()`, which generate calls to `div()`. ERT—Generated code includes this file when either: • Your model includes a Stateflow chart, and you select **Support: floating-point numbers**. • Your model includes a math function block configured for `mod()` or `rem()`, which generate calls to `div()`.
`<string.h>`	Provides memory functions such as `memset()` and `memcpy()` GRT—Generated code includes this file when your model initialization code calls `memset()`. ERT—Generated code includes this file when a block or model initialization code calls `memcpy()` or `memset()`. For a list of relevant blocks, in the Command Window, type: `showblockdatatypetable` Look for blocks with the N2 note. To omit calls to `memset()` from model initialization code, select the **Remove root level I/O zero initialization** and **Remove internal data zero initialization** optimization configuration parameters.

Code Generator Header Files

Dependencies in the table for generated header files apply to the system target files `grt.tlc` and `ert.tlc`. System target files derived from these base system target files can have additional header dependencies. Code generation for blocks from blocksets, embedded targets, and custom S-functions can introduce additional header dependencies.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`builtin_typeid_types.h`	Defines an enumerated type corresponding to built-in data types GRT and ERT—Generated code includes this file when one or more of these conditions apply: • Your model contains a Stateflow chart that uses messages. • Your model configuration enables: **MAT-file logging**. See "MAT-file logging" (Simulink Coder). • Your model configuration selects C API options at **Code Generation** > **Interface**.
`dt_info.h`	Defines data structures for external mode GRT and ERT—Generated code includes this file when your model configuration enables external mode.
`ext_work.h`	Defines external mode functions GRT and ERT—Generated code includes this file when your model configuration enables external mode.
`fixedpoint.h`	Provides fixed-point support for noninlined S-functions GRT—Generated code includes this file. ERT—Generated code includes this file when either: • Your model uses noninlined S-functions. • Your model configuration selects **Classic call interface**.
`model_reference_types.h`	Contains type definitions for timing bridges GRT and ERT—Generated code includes this file when building a reference model or building a model that contains model blocks.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
*model*_types.h	Defines model-specific data types GRT and ERT—Generated code includes this file.
multiword_types.h	Contains type definitions for multiword-wide data types and their word-size chunks GRT and ERT—Generated code includes this file when one or more of these conditions apply: • Your model uses multiword data types. • Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder). • Your model configuration enables **Code Generation** > **Interface** > **External mode**.
rtGetInf.h rtGetNaN.h rt_nonfinite.h	Support nonfinite numbers GRT—Generated code includes this file when one or more of these conditions apply: • Your model contains S-functions. • The generated code requires nonfinite numbers. • Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder). • Your model configuration selects the **Classic call interface**. ERT—Generated code includes this file when one or more of these conditions apply: • Your model contains S-functions. • The generated code requires nonfinite numbers. • Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder).

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`rt_defines.h`	Contains type definitions for special mathematical constants (such as π and *e*) and defines the `UNUSED_PARAMETER` macro GRT and ERT—Generated code includes this file when either: • The generated code requires a mathematical constant definition. • The function body does not access a required model function argument.

`rt_logging.h`	Supports MAT-file logging and includes:
	
	`rtwtypes.h`
	`builtin_typeid_types.h`
	`multiword_types.h`
	`rt_mxclassid.h`
	`rtw_matlogging.h`
	
	GRT—Generated code includes this file.
	
	ERT—Generated code includes this file when you model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder).

`rt_mxclassid.h`	Defines `mxArray` class ID enumerations GRT and ERT—Generated code includes this file when the code includes `rt_logging.c`.
`rtw_continuous.h`	Supports continuous time GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects **Support: continuous time** and when the code does not already include `simstruc.h`.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`rtw_extmode.h`	Supports external mode GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects external mode and when the code does not already include `simstruc.h`.
`rtw_matlogging.h`	Supports MAT-file logging GRT—Generated code includes this file when the code includes `simstruc_types.h` and `rt_logging.h`. ERT—Generated code includes this file when the code includes `rt_logging.h`.
`rtw_solver.h`	Supports continuous states GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects **Support: continuous time** and when the code does not already include `simstruc.h`.
`rtwtypes.h`	Defines code generator data types GRT—Generated code includes this file. Use the complete version of the file, which includes `tmwtypes.h` and `simstruc_types.h`. See `simstruc_types.h` for dependencies. ERT—Generated code includes this file. Use the complete or optimized version of the file. See “rtwtypes.h” on page 33-49. If you include `rtwtypes.h` and `tmwtypes.h` in external code that you integrate with generated code, the `#include` for `rtwtypes.h` must precede the `#include` for `tmwtypes.h`. This ordering of `#include` statements preserves target-specific type definitions. If you reverse the order, a compiler error occurs.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files

`simstruc.h`	Supports calling noninlined S-functions that use the `Simstruct` definition; also includes:
	
	`limits.h`
	`string.h`
	`tmwtypes.h`
	`simstruc_types.h`
	
	GRT—Generated code includes this file.
	
	ERT—Generated code includes this file when either:
	
	• Your model uses noninlined S-functions.
	• Your model configuration selects **Classic call interface**.

`simstruc_types.h`	Provides definitions that the generated code uses and includes the header files:
	
	`rtw_matlogging.h`
	`rtw_extmode.h`
	`rtw_continuous.h`
	`rtw_solver.h`
	`sysran_types.h`
	
	GRT—Generated code includes this file when the code includes `rtwtypes.h`.
	
	ERT—Generated code does not include this file. For ERT, `rtwtypes.h` contains definitions, and *`model`*`.h` contains header files.

`sysran_types.h`	Supports external mode GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects external mode and when the code does not already include `simstruc.h`.

Add Build Process Dependencies

When you specify a system target file for code generation, the code generator can build a standalone executable program that can run on the development computer. To build the executable program, the code generator uses the selected compiler and the generated makefile for a toolchain approach or for a template makefile (TMF) approach build processes. Part of the makefile generation process is to add source file, header file, and library file information (the dependencies) in the generated makefile for a compilation. Or, for a specific application, you can add the generated files and file dependencies through a configuration management system.

The generated code for a model consists of a small set of files. (See "Manage Build Process Files" (Simulink Coder).) These files have dependencies on other files, which occur due to:

- Header file inclusions
- Macro declarations
- Function calls
- Variable declarations

The model or external code introduces dependencies for various reasons:

- Blocks in a model generate code that makes function calls. These calls can occur in several forms:
  - Included source files (not generated) declare the called functions. In cases such as a blockset, manage these source file dependencies by compiling them into a library file.
  - The generated code makes calls to functions in the run-time library provided by the compiler.
  - Some function dependencies also are generated files, which are referred to as shared utilities. Some examples are fixed-point utilities and non-finite support functions. These dependencies are referred to as shared utilities. The generated functions can appear in files in the build folder for standalone models or in the `_sharedutils` folder under the `slprj` folder for builds that involve model reference.
- Models with continuous time require solver source code files.
- Code generator options such as external mode, C API, and MAT-file logging.
- External code specifies dependencies.

For information about adding file dependencies in information for the build process, see the following:

In this section...

File Dependency Information for the Build Process

The code generator provides several mechanisms to input file dependency information into the build process. The mechanisms depend on whether your dependencies are block-based or are model- or system target file-based.

For block dependencies, consider using:

- S-functions and blocksets
  - Add folders that contain S-function MEX-files that the model uses to the header include path.
  - Create makefile rules for these folders to allow for finding source code.
  - Specify additional source file names with the S-Function block parameter `SFunctionModules`.
  - Specify additional dependencies with the `rtwmakecfg.m` mechanism. See "Use rtwmakecfg.m API to Customize Generated Makefiles" (Simulink Coder).

  For more information on applying these approaches to legacy or external code integration, see "Import Calls to External Code into Generated Code with Legacy Code Tool" (Simulink Coder).
- S-Function Builder block, which provides its own UI for specifying dependency information

For model- or system target file-based dependencies, such as external header files, consider using:

- The **Code Generation** > **Custom Code** pane in the Configuration Parameters dialog box. You can specify additional libraries, source files, and include folders.
- TLC functions `LibAddToCommonIncludes()` and `LibAddToModelSources()`. You can specify dependencies during the TLC phase. See "LibAddToCommonIncludes(incFileName)" (Simulink Coder) and

"LibAddSourceFileCustomSection(file, builtInSection, newSection)" (Simulink Coder). The Embedded Coder product also provides a TLC-based customization template for generating additional source files.

Generated Makefile Dependencies

For toolchain approach or template makefile (TMF) approach build processes, the code generator generates a makefile. For TMFs, the generated makefile provides token expansion in which the build process expands different tokens in the makefile to include the additional dependency information. The resulting makefile contains the complete dependency information. See "Customize Template Makefiles" (Simulink Coder).

The generated makefile contains:

- Names of the source file dependencies
- Folders where source files are located
- Location of the header files
- Precompiled library dependencies
- Libraries that the `make` utility compiles and creates

A property of `make` utilities is that you do not have to specify the specific location for a given source C or C++ file. If a rule exists for that folder and the source file name is a prerequisite in the makefile, the make utility can find the source file and compile it. The C or C++ compiler (preprocessor) does not require absolute paths to the headers. The compiler finds header file with the name of the header file by using an `#include` directive and an include path. The generated C or C++ source code depends on this standard compiler capability.

Libraries are created and linked against, but occlude the specific functions that the program calls.

These properties can make it difficult to determine the minimum list of file dependencies manually. You can use the makefile as a starting point to determine the dependencies in the generated code. For an example that shows how to identify dependencies, see "Relocate Code to Another Development Environment with packNGo" (Simulink Coder).

Another approach to determining the dependencies is using linker information, such as a linker map file, to determine the symbol dependencies. The map file provides the location of code generator and blockset source and header files to help in locating the dependencies.

Code Generator Static File Dependencies

Several locations in the MATLAB folder tree contain static file dependencies specific to the code generator:

- *matlabroot*`/rtw/c/src` (open)

  This folder has subfolders and contains additional files must be compiled. Examples include solver functions (for continuous time support), external mode support files, C API support files, and S-function support files. Include source files in this folder into the build process with the `SRC` variables of the makefile.
- Header files in the folder `matlabroot/rtw/extern/include`
- Header files in the folder `matlabroot/simulink/include`

  These folders contain additional header file dependencies such as `tmwtypes.h`, `simstruc_types.h`, and `simstruc.h`.

  Note For ERT-based system target files, you can avoid several header dependencies. ERT-based system target files generate the minimum set of type definitions, macros, and so on, in the file `rtwtypes.h`.

Blockset Static File Dependencies

Blockset products with S-function code apply the `rtwmakecfg.m` mechanism to provide the code generator with dependency information. The `rtwmakecfg.m` file from the blockset contains the list of include path and source path dependencies for the blockset. Typically, blocksets create a library from the source files to which the generated model code can link. The libraries are created and identified when you use the `rtwmakecfg.m` mechanism.

To locate the `rtwmakecfg.m` files for blocksets in your MATLAB installed tree, use the following command:

```
>> which -all rtwmakecfg.m
```

If the model that you are compiling uses one or more of the blocksets listed by the `which` command, you can determine folder and file dependency information from the respective `rtwmakecfg.m` file.

Folder Dependency Information for the Build Process

You can add `#include` statements to generated code. Such references can come from several sources, including TLC scripts for inlining S-functions, custom storage classes, bus objects, and data type objects. The included files consist of header files for external code or other customizations. You can specify compiler include paths with the `-I` compiler option. The build process uses the specified paths to search for included header files.

Usage scenarios for the generated code include, but are not limited to, the following:

- A custom build process compiles generated code that requires an environment-specific set of `#include` statements.

  In this scenario, the build process invokes the code generator when you select the **Generate code only** check box. Consider using fully qualified paths, relative paths, or just the header file names in the `#include` statements. Use include paths.

- The build process compiles the generated code.

  In this case, you can specify compiler include paths (`-I`) for the build process in several ways:

  - Specify additional include paths on the **Code Generation** > **Custom Code** pane in the Configuration Parameters dialog box. The code generator propagates the include paths into the generated makefile.
  - The `rtwmakecfg.m` mechanism allows S-functions to introduce additional include paths into the build process. The code generator propagates the include paths into the generated makefile.
  - When building a model that uses a custom system target file and is makefile-based, you can directly add the include paths into the template makefile that the system target file uses.
  - Use the `make` command to specify a `USER_INCLUDES` make variable that defines a folder in which the build process searches for included files. For example:

    ```
    make_rtw USER_INCLUDES=-Id:\work\feature1
    ```

    The build process passes the custom includes to the command-line invocation of the make utility, which adds them to the overall flags passed to the compiler.

Use `#include` Statements and Include Paths

Consider the following approaches for using `#include` statements and include paths with the build process to generate code that remains portable and minimizes compatibility problems with future versions.

Assume that additional header files are:

```
c:\work\feature1\foo.h
c:\work\feature2\bar.h
```

- An approach is to include in the `#include` statements only the file name, such as:

  ```
  #include "foo.h"
  #include "bar.h"
  ```

  Then, the include path passed to the compiler contains folders in which the headers files exist:

  ```
  cc -Ic:\work\feature1 -Ic:\work\feature2     ...
  ```

- Another approach is to use relative paths in `#include` statements and provide an anchor folder for these relative paths using an include path, for example:

  ```
  #include "feature1\foo.h"
  #include "feature2\bar.h"
  ```

Then, specify the anchor folder (for example `\work`) to the compiler:

```
 cc -Ic:\work   ...
```

Avoid These Folder Dependencies

When using the build process, avoid dependencies on folders in the build process "Code generation folder" (Simulink), such as the *`model`*`_ert_rtw` folder or the `slprj` folder. Do not use paths in `#include` statements that are relative to the location of the generated source file. For example, if your MATLAB code generation folder is `c:\work`, the build process generates the *`model`*`.c` source file into a subfolder such as:

```
c:\work\model_ert_rtw\model.c
```

The *`model`*`.c` file has `#include` statements of the form:

```
#include "..\feature1\foo.h"
#include "..\feature2\bar.h"
```

It is preferable to use one of the other suggested approaches because the relative path creates a dependency on the code generator folder structure.

More About

- “Manage Build Process Folders” (Simulink Coder)
- “Manage Build Process Files” (Simulink Coder)
- “Manage Build Process File Dependencies” (Simulink Coder)
- “Enable Build Process for Folder Names with Spaces” (Simulink Coder)
- “Build and Run a Program” (Simulink Coder)

Enable Build Process for Folder Names with Spaces

The code generator uses alternate folder name support, which is specific to your operating system, to process folder names that include spaces. On Windows systems, the code generator maps a drive corresponding to the MATLAB installation folder for either of these conditions:

- The `matlabroot` folder is a UNC location.
- The path the `matlabroot` folder contains spaces, and the system has no alternate name support.

The build process provides similar support for other build-related folders. For a summary of support and limitations, see "Build Process Folder Support on Windows" (Simulink Coder).

Spaces in folder names can appear in the paths to build-related locations:

- `matlabroot`—path to your MATLAB installation folder.

  An example is a `matlabroot` similar to `C:\Program Files\MATLAB\R2015b`.
- `pwd`—current working folder from which you start the build.

  An example is a `pwd` at the start of a build similar to `C:\Users\username \Documents\My Work`.
- The installation folder for a compiler that the build process uses.

If your work environment includes one or more of the preceding scenarios, use the following support mechanisms for the build process:

- If you are using the toolchain approach to build generated code, the toolchain manages spaces in folder names by using alternate names from the platform (for example, Windows or UNIX). For more information about how the toolchain `TransformPathsWithSpaces` method manages these names, see addAttribute (coder.make.ToolchainInfo) (MATLAB Coder).
- If you are using the template makefile approach to build generated code, the template makefile (`.tmf`) requires code to manage spaces in folder names. When the alternate folder names (Windows short names) differ from the file system folder names (Windows long names), add this code to the makefile.

```
ALT_MATLAB_ROOT          = |>ALT_MATLAB_ROOT<|
ALT_MATLAB_BIN           = |>ALT_MATLAB_BIN<|
!if "$(MATLAB_ROOT)" != "$(ALT_MATLAB_ROOT)"
```

```
MATLAB_ROOT = $(ALT_MATLAB_ROOT)
!endif
!if "$(MATLAB_BIN)" != "$(ALT_MATLAB_BIN)"
MATLAB_BIN = $(ALT_MATLAB_BIN)
!endif
```

When the values of the location tokens are not equal, this code replaces `MATLAB_ROOT` with `ALT_MATLAB_ROOT`. The replacement indicates that the path to your MATLAB installation folder includes spaces. This code applies the same type of replacement for `MATLAB_BIN` with `ALT_MATLAB_BIN`. The preceding code is specific to `nmake`. For platform-specific examples, see the supplied template makefiles.

With either build approach, when there is an issue with support for creation of alternate names (short names), build errors can occur on Windows. If a build generates an error message similar to the following message, see "Troubleshooting Errors When Folder Names Have Spaces" (Simulink Coder).

```
NMAKE : fatal error U1073: don't know how to make ' ...
```

When using operating system commands, such as `system` or `dos`, enclose paths that specify executable files or command parameters in double quotes (`" "`). For example:

```
system('dir "D:\Applications\Common Files"')
```

Build Process Folder Support on Windows

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows Platform

`matlabroot` folder
 	
Note: The `matlabroot` value is derived from the MATLAB installation location.
	During a build, a UNC location such as:
	
	`\\networkdrive\matlab\R20xxb`
	
	could be remapped as:
	
	`T:\`
	
	During a build on a Windows system with short file name (8.3) support (default for Windows using NTFS), the build process uses the Windows API `getShortPathName()` for the folder location.
		Build process folder support available independent of file system (NTFS or ReFS) or file system configuration for short file name support.
		
		Limitations:
		
		On systems that require drive mapping for the installation location, the build process requires that a drive letter is available for mapping.

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows Platform

	During a build on a Windows system without short file name (8.3) support (systems using ReFS or using NTFS with 8.3 support disabled), a location with spaces in the path such as:
	`C:\Program Files\MATLAB\R20xxb`
	could be remapped as:
	`T:\R20xxb`
		On systems without short file name (8.3) support (using ReFS or using NTFS with 8.3 support disabled), the final folder in the installation location cannot contain spaces. For example, a final folder name:
		`C:\Program Files\MATLAB\R20xxb sp1`
		is not supported.

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows Platform
Code generation folder Simulation cache folder Custom code source file locations—among others, these locations include folders specified by: • `rtwmakecfg.` • **Configuratio Parameters > Code Generation > Custom Code > Additional build information** • Code replacement library	For UNC locations, build process temporarily maps a drive by using the shell commands `pushd` and `popd`.	Build process folder support is available independent of file system (NTFS or ReFS) or file system configuration for short path name support.
	For paths with spaces, build process uses the Windows short path name (8.3) by using the Windows API: `getShortPathName()`	Build process folder support depends on NTFS file system and requires Windows default support. Registry sets value of 2 or 0 for: `NtfsDisable8dot3NameCreation` **Limitations:** Build process does not support spaces in the path to these folders for: • NTFS file system with short path name support disabled • ReFS file system (this file system does not support short path names)

Troubleshooting Errors When Folder Names Have Spaces

On Windows, when there is an issue with support for creation of short file names, build process errors can occur. When this issue affects a build, you see an error message similar to:

```
NMAKE : fatal error U1073: don't know how to make 'C:\Work\My'
```

This message can occur if a space in the folder name (`C:\Work\My Models`) prevents the build process from finding the model or a file to build. For descriptions of the build-

related folders that are sensitive to a space in the folder name or path, see "Build Process Folder Support on Windows" (Simulink Coder).

To avoid issues from folder names with spaces when Windows short file name support for file names is disabled, do not use paths with spaces. For example, install third-party software to paths without spaces. Do not use paths with spaces for folders containing your models, source files, or libraries.

An issue can occur with builds that use folder names with spaces, because it is possible to disable Windows alternate name support. The build process uses this alternate name support on Windows systems. There are many terms for this file, folder, and path alternate name support:

- 8.3 name
- DOS path
- short file name (SFN, ShortFileName)
- long name alias
- Windows path alias

Verify the type of file system that the drive uses. In Windows Explorer, right-click the drive icon and select properties.

- If the file system is ReFS (Resilient File System), it is an issue. The ReFS does not provide short file name support. Except for the MATLAB installation folder, the build process does not support folder names with spaces for the ReFS file system. If your work environment requires short file name support for the build folder or for additional external code folders, do not use ReFS.
- If the file system is NTFS (New Technology File System), it is possible that the build error is related to a registry setting incompatibility. Continue with troubleshooting steps.

The error could stem from an issue with short file name support on a system using NTFS. Check the Windows registry setting that enables the creation of short names for files, folders, and paths.

1. From the Windows Start menu, type `cmd`, right-click the `cmd.exe` icon, and select `Run as administrator`.
2. Change to the `windows\system32` folder and query the `NtfsDisable8dot3NameCreation` status by typing:

   ```
   > fsutil 8dot3name query
   ```

3. If the registry state of `NtfsDisable8dot3NameCreation` is not 2, the default (Volume level setting), change the value to 2 by typing:

   ```
   > fsutil 8dot3name set 2
   ```

   For more information about enabling creation of short names. See http://technet.microsoft.com/en-us/library/ff621566.aspx.

   Changing the registry setting enables creation of short names only for files and folders that are created after the change.

4. To create short names for files created while short name creation was disabled, at the Windows command line, use the `fsutil` utility.

   To set the short name, the syntax is:

   ```
   > fsutil file setshortname <FileName> <ShortName>
   ```

   For example, to create the short name `PROGRA~1` for the long name `C:\Program Files`, type:

   ```
   > fsutil file setshortname "C:\Program Files" PROGRA~1
   ```

   The `C:\Program Files` folder name is in quotations because it has spaces.

5. To verify that the short name was created, use the `dir` command with `/x` option to show short names.

   ```
   > dir C:\ /x
   ```

Code Generation of Matrices and Arrays

In this section...

MATLAB, Simulink, and the code generator store matrix data and arrays (1–D, 2–D, ...) in column-major format as a vector. Column-major format orders elements in a matrix starting from the first column, top to bottom, and then moving on to the next column. For example, the following 3x3 matrix:

```
A =
     1   2   3
     4   5   6
     7   8   9
```

translates to an array of length 9 in the following order:

```
A(1) = A(1,1) = 1;
A(2) = A(2,1) = 4;
A(3) = A(3,1) = 7;
A(4) = A(1,2) = 2;
A(5) = A(2,2) = 5;
```

and so on.

In column-major format, the next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory:

- `A(i)` and `A(i+1)`
- `B(i,j)` and `B(i+1,j)`
- `C(i,j,k)` and `C(i+1,j,k)`

For more information on the internal representation of MATLAB data, see “MATLAB Data” (MATLAB) in the MATLAB External Interfaces document.

Code generation software uses column-major format for several reasons:

- The world of signal and array processing is largely column major: MATLAB, LAPack, Fortran90, DSP libraries.

- A column is equivalent to a channel in frame-based processing. In this case, column-major storage is more efficient.
- A column-major array is self-consistent with its component submatrices:
  - A column-major 2–D array is a simple concatenation of 1–D arrays.
  - A column-major 3–D array is a simple concatenation of 2–D arrays.
  - The stride is the number of memory locations to index to the next element in the same dimension. The stride of the first dimension is one element. The stride of the nth dimension element is the product of sizes of the lower dimensions.
  - Row-major n-D arrays have their stride of 1 for the highest dimension. Submatrix manipulations are typically accessing a scattered data set in memory, which does not allow for efficient indexing.

C typically uses row-major format. MATLAB and Simulink use column-major format. You cannot configure the code generation software to generate code with row-major ordering. If you are integrating external C code with the generated code, consider the following:

To	Consider
Integrate row-major data in external C code with Simulink generated functions.	• Transposing the row-major data in your external C code into column-major format as a 1–D array. • Using "Access Data Through Functions with Custom Storage Class `GetSet`" on page 23-92. The `GetSet` custom storage class replaces get (read from) and set (write to) with user-specified `GetSet` functions. The user-specified `GetSet` function has a single index argument, requiring the function to process the argument and access the targeted row and column data element. Using the `GetSet` function impacts code efficiency.
Integrate external C code functions requiring row-major data with Simulink generated data.	Using the Legacy Code Tool option `convert2DMatrixToRowMajor` to create an S-function that integrates external code functions with Simulink generated data. See `legacy_code`. The generated code stores the data as a 1–D array. Using `convert2DMatrixToRowMajor` impacts code efficiency.

Code Generator Matrix Parameters

The compiled model file, *model*.rtw, represents matrices as character vectors in MATLAB syntax, without an implied storage format. This format allows you to copy the character vector out of an .rtw file, paste it into a MATLAB file, and have it recognized by MATLAB.

The code generator declares Simulink block matrix parameters as scalar or 1-D array variables

```
real_T scalar;
real_T mat[ nRows * nCols ];
```

real_T can be a data type supported by Simulink. It matches the variable type given in the model file.

For example, the 3-by-3 matrix in the 2–D Look-Up Table block

```
    1   2   3
    4   5   6
    7   8   9
```

is stored in *model*.rtw as

```
Parameter {
  Name   "OutputValues"
  Value   Matrix(3,3)
[[1.0, 2.0, 3.0]; [4.0, 5.0, 6.0]; [7.0, 8.0, 9.0];]
  String  "t"
  StringType   "Variable"
  ASTNode {
     IsNonTerminal  0
     Op  SL_NOT_INLINED
     ModelParameterIdx 3
    }
}
```

and results in this definition in *model*.h.

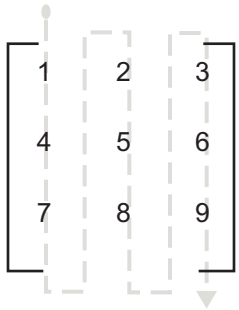
```
typedef struct Parameters_tag {
  real_T s1_Look_Up_Table_2_D_Table[9];
  /* Variable:s1_Look_Up_Table_2_D_Table
   * External Mode Tunable:yes
   * Referenced by block:
```

```
   * <S1>/Look-Up Table (2-D
   */

  [ ... other parameter definitions ... ]

} Parameters;
```

The *model*.h file declares the actual storage for the matrix parameter. You can see that the format is column-major.



```
Parameters model_P = {
  /* 3 x 3 matrix s1_Look_Up_Table_2_D_Table */
  { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 },
  [ ... other parameter declarations ...]
};
```

Internal Data Storage for Complex Number Arrays

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In Simulink and the code generator, the parts are stored in an "interleaved" format. The numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines, for Mux blocks, and other "virtual" signal manipulation blocks. For example, the signals do not actively copy their inputs, just the references.

Generate Shared Utility Code

Blocks in a model can require common functionality to implement their algorithm. Consider modularizing this functionality into standalone support or helper functions. This approach can be more efficient than inlining the code for the functionality for each block instance. These points help with the decision to use a library or a shared utility:

- Package functions that can have multiple callers into a library when the functions are defined statically. That is, the function source code exists in a file before you use the code generator to produce code for your model.
- Package functions that can have multiple callers as shared utilities (produced during code generation) when the functions cannot be defined statically. For example, several model- and block-specific properties specify which functions are used and their behavior. Also, these properties determine type definitions (for example, `typedef`) in shared utility header files. The number of possible combinations of properties that determine unique behavior make it impractical to define statically the possible function files before code generation.

In this section...

Control Placement of Shared Utility Code

Control placement of shared utility code with the **Shared code placement** option in **Configuration Parameters** > **Code Generation** > **Interface** pane. The default option value is `Auto`. For this setting, the code generator places code required for fixed-point and other utilities in the *`model`*`.c` file, the *`model`*`.cpp` file, or a separate file in the build folder (for example, `vdp_grt_rtw`) if a model does not contain existing shared utility code or one of the following blocks:

- Model blocks
- Simulink Function blocks
- Function Caller blocks

- calls to Simulink Functions from Stateflow or MATLAB Function blocks

If a model contains one or more of the above blocks, the code generator creates and uses a shared utilities folder within `slprj`. The naming convention for shared utility folders is `slprj/target/_sharedutils`. *`target`* is `sim` for simulations with Model blocks or the name of the system target file for code generation.

```
slprj/sim/_sharedutils      % folder used with simulation
slprj/grt/_sharedutils      % folder used with grt.tlc STF
slprj/ert/_sharedutils      % folder used with ert.tlc STF
slprj/mytarget/_sharedutils % folder used with mytarget.tlc STF
```

To force a model build to use the `slprj` folder for shared utility generation, even when the current model does not contain existing shared utility code or one of the blocks listed above, set the **Shared code placement** option to `Shared location`. The code generator places utilities under the `slprj` folder rather than in the normal build folder. This setting is useful when you are manually combining code from several models, as it prevents symbol collisions between the models.

Control Placement of rtwtypes.h for Shared Utility Code

The generated `rtwtypes.h` header file provides fundamental type definitions, `#define` statements, and enumerations. For more information, see “rtwtypes.h” on page 33-49.

Control placement of rtwtypes.h file by selecting whether the build process uses the shared utilities folder. If the model build uses a shared utilities folder, the build process places `rtwtypes.h` in `slprj/target/_sharedutils`. Otherwise, the software places `rtwtypes.h` in *`model_target`*`_rtw`.

Adding a model to a model hierarchy or changing an existing model in the hierarchy can result in updates to the shared `rtwtypes.h` file during code generation. If updates occur, recompile and, depending on your development process, reverify previously generated code. To minimize updates to the `rtwtypes.h` file, make the following changes in the Configuration Parameters dialog box:

- On the **Interface** pane, select **Support: complex numbers** even if the model does not currently use complex data types. Selecting this option protects against a future requirement to add support for complex data types when integrating code.
- On the **All Parameters** tab, clear **Support: non-inlined S-functions**. If you use noninlined S-functions in the model, this option generates an error.
- On the **All Parameters** tab, clear **Classic call interface**. Disables use of the GRT interface.

Avoid Duplicate Header Files for Exported Data

The exported header files appear in the shared utility folder when:

- You control the file placement of declarations for signals, parameters, and states by applying storage classes and custom storage classes.
- The code generator places utility code in a shared location.

For example, you can specify a header file for a piece of data through:

- The **Code Generation** tab in a Signal Properties dialog box.
- The `HeaderFile` property of a data object. Data objects are objects of the classes `Simulink.Signal` and `Simulink.Parameter`.

If you want the declaration to appear in the file *`model`*`.h`, it is a best practice to leave the header file name unspecified. By default, the code generator places data declarations in *`model`*`.h`.

If you specify *`model`*`.h` as the header file name, and if the code generator places utility code in a shared location, you cannot generate code from the model. The code generator cannot create the file *`model`*`.h` in both the model build folder and the shared utility folder.

Reduce Shared Utility Code Generation with Incremental Builds

You can specify that the model build generates C source files in a shared utilities folder. See “Control Placement of Shared Utility Code” on page 33-80. These files include C source files that contain function definitions and header files that contain macro definitions. For this discussion, the term functions means functions and macros.

Blocks within the same model and blocks in different models can use a shared function when you use model reference or when you build multiple standalone models from the same start build folder. The code generator produces the code for a given function only once for the block that first triggers code generation. As the product determines the requirement to generate function code for subsequent blocks, it performs a file existence check. If the file exists, the model build does not regenerate the function. The shared utility code mechanism requires that a given function and file name represent the same functional behavior regardless of which block or model generates the function. To satisfy this requirement:

- Model properties that determine function behavior contribute to the shared utility checksum or determine the function and file name.
- Block properties that determine the function behavior also determine the function and file name.

During compilation, makefile rules for the shared utilities folder select compilation of only new C files and incrementally archive the object file into the shared utility library, `rtwshared.lib`, or `rtwshared.a`. Incremental compilation also occurs.

Manage the Shared Utility Code Checksum

When a model configuration sets **Configuration Parameters** > **Code Generation** > **Interface** > **Shared code placement** as **Shared location** or when the model contains Model blocks, the code generator places the shared code in the shared utilities folder. The build process generates a shared utilities checksum of the code generation configuration for the shared code.

During subsequent code generation, if the checksum file `slprj/target/_sharedutils/checksummap.mat` exists relative to the current folder, the code generator reads that file. The code generator verifies that the current model that you are building has configuration properties that match the checksum of properties from the shared utility model. If mismatches occur between the properties defined in `checksummap.mat` and the current model properties, you see an error. Use the error message to manage the checksum (for example, diagnose and resolve the configuration issues with the current model).

For more information, see "Reduce Shared Utility Code Generation with Incremental Builds" on page 33-82.

In this section...

View the Shared Utility Checksum Hash Table

It is helpful to view the property values that contribute to the checksum. This example uses the `rtwdemo_lct_start_term.slx` model. To load the `checksum.mat` file into MATLAB and view the `targetInfoStruct` that defines the checksum-related properties:

1. Open the `rtwdemo_lct_start_term.slx` model. In the Command Window, type:

   ```
   rtwdemo_lct_start_term
   ```

2. Create and move to a new working folder.

   ```
   mkdir C:\Temp\demo
   cd C:\Temp\demo
   ```

3. Save a copy of the model in the folder.
4. Build the model by using the **Simulink** > **Code** > **C/C++ Code** > **Build Model** command. This model is already set up to produce shared utilities.

5. Move to the `_sharedutils` folder created by the build process.

```
cd C:\Temp\demo\slprj\grt\_sharedutils
```

6. Load the `checksummap.mat` file into MATLAB.

```
load checksummap
```

7. Display the contents of `hashTbl.targetInfoStruct` and examine the checksum-related property values.

```
hashTbl.targetInfoStruct
```

For this example, the Command Window displays `hashTbl.targetInfoStruct` for the shared utilities that you generated from the model:

```
                ShiftRightIntArith: 'on'
            ProdShiftRightIntArith: 'on'
                        Endianess: 'LittleEndian'
                    ProdEndianess: 'LittleEndian'
                      wordlengths: '8,16,32,32,64,32,64,64,64,64'
                  Prodwordlengths: '8,16,32,32,64,32,64,64,64,64'
                   TargetWordSize: '64'
                     ProdWordSize: '64'
                TargetHWDeviceType: 'Custom Processor->MATLAB Host Computer'
                  ProdHWDeviceType: 'Intel->x86-64 (Windows64)'
               TargetIntDivRoundTo: 'Zero'
                 ProdIntDivRoundTo: 'Zero'
                           tmfName: ''
                      toolchainName: ''

               ProdLongLongMode: 'off'
CollapseNonTrivialExpressions: 'false'
```

Relate the Shared Utility Checksum to Configuration Parameters

Examine the `targetInfoStruct` hash table from the shared utility model. Some key-value pairs relate directly to a model property. Other pairs relate to groups of properties.

The following table describes the key-value pairs.

Key Names	Model Properties
ShiftRightIntArith	`TargetShiftRightIntArith`
ProdShiftRightIntArith	`ProdShiftRightIntArith`
Endianess	`TargetEndianess`
ProdEndianess	`ProdEndianess`
wordlengths	`TargetBitPerChar`, `TargetBitPerShort`, `TargetBitPerInt`, `TargetBitPerLong`, `TargetBitPerLongLong`, `TargetBitPerFloat`, `TargetBitPerDouble`, `TargetBitPerPointer`
Prodwordlengths	`ProdBitPerChar`, `ProdBitPerShort`, `ProdBitPerInt`, `ProdBitPerLong`, `ProdBitPerLongLong`, `ProdBitPerFloat`, `ProdBitPerDouble`, `ProdBitPerPointer`
TargetWordSize	`TargetWordSize`
ProdWordSize	`ProdWordSize`
TargetHWDeviceType	`TargetHWDeviceType`
ProdHWDeviceType	`ProdHWDeviceType`

Key Names	Model Properties
TargetIntDivRoundTo	`TargetIntDivRoundTo`
ProdIntDivRoundTo	`ProdIntDivRoundTo`
tmfName	`TemplateMakefile`
toolchainName	`Toolchain`
computer	return value of the `computer` command
UseDivisionForNetSlopeComputation	`UseDivisionForNetSlopeComputation`
PurelyIntegerCode	`PurelyIntegerCode`
PortableWordSizes	`PortableWordSizes`
SupportNonInlinedSFcns	`SupportNonInlinedSFcns`
TargetLibSuffix	Removed (not used)
RTWReplacementTypes	`EnableUserReplacementTypes`, `ReplacementTypes`
MaxIdInt8	`MaxIdInt8`
MinIdInt8	`MinIdInt8`
MaxIdUint8	`MaxIdUint8`
MaxIdInt16	`MaxIdInt16`
MinIdInt16	`MinIdInt16`
MaxIdUint16	`MaxIdUint16`
MaxIdInt32	`MaxIdInt32`
MinIdInt32	`MinIdInt32`
MaxIdUint32	`MaxIdUint32`
BooleanTrueId	`BooleanTrueId`
BooleanFalseId	`BooleanFalseId`
TypeLimitIdReplacementHeaderFile	`TypeLimitIdReplacementHeaderFile`
SharedCodeRepository	reserved (internal use only)
TargetLang	`TargetLang`
PreserveExternInFcnDecls	`PreserveExternInFcnDecls`
EnableSignedRightShifts	`EnableSignedRightShifts`

Key Names	Model Properties
EnableSignedLeftShifts	`EnableSignedLeftShifts`
TflName	`CodeReplacementLibrary`
TflCheckSum	reserved (internal use only)
UtilMemSecName	`MemSecFuncSharedUtil`, `MemSecPackage`
CodeCoverageChecksum	reserved (internal use only)
TargetLargestAtomicInteger	`TargetLargestAtomicInteger`
TargetLargestAtomicFloat	`TargetLargestAtomicFloat`
ProdLargestAtomicInteger	`ProdLargestAtomicInteger`
ProdLargestAtomicFloat	`ProdLargestAtomicFloat`
LongLongMode	`TargetLongLongMode`
ProdLongLongMode	`ProdLongLongMode`
CollapseNonTrivialExpressions	reserved (internal use only)

Generate Shared Utility Code for Fixed-Point Functions

An important set of generated functions that the model build places in the shared utility folder are the fixed-point support functions. Based on model and block properties, there are many possible versions of fixed-point utilities functions that make it impractical to provide a complete set as static files. Generating only the required fixed-point utility functions during the code generation process is an efficient alternative.

The shared utility checksum mechanism makes sure that several critical properties are identical for models that use the shared utilities. For the fixed-point functions, there are additional properties that determine function behavior. The mechanism codes these properties into the functions and file names to maintain requirements. The additional properties include:

Category	Function/Property
Block properties	• Fixed-point operation that the block performs • Fixed-point data type and scaling (`Slope`, `Bias`) of function inputs and outputs • Overflow handling mode (`Saturation`, `Wrap`) • Rounding Mode (`Floor`, `Ceil`, `Zero`)
Model properties	`get_param(bdroot, 'NoFixptDivByZeroProtection')`

The property-based naming convention for the fixed-point utilities is as follows:

```
operation + [zero protection] + output data type + output bits +
[input1 data] + input1 bits + [input2 data type + input2 bits] +
[shift direction] + [saturate mode] + [round mode]
```

The file names shown are examples of generated fixed-point utility files. The function or macro names in the file are identical to the file name without the extension.

```
FIX2FIX_U12_U16.c
FIX2FIX_S9_S9_SR99.c
ACCUM_POS_S30_S30.h
MUL_S30_S30_S16.h
div_nzp_s16s32_floor.c
div_s32_sat_floor.c
```

For these examples, the table shows how the respective fields correspond.

The `ACCUM_POS` example uses the output variable as one of the input variables. So, the file and macro name only contain the output and second input.

The second `div` example has identical data type and bits for both inputs and the output. So, the file and function name only include the output.

Operation	FIX2FIX	FIX2FIX	ACCUM_POS	MUL	div	div
Zero protection	NULL	NULL	NULL	NULL	_nzp	NULL
Output data type	_U	_S	_S	_S	_s	_s
Output bits	12	9	30	30	16	32
Input data type	_U	_S	_S	_S [and _S]	s	NULL
Input bits	16	9	30	30 [and 16]	32	NULL
Shift direction	NULL	SR99	NULL	NULL	NULL	NULL
Saturate mode	NULL	NULL	NULL	NULL	NULL	_sat
Round mode	NULL	NULL	NULL	NULL	_floor	_floor

Generate Shared Utility Code for Custom Data Types

By default, if a model employs a custom data type (such as a `Simulink.AliasType` object or an enumeration class), the code generator places the corresponding type definition (`typedef`) in the *`model`*`_types.h` file. When you generate code from multiple models, each model duplicates the type definition. These duplicate definitions can prevent you from compiling the bodies of generated code together.

However, you can configure the code generator to place a single type definition in a header file in the `_sharedutils` folder. Then, when you generate code from a model, if the type definition already exists in the `_sharedutils` folder, the code generator does not duplicate the definition, but instead reuses it through inclusion (`#include`).

Through this mechanism, you can share:

- Simulink data type objects that you instantiate from the classes `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType`. For basic information about creating and using these objects, see “What Are User-Defined Data Types?” on page 21-2 and Simulink.Bus.
- Enumerations that you define, for example, by authoring an `enum` class in a script file or by using the function `Simulink.defineIntEnumType`. For basic information about defining enumerations in Simulink, see “Use Enumerated Data in Simulink Models” (Simulink).

To share a custom data type across multiple models:

1. Define the data type. For example, create the `Simulink.AliasType` object.
2. Set data scope and header file properties to specific values that enable sharing.

   For a data type object, set the `DataScope` property to `'Exported'` and, optionally, specify the header file name through the `HeaderFile` property.

   For an enumeration that you define as an `enum` class in a script file, implement the `getDataScope` method (with return value `'Exported'`) and, optionally, implement the `getHeaderFile` method.

   For an enumeration that you define by using the `Simulink.defineIntEnumType` function, set the `'DataScope'` pair argument to `'Exported'` and, optionally, specify the `'HeaderFile'` pair argument
3. Use the data type in the models.

4. Before generating code from each model, set **Configuration Parameters** > **Code Generation** > **Interface** > **Shared code placement** to `Shared location`.
5. Generate code from the models.

Note: You can configure the definition of the custom data type to appear in a header file in the `_sharedutils` folder. The shared utility functions that the model build generates into the `_sharedutils` folder do not use the custom data type name. Only model code located in code folders for each model uses the custom data type name.

Cross-Release Shared Utility Code Reuse

In this section...

When you generate code for a model, the code generator by default creates shared utility files that the model requires. When you generate code with different releases, the code generators can produce functionally identical shared files that contain some nonfunctional differences. For example, different comments and different coding style. When you use the same release to generate code for different models in different folders, you can also produce shared files with nonfunctional differences. For example, if you specify different `ParenthesesLevel` or `ExpressionFolding` values for the models, the code generator can produce shared files that contain different comments or different coding styles.

Integrated code that includes functionally identical shared files:

- Is more expensive to verify because each shared file requires verification.
- Produces compilation errors if the shared files define duplicate symbols.

If you have an Embedded Coder license, you can avoid these issues by specifying the reuse of shared code from an existing folder, for example, a read-only library of verified code. In this case, the code generator does not create new shared utility files. The build process uses external code or previously generated shared utility code from the folder. An administrator maintains and updates the read-only library.

Workflow to Reuse Shared Utility Code

1. In the **Configuration Parameters > All Parameters > Existing shared code** field, enter the full path to your shared code folder.
2. Verify that the **Configuration Parameters > All Parameters > Use only existing shared code** diagnostic is set to `error` (default).
3. Remove the `slprj` folder or move to a new working folder.
4. Build your model. If you do not see an error, your shared code folder contains the required shared utility files.
5. If files are missing from the shared code folder, you see an error. To continue code generation with a locally generated version of the missing shared utility files:

a Set **Configuration Parameters > All Parameters > Use only existing shared code** to `warning`.

b Rebuild your model. The code generation process uses a locally generated version of the missing shared utility files.

c Provide the administrator of the verified code library with your model and information about missing shared utility files. With the model, the administrator generates the required shared utility files. Using `sharedCodeUpdate`, the administrator adds the files to the shared code folder.

d When the files are available in the shared code folder, repeat steps 1–4.

If the shared utility code is generated from library subsystems that are shared across models (Simulink Coder), you cannot reuse the code *across* releases because the code is release-specific—the symbol name and file name mangling includes the release number. The administrator must add the shared utility code generated for each release to the shared code folder.

The `sharedCodeUpdate` function can add files to the shared code folder that have identical content but different file and function names. This behavior is useful when you have different model components that require their own shared utility functions. Although some code is duplicated, the different model components can access the shared utility functions with which they were verified. To force model components to have their own versions of shared utility functions, configure naming rules to insert the model name into shared utility identifiers (Simulink Coder).

Required Edits to Reuse Shared Utility Code

For most shared utility code files, you can specify master copies that you can reuse across releases without modifying the files. With some files, for example, `rtwtypes.h`, and `zero_crossing_types.h`, there are situations where manual editing is required to produce master copies that you can use with generated code from different releases. For example:

- The `rtwtypes.h` file generated by R2010a contains a checksum.

  ```
  /* This ID is used to detect inclusion of an incompatible rtwtypes.h */
  #define RTWTYPES_ID_C08S16I32L64N64F0
  ```

  For each R2010a version of `rtwtypes.h` that you want to include in your integration, copy the corresponding `#define` statement into your master copy of `rtwtypes.h`.

- In R2015a, the zero-crossing definitions moved from `rtwtypes.h` into `zero_crossing_types.h`. To create an `rtwtypes.h` file that is compatible with generated model code from different releases, in your master copy of `rtwtypes.h`, insert this statement.

  ```
  #include "zero_crossing_types.h"
  ```
  Remove definitions from `rtwtypes.h` that `zero_crossing_types.h` provides.

Cross-Release Code Integration

In this section...

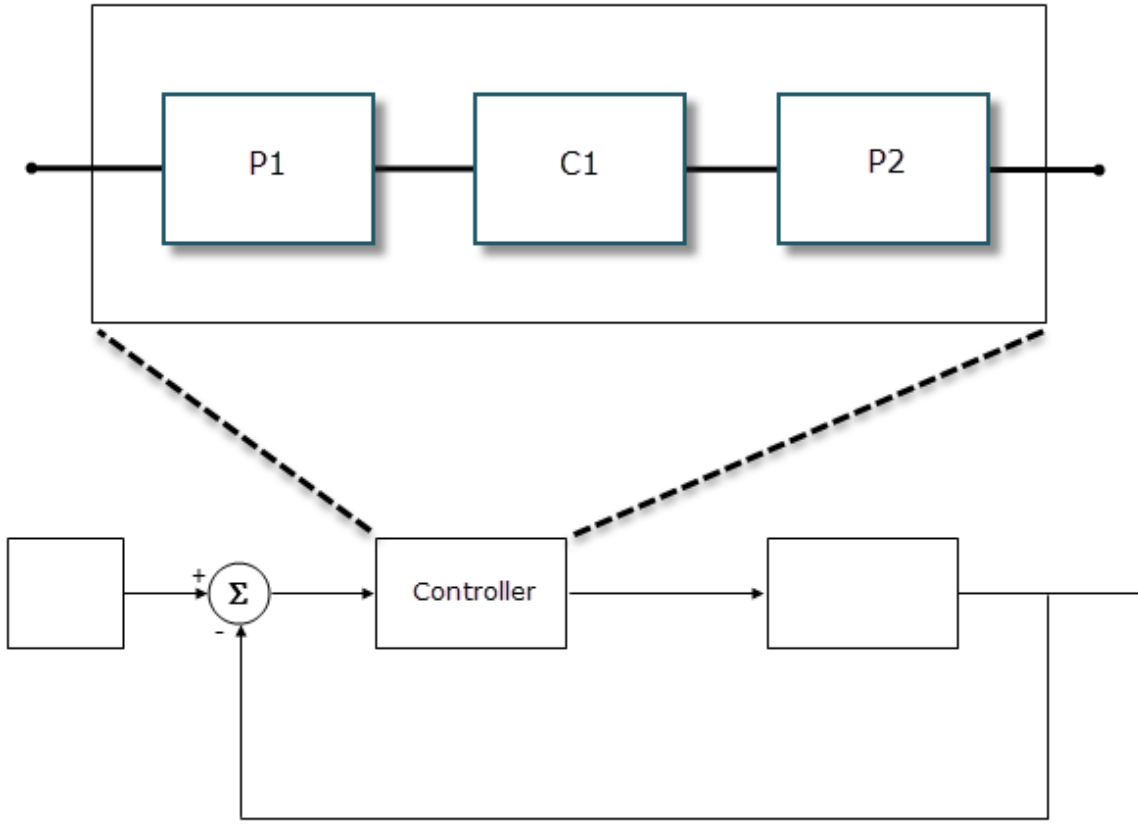
If you have an Embedded Coder license, you can integrate generated C code from previous releases (R2010a and later) with generated code from the current release when:

- The source models are single-rate.
- The source models are set to generate nonreusable code with function prototype control (root-level Inport and Outport blocks are mapped to step function arguments).
- The generated C code is from top-model and subsystem build processes.

If you can reuse existing code without modification, you can reduce the cost of reverification.

Workflow

Consider this control system model.



The `Controller` Model block references a model that consists of three components:

- `P1` is a Model block, which references a model developed with a previous release, for example, R2015b. The generated model code, with the standalone code interface, is in the folder `P1_ert_rtw`.
- `C1` is a Model block, which references a model that you are developing in the current release.
- `P2` is a subsystem block developed with a previous release, for example, R2016a. The generated subsystem code is in the folder `P2_ert_rtw`.

To integrate code from previous releases with generated code from the current release, use this workflow:

1 Export components from previous releases

a Add the `crossReleaseExport` function to the search paths for previous releases. For example, in the Command Window of a previous release, run this command:

```
addpath(fullfile(matlabRootCR, 'toolbox','coder','xrelexport'));
```

`matlabRootCR` is the `matlabroot` value for your current release.

b Using the previous releases, export generated component code. For example:

- From R2015b, run:

  ```
  crossReleaseExport(fullfile(folderPath,'P1_ert_rtw'))
  ```

- From R2016a, run:

  ```
  crossReleaseExport(fullfile(folderPath,'P2_ert_rtw'))
  ```

The `crossReleaseExport` function creates export artifacts in new folders `P1_R2015b` and `P2_R2016a`.

2 Specify an existing shared code folder

You can specify the reuse of shared code from an existing folder, for example, a library of verified code that an administrator maintains and updates. Specify the shared code folder for model components that require code generation in the current release, for example, `Controller` and `C1`.

In the **Configuration Parameters > All Parameters > Existing shared code** field, enter the full path to the shared code folder.

3 Import components into current release

From the current release, using export artifacts created in step 2, import generated component code from previous releases as software-in-the-loop (SIL) blocks or processor-in-the-loop (PIL) blocks. For example:

```
crossReleaseImport(P1_R2015bFullPath,'Controller', ...
'SimulationMode','SIL');
crossReleaseImport(P2_R2016aFullPath,'Controller', ...
'SimulationMode','SIL');
```

`P1_R2015bFullPath` and `P2_R2016aFullPath` are paths to the export artifact folders, `P1_R2015b` and `P2_R2016a`, created in step 1.

The `crossReleaseImport` function creates software-in-the-loop (SIL) blocks and subfolders:

- `P1_R2015b_sil` and `P1_R2015b_sil_resources`
- `P2_R2016a_sil` and `P2_R2016a_sil_resources`

4 Incorporate components into current release model

To replace components with SIL or PIL blocks, use the Simulink Editor or the `pil_block_replace` command. For example:

- Replace `P1` with `P1_R2015b_sil`.
- Replace `P2` with `P1_R2016a_sil`.

When you run a model simulation, the simulation runs the previous release code through the SIL or PIL blocks.

When you build the `Controller` model (`rtwbuild('Controller')`), the code generator does not generate new code for the components represented by the SIL or PIL blocks. The model code calls code generated by previous releases.

Limitations

The cross-release code integration workflow does not support:

- Export-function models.
- Model blocks inside the exported component. For a workaround, see “Incorporate Model Reference Code” on page 33-100.
- AUTOSAR code generation.
- Simulink Function, Function Caller, and Data Store Memory blocks across the boundaries of code generated by different releases.
- Parameter tuning through the SIL or PIL blocks.
- The integration of generated code from releases before R2010a.
- The import of generated code from the current release into a previous release (forward compatibility).
- The export of files located in the MATLAB root folder of the previous release, for example, blockset library files.
- The export and import of generated code from models with non-inlined S-functions.

- C-API on page 43-2.

You can export a Model block component only if the referenced model has these settings:

- `ModelReferenceNumInstancesAllowed` is `Single`.
- `SuppressErrorStatus` is `on`.

At the end of the model build process, the code generation report displays shared files that are directly used by the integration model, for example, `Controller`. The report does not display shared files used by the components of the model, for example, `P1` and `P2`.

Incorporate Model Reference Code

Suppose a Model block in a component references a model through the model reference code interface. When you use `crossReleaseExport` to export generated code from a previous release, the function does not export the referenced model code. You see a warning:

```
Cross-release export does not support model references. Generated code
for the following models will not be exported:
```

To work around this limitation, before running `crossReleaseImport`, use the `sharedCodeUpdate` function to import the generated code for the referenced model into your specified shared code folder.

```
sharedCodeUpdate(referencedModelCodeFolder,existingSharedCodeFolder);
```

The function creates a subfolder for the copied referenced model code.

If you try to import the component code without the referenced model code, `crossReleaseImport` produces a build error.

`Simulink.Bus` Support

To use a bus object as a data type in cross-release code integration, use one of these approaches.

Approach	Details
Exported bus	In the previous release, before generating code, specify these properties of the Simulink.Bus object: • `DataScope` — Set to `Exported`.

Approach	Details
	• `HeaderFile` — Specify a file name, for example, `prevRelBusType`. The code generator creates `prevRelBusType.h` in the shared utility code folder. This header file contains the definition for the `Simulink.Bus` data type. Use `sharedCodeUpdate` to add `prevRelBusType.h` to the shared code folder that `ExistingSharedCode` specifies. For R2010a and R2010b, the `DataScope` property is not available. Do not assign a value to the `HeaderFile` property. The code generator creates the `Simulink.Bus` data type definition in `modelName_types.h`, which is located in the code generation folder for the model.
	In the current release, before running `crossReleaseImport`, set the `DataScope` property of the Simulink.Bus object to `Imported`. When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the `Simulink.Bus` data type definition in `prevRelBusType.h`. If the imported code is from R2010a or R2010b, specify these properties of the Simulink.Bus object: • `DataScope` — Set to `Imported`. • `HeaderFile` — Set to file path for `modelName_types.h`, which is in the imported code folder. When you build the integration model, the build process uses the `Simulink.Bus` data type definition in `modelName_types.h`.
Imported bus	In the previous release, before generating code, specify these properties of the Simulink.Bus object: • `DataScope` — Set to `Imported`. • `HeaderFile` — Specify a path to a file that contains the `Simulink.Bus` data type definition, for example, `aBusType.h`. For R2010a and R2010b, the `DataScope` property is not available. For the `HeaderFile` property, specify a path to a file that contains the `Simulink.Bus` data type definition, for example, `aBusType.h`.

Approach	Details
	In the current release, after importing generated code, you do not have to change the Simulink.Bus. When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the `Simulink.Bus` data type definition from `aBusType.h`. If the imported code is from R2010a or R2010b, specify these properties of the Simulink.Bus object: • `DataScope` — Set to `Imported`. • `HeaderFile` — Set to `aBusType.h`. When you build the integration model, the build process uses the `Simulink.Bus` data type definition in `aBusType.h`.

Parameter Tuning

For a component from a previous release, you can export a block parameter `P` as an inline value in generated code. Before generating code:

- For R2015a and earlier releases, set `InlineParameters` or `InlineParams` to `on`.
- For R2015b and later releases, set `DefaultParameterBehavior` to `Inlined`.

To control tunability in the integration model through a single instance of `P`:

1. Before generating code in the previous release, apply the `ExportedGlobal` storage class to the `Simulink.Parameter` object for `P`.
2. In the integration model, use the `ImportedExtern` storage class to reference `P`.

You can use the `SimulinkGlobal` storage class for the exported component and integration model. This approach produces separate parameter definitions and values for `P`: one set for the component from the previous release and another set for the rest of the integration model.

On a Macintosh OS X system, which supports the Clang compiler, a top-model SIL or PIL simulation of the integration model with default **Build configuration** settings produces a compilation error. To work around this limitation, modify the default settings:

1. Get the build tool from the default toolchain.

```
tc = coder.make.getDefaultToolchain;
cComp = tc.getBuildTool('C Compiler');
```

2. Extract the C compiler standard options.

```
stdMaps = cComp.SupportedStandard.getLangStandardMaps;
optionValues = stdMaps.getCompilerOptions('*');
```

3. Remove `-fno-common` from the standard options for the C and C++ compilers.

```
optionToRemove = '-fno-common';
optionsToKeep = strrep(optionValues, optionToRemove, '');
c_standard_opts_id = '$(C_STANDARD_OPTS)';

custToolChainOpts = get_param(model,'CustomToolchainOptions');
custToolChainOpts{2} = strrep(custToolChainOpts{2}, c_standard_opts_id, optionsToKeep);

set_param(model, 'CustomToolchainOptions',custToolChainOpts);
```

Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release

In a previous release, suppose that you developed a model component, generated code for the component, and tested and deployed the generated code. Now, in the current release, you want to add features to the model component and use the model component in system development and code generation. Before you proceed, you can compare the functional behavior of the model component and the generated code from the previous release.

To test the numerical equivalence between the model component and the generated code from the previous release, use Simulink Test. With the Test Manager (Simulink Test), you can perform back-to-back tests and output comparisons:

1. Bring the model component into the current release as a Model block with the **Simulation mode** block parameter set to `Normal`.
2. With the Model block, create a top model that specifies test input data.
3. Import the code generated in the previous release into the current release as a SIL block.
4. With the SIL block, create another top model that specifies the same the test input data.
5. In the Test Manager, create an equivalence test case that runs simulations of the top models and compares outputs.

6 Run the test case and review results.

For more information, see Test Manager examples in "Simulink Test Examples" (Simulink Test).

Note: If you want to compare the behavior of generated code from the current and previous release, in step 1, specify these Model block parameters:

- Set **Simulation mode** to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`.
- Set **Code interface** to `Top model`.

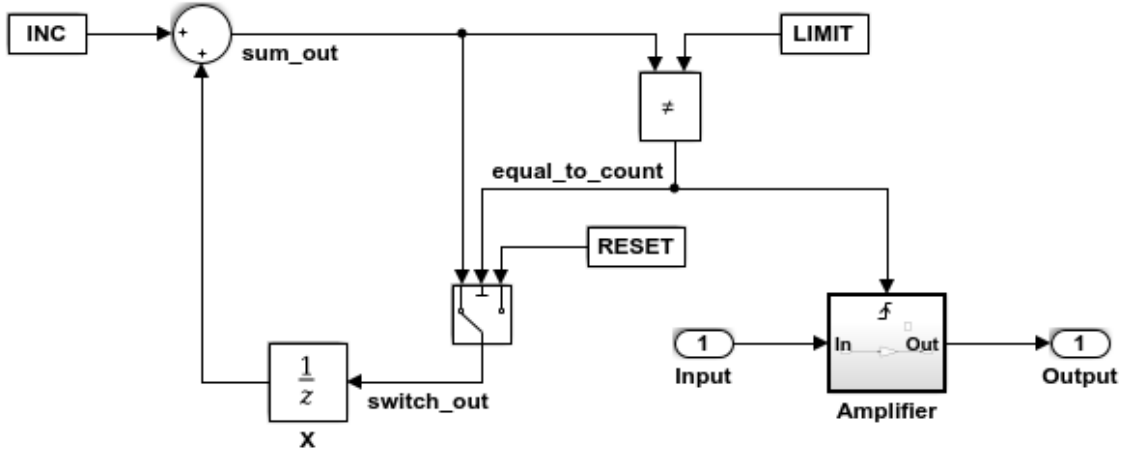
Generate Code Using Simulink® Coder™

This example shows how to select a target for a Simulink® model, generate C code for real-time simulation, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks `INC`, `LIMIT`, and `RESET`. `Input` and `Output` represent I/O for the model. The `Amplifier` subsystem amplifies the input signal by gain factor `K`, which updates when signal `equal_to_count` is `true`.

1. Open the model. For example, type the following commands at the MATLAB® command prompt.

```
model='rtwdemo_rtwintro';
open_system(model)
```

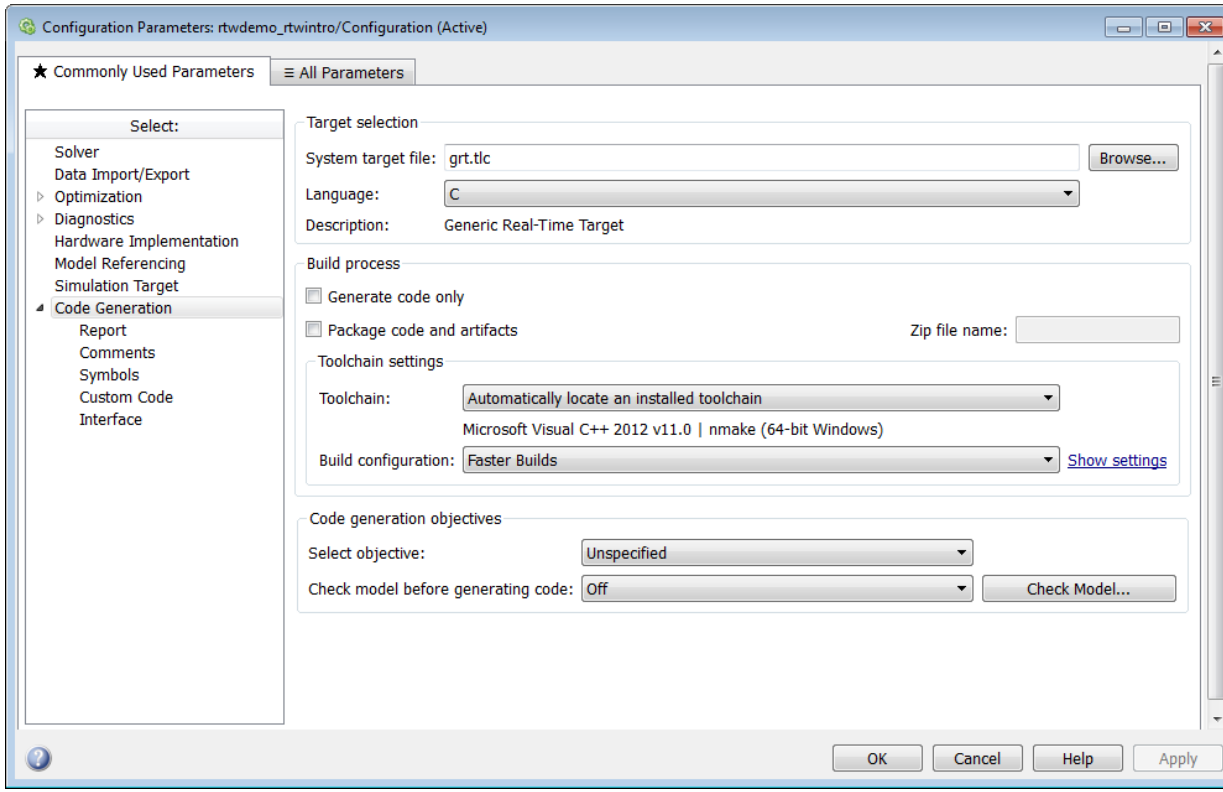


2. Open the Configuration Parameters dialog box from the model editor by clicking **Simulation > Configuration Parameters**.

Alternately, type the following commands at the MATLAB® command prompt.

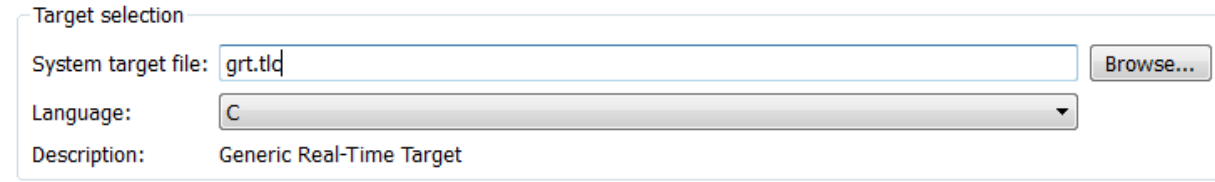
```
cs = getActiveConfigSet(model);
openDialog(cs);
```

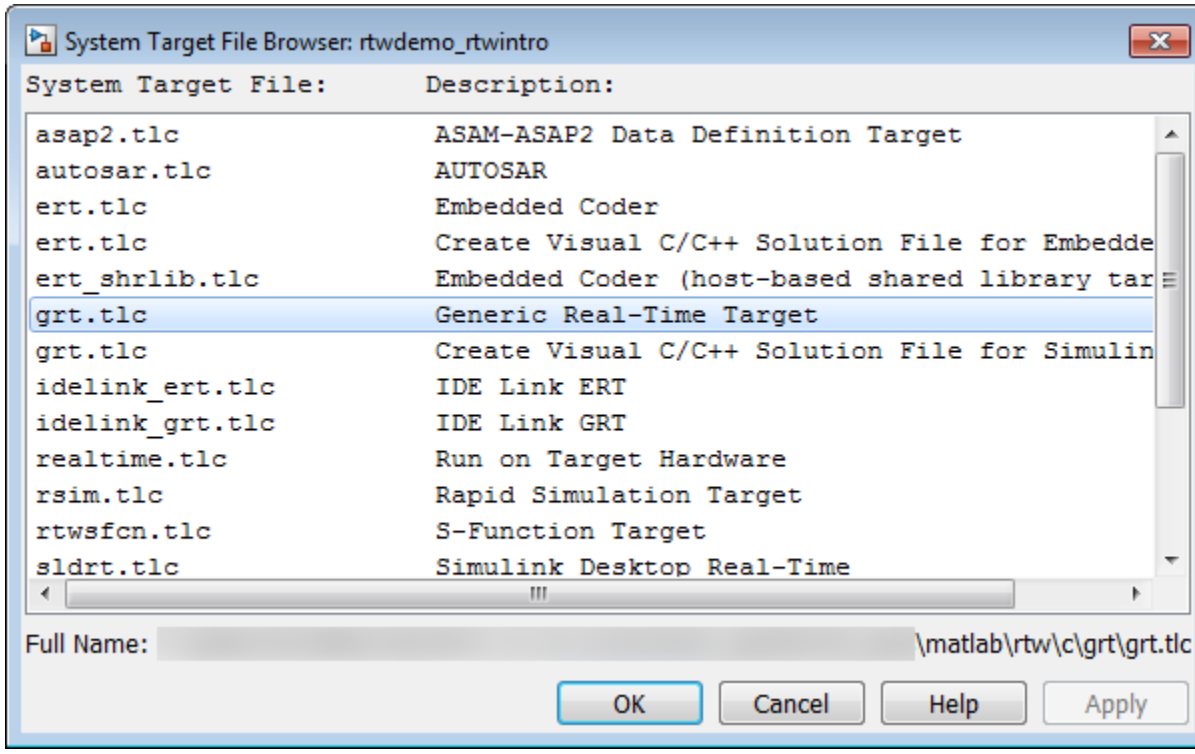
3. Select the **Code Generation** node.



4. In the **Target Selection** pane, click **Browse** to select a target.

You can generate code for a particular target environment or purpose. Some built-in targeting options are provided using system target files, which control the code generation process for a target.





5. Select the **Generic Real-Time (GRT)** target and click **Apply**.

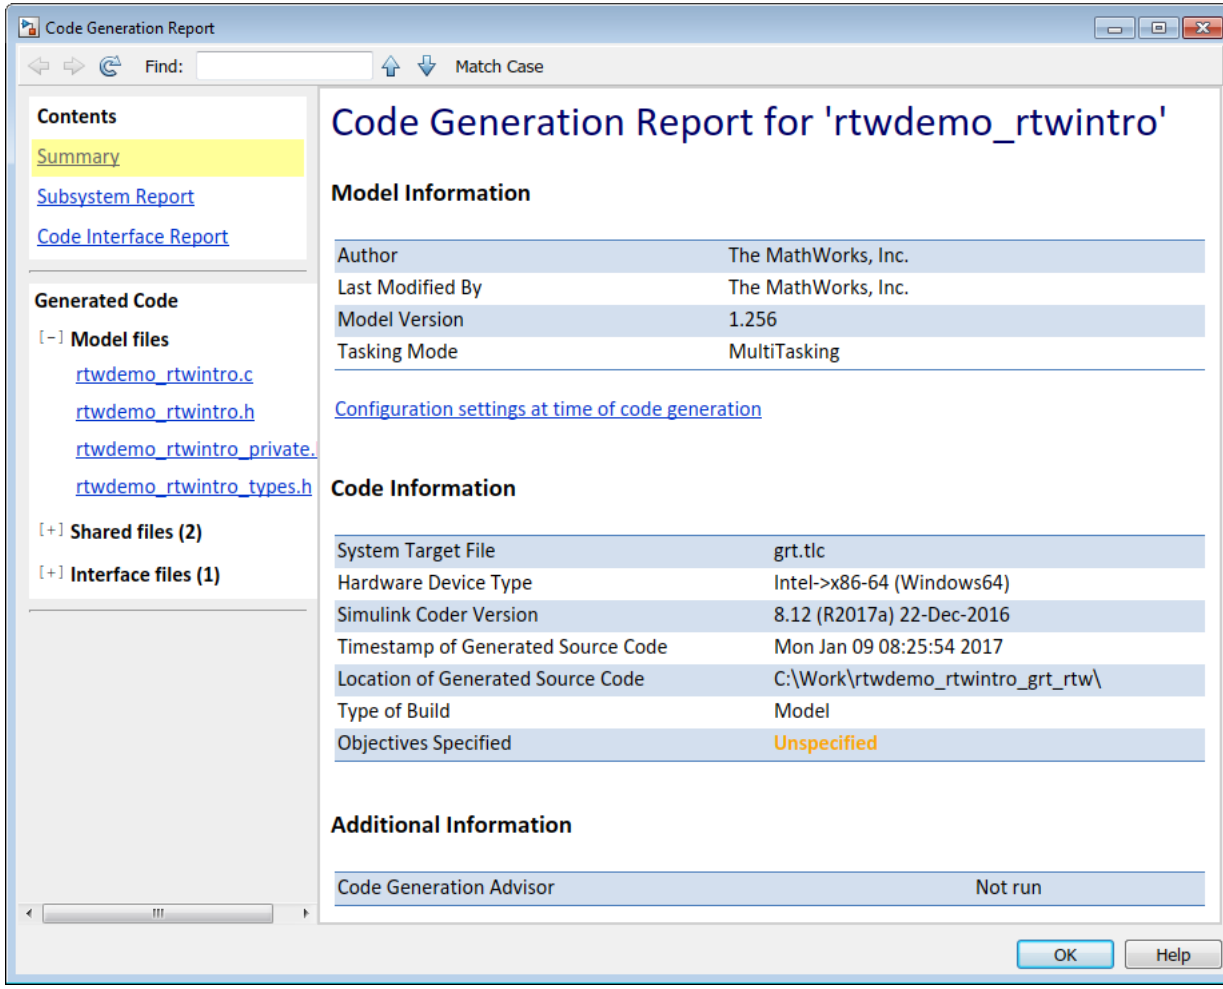
Optionally, in the **Code Generation Advisor** pane set the **Select objective** field to **Execution efficiency** or **Debugging**. Then click **Check model...** to identify and systematically change parameters to meet your objectives.

6. In the model window, initiate code generation and the build process for the model by using any of the following options:

- Click the Build Model button.
- Press **Ctrl+B**.
- Select **Code** > **C/C++ Code** > **Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

7. View the code generation report that appears.

The report includes links to model files such as `rtwdemo_rtwintro.c` and associated utility and header files.



The figure below contains a portion of `rtwdemo_rtwintro.c`

Step function for model: rtwdemo_rtwintro

File: rtwdemo_rtwintro.c

```
1   /* Model step function */
2   void rtwdemo_rtwintro_step(void)
3   {
4     uint8_T rtb_sum_out;
5     boolean_T rtb_equal_to_count;
6
7     /* Sum: '<Root>/Sum' incorporates:
8      *  Constant: '<Root>/INC'
9      *  UnitDelay: '<Root>/X'
10     */
11    rtb_sum_out = (uint8_T)(1U + (uint32_T)rtwdemo_rtwintro_DWork.X);
12
13    /* RelationalOperator: '<Root>/RelOpt' incorporates:
14     *  Constant: '<Root>/LIMIT'
15     */
16    rtb_equal_to_count = (rtb_sum_out != 16);
17
18    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
19     *  TriggerPort: '<S1>/Trigger'
20     */
21    if (rtb_equal_to_count && (rtwdemo_rtwintro_PrevZCSigState.Amplifier_Trig_ZCE
22          != POS_ZCSIG)) {
23      /* Outport: '<Root>/Output' incorporates:
24       *  Gain: '<S1>/Gain'
25       *  Inport: '<Root>/Input'
26       */
27      rtwdemo_rtwintro_Y.Output = rtwdemo_rtwintro_U.Input << 1;
28    }
29
30    rtwdemo_rtwintro_PrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)
31      (rtb_equal_to_count ? (int32_T)POS_ZCSIG : (int32_T)ZERO_ZCSIG);
32
33    /* End of Outputs for SubSystem: '<Root>/Amplifier' */
34
35    /* Switch: '<Root>/Switch' */
36    if (rtb_equal_to_count) {
37      /* Update for UnitDelay: '<Root>/X' */
38      rtwdemo_rtwintro_DWork.X = rtb_sum_out;
39    } else {
40      /* Update for UnitDelay: '<Root>/X' incorporates:
41       *  Constant: '<Root>/RESET'
42       */
43      rtwdemo_rtwintro_DWork.X = 0U;
44    }
45
46    /* End of Switch: '<Root>/Switch' */
47  }
```

8. Close the model.

```
bdclose(model)
rtwdemoclean;
```

Source Code Generation in Embedded Coder

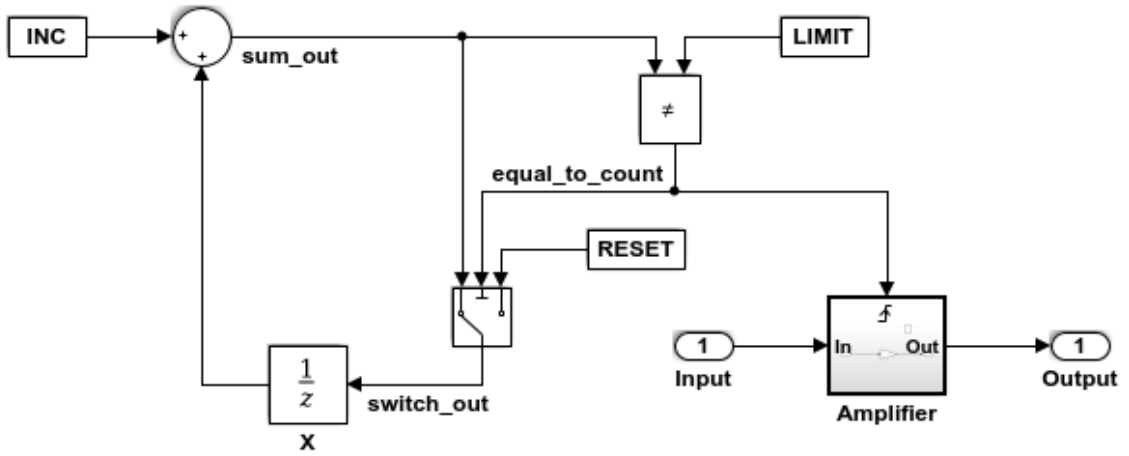
Generate Code Using Embedded Coder®

This example shows how to select a target for a Simulink® model, configure options, generate C code for embedded systems, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks `INC`, `LIMIT`, and `RESET`. `Input` and `Output` represent I/O for the model. The `Amplifier` subsystem amplifies the input signal by gain factor `K`, which updates when signal `equal_to_count` is `true`.

1. Open the model.

```
model='rtwdemo_rtwecintro';
open_system(model)
```

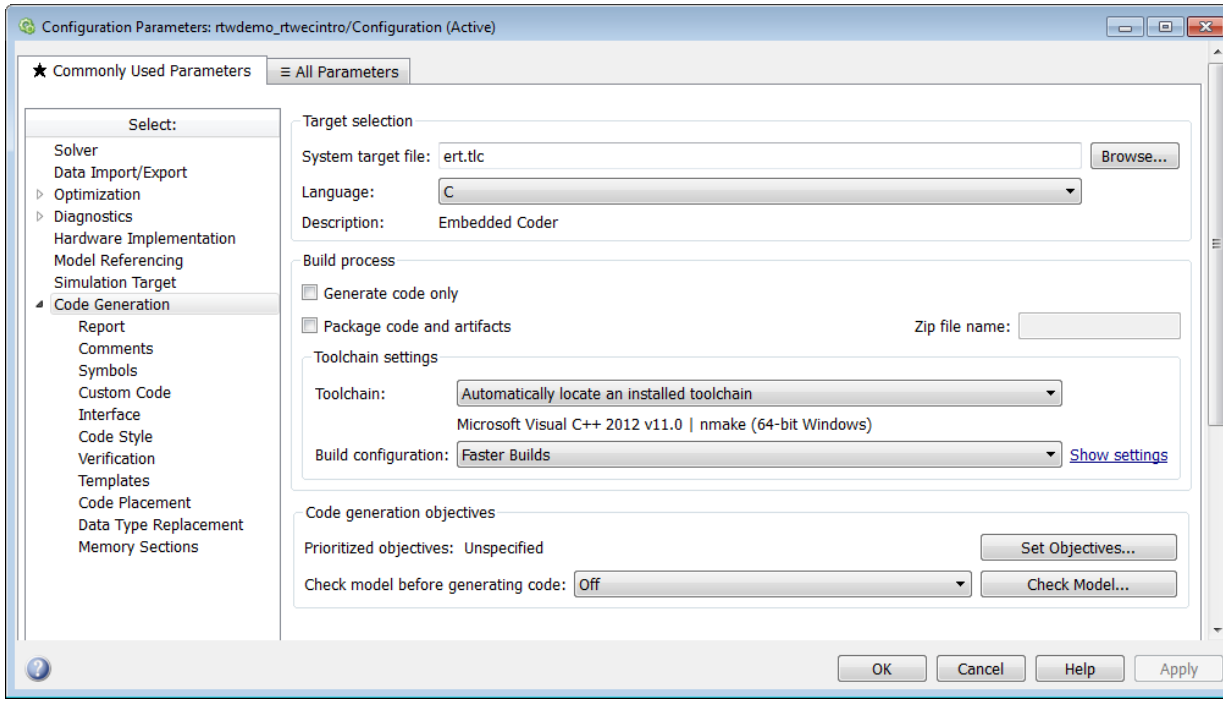


2. Open the **Configuration Parameters** dialog box from the model editor by clicking **Simulation > Model Configuration Parameters**.

Alternately, type the following commands at the MATLAB® command prompt.

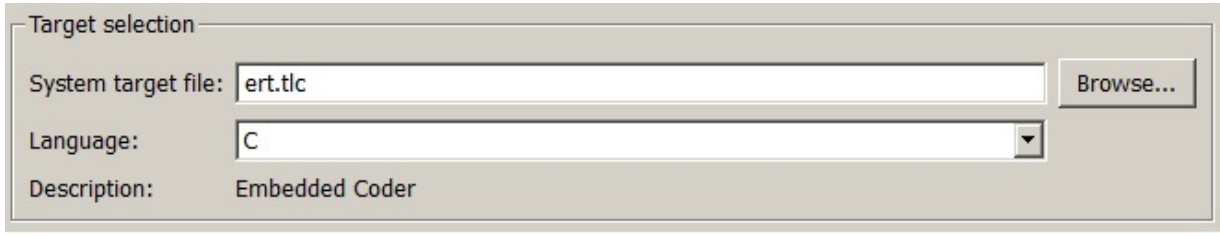
```
cs = getActiveConfigSet(model);
openDialog(cs);
```

3. Select the **Code Generation** node.

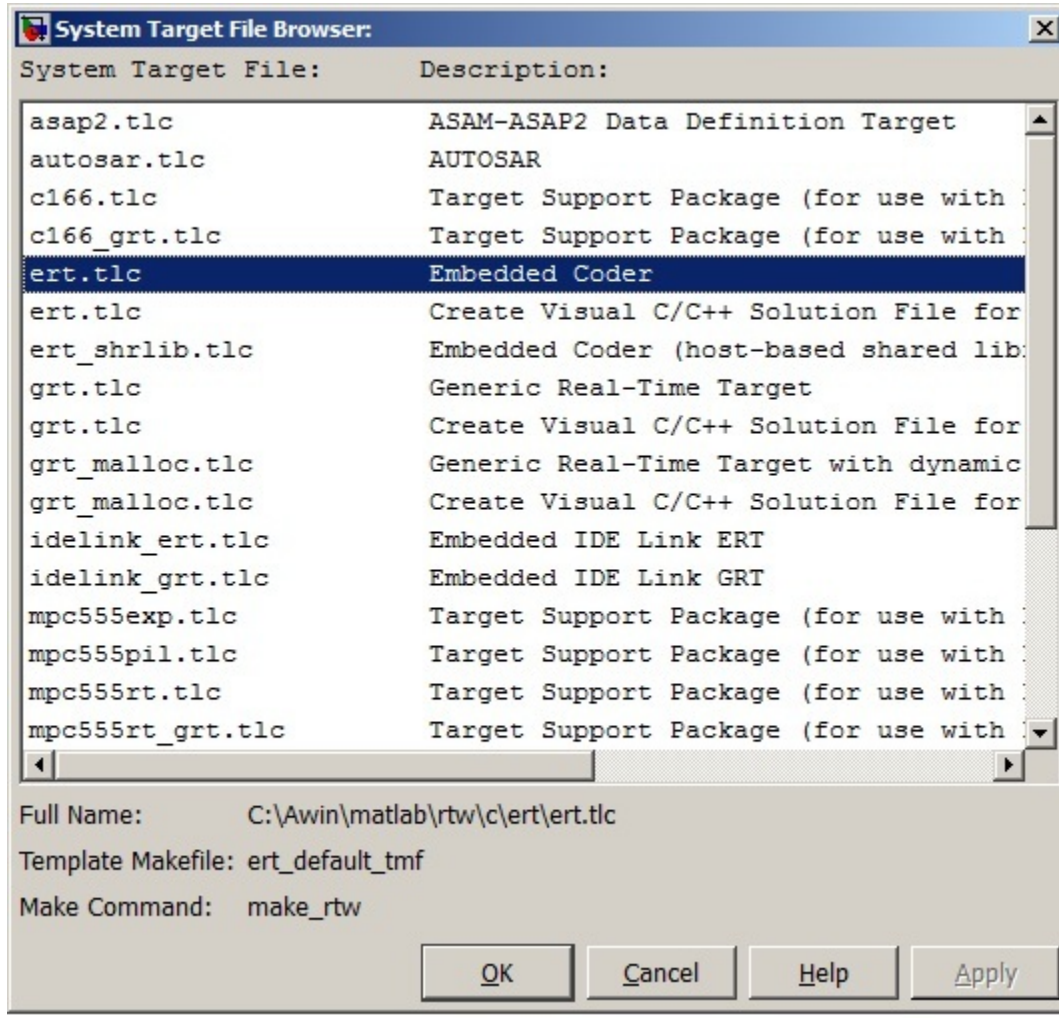


4. In the **Target Selection** pane, click **Browse** to select a target.

You can generate code for a particular target environment or purpose. Some built-in targeting options are provided using system target files, which control the code generation process for a target.



Target selection
System target file:
ert.tlc
Browse...
Language:
C
Description:
Embedded Coder

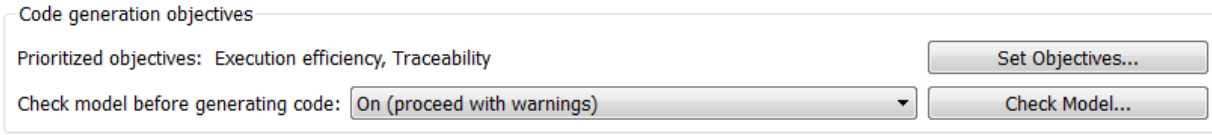


5. Select the **Embedded Real-Time (ERT)** target and click **Apply**.

The ERT target includes a utility to specify and prioritize code generation settings based on your application objectives.

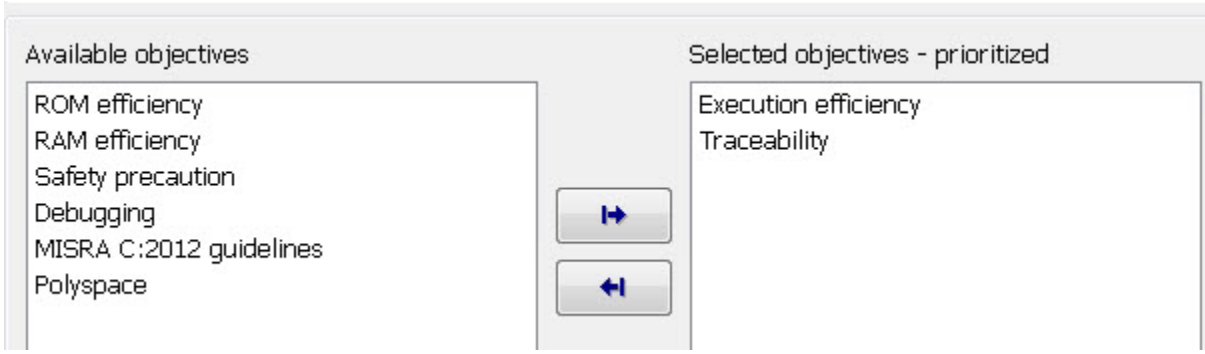
6. In the **Code Generation Advisor** pane, click **Set Objectives**.

You can set and prioritize objectives for the generated code. For example, while code traceability might be a very important criterion for your application, you might not want to prioritize it at the cost of code execution efficiency.



7. In the **Set Objectives** pane, select **Execution efficiency** and **Traceability**. Click **OK**.

You can select and prioritize a combination of objectives before generating code.

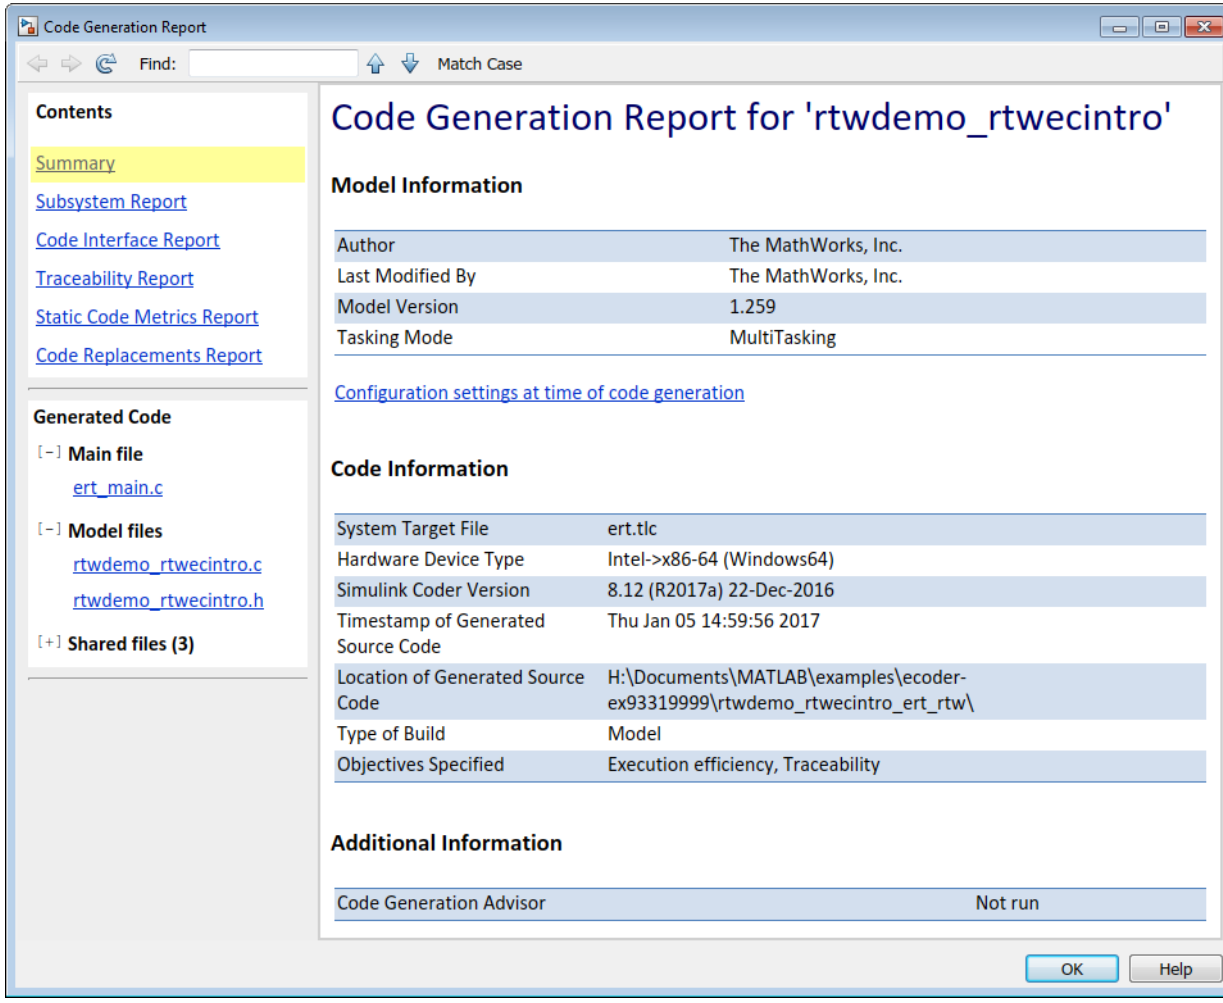


8. In the model window, initiate code generation and the build process for the model by using any of the following options:

- Click the Build Model button.
- Press **Ctrl+B**.
- Select **Code** > **C/C++ Code** > **Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

9. View the code generation report that appears.

The report includes `rtwdemo_rtwecintro.c`, associated utility and header files, and traceability and validation reports.



The figure below contains a portion of `rtwdemo_rtwecintro.c`

Step function for model: rtwdemo_rtwecintro

File: rtwdemo_rtwecintro.c

```
1   /* Model step function */
2   void rtwdemo_rtwecintro_step(void)
3   {
4     boolean_T rtb_equal_to_count;
5
6     /* Sum: '<Root>/Sum' incorporates:

8      *  UnitDelay: '<Root>/X'
9      */
10    rtDWork.X = (uint8_T)(1U + (uint32_T)rtDWork.X);
11
12    /* RelationalOperator: '<Root>/RelOpt' incorporates:
13     *  Constant: '<Root>/LIMIT'
14     */
15    rtb_equal_to_count = (rtDWork.X != 16);
16
17    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
18     *  TriggerPort: '<S1>/Trigger'
19     */
20    if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
21    {
22      /* Outport: '<Root>/Output' incorporates:
23       *  Gain: '<S1>/Gain'
24       *  Inport: '<Root>/Input'
25       */
26      rtY.Output = rtU.Input << 1;
27    }
28
29    rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
30      POS_ZCSIG : (int32_T)ZERO_ZCSIG);
31
32    /* End of Outputs for SubSystem: '<Root>/Amplifier' */
33
34    /* Switch: '<Root>/Switch' */
35    if (!rtb_equal_to_count) {
36      /* Update for UnitDelay: '<Root>/X' incorporates:
37       *  Constant: '<Root>/RESET'
38       */
39      rtDWork.X = 0U;
40    }
41
42    /* End of Switch: '<Root>/Switch' */
43  }
```

10. Close the model.

```
bdclose(model)
rtwdemoclean;
```

More About

- "Generate Code with the Quick Start Tool" on page 34-10

Generate Code with the Quick Start Tool

The Quick Start tool helps you prepare a model for generating readable, efficient code. To start the tool, from the model window, select **Code > C/C++ > Embedded Coder Quick Start**.

After you start the tool, you must answer these questions about the code that you want to generate:

- What is the model or subsystem for code generation?
- What is the type of code output for your generated code?
- What is the target hardware processor type?
- What is your primary code generation objective?

The tool validates your choices against the model and presents the parameter changes required to generate code. If you choose to generate code, the tool applies the changes to your configuration set and generates the code. After code generation, you can view the code generation report and find information on building, customizing, optimizing, and packaging the code.

Quick Start Model Analysis

At each step of the Quick Start process, the tool validates your model against your selections. The tool determines if there are model conditions that prevent you from proceeding with code generation. During the analysis step, the tool must also examine your model or subsystem for answers to the following questions. The answers help determine the best configuration for the deployment of your code.

How many sample rates are in your system?

The Quick Start tool evaluates your model to determine the number of periodic sample rates in your system.

Single rate	Your model has only one periodic sample rate. The generated code has a single-entry point function that runs at the time interval of the sample rate.
Multirate	Your model has more than one periodic sample rate. It is possible that the generated code does not execute at the same time intervals. Following the analysis step, you can choose to generate a single-entry point function for each

	of the sample rates, or generate a different entry point function for each sample rate. If you choose to generate multitasking code, the code generator produces multiple entry-point functions. These functions run as multiple tasks. Each entry point function is called at an interval defined by the sample rate that is configured in the model.

Note: If your model contains an asynchronous rate, an additional entry point function is generated to run at the specific interrupt time.

For more information about sample rates, see "Time-Based Scheduling and Code Generation" (Simulink Coder).

Does your system contain continuous states?

The Quick Start tool evaluates your model for continuous blocks to determine the correct solver to use.

No	If your system does not contain continuous states, the Quick Start tool configures your model to use a fixed-step discrete solver for code generation if you have not selected one.
Yes	If your system does contain continuous states, the Quick Start tool configures your model to use a fixed-step continuous solver for code generation if you have not selected one. It also selects the `SupportContinuous` configuration parameter.

For more information on solvers, see "About Solvers" (Simulink).

Did you configure your system for export function calls?

The Quick Start tool evaluates your model to see if scheduler code must be generated.

No	If you did not configure your system for export function calls, the generated code includes code for the system algorithm and scheduler code.
Yes	If you configured your system for export function calls, the generated code includes code for the system algorithm. You can manually write the scheduler code or generate it from other models.

For more information, see “Export-Function Models” (Simulink).

Does your system contain referenced models?

The Quick Start tool evaluates your model to see if it depends on code from other models.

No	If your system does not contain referenced models, the generated code does not depend on code from other models.
Yes	If your system contains referenced models, the generated code for your model depends on other modules generated from referenced models. The code generator can optimize the generated code because it is aware of the relationship between your model and the referenced models.

For more information, see “Code Generation of Referenced Models” (Simulink Coder).

Configuration Parameter Changes for Models with a Configuration Reference

To apply configuration parameter changes to a model with an active configuration reference, the Quick Start tool:

- Creates a new `Simulink.ConfigSet` object, `QuickStart_`*`timestamp`*, in the workspace or data dictionary that contains the original configuration set. The new object is a copy of the original configuration set with the parameter changes applied.
- Creates a new `Simulink.ConfigSetRef` object that points to the new configuration set object.
- Attaches the new configuration reference to the model and makes it the active configuration.

To restore the original configuration set, activate the original `Simulink.ConfigSetRef` object.

Note: If the Quick Start tool creates the new configuration set object in the MATLAB workspace, you must save it to preserve the configuration set after the MATLAB session ends. For more information, see “Save a Configuration Set” (Simulink).

Next Steps

After you have generated code by using Quick Start, possible next steps are:

- “Open Code Generation Report” on page 35-8
- “Code Appearance”
- “Build Process”
- “Application Objectives Using Code Generation Advisor” (Simulink Coder)
- “Manage a Configuration Set” (Simulink)
- “Configure Model and Generate Code” (Simulink Coder)
- “Relocate Code to Another Development Environment” (Simulink Coder)

Manage File Packaging of Generated Code Modules

The code generator produces code modules. The file packaging configuration controls where the code generator places code into code modules and header files.

To locate and examine the generated code files, use the HTML code generation report. The code generation report provides a table of hyperlinks that you click to view the generated code in the MATLAB Help browser. For more information, see "Traceability in Code Generation Report" on page 35-15.

In this section...

Generated Code Modules

The code generator creates a build folder in your working folder to store generated source code. The build folder contains object files, a makefile, and other files created during the code generation process. The default name of the build folder is *`model`*`_ert_rtw`.

Code Modules and Header Files Affected by File Packaging summarizes the structure of source code that the code generator produces.

You can customize the generated set of files in several ways:

- File packaging formats: Manage the number of source files generated for your model. In the Configuration Parameter dialog box, on the **Code Generation > Code Placement** pane, specify the **File packaging format** parameter. For more information, see "Customize Generated Code Modules" on page 34-17.
- Nonvirtual subsystem code generation: Instruct the code generation software to generate separate functions within separate code files for nonvirtual subsystems. You can control the names of the functions and of the code files. For further information, see "Code Generation of Subsystems" (Simulink Coder).
- Custom storage classes: Use custom storage classes to partition generated data structures into different files based on file names that you specify. For further information, see "Introduction to Custom Storage Classes" on page 23-2.

- Module Packaging Features (MPF): Direct the generated code into a required set of `.c` or `.cpp` and `.h` files, and control the internal organization of the generated files. For details, see "Data, Function, and File Definition".

Code Modules and Header Files Affected by File Packaging

File	Description
`model``.c` or `.cpp`	Contains entry points for code implementing the model algorithm (for example, *`model`*`_step`, *`model`*`_initialize`, and *`model`*`_terminate`).
`model``_private.h`	Contains local macros and local data that the model and subsystems require. This file is included in the `model`.c file as a `#include` statement. You do not need to include *`model`*`_private.h` when interfacing handwritten code to the generated code of a model.
`model``.h`	Declares model data structures and a public interface to the model entry-points and data structures. Provides an interface to the real-time model data structure (*`model`*`_M`) with accessor macros. The code generator: • Produces a separate header file for each Simulink Function block in a model. • Includes *`model`*`.h` in the subsystem `.c` or `.cpp` files of a model. If you interface handwritten code to generated code for one or more models, include *`model`*`.h` for each of those models.
`model``_data.c` or `.cpp`	Contains (if conditionally generated) the declarations for the parameters data structure, the constant block I/O data structure, and any zero representations for the model structure data types. If the model does not use these data structures and zero representations, *`model`*`_data.c` or `.cpp` is not generated. These structures and zero representations are declared `extern` in *`model`*`.h`.
`model``_types.h`	Provides forward declarations for the real-time model data structure and the parameters data structure. Function declarations of reusable functions can require these declarations. Provides type definitions for user-defined types that the model uses.

File	Description
`rtwtypes.h`	Defines data types, structures, and macros required by generated code. For more information, see "Control Placement of rtwtypes.h for Shared Utility Code" (Simulink Coder).
`multiword_types.h`	Contains type definitions for wide data types and their chunks. File is generated when multiword data types are used or when you select one or more of these configuration parameters: • **All Parameters > MAT-file logging** • **Code Generation > Interface > External mode**
`model_reference_types.h`	Contains type definitions for timing bridges. File is generated for a model reference target or a model containing model reference blocks.
`builtin_typeid_types.h`	Defines an enumerated type corresponding to built-in data types. File is generated when your model contains a Stateflow chart that uses messages or when you select one or more of these configuration parameters: • **All Parameters > MAT-file logging** • Any C API option at **Code Generation > Interface**
`zero_crossing_types.h`	Contains zero-crossing definitions for models with triggered subsystems where the trigger is `rising`, `falling`, or `either`. File is generated only if required by the model.
`ert_main.c` or `.cpp`	(optional file) If the **Generate an example main program** option is on (default), this file is generated. For more information, see "Generate an example main program".
`rtmodel.h`	(optional file) If the **Generate an example main program** option is off, this file is generated. For more information, see "Generate an example main program". Contains `#include` directives required by the `rt_main.c` or `rt_cppclass_main.cpp` static main program module. Includes `rtmodel.h` to access model-specific data structures and entry points, because the static main program module is not created at code generation time. For more information, see "Static Main Program Module" on page 49-10.

File	Description
*model*_capi.c or .cpp *model*_capi.h	(optional file) Provides data structures that enable a running program to access model signals, states, and parameters without external mode. To learn how to generate and use the *model*_capi.c or .cpp and .h files, see "Exchange Data Between Generated and External Code Using C API" (Simulink Coder) in the Simulink Coder documentation.

User-Written Code Modules

Code that you write to interface with generated model code usually includes a customized main module. Base this module on a main program provided by the code generation software. This customized main module can also include interrupt handlers, device driver blocks and other S-functions, and other supervisory or supporting code.

Establish a working folder for your own code modules. Put your working folder on the MATLAB path. At minimum, inform the build process about the location of your source and object files with **Additional build information** in the **Code Generation > Custom Code** pane. Your development process could require generating code for a particular microprocessor or development board and deploying the code on target hardware with a cross-development system. To accomplish these goals, make more extensive modifications to the ERT-based system target file.

For information on how to customize your ERT-based system target file for your production requirements, see "Target Development" (Simulink Coder).

Customize Generated Code Modules

A configuration parameter is available to specify how the code generator packages generated source code into files. The configuration parameter **File packaging format** options are located in the Configuration Parameter dialog box, on the **Code Generation > Code Placement** pane, in the **Code packaging** section. The options are `Modular`, `Compact (with separate data file)`, and `Compact`. The table describes the files generated for each file packaging format and the files that have been removed.

Generated Files According to File Packaging Format

File Packaging Format	Generated Files	Removed Files
`Modular` (default)	*model*.c	None

File Packaging Format	Generated Files	Removed Files
	subsystem files (optional) *model*.h *model*_types.h *model*_private.h *model*_data.c (conditional)	
Compact (with separate data file)	*model*.c *model*.h *model*_data.c (conditional)	*model*_private.h *model*_types.h (conditional, see Removed Files According to File Packaging Format)
Compact	*model*.c *model*.h	*model*_data.c *model*_private.h *model*_types.h (conditional, see Removed Files According to File Packaging Format)

The table describes content placement from the removed files.

Removed Files According to File Packaging Format

Removed File	Generated Content In File
*model*_private.h	*model*.c and *model*.h
*model*_types.h	*model*.h
*model*_data.c	*model*.c

You can specify a different file packaging format for each referenced model.

The **Configuration Parameter > Code Generation > Interface > Shared code placement** selection interacts with file packaging operations. If you specify **Shared code placement** as `Shared location`, the code generator generates separate files for utility code in a shared location, regardless of the file packaging format. If you specify

the **Shared code placement** as `Auto`, the code generator generates code for utilities according to the file packaging format selection.

- `Modular`: Some shared utility files are in the build folder.
- `Compact (with separate data file)`: Utility code is generated in *`model`*`.c`.
- `Compact`: Utility code is generated in *`model`*`.c`.

File packaging formats `Compact` and `Compact (with separate data file)` generate *`model`*`_types.h` for models containing:

- A Model Variants block or a Variant Subsystem block. The *`model`*`_types.h` file includes preprocessor directives defining the variant objects associated with a variant block.
- Custom storage classes generating a separate header file.

File packaging formats `Compact` and `Compact (with separate data file)` are not compatible with:

- A model containing a subsystem, which is configured to generate separate source files
- A model containing a noninlined S-function
- A model for which **Shared code placement** is set to `Auto`, which uses data objects for which **Data scope** is set to `Exported`

- "Manage Build Process Files" on page 33-42
- "Manage Build Process File Dependencies" on page 33-52

Generate Reentrant Code from Top-Level Models

To generate reentrant multi-instance code from a model, select `Reusable function` code interface packaging. When you select the `Reusable function` code interface for an ERT-based model:

- By default, the generated *`model`*`.c` source file does not contain an allocation function that dynamically allocates model data for each instance of the model. Use the **Use dynamic memory allocation for model initialization** option to control whether an allocation function is generated.
- The generated code passes the real-time model data structure in, by reference, as an argument to *`model`*`_step` and the other model entry point functions.
- The real-time model data structure is exported with the *`model`*`.h` header file.
- By default, root-level input and output arguments are passed to the reusable model entry-point functions as individual arguments. Use the **Pass root-level I/O as** parameter to control whether root-level input and output arguments are passed. This selection chooses whether this I/O is included in the real-time model data structure that is passed to the functions, passed as individual arguments, or passed as references to an input structure and an output structure.

To configure an ERT-based model to generate reusable, reentrant code:

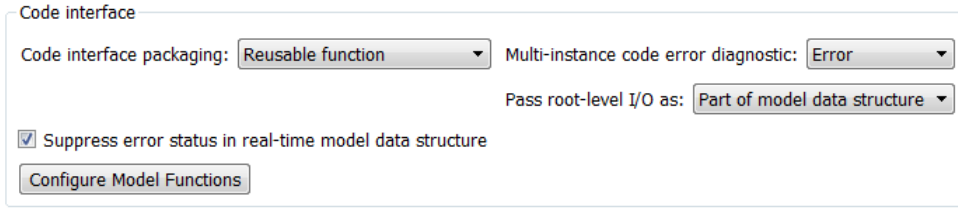
1. In the **Code Generation > Interface** pane of the Configuration Parameters dialog box, set **Code interface packaging** (Simulink Coder) to the value `Reusable function`. This action enables the parameters **Multi-instance code error diagnostic**, **Pass root-level I/O as**, and **All Parameters > Use dynamic memory allocation for model initialization**.
2. Examine the setting of **Multi-instance code error diagnostic** (Simulink Coder). Leave the parameter at its default value `Error` unless you have a specific need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.
3. Configure **Pass root-level I/O as** (Simulink Coder) to control how root-level model input and output are passed to `model_step` and the other generated model entry-point functions.

   When you set **Code interface packaging** to `Reusable function`, model data (such as block I/O, DWork, and parameters) is packaged into the real-time model data structure, and the model structure is passed to the model entry-point functions. If you set **Pass root-level I/O as** to `Part of model data structure`, the

root-level model input and output also are packaged into the real-time model data structure.

4. If you want the generated model code to contain a function that dynamically allocates memory for model instance data, on the **All Parameters** tab, select the option **Use dynamic memory allocation for model initialization** (Simulink Coder). If you do not select this option, the generated code statically allocates memory for model data structures.
5. Generate model code.
6. Examine the model entry-point function interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point functions, see "Entry-Point Functions and Scheduling" (Simulink Coder).

For an example of a model configured to generate reusable, reentrant code, open the example model rtwdemo_reusable. Click the button **View Interface Configuration** and examine the **Code interface** parameters on the **Code Generation > Interface** pane.



More About

- "Entry-Point Functions and Scheduling" (Simulink Coder)

Report Generation in Embedded Coder

Reports for Code Generation

In this section...

The code generator software produces an HTML code generation report so that you can view and analyze the generated code. When your model is built, the code generation process produces an HTML file that is displayed in an HTML browser or in the Model Explorer. The code generation report includes:

- The **Summary** section that contains model and code information, including **Author**, **Tasking Mode**, **System Target File**, **Hardware Device Type**, and code generation objectives information. The **Configuration settings at the time of code generation** link opens a noneditable view of the Configuration Parameters dialog box. The dialog box shows the Simulink model settings at the time of code generation, including TLC options.
- The **Subsystem Report** section that contains information on nonvirtual subsystems in the model.
- In the **Generated Files** section on the **Contents** pane, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code, global variables are hypertext that links to their definitions.

For an example, see "Generate a Code Generation Report" on page 35-5.

If you have a Simulink Report Generator license, you can document your code generation project in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. For an example of how to create a Microsoft Word report, see "Document Generated Code with Simulink Report Generator" on page 35-52.

HTML Code Generation Report Location

The default location for the code generation report files is in the `html` subfolder of the build folder, *`model_target`*`_rtw/html/`. *`target`* is the name of the **System target file** specified on the **Code Generation** pane. The default name for the top-level HTML report file is *`model`*`_codegen_rpt.html` or *`subsystem`*`_codegen_rpt.html`. For

more information on the location of the build folder, see “Manage Build Process Folders” (Simulink Coder).

HTML Code Generation Report for Referenced Models

To generate a code generation report for a top model and code generation reports for each referenced model, you need to specify the **Create code generation report** on the **Code Generation > Report** pane for the top model and each referenced model. You can open the code generation report of a referenced model in one of two ways:

- From the top-model code generation report, you can access the referenced model code generation report by clicking a link under **Referenced Models** in the left navigation pane. Clicking a link opens the code generation report for the referenced model in the browser. To navigate back to the top model code generation report, use the **Back** button at the top of the left navigation pane.
- From the referenced model diagram window, select **Code > C/C++ Code > Code Generation Report > Open Model Report**.

For more information, see “Generate Code for Referenced Models” (Simulink Coder)

HTML Code Generation Report Extensions

If you have an Embedded Coder license, the code generator enhances the HTML code generation report. Configure your model to include the following sections in the report:

- The **Code Interface Report** section provides information about the generated code interface, including model entry-point functions and input/output data. For more information, see “Analyze the Generated Code Interface” on page 35-21.
- The **Traceability Report** section allows you to account for **Eliminated / Virtual Blocks** that are untraceable versus the listed **Traceable Simulink Blocks / Stateflow Objects / MATLAB Scripts**. This provides a complete mapping between model elements and code. For more information, see “Customize Traceability Reports” on page 61-29.
- The **Static Code Metrics Report** section provides statistics of the generated code. Metrics are estimated from static analysis of the generated code. For more information, see “Static Code Metrics” on page 35-34.
- The **Code Replacements Report** section allows you to account for code replacement library (CRL) functions that were used during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the

replacement. For more information, see “Analyze Code Replacements in Generated Code” on page 35-50.

- The model Web view displays an interactive model diagram within the code generation report and supports traceability between the source code and the model. Therefore, you can share your model and generated code outside of the MATLAB environment. For more information, see “Web View of Model in Code Generation Report” on page 35-17.

On the **Contents** pane, in the **Generated Files** section, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code:

- If you enable code-to-model traceability, hyperlinks within the displayed source code navigate to the blocks or subsystems from which the code is generated. For more information, see “Traceability in Code Generation Report” on page 35-15 and “Trace Code to Model Objects by Using Hyperlinks” on page 61-6.
- If you enable model-to-code traceability, you can navigate to the generated code for a block in the model. For more information, see “Trace Model Objects to Generated Code” on page 61-8.
- If you set the **Code coverage tool** parameter on the **Code Generation > Verification** pane, you can view the code coverage data and annotations. For more information, see “Configure Code Coverage with Third-Party Tools” on page 67-10.
- If you select the **Static code metrics** check box on the **Code Generation > Report** pane, you can view code metrics information and navigate to code definitions and declarations in the generated code. For more information, see “View Static Code Metrics and Definitions Within the Generated Code” on page 35-36.

Related Examples

- “Traceability in Code Generation Report” on page 35-15

Generate a Code Generation Report

To generate a code generation report when the model is built:

1. In the Simulink Editor, select **Code > C/C++ Code > Code Generation Report > Options**. The Configuration Parameters dialog box opens with the **Code Generation > Report** pane visible.
2. Select the **Create code generation report** (Simulink Coder) parameter.
3. If you want the code generation report to automatically open after generating code, select the **Open report automatically** (Simulink Coder) parameter (which is enabled by selecting **Create code generation report**).
4. Generate code.

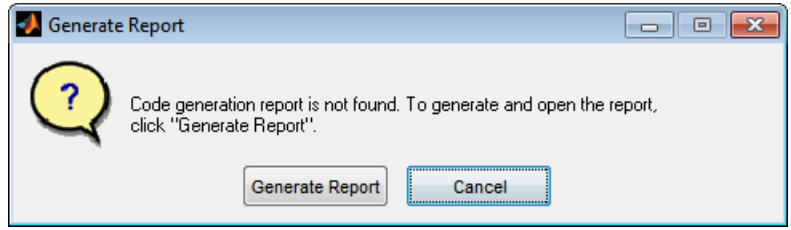
The build process writes the code generation report files to the `html` subfolder of the build folder (see "HTML Code Generation Report Location" on page 35-2). Next, the build process automatically opens a MATLAB Web browser window and displays the code generation report.

To open an HTML code generation report at any time after a build, see "Open Code Generation Report" on page 35-8 and "Generate Code Generation Report After Build Process" on page 35-6.

Generate Code Generation Report After Build Process

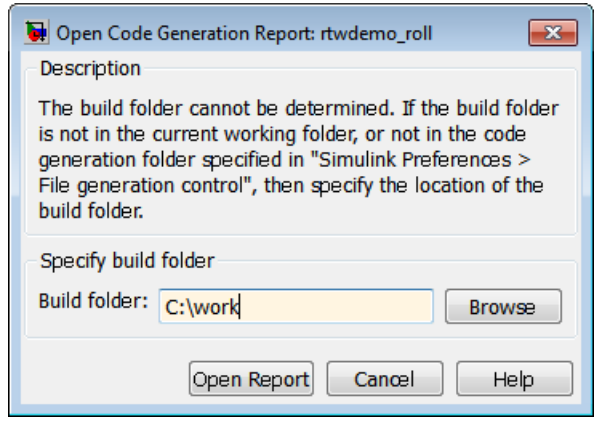
After generating code, if you did not configure your model to create a code generation report, you can generate a code generation report without rebuilding your model.

1. In the model diagram window, select **Code > C/C++ Code > Code Generation Report > Open Model Report**.
2. If your current working folder contains the code generation files the following dialog opens.



Click **Generate Report**.

3. If the code generation files are not in your current working directory, the following dialog opens.



Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

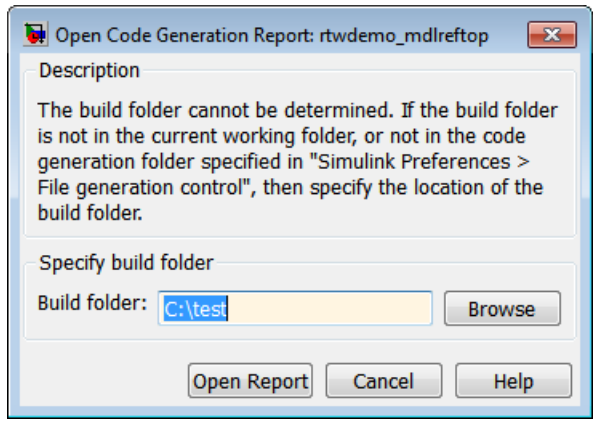
The software generates a report, *model*_codgen_rpt.html, from the code generation files in the build folder you specified.

Note: An alternative method for generating the report after the build process is complete is to configure your model to generate a report and build your model. In this case, the software generates the report without regenerating the code.

Open Code Generation Report

You can refer to existing code generation reports at any time. If you generated a code generation report, in the Simulink Editor, you can open the report by selecting the menu option **Code > C/C++ Code > Code Generation Report > Open Model Report**. If you are opening a report for a subsystem, select **Open Subsystem Report**. A Simulink Coder license is required to view the code generation report. An Embedded Coder license is required to view a code generation report enhanced with Embedded Coder features.

If your current working folder does not contain the code generation files and the code generation report, the following dialog box opens:



Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

Alternatively, you can open the code generation report (`model_codegen_rpt.html` or `subsystem_codegen_rpt.html`) manually into a MATLAB Web browser window, or in another Web browser. For the location of the generated report files, see "HTML Code Generation Report Location" on page 35-2.

Limitation

After building your model or generating the code generation report, if you modify legacy or custom code, you must rebuild your model or regenerate the report for the code generation report to include the updated legacy source files. For example, if you modify your legacy code, and then use the **Code > C/C++ Code > Code Generation**

Report > Open Model Report menu to open an existing report, the software does not check if the legacy source file is out of date compared to the generated code. Therefore, the code generation report is not regenerated and the report includes the out-of-date legacy code. This issue also occurs if you open a code generation report using the `coder.report.open` function.

To regenerate the code generation report, do one of the following:

- Rebuild your model.
- Generate the report using the `coder.report.generate` function.

Generate Code Generation Report Programmatically

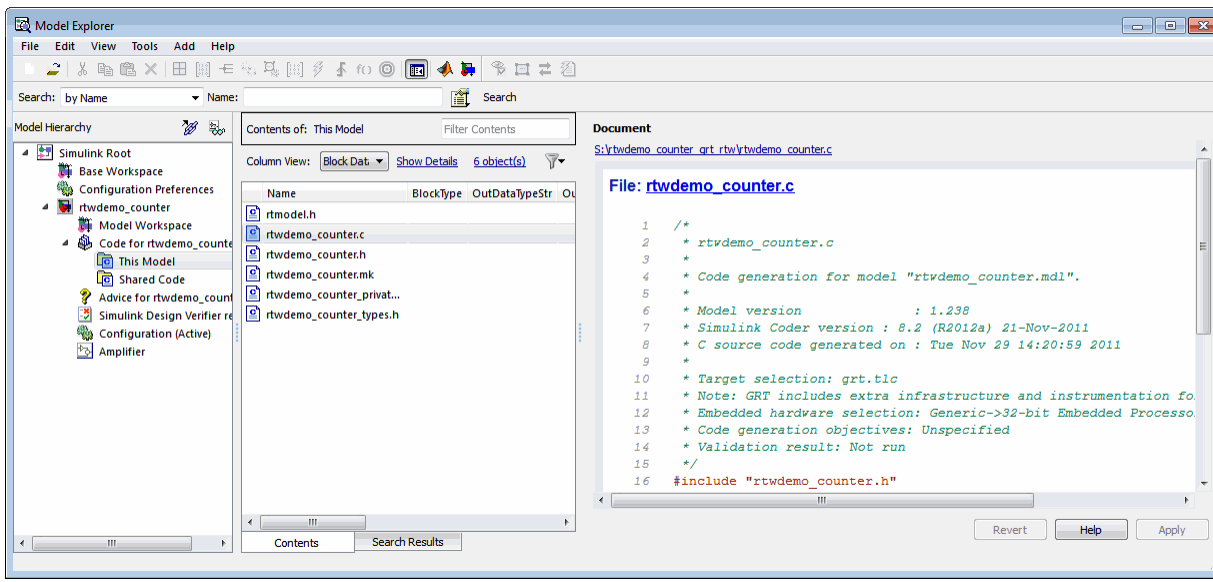
At the MATLAB command line, you can generate, open, and close an HTML Code Generation Report with the following functions:

- `coder.report.generate` generates the code generation report for the specified model.
- `coder.report.open` opens an existing code generation report.
- `coder.report.close` closes the code generation report.

View Code Generation Report in Model Explorer

After generating an HTML code generation report, you can view the report in the right pane of the Model Explorer. You can also browse the generated files directly in the Model Explorer.

When you generate code, or open a model that has generated code for its current target configuration in your working folder, the **Hierarchy** (left) pane of Model Explorer contains a node named **Code for *`model`***. Under that node are other nodes, typically called `This Model` and `Shared Code`. Clicking `This Model` displays in the **Contents** (middle) pane a list of generated source code files in the build folder of that model. The next figure shows code for the `rtwdemo_counter` model.



In this example, the file `S:/rtwdemo_counter_grt_rtw/rtwdemo_counter.c` is being displayed. To view a file in the **Contents** pane, click it once.

The views in the **Document** (right) pane are read only. The code listings there contain hyperlinks to functions and macros in the generated code. Clicking the file hyperlink opens that source file in a text editing window where you can modify its contents.

If an open model contains Model blocks, and if generated code for these models exists in the current `slprj` folder, nodes for the referenced models appear in the **Hierarchy** pane

one level below the node for the top model. Such referenced models do not need to be open for you to browse and read their generated source files.

If the code generator produces shared utility code for a model, a node named `Shared Code` appears directly under the **This Model** node. It collects source files that exist in the `./slprj/`*`target`*`/_sharedutils` subfolder.

Note You cannot use the **Search** tool built into Model Explorer toolbar to search generated code displayed in the Code Viewer. On PCs, typing **Ctrl+F** when focused on the **Document** pane opens a Find dialog box that you can use to search for text in the currently displayed file. You can also search for text in the HTML report window, and you can open the files in the editor.

Package and Share the Code Generation Report

In this section...

Package the Code Generation Report

To share the code generation report, you can package the code generation report files and supporting files into a zip file for transfer. The default location for the code generation report files is in two folders:

- `/slprj`
- `html` subfolder of the build folder, *`model_target`*`_rtw`, for example `rtwdemo_counter_grt_rtw/html`

To create a zip file from the MATLAB command window:

1. In the Current Folder browser, select the two folders:
   - `/slprj`
   - Build folder: *`model_target`*`_rtw`
2. Right-click to open the context menu.
3. In the context menu, select **Create Zip File**. A file appears in the Current Folder browser.
4. Name the zip file.

Alternatively, you can use the MATLAB `zip` command to zip the code generation report files:

```
zip('myzip',{'slprj','rtwdemo_counter_grt_rtw'})
```

Note: If you need to relocate the static and generated code files for a model to another development environment, such as a system or an integrated development environment (IDE) that does not include MATLAB and Simulink products, use the code generator pack-and-go utility. For more information, see "Relocate Code to Another Development Environment" (Simulink Coder).

View the Code Generation Report

To view the code generation report after transfer, unzip the file and save the two folders at the same folder level in the hierarchy. Navigate to the *model_target*_rtw/html/ folder and open the top-level HTML report file named *model*_codgen_rpt.html or *subsystem*_codegen_rpt.html in a Web browser.

Traceability in Code Generation Report

This example shows how to create an HTML code generation report which includes links to trace between the source code and the Simulink model window.

1. With your ERT-based model open, open the Configuration Parameters dialog box or Model Explorer and navigate to the **Code Generation > Report** pane.
2. Select **Create code generation report** if it is not already selected. By default, **Open report automatically** and **Code-to-model** on the **All Parameters** tab are selected. **Model-to-code** is not selected.
3. Select the **Model-to-code** parameter on the **All Parameters** tab.
4. If your model contains referenced models and you want to enable traceability for the referenced model's code generation report, repeat steps 2–3 for each referenced model.
5. Press **Ctrl+B** to generate code for your model. The build process opens the code generation report in a MATLAB Web browser.
6. In the left navigation pane, select a source code file. The source code and line numbers in the right pane contain hyperlinks to blocks in the model.
7. Click a code or line number hyperlink. The model diagram window displays and highlights the corresponding block or blocks in the model.
8. To highlight the generated code for a block in your Simulink model, right-click the block and select **C/C++ Code > Navigate to C/C++ Code**. This selection highlights the generated code for the block in the HTML code generation report.
9. If you have a referenced model in your model, in the left navigation pane, below **Reference Models**, click the link to a referenced model. The code generation report for the referenced model is now displayed in the window.
10. In the left navigation pane, click the **Back** button to go back to the previous code generation report.

Web View of Model in Code Generation Report

In this section...

About Model Web View

To review and analyze the generated code, it is helpful to navigate between the code and model. You can include a Web view of the model within the HTML code generation report. You can then share your model and generated code outside of the MATLAB environment. When you generate the report, the Web view includes the block diagram attributes displayed in the Simulink Editor, such as, block sorted execution order, signal properties, and port data types.

A Simulink Report Generator license is required to include a Web view (Simulink Report Generator) of the model in the code generation report.

Browser Requirements for Web View

Web view requires a Web browser that supports Scalable Vector Graphics (SVG). Web view uses SVG to render and navigate models.

You can use the following Web browsers:

- Mozilla Firefox Version 1.5 or later, which has native support for SVG. To download the Firefox browser, go to `www.mozilla.com/`.
- The Microsoft Internet Explorer® Web browser with the Adobe® SVG Viewer plug-in. To download the Adobe SVG Viewer plug-in, go to `www.adobe.com/svg/`.
- Apple Safari Web browser

Generate HTML Code Generation Report with Model Web View

This example shows how to create an HTML code generation report which includes a Web view of the model diagram.

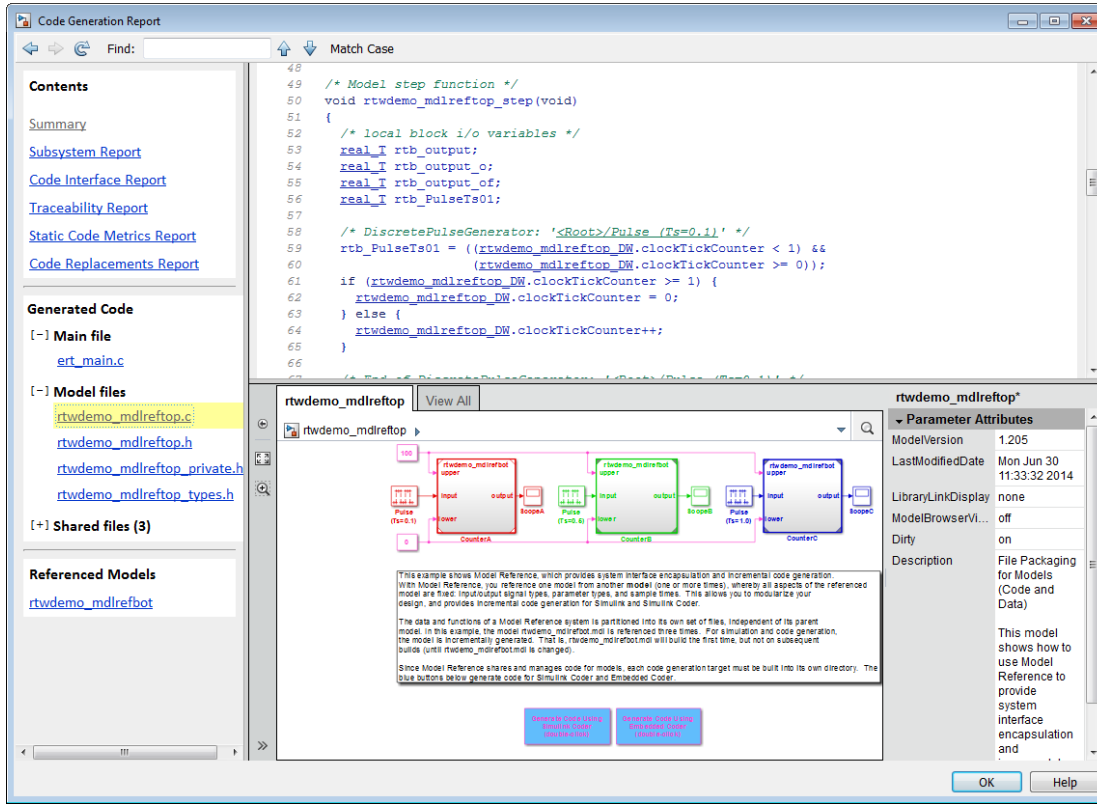
1 Open the `rtwdemo_mdlreftop` model.

2. Open the Configuration Parameters dialog box or Model Explorer and navigate to the **Code Generation** pane.
3. Specify `ert.tlc` for the **System target file** parameter.
4. Open the **Code Generation** > **Report** pane.
5. Select the following parameters:
   - **Create code generation report**
   - **Open report automatically**
   - **Generate model Web view**
6. On the **All Parameters** tab, select the parameters **Code-to-model** and **Model-to-code**.

Note: These settings specify only the top model, not referenced models.

---

7. Open the Configuration Parameters for the referenced model, `rtwdemo_mdlrefbot` and perform steps 3–6.
8. Save the models, `rtwdemo_mdlreftop` and `rtwdemo_mdlrefbot`.
9. From the top model diagram, press Ctrl+B. After building the model and generating code, the code generation report for the top model opens in a MATLAB Web browser.
10. In the left navigation pane, select a source code file. The corresponding source code is displayed in the right pane and includes hyperlinks.



11 Click a link in the code. The model Web view displays and highlights the corresponding block in the model.

12 To highlight the generated code for a referenced model block in your model, click `CounterB`. The corresponding code is highlighted in the source code pane.

Note: You cannot open the referenced model diagram in the Web view by double-clicking the referenced model block in the top model.

13 To open the code generation report for a referenced model, in the left navigation pane, below **Referenced Models**, click the link, `rtwdemo_mdlrefbot`. The source files for the referenced model are displayed along with the Web view of the referenced model.

14 To go back to the code generation report for the top model, at the top of the left navigation pane, click the **Back** button until the top model's report is displayed.

For more information about exploring a model in a Web view, see "Navigate the Web View" (Simulink Report Generator).

For more information about navigating between the generated code and the model diagram, see :

- "Trace Model Objects to Generated Code" on page 61-8
- "Trace Code to Model Objects by Using Hyperlinks" on page 61-6

Model Web View Limitations

The HTML code generation report includes the following limitations when using the model Web view:

- Code is not generated for virtual blocks. In the model Web view of the code generation report, when tracing between the model and the code, when you click a virtual block, it is highlighted yellow.
- In the model Web view, you cannot open a referenced model diagram by double-clicking the referenced model block in the top model. Instead, open the code generation report for the referenced model by clicking a link under **Referenced Models** in the left navigation pane.
- Stateflow truth tables, events, and links to library charts are not supported in the model Web view.
- Searching in the code generation report does not find or highlight text in the model Web view.
- If you navigate from the actual model diagram (not the model Web view in the report), to the source code in the HTML code generation report, the model Web view is disabled and not visible. To enable the model Web view, open the report again, see "Open Code Generation Report" (Simulink Coder).
- For a subsystem build, the traceability hyperlinks of the root level inport and outport blocks are disabled.
- "Traceability Limitations" on page 61-32 that apply to tracing between the code and the actual model diagram.

Analyze the Generated Code Interface

In this section...

Code Interface Report Overview

When you select the **Create code generation report** option for an ERT-based model, a **Code Interface Report** section is automatically included in the generated HTML report. The **Code Interface Report** section provides documentation of the generated code interface, including model entry-point functions and interface data, for consumers of the generated code. The information in the report can help facilitate code review and code integration.

The code interface report includes the following subsections:

- **Entry point functions** — interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.
- **Inports** and **Outports** — interface information about each model inport and outport.
- **Interface Parameters** — interface information about tunable parameters that are associated with the model.
- **Data Stores** — interface information about global data stores and data stores with non-`auto` storage that are associated with the model.

For limitations that apply to code interface reports, see "Code Interface Report Limitations" on page 35-32.

For illustration purposes, this section uses the following models:

- `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window) for examples of report subsections
- `rtwdemo_mrmtbb` for examples of timing information
- `rtwdemo_fcnprotoctrl` for examples of function argument and return value information

Generating a Code Interface Report

To generate a code interface report for your model:

1. Open your model, go to the **Code Generation** pane of the Configuration Parameters dialog box, and select `ert.tlc` or an ERT-based **System target file**, if one is not already selected.
2. Go to the **Code Generation** > **Report** pane of the Configuration Parameters dialog box and select the option **Create code generation report**, if it is not already selected. The `rtwdemo_basicsc`, `rtwdemo_mrmtbb`, and `rtwdemo_fcnprotoctrl` models used in this section select multiple **Report** pane options by default. But selecting only **Create code generation report**, generates a **Code Interface Report** section in the HTML report.

   Alternatively, you can programmatically select the option by issuing the following MATLAB command:

   ```
   set_param(bdroot, 'GenerateReport', 'on')
   ```

   If the **All parameters** tab option **Code-to-model** is selected, the generated report contains hyperlinks to the model. Leave this value selected unless you plan to use the report outside the MATLAB environment.
3. Build the model. If you selected the **Report** pane option **Open report automatically**, the code generation report opens automatically after the build process is complete. (Otherwise, you can open it manually from within the model build folder.)
4. To display the code interface report for your model, go to the **Contents** pane of the HTML report and click the **Code Interface Report** link. For example, here is the generated code interface report for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

Code Interface Report for rtwdemo_basicsc

Table of Contents

Entry Point Functions

Function: rtwdemo_basicsc_initialize

Prototype	**void rtwdemo_basicsc_initialize(void)**
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

Function: rtwdemo_basicsc_step

Prototype	**void rtwdemo_basicsc_step(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

Inports

[-]

Block Name	Code Identifier	Data Type	Dimension
<Root>/In1	input1	real32_T	1
<Root>/In2	input2	real32_T	1
<Root>/In3	input3	real32_T	1
<Root>/In4	input4	real32_T	1

Outports

Block Name	Code Identifier	Data Type	Dimension
<Root>/Out1	output	real32_T	1

Interface Parameters

[-]

Parameter Source	Code Identifier	Data Type	Dimension
K2	K2	real_T	1
LOWER	LOWER	real32_T	1
T1Break	T1Break	real32_T	[1 11]
T1Data	T1Data	real32_T	[1 11]
T2Break	T2Break	real32_T	[1 3]
T2Data	T2Data	real32_T	[3 3]
UPPER	UPPER	real32_T	1
K1	K1	int8_T	1

Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<Root>/Data Store Memory	mode	boolean_T	1

For help navigating the content of the code interface report subsections, see "Navigating Code Interface Report Subsections" on page 35-24. For help interpreting the content of the code interface report subsections, see the sections beginning with "Interpreting the Entry Point Functions Subsection" on page 35-25.

Navigating Code Interface Report Subsections

To help you navigate code interface descriptions, the code interface report provides collapse/expand tokens and hyperlinks, as follows:

- For a large subsection, the report provides `[-]` and `[+]` symbols that allow you to collapse or expand that section. In the example in the previous section, the symbols are provided for the **Inports** and **Interface Parameters** sections.
- Several forms of hyperlink navigation are provided in the code interface report. For example:
  - The **Table of Contents** located at the top of the code interface report provides links to each subsection.
  - You can click each function name to go to its definition in *`model`*`.c`.
  - You can click each function's header file name to go to the header file source listing.
  - If you selected the **All Parameters** tab option **Code-to-model** for your model, to go to the corresponding location in the model display, you can click hyperlinks for any of the following:
    - Function argument
    - Function return value
    - Inport
    - Outport
    - Interface parameter (if the parameter source is a block)
    - Data store (if the data store source is a Data Store Memory block)

For backward and forward navigation within the HTML code generation report, use the **Back** and **Forward** buttons above the **Contents** section in the upper-left corner of the report.

Interpreting the Entry Point Functions Subsection

The **Entry Point Functions** subsection of the code interface report provides the following interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.

Field	Description
Function:	Lists the function name. You can click the function name to go to its definition in *`model`*`.c`.
Prototype	Displays the function prototype, including the function return value, name, and arguments.
Description	Provides a text description of the function's purpose in the application.
Timing	Describes the timing characteristics of the function, such as how many times the function is called, or if it is called periodically, and at what time interval. For a multirate timing example, see the following `rtwdemo_mrmtbb` report excerpt.
Arguments	If the function has arguments, displays the number, name, data type, and Simulink description for each argument. If you select the **All Parameters** tab option **Code-to-model** for your model, you can click the hyperlink in the description to go to the block corresponding to the argument in the model display. For argument examples, see the `rtwdemo_fcnprotoctrl` report excerpt below.
Return value	If the function has a return value, this field displays the return value data type and Simulink description. If you selected the **All Parameters** tab option **Code-to-model** for your model, you can click the hyperlink in the description to go to the block corresponding to the return value in the model display. For a return value example, see the following `rtwdemo_fcnprotoctrl` report excerpt.
Header file	Lists the name of the header file for the function. You can click the header file name to go to the header file source listing.

For example, here is the **Entry Point Functions** subsection for the model `rtwdemo_basicsc`.

Entry Point Functions

Function: rtwdemo_basicsc_initialize

Prototype	**void rtwdemo_basicsc_initialize(void)**
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

Function: rtwdemo_basicsc_step

Prototype	**void rtwdemo_basicsc_step(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

To illustrate how timing information might be listed for a multirate model, here are the **Entry Point Functions** and **Inports** subsections for the model `rtwdemo_mrmtbb`. This multirate, discrete-time, multitasking model contains Inport blocks 1 and 2, which specify 1-second and 2-second sample times, respectively. The sample times are constrained to the specified times by the **Periodic sample time constraint** option on the **Solver** pane of the Configuration Parameters dialog box.

Entry Point Functions

Function: rtwdemo_mrmtbb_initialize

Prototype	**void rtwdemo_mrmtbb_initialize(void)**
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Function: rtwdemo_mrmtbb_step0

Prototype	**void rtwdemo_mrmtbb_step0(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Function: rtwdemo_mrmtbb_step1

Prototype	**void rtwdemo_mrmtbb_step1(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 2 seconds
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Function: rtwdemo_mrmtbb_terminate

Prototype	**void rtwdemo_mrmtbb_terminate(void)**
Description	Termination entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Inports

Block Name	Code Identifier	Data Type	Dimension
<Root>/In1_1s	rtwdemo_mrmtbb_U.In1_1s	real_T	1
<Root>/In2_2s	rtwdemo_mrmtbb_U.In2_2s	real_T	1

To illustrate how function arguments and return values are displayed in the report, here is the entry-point function description of the model step function for model `rtwdemo_fcnprotoctrl`.

Function: rtwdemo_fcnprotoctrl_step_custom

Prototype	**boolean_T rtwdemo_fcnprotoctrl_step_custom(const real_T argIn1, const BusObject *const argIn2, BusObject *argOut2, const BusObject *const argIn3, uint8_T *argIn4)**
Description	Output entry point of generated code
Timing	Can be called at any time
Arguments	[-]

#	Name	Data Type	Description
1	argIn1	const real_T	<Root>/In1
2	argIn2	const BusObject *const	<Root>/In2
3	argOut2	BusObject *	<Root>/Out2
4	argIn3	const BusObject *const	<Root>/In3
5	argIn4	uint8_T *	<Root>/In4

Return value	Data Type	Description
	boolean_T	<Root>/Out1
Header file	rtwdemo_fcnprotoctrl.h	

Interpreting the Inports and Outports Subsections

The **Inports** and **Outports** subsections of the code interface report provide the following interface information about each inport and outport in the model.

Field	Description
Block Name	Displays the Simulink block name of the inport or outport. If you selected the **All Parameters** tab option **Code-to-model** for your model, you can click on each inport or outport **Block Name** value to go to its location in the model display.
Code Identifier	Lists the identifier associated with the inport or outport data in the generated code, as follows: • If the data is defined in the generated code, the field displays the identifier text.

Field	Description
	• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label '`Imported data:`'. • If the data is neither defined nor declared in the generated code — for example, if **Reusable function** code interface packaging is selected for the model — the field displays the text '`Defined externally`'.
Data Type	Lists the data type of the inport or outport.
Scaling	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. **Note:** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see "Fixed-Point Data Type and Scaling Notation" (Fixed-Point Designer).
Dimension	Lists the dimensions of the inport or outport (for example, `1` or `[4, 5]`).

For example, here are the **Inports** and **Outports** subsections for the model `rtwdemo_basicsc`.

Inports

[-]

Block Name	Code Identifier	Data Type	Dimension
<Root>/In1	input1	real32_T	1
<Root>/In2	input2	real32_T	1
<Root>/In3	input3	real32_T	1
<Root>/In4	input4	real32_T	1

Outports

Block Name	Code Identifier	Data Type	Dimension
<Root>/Out1	output	real32_T	1

Interpreting the Interface Parameters Subsection

The **Interface Parameters** subsection of the code interface report provides the following interface information about tunable parameters that are associated with the model.

Field	Description
Parameter Source	Lists the source of the parameter value, as follows: • If the source of the parameter value is a block, the field displays the block name, such as `<Root>/Gain2` or `<S1>/Lookup1`. If you selected the **All Parameters** tab option **Code-to-model** for your model, you can click the **Parameter Source** value to go to the parameter's location in the model display. • If the source of the parameter value is a workspace variable, the field displays the name of the workspace variable.
Code Identifier	Lists the identifier associated with the tunable parameter data in the generated code, as follows: • If the data is defined in the generated code, the field displays the identifier text. • If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label `'Imported data:'`. • If the data is neither defined nor declared in the generated code — for example, if **Reusable function** code interface packaging is selected for the model — the field displays the text `'Defined externally'`.
Data Type	Lists the data type of the tunable parameter.
Scaling	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. **Note:** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see "Fixed-Point Data Type and Scaling Notation" (Fixed-Point Designer).

Field	Description
Dimension	Lists the dimensions of the tunable parameter (for example, `1` or `[4, 5, 6]`).

For example, here is the **Interface Parameters** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

Interface Parameters

[-]

Parameter Source	Code Identifier	Data Type	Dimension
K2	K2	real_T	1
LOWER	LOWER	real32_T	1
T1Break	T1Break	real32_T	[1 11]
T1Data	T1Data	real32_T	[1 11]
T2Break	T2Break	real32_T	[1 3]
T2Data	T2Data	real32_T	[3 3]
UPPER	UPPER	real32_T	1
K1	K1	int8_T	1

Interpreting the Data Stores Subsection

The **Data Stores** subsection of the code interface report provides the following interface information about global data stores and data stores with non-`auto` storage that are associated with the model.

Field	Description
Data Store Source	Lists the source of the data store memory, as follows: • If the data store is defined using a Data Store Memory block, the field displays the block name, such as `<Root>/DS1`. If you selected the **All Parameters** tab option **Code-to-model** for your model, you can click on the **Data Store Source** value to go to the data store's location in the model display. • If the data store is defined using a `Simulink.Signal` object, the field displays the name of the `Simulink.Signal` object.
Code Identifier	Lists the identifier associated with the data store data in the generated code, as follows: • If the data is defined in the generated code, the field displays the identifier text.

Field	Description
	• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label '`Imported data:`'. • If the data is neither defined nor declared in the generated code — for example, if **Reusable function** code interface packaging is selected for the model — the field displays the text '`Defined externally`'.
Data Type	Lists the data type of the data store.
Scaling	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. **Note:** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see "Fixed-Point Data Type and Scaling Notation" (Fixed-Point Designer).
Dimension	Lists the dimensions of the data store (for example, `1` or `[1, 2]`).

For example, here is the **Data Stores** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<Root>/Data Store Memory	mode	boolean_T	1

Code Interface Report Limitations

The following limitations apply to the code interface section of the HTML code generation reports.

- The code interface report does not support the GRT interface with an ERT target or **C ++ class** code interface packaging. For these configurations, the code interface report is not generated and does not appear in the HTML code generation report **Contents** pane.
- The code interface report supports data resolved with most custom storage classes (CSCs), except when the CSC properties are set in any of the following ways:

  - The CSC property **Type** is set to `FlatStructure`. For example, the `BitField` and `Struct` CSCs in the Simulink package have **Type** set to `FlatStructure`.
  - The CSC property **Type** is set to `Other`. For example, the `GetSet` CSC in the Simulink package has **Type** set to `Other`.
  - The CSC property **Data access** is set to `Pointer`, indicating that imported symbols are declared as pointer variables rather than simple variables. This property is accessible only when the CSC property **Data scope** is set to `Imported` or `Instance-specific`.

  In these cases, the report displays empty **Data Type** and **Dimension** fields.
- For outports, the code interface report cannot describe the associated memory (data type and dimensions) if the memory is optimized. In these cases, the report displays empty **Data Type** and **Dimension** fields.
- The code interface report does not support data type replacement using the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box. The data types listed in the report will link to built-in data types rather than their specified replacement data types.

Static Code Metrics

In this section...

About Static Code Metrics

The code generator performs static analysis of the generated C or C++ code and provides these metrics in the **Static Code Metrics Report** section of the HTML Code Generation Report.

You can use the information in the report to:

- Find the number of files and lines of code in each file.
- Estimate the number of lines of code and stack usage per function.
- Compare the difference in terms of how many files, functions, variables, and lines of code are generated every time you change the model or MATLAB algorithm.
- Determine a target platform and allocation of RAM to the stack, based on the size of global variables plus the estimated stack size.
- Determine possible performance slow points, such as the largest global variables or the most costly call path in terms of stack usage.
- View the cyclomatic complexity of a function, which counts the number of linearly independent paths through a function.
- View the function call tree. Determine the longest call path to estimate the worst case execution timing.
- View how target functions, provided by the selected code replacement library, are used in the generated code.

For examples, see

- "Generate Static Code Metrics Report for Simulink Model" on page 35-38
- "Generate a Static Code Metrics Report for MATLAB Code" on page 35-43

Static Code Metrics Analysis

Static analysis of the generated code is performed only on the source code without executing the program. The results of the static code metrics analysis are included in the **Static Code Metrics** section of the HTML Code Generation Report. The report is not available if you generate a MEX function from MATLAB code.

Static analysis of the generated source code files:

- Uses the specified C data types. For Simulink models, you specify these data types in the **Hardware Implementation** > **Production hardware** pane of the Configuration Parameters dialog box. For code generation from MATLAB code, you specify them in the **Hardware** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. Actual object code metrics might differ due to target-specific compiler and platform settings.
- Includes custom code only if you specify it. For Simulink models, you specify custom code on the **Code Generation** > **Custom Code** pane in the model configuration. For code generation from MATLAB code, you specify it on the **Debugging** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. An error report is generated if the generated code includes platform-specific files not contained in the standard C run-time library.
- For Simulink models, includes the generated code from referenced models.
- Uses 1-byte alignment for all members of a structure for estimating global and local data structure sizes. The size of a structure is calculated by summing the sizes of all of its fields. This estimation represents the smallest possible size for a structure.
- Calculates the self stack size of a function as the size of local data within a function, excluding input arguments. The accumulated stack size of a function is the self stack size plus the maximum of the accumulated stack sizes of its called functions. For example, if the accumulated stacks sizes for the called functions are represented as `accum_size1...accum_sizeN`, then the accumulated stack size for a function is

  ```
  accumulated_stack_size = self_stack_size + max(accum_size1,...,accum_sizeN)
  ```
- When estimating the stack size of a function, static analysis stops at the first instance of a recursive call. The **Function Information** table indicates when recursion occurs in a function call path. Code generation generates only recursive code for Stateflow event broadcasting and for graphical functions if it is written as a recursive function.
- Calculates the cyclomatic complexity of a function as the number of decisions plus one:

  ```
  CC = Number of decisions + 1
  ```

The following constructs add a decision:

- If statement
- Else-If statement
- Switch statement (1 decision for each `case` branch)
- Loop statements: While, For, Do-while

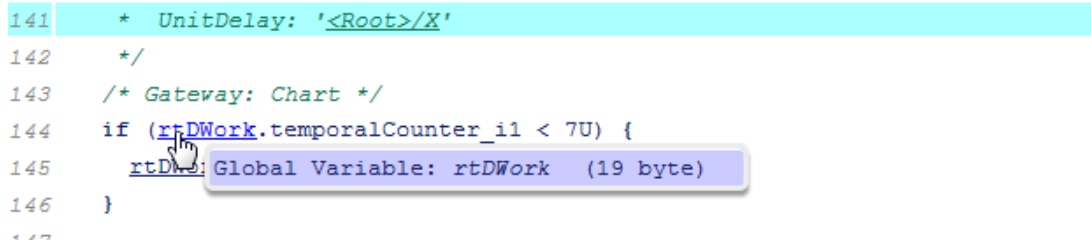
Note: Boolean operators in the above constructs do not add extra decisions.

- Does not include `ert_main.c`, because you have the option to provide your own `main.c`.

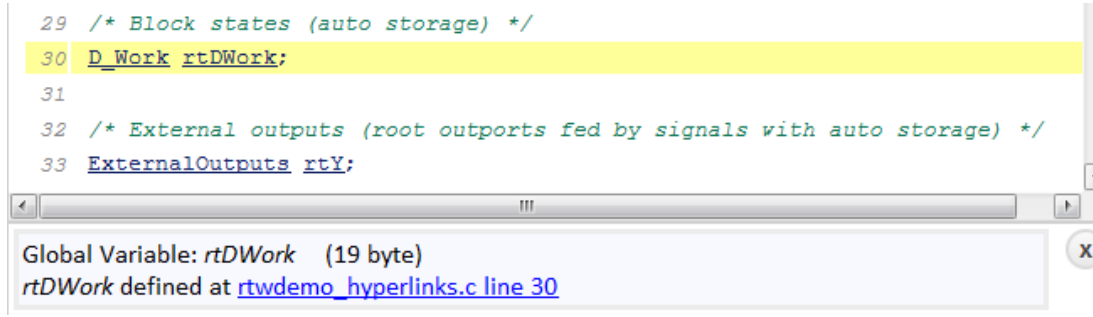
View Static Code Metrics and Definitions Within the Generated Code

When you view code in the code generation report, to get access to code metrics and definitions, you can use the following tools:

- On the **Code Generation > Report** pane, if you select the **Static code metrics** check box you can hover your cursor over global variables and functions in the code window to see code metrics information.



- In the code window, if you click linked variables or functions, the code inspect window is displayed. The window provides links to definitions for the variables or functions. On the **Code Generation > Report** pane, if you selected the **Static code metrics** check box, you can also see code metrics information for the variable or function.



29 /* Block states (auto storage) */
30 D_Work rtDWork;
31
32 /* External outputs (root outports fed by signals with auto storage) */
33 ExternalOutputs rtY;
Global Variable: rtDWork (19 byte)
rtDWork defined at rtwdemo_hyperlinks.c line 30

Generate Static Code Metrics Report for Simulink Model

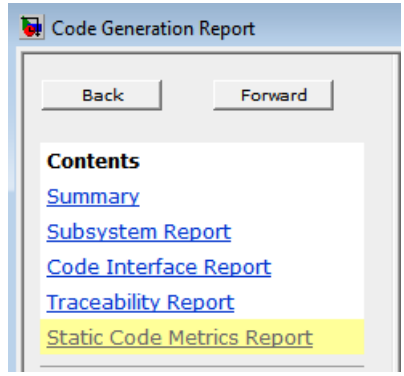
The **Static Code Metrics Report** is a section included in the HTML Code Generation Report. For more information on the static analysis of the generated code, see "Static Code Metrics Analysis" on page 35-35.

1. Before generating the HTML Code Generation Report, open the Configuration Parameters dialog box for your model. On the **Code Generation > Report** pane, select the "Static code metrics" (Simulink Coder) check box.

   If your model includes referenced models, select the **Static code metrics** check box in each referenced model's configuration set. Otherwise, you cannot view a separate static code metrics report for a referenced model.

2. Press **Ctrl+B** to build your model and generate the HTML code generation report. For more information, see "Traceability in Code Generation Report" on page 35-15.

3. If the HTML Code Generation Report is not already open, open the report. On the left navigation pane, in the **Contents** section, select **Static Code Metrics Report**.



4. To see the generated files and how many lines of code are generated per file, look at the **File Information** section.

1. File Information [hide]

[-] Summary (excludes ert_main.c)

Number of .c files : 2
Number of .h files : 4
Lines of code : 1,132
Lines : 1,958

[-] File details

File Name	Lines of Code	Lines	Generated On
fuel_rate_control.c	665	1,107	06/10/2016 4:17 PM
fuel_rate_control_data.c	253	342	06/10/2016 4:17 PM
rtwtypes.h	97	177	06/10/2016 4:17 PM
fuel_rate_control.h	88	249	06/10/2016 4:17 PM
fuel_rate_control_types.h	22	52	06/10/2016 4:17 PM
fuel_rate_control_private.h	7	31	06/10/2016 4:17 PM

5 Hover your cursor over column titles and some column values to see a description of the corresponding data.

6 If your model includes referenced models, the File information section includes a **Referenced Model** column. In this column, click the referenced model name to open its static code metrics report. If the static code metrics report is not available for a referenced model, specify the **Static code metrics** parameter in the referenced model's configuration set and rebuild your model.

7 To view the global variables in the generated code, their size, and the number of accesses, see the **Global Variables** section.

2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] fuel_rate_control_DW	23	175	78
[+] fuel_rate_control_B	21	42	26
[+] fuel_rate_control_U	16	27	24
[+] fuel_rate_control_M_	8	0*	0*
[+] fuel_rate_control_Y	4	4	3
Total	**72**	**248**	

* The global variable is not directly used in any function.

The **Reads/Writes** column displays the total number of read and write accesses to the global variable. The **Reads/Writes in a Function** column displays the maximum number of read and write accesses to the global variable within a function. You use this information is to estimate the benefit of turning on optimizations, which

reduce the number of global references. For more information, see “Optimize Global Variable Usage” on page 55-2.

Click [+] to expand structures.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[−] fuel_rate_control_DW	23	175	78
DiscreteIntegrator_DSTATE	4	5	4
ThrottleTransient_states	4	4	3
DiscreteFilter_states	4	4	3
DiscreteFilter_states_i	4	4	3
[+] bitsForTID0	5	156	60
temporalCounter_i1	2	7	5
[−] fuel_rate_control_B	21	42	26
[+] es_o	16	23	18
fuel_mode	4	15	8
O2_normal	1	6	4
[−] fuel_rate_control_U	16	27	24
[+] sensors	16	27	24
[−] fuel_rate_control_M_	8	0*	0*
errorStatus	8	0	0
[−] fuel_rate_control_Y	4	4	3
fuel_rate	4	4	3
Total	**72**	**248**	

* The global variable is not directly used in any function.

8 To navigate from the report to the source code, click a global variable or function name. These names are hyperlinks to their definitions.

9 To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree** at the top of the table.

3. Function Information [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View:Call Tree | Table

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[-] fuel_rate_control_step	52	16	272	504	43
look2_iflf_linlca	36	36	55	100	12
[-] fuel_rate_control_Fail	4	4	67	103	13
fuel_rate_control_Fueling_Mode	0	0	166	240	19
fuel_rate_control_Fueling_Mode	0	0	166	240	19
[+] fuel_rate_control_initialize	0	0	43	67	1
fuel_rate_control_terminate	0	0	0	4	1

`ert_main.c` is not included in the code metrics analysis, therefore it is not shown in the call tree format. The **Complexity** column includes the cyclomatic complexity of each function.

10 To view the functions in a table format, click **Table**.

3. Function Information [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | Table

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
fuel_rate_control_Fail	fuel_rate_control_step (9)	4	4	67	103	13
fuel_rate_control_Fueling_Mode	fuel_rate_control_step fuel_rate_control_Fail (2)	0	0	166	240	19
fuel_rate_control_initialize		0	0	43	67	1
fuel_rate_control_step		52	16	272	504	43
fuel_rate_control_terminate		0	0	0	4	1
look2_iflf_linlca	fuel_rate_control_step (5)	36	36	55	100	12
memset	fuel_rate_control_initialize (2)	*Not available*	-	-	-	-

The second column, **Called By**, lists functions that call the function listed in the first column, using the following criteria:

- If a function is called by multiple functions, all functions are listed.
- If a function has no called function, this column is empty.

For example, `Fueling_Mode` is called by `Fail` and `fuel_rate_control_step`. The number of call sites is included in parentheses. `Fail` calls `Fueling_Mode` twice.

Generate a Static Code Metrics Report for MATLAB Code

Generate a Static Code Metrics Report Using the MATLAB Coder App

This example shows how to generate a static code metrics report for a static C library that is generated from MATLAB code using the MATLAB Coder app.

By default, if you have an Embedded Coder license, when you use MATLAB Coder to generate standalone C/C++ code, the code generation report includes a static code metrics report. The static code metrics report is not available for generated MEX functions.

Create the Example Files

1. In a local, writable folder, create a MATLAB file, `moving_average.m`, that contains:

```
function [avg,z] = moving_average(x,z)
    %#codegen
    z(2:end) = z(1:end-1);  % Update buffer
    z(1) = x;               % Add new value
    avg = mean(z);          % Compute moving average
end
```

2. In the same local, writable folder, create a test file, `moving_average_test.m`, that contains:

```
function moving_average_test( )
    z = zeros(10,1);
    for i = 1:10
        [avg, z] = moving_average(i,z);
    end
    disp(avg)
end
```

Set Up the MATLAB Coder Project

1. To open the MATLAB Coder app and set up a project, at the command line, enter:

```
coder -new moving_average.prj
```

   The app adds `moving_average` to the list of entry-point functions.

2. Click **Next** to go to the **Define Input Types** step.

Define Input Types

1. To automatically define the input types, select or enter the test file `moving_average_test.m`. Click **Autodefine Input Types**.

   The app determines that `x` is `double(1x1)` and `z` is `double(10x1)`.
2. Click **Next** to go to the **Check for Run-Times Issues** step.

   The **Check for Run-Time Issues** step generates a MEX file from your entry-point functions, runs the MEX function, and reports issues. This step is optional. However, it is a best practice to perform this step. You can detect and fix run-time errors that are harder to diagnose in the generated C code.

Check for Run-Time Issues

1. To open the **Check for Run-Time Issues** dialog box, click the **Check for Issues** arrow  .

   The app populates the test file field with `moving_average_test.m`, the test file that you used to define input types.
2. Click **Check for Issues**.

   The app does not detect issues.
3. Click **Next** to go to the **Generate Code** step.

Configure the Build Settings

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to `Static library`.

   The default output file name is `moving_average`.
3. Click **More Settings**.
4. On the **Debugging** tab, verify that the **Static code metrics** check box is selected.
5. Click **Close**.

Generate C Code

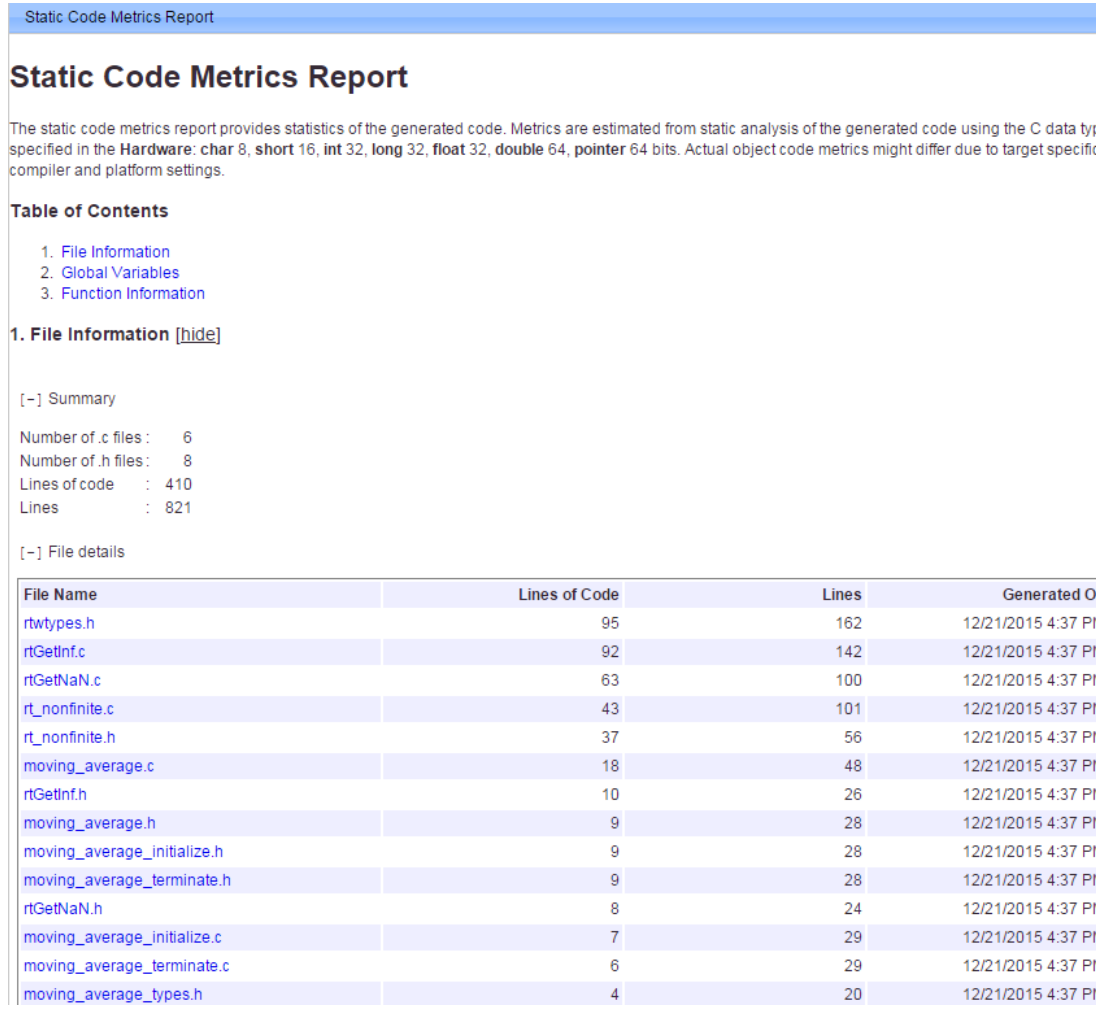
1. To generate the library, click **Generate**.

MATLAB Coder generates a C static library and supporting files in the default folder, `codegen/lib/moving_average`.

2. Click **Next** to go to the **Finish Workflow** step.

View the Static Code Metrics Report

1. To open the code generation report, under **Generated Output**, click **Code Generation Report**.
2. In the code generation report, click **Static Code Metrics Report**.
3. To see the generated files and the number of lines of code per file, click **File Information**.



Static Code Metrics Report

Static Code Metrics Report

The static code metrics report provides statistics of the generated code. Metrics are estimated from static analysis of the generated code using the C data types specified in the **Hardware**: **char** 8, **short** 16, **int** 32, **long** 32, **float** 32, **double** 64, **pointer** 64 bits. Actual object code metrics might differ due to target specific compiler and platform settings.

Table of Contents

1. File Information
2. Global Variables
3. Function Information

1. File Information [hide]

[-] Summary

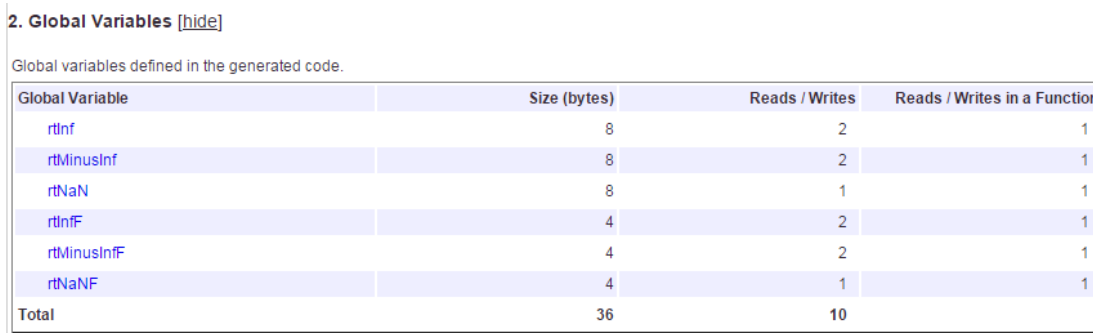
4 To see the global variables in the generated code, go to the **Global Variables** section.



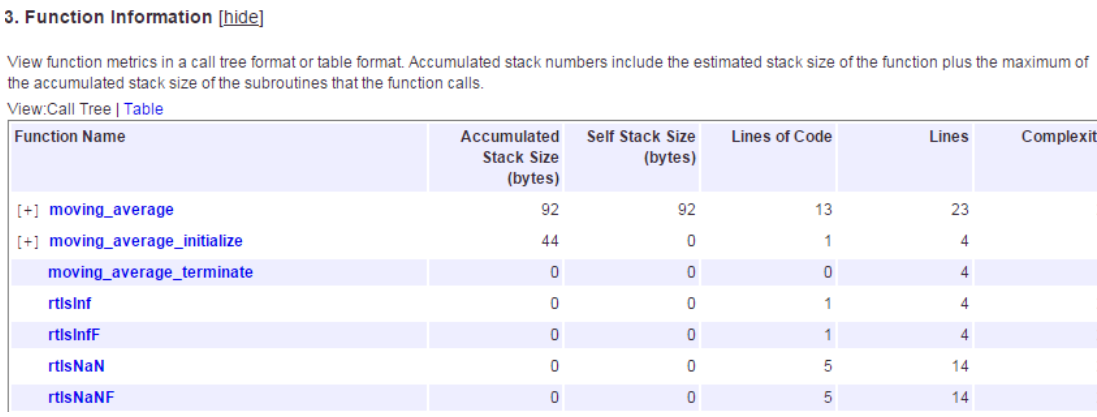
2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
rtInf	8	2	1
rtMinusInf	8	2	1
rtNaN	8	1	1
rtInfF	4	2	1
rtMinusInfF	4	2	1
rtNaNF	4	1	1
Total	36	10	

To navigate from the report to the source code, click a global variable name.

5 To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree**.



3. Function Information [hide]

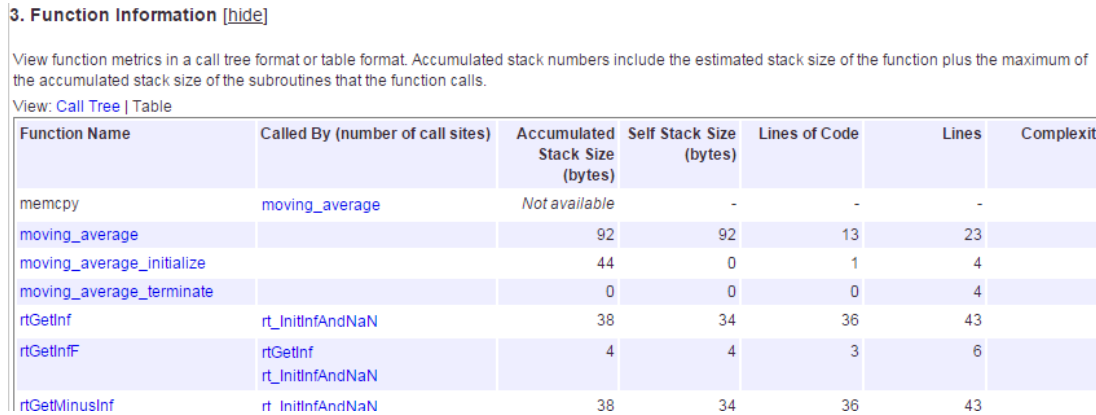
View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View:Call Tree | Table

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[+] moving_average	92	92	13	23	2
[+] moving_average_initialize	44	0	1	4	1
moving_average_terminate	0	0	0	4	1
rtIsInf	0	0	1	4	2
rtIsInfF	0	0	1	4	2
rtIsNaN	0	0	5	14	2
rtIsNaNF	0	0	5	14	2

To navigate from the report to the function code, click a function name.

6 To view the functions in a table format, click **Table**.



3. Function Information [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | Table

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
memcpy	moving_average	*Not available*	-	-	-	-
moving_average		92	92	13	23	2
moving_average_initialize		44	0	1	4	1
moving_average_terminate		0	0	0	4	1
rtGetInf	rt_InitInfAndNaN	38	34	36	43	5
rtGetInfF	rtGetInf rt_InitInfAndNaN	4	4	3	6	1
rtGetMinusInf	rt_InitInfAndNaN	38	34	36	43	5

The second column, **Called By**, lists functions that call the function listed in the first column. If multiple functions call the function, all functions are listed. If no functions call the function, this column is empty.

Enable a Static Code Metrics Report at the Command Line

To enable a static code metrics report at the command line:

1. Create a code generation configuration object for standalone code generation. For example, to generate a static library, use:

   ```
   cfg = coder.config('lib', 'ecoder', true);
   ```

2. Generate code, passing the configuration object as a parameter and specifying the `-report` option. For example:

   ```
   codegen -config cfg -report foo
   ```

Alternatively, you can:

1. Create a code generation configuration object for standalone code generation. For example, to generate a static library:

   ```
   cfg = coder.config('lib', 'ecoder', true);
   ```

2. Set the configuration object `GenerateReport` and `GenerateCodeMetricsReport` parameters to `true`.

   ```
   cfg.GenerateReport = true;
   ```

```
cfg.GenerateCodeMetricsReport = true;
```

3 Generate code, passing the configuration object as a parameter. For example:

```
codegen -config cfg foo
```

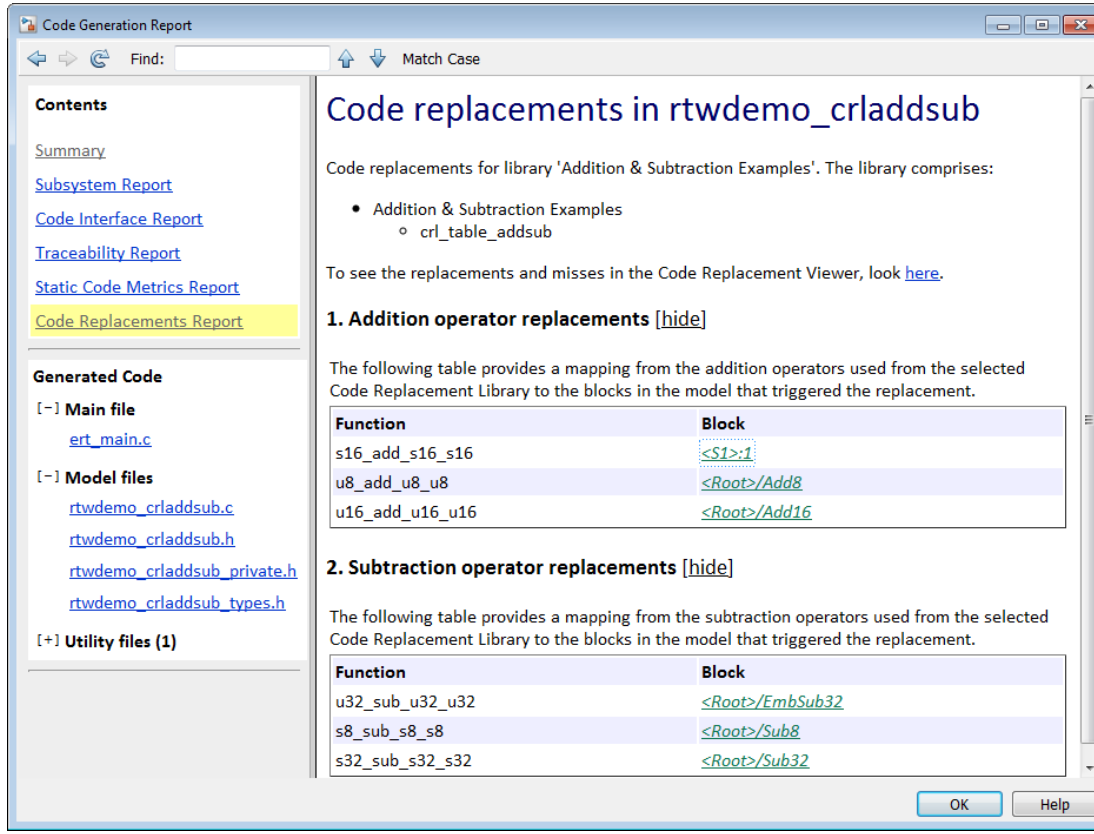
Analyze Code Replacements in Generated Code

When you select the check box **Summarize which blocks triggered code replacements** (Simulink Coder) for an ERT-based model, a Code Replacements Report section is automatically included in the generated HTML report. The Code Replacements Report section documents the code replacement library (CRL) functions that were used for code replacements during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. To enable display of the Simulink block information, select the **Code Generation > Comments** check box **Include comments**. On the same pane, select either the **Simulink block / Stateflow object comments** check box or the **Simulink block descriptions** check box if present, or both.

You can use the report to:

- Determine which replacement functions were used in the generated code.
- Trace each replacement instance back to the block that triggered the replacement.

The figure below shows a Code Replacements Report generated for the CRL model rtwdemo_crladdsub. Each replacement function used is listed with a link to the block that triggered the replacement.



If you click a block path in the report, the block that triggered the replacement is highlighted in the model diagram. If the replacement was triggered by a Stateflow chart or a MATLAB function, a window opens to display the chart or function.

For more information, see Trace Code Replacements Generated Using Your Code Replacement Library on page 51-82.

Document Generated Code with Simulink Report Generator

In this section...

The Simulink Report Generator software creates documentation from your model in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. This example shows one way to document a code generation project in Microsoft Word. The generated report includes:

- System snapshots (model and subsystem diagrams)
- Block execution order list
- Simulink Coder and model version information for generated code
- List of generated files
- Optimization configuration parameter settings
- System target file selection and build process configuration parameter settings
- Subsystem map
- File name, path, and generated code listings for the source code

To adjust Simulink Report Generator settings to include custom code and then generate a report for a model, complete the following tasks:

1. "Generate Code for the Model" on page 35-53
2. "Open the Report Generator" on page 35-53
3. "Set Report Name, Location, and Format" on page 35-55
4. "Include Models and Subsystems in a Report" on page 35-56
5. "Customize the Report" on page 35-57
6. "Generate the Report" on page 35-58

A Simulink Report Generator license is required for the following report formats: PDF, RTF, Microsoft Word, and XML. For more information on generating reports in these formats, see the Simulink Report Generator documentation.

Generate Code for the Model

Before you use the Report Generator to document your project, generate code for the model.

1. In the MATLAB Current Folder browser, navigate to a folder where you have write access.
2. Create a working folder from the MATLAB command line by typing:

   ```
   mkdir report_ex
   ```

3. Make `report_ex` your working folder:

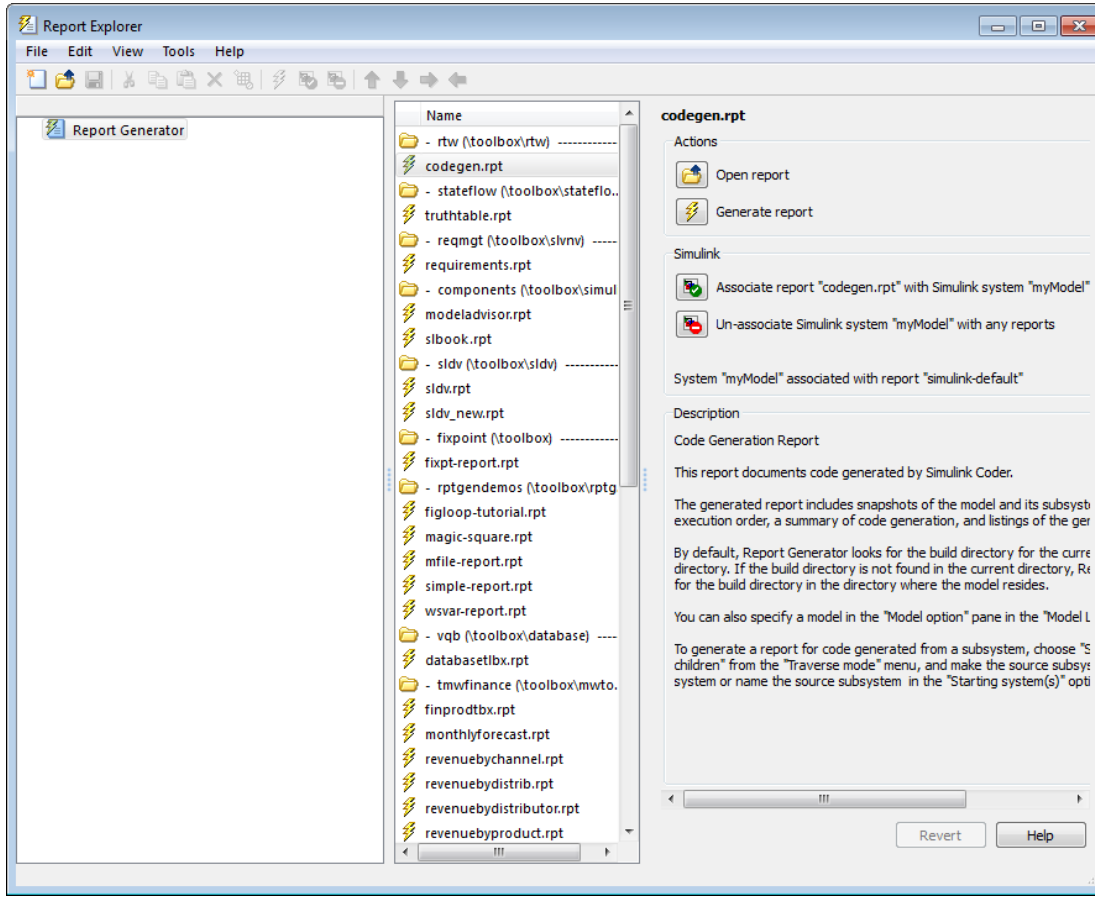
   ```
   cd report_ex
   ```

4. Open the `slexAircraftExample` model by entering the model name on the MATLAB command line.
5. In the model window, choose **File > Save As**, navigate to the working folder, `report_ex`, and save a copy of the `slexAircraftExample` model as `myModel`.
6. Open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu.
7. Select the **Solver** pane. In the **Solver options** section, specify the **Type** parameter as `Fixed-step`.
8. Select the **Code Generation** pane. Select **Generate code only**.
9. Click **Apply**.
10. In the model window, press **Ctrl+B**. The build process generates code for the model.

Open the Report Generator

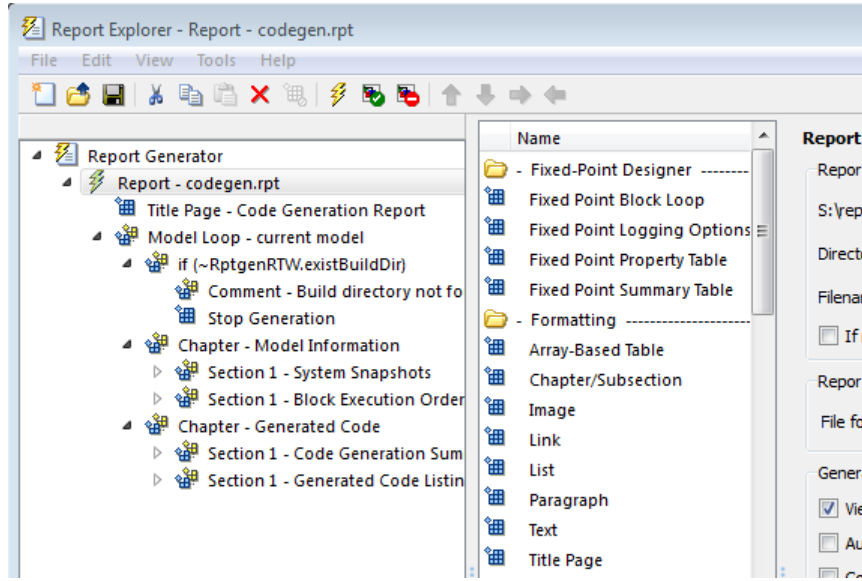
After you generate the code, open the Report Generator.

1. In the model diagram window, select **Tools > Report Generator**.
2. In the Report Explorer window, in the options pane (center), click the folder **rtw (\toolbox\rtw)**. Click the setup file that it contains, **codegen.rpt**.



3

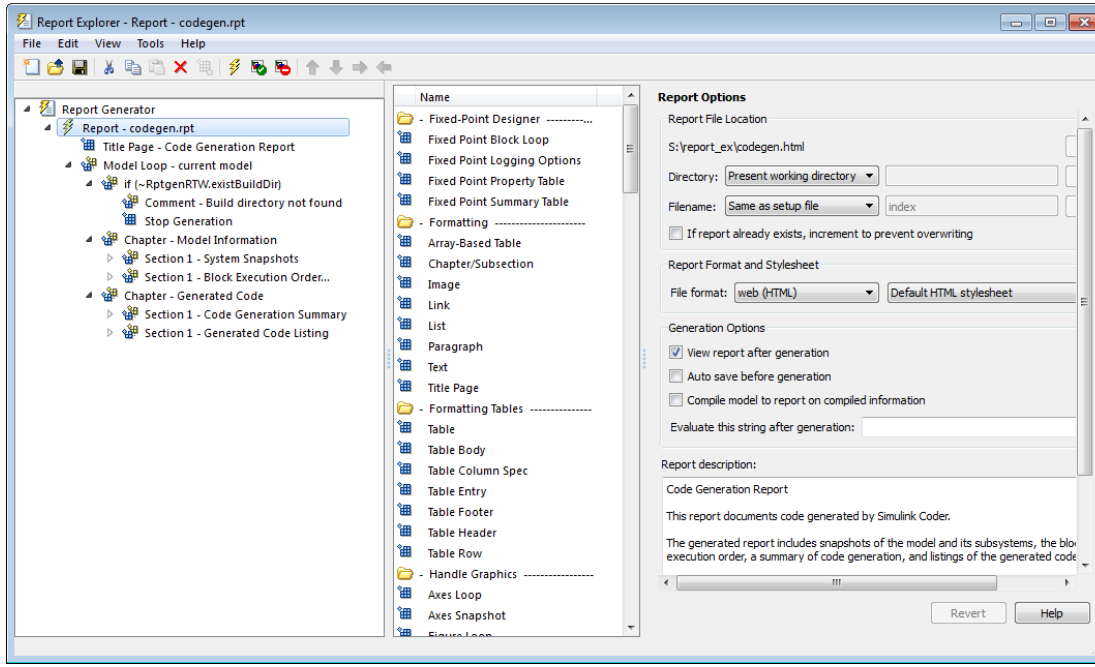
Double-click **codegen.rpt** or select it and click the **Open report** button  . The Report Explorer displays the structure of the setup file in the outline pane (left).



Set Report Name, Location, and Format

Before generating a report, you can specify report output options, such as the folder, file name, and format. For example, to generate a Microsoft Word report named `MyCGModelReport.rtf`:

1 In the properties pane, under **Report Options**, review the options listed.



2 Leave the **Directory** field set to `Present working directory`.

3 For **Filename**, select `Custom:` and replace `index` with the name `MyModelCGReport`.

4 For **File format**, specify `Rich Text Format` and replace `Standard Print` with `Numbered Chapters & Sections`.

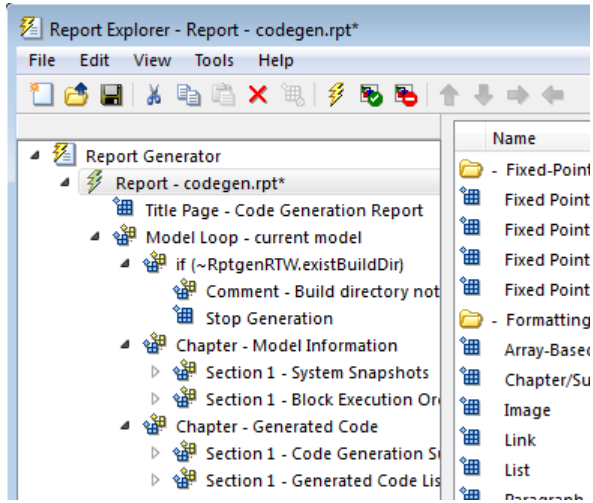
Include Models and Subsystems in a Report

Specify the models and subsystems that you want to include in the generated report by setting options in the Model Loop component.

1 In the outline pane (left), select **Model Loop**. Report Generator displays Model Loop component options in the properties pane.

2 If not already selected, select `Current block diagram` for the **Model name** option.

3 In the outline pane, click **Report - codegen.rpt***.



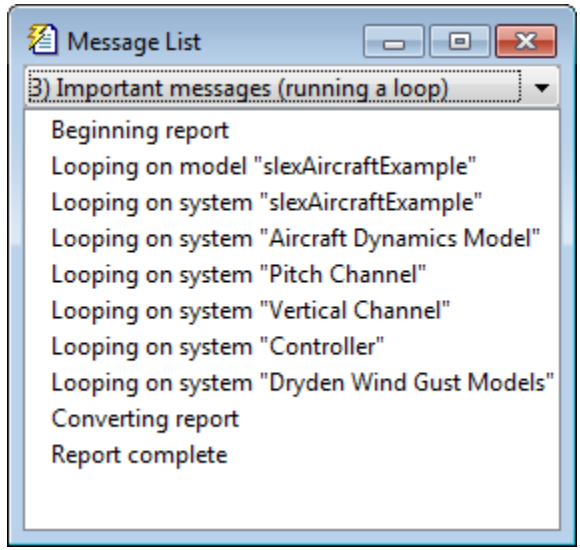
Customize the Report

After specifying the models and subsystems to include in the report, you can customize the sections included in the report.

1. In the outline pane (left), expand the node **Chapter - Generated Code**. By default, the report includes two sections, each containing one of two report components.
2. Expand the node **Section 1 — Code Generation Summary**.
3. Select **Code Generation Summary**. Options for the component are displayed in the properties pane.
4. Click **Help** to review the report customizations that you can make with the Code Generation Summary component. For this example, do not customize the component.
5. In the Report Explorer window, expand the node **Section 1 — Generated Code Listing**.
6. Select **Import Generated Code**. Options for the component are displayed in the properties pane.
7. Click **Help** to review the report customizations that you can make with the Import Generated Code component.

Generate the Report

After you adjust the report options, from the **Report Explorer** window, generate the report by clicking **File** > **Report**. A **Message List** dialog box opens, which displays messages that you can monitor as the report is generated. Model snapshots also appear during report generation. The **Message List** dialog box might be hidden behind other dialog boxes.



When the report is complete, open the report, `MyModelCGReport.rtf` in the folder `report_ex` (in this example).

Code Appearance in Embedded Coder

Add Custom Comments to Generated Code

You can include auto-generated comments in the generated code as described in "Configure Code Comments" (Simulink Coder). For ERT targets, include additional custom comments by setting parameters on the **Code Generation > Comments** pane in the Configuration Parameters dialog box. With these parameters, you can enable or suppress generation of descriptive information in comments for blocks and other model elements.

Goal	Specify
Include the text specified in the **Description** field of a block's Block Properties dialog box as comments in the code generated for each block.	**Simulink block descriptions**
Add a comment that includes the block name at the start of the code for each block.	**Simulink block descriptions**
Include the text specified in the **Description** field of a Simulink data object (such as a signal, parameter, data type, or bus) in the Simulink Model Explorer as comments in the code generated for each object.	**Simulink data object descriptions**
Include comments just above signals and parameter identifiers in the generated code as specified in the MATLAB or TLC function.	**Custom comments (MPT objects only)**
Include the text specified in the **Description** field in the Properties dialog box for a Stateflow object as comments just above the code generated for each object.	**Stateflow object descriptions**
Include requirements assigned to Simulink blocks in the generated code comments (for more information, see "Generate Code for Models with Requirements Links" (Simulink Verification and Validation)).	**Requirements in block comments**

When you select **Simulink block descriptions**:

- The code generator includes strings for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If those strings are unrepresented in the character set encoding for the model, the code generator replaces

the strings with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ア with the escape sequence `&#x30A2;`. For more information, see "Internationalization and Code Generation" (Simulink Coder).

- The code generation software automatically inserts comments into the generated code for custom blocks. Therefore, you do not need to include block comments in the associated TLC file for a custom block.

  Note: If you have existing TLC files with manually inserted comments for block descriptions, the code generation process emits these comments instead of the automatically generated comments. Consider removing existing block comments from your TLC files. Manually inserted comments might be poorly formatted in the generated code and code-to-model traceability might not work.

- For virtual blocks or blocks that have been removed due to block reduction, comments are not generated.

For more information, see "Model Configuration Parameters: Code Generation Comments" (Simulink Coder).

Add Custom Comments for Variables in the Generated Code

To control code generation options for signals, states, and parameters in a model, you can create data objects in a workspace or data dictionary. You can generate comments in the code that help you to document the purpose and properties of the data in each object. Associate handwritten comments with each object, or write a function that generates comments based on the properties of the object.

For more information about data objects, see "Data Objects" (Simulink).

In this section...

Embed Handwritten Comments for Signals or Parameters

To embed handwritten comments in the generated code near the definition of a signal, state, or parameter:

1. Create a data object to represent a signal, state, or parameter. You can use a data object from any package. For example, use a data object of the classes `Simulink.Signal` or `Simulink.Parameter`, which are defined in the package `Simulink`.

   ```
   myParam = Simulink.Parameter(15.23);
   ```

2. Set the storage class of the data object so that optimizations do not eliminate the signal or parameter from the generated code. For example, use the storage class `ExportedGlobal`.

   ```
   myParam.StorageClass = 'ExportedGlobal';
   ```

3. Set the `Description` property of the object. The description that you specify appears in the generated code as lines of comments.

   ```
   myParam.Description = 'This parameter represents wind speed.';
   ```

4. Set **Configuration Parameters** > **Code Generation** > **System target file** to an ERT-based target such as `ert.tlc`.

   To generate comments from data object descriptions, you must use an ERT-based target.

5 Select **Configuration Parameters** > **Code Generation** > **Comments** > **Simulink data object descriptions**.

6 Generate code from the model. In the code, the data object description appears near the definition of the corresponding variable.

```
/* Exported block parameters */
real_T myParam = 15.23;     /* Variable: myParam
                             * Referenced by: '<S1>/Gain'
                             * This parameter represents wind speed.
                             */
```

Generate Dynamic Comments Based on Data Properties

You can generate dynamic comments that include the properties of the data object such as data type, units, and dimensions. If you change the properties of the data object in Simulink, the code generator maintains the accuracy of the comments. For example, this comment displays some of the property values for a data object named `MAP`:

```
/*     Unit:       psi                                          */
/*     Owner:                                                   */
/*     DefinitionFile: specialDef                               */
real_T MAP = 0.0;
```

1 Create a data object from the package `mpt` and apply a custom storage class to the object. The default storage class for objects that you create from the package `mpt` is the custom storage class `Global (Custom)`.

```
MAP = mpt.Signal;
```

To generate dynamic comments, you must use a data object from the package `mpt`, and you must apply a custom storage class to the object.

2 Write a MATLAB or TLC function that generates the comment text. For an example MATLAB function, see the function *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwdemo_comments_mptfun.m`.

The function must accept three input arguments that correspond to `objectName`, `modelName`, and `request`. If you write a TLC file, you can use the library function `LibGetSLDataObjectInfo` to get the property values of the data object.

3 Save the function as a MATLAB file or a TLC file, and place the file in a folder that is on your MATLAB path.

4. In the model, select **Configuration Parameters > Code Generation > Comments > Custom comments (MPT objects only)**.
5. Set **Custom comments function** to the name of the MATLAB file or TLC file that you created.
6. Generate code from the model. The comments that your function generates appear near the code that represents each data object.

Limitations

- To generate comments by using the **Custom comments (MPT objects only)** and **Custom comments function** options, you must create data objects from the package `mpt`. The data objects must use a custom storage class.
- Only the custom storage classes from the `mpt` package that create unstructured variables support a custom comments function.

Add Global Comments

In this section...

The following examples show how to add a global comment to a Simulink model so that the comment text appears in the generated file or files where you want. Specify a template symbol name with a Simulink DocBlock, a Simulink annotation, or a Stateflow note. You can also use a sorted-notes capability that works with Simulink annotations or Stateflow notes (but not DocBlocks). For more information about template symbols, see "Template Symbols and Rules" on page 36-90.

Note Template symbol names `Description` and `ModifiedHistory` also are fields in the Model Properties dialog box. If you use one of these symbol names for global comment text, and its Model Properties field also has text in it, both names appear in the generated files.

Use a Simulink DocBlock to Add a Comment

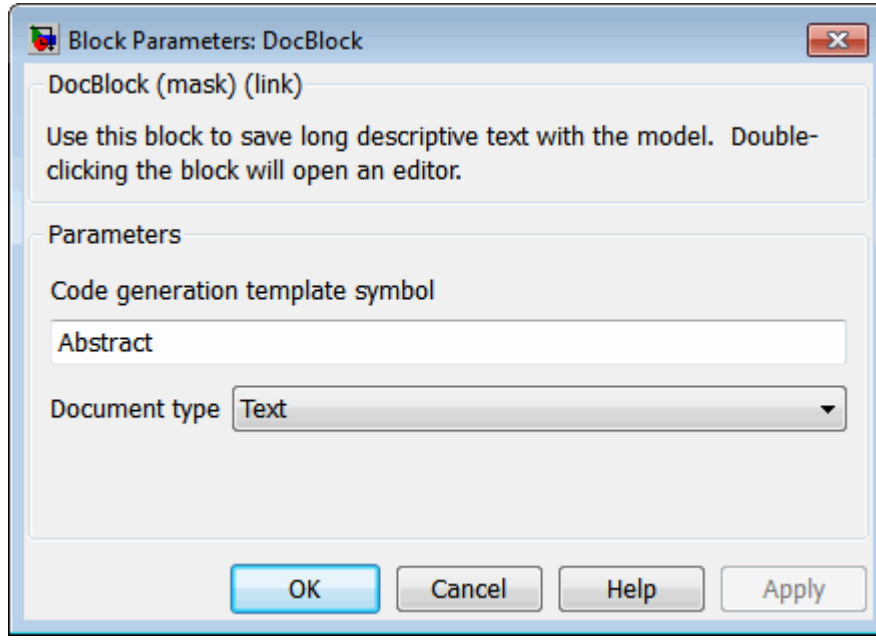
1. With the model open, from the **View** menu, select **Library Browser**.
2. Drag the DocBlock from **Model-Wide Utilities** in the Simulink library into the model.
3. Double-click the DocBlock and type the comment that you want in the editor. Save and close the editor.
4. Right-click the DocBlock and select **Mask > Mask Parameters**.
5. In the **Code generation template symbol** box, type one of the following:

   - `Abstract`
   - `Description`
   - `History`
   - `ModifiedHistory`

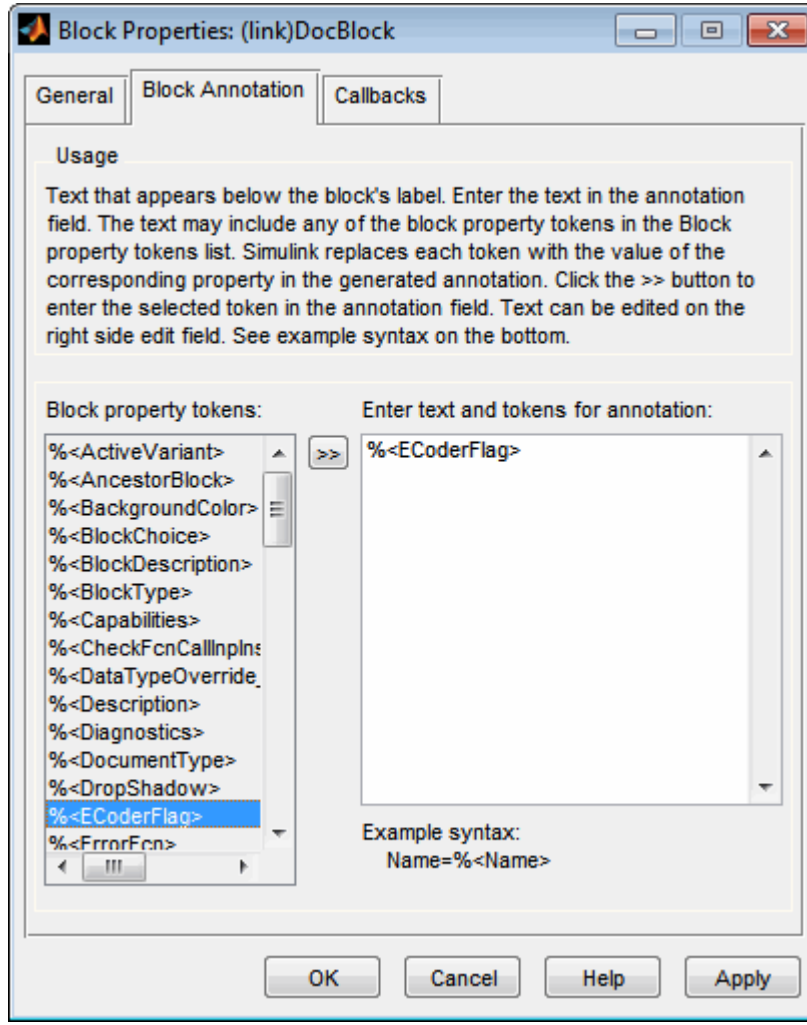
- `Notes`

Click **OK**. Template symbol names are case sensitive.

If you are using a DocBlock to add comments to your code, set the **Document type** to `Text`. If you set **Document type** to `RTF` or `HTML`, your comments will not appear in the code.



6 In the Block Properties dialog box, on the **Block Annotation** tab, select `%<ECoderFlag>` and click **OK**. The symbol name that you typed in the previous step now appears under the DocBlock in the model.



7 Save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

8 To add more comments to the generated files, repeat steps 1–7.

Use a Simulink Annotation to Add a Comment

1. Double-click the unoccupied area on the model where you want to place the comment. See "Describe Models Using Annotations" (Simulink).
2. Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:

   - `Abstract`
   - `Description`
   - `History`
   - `ModifiedHistory`
   - `Notes`

   For example, type `<S:Description>This is the description I want`. Template symbol names are case sensitive. (The `"S"` before the colon indicates "symbol.") If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with "Use Sorted Notes to Add Comments" on page 36-12.
3. Click outside the rectangle and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with "Use Sorted Notes to Add Comments" on page 36-12.
4. To add one or more other comments to the generated files, repeat steps 1–3.

Use a Stateflow Note to Add a Comment

1. Right-click the unoccupied area on the Stateflow chart where you want to place the comment.
2. Select the annotation icon from the palette.
3. Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:

   - `Abstract`
   - `Description`

- `History`
- `ModifiedHistory`
- `Notes`

For example, type `<S:Description>This is the description I want`. Template symbol names are case sensitive. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with "Use Sorted Notes to Add Comments" on page 36-12.

4 Click outside the note and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

5 To add one or more other comments to the generated files, repeat steps 1–4.

Use Sorted Notes to Add Comments

The sorted-notes capability allows you to add automatically sorted comments to the generated files. The code generator places these comments in each generated file at the location that corresponds to where the `Notes` symbol is located in the template file.

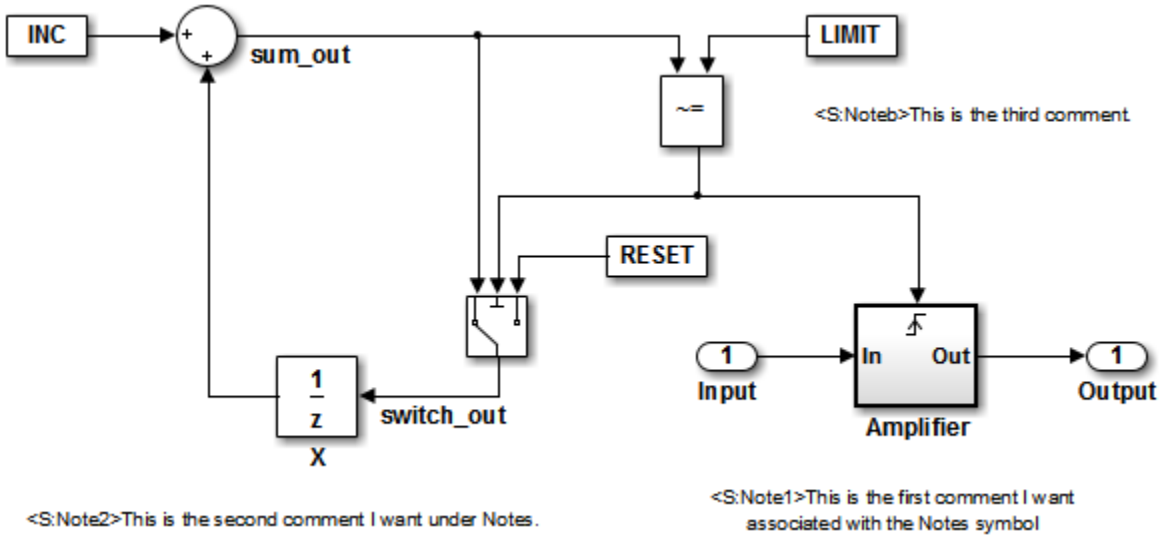
The code generator uses the following sorting order:

- Numbers before letters.
- Among numbers, 0 is first.
- Among letters, uppercase are before lowercase.

You can use sorted notes with a Simulink annotation or a Stateflow note, but not with a DocBlock.

- In the Simulink annotation or the Stateflow note, type `<S:NoteY>` followed by the first comment. `Y` is a number or a letter.
- Repeat for as many additional comments you want. Replace `Y` with a subsequent number or letter.

The figure illustrates sorted notes on a model, and where the code generator places each note in a generated file.



The relevant fragment from the generated file for this model is:

```
** NOTES

** Note1: This is the first comment I want
associated with the Notes symbol.
Note2: This is the second comment I want under Notes.
Noteb: This is the third comment.

**
```

Specify Comment Style

For ERT-based models, the comment style used in generated code is determined by the programming language selected for the model:

- C code uses `/*...*/` notation for both single-line and multiple-line comments.
- C++ code uses `//...` notation and contains only single-line comments.

If you have an Embedded Coder license, you can modify the comment style for generated code using the command-line parameter `CommentStyle`. The parameter takes the following values:

Value	Description
`Auto` (default)	For C, generate single or multiple-line comments delimited by `/*` and `*/`. For C++, generate single-line comments preceded by `//`.
`Multi-line`	Generate single or multiple-line comments delimited by `/*` and `*/`.
`Single-line`	Generate single-line comments preceded by `//`.

For example, the following command sets the comment style to single-line comments:

```
>> set_param('rtwdemo_counter','CommentStyle','Single-line')
```

Here is an example of code generated using the single-line comment style:

```
// Sum: '<Root>/Sum' incorporates:
//   Constant: '<Root>/INC'
//   UnitDelay: '<Root>/X'

rtb_sum_out = (uint8_T)(1U + rtwdemo_counter_DW.X);
```

Note: For C code generation, select `Single-line` only if your compiler supports it

Customize Generated Identifier Naming Rules

In this section...

For GRT and RSim targets, the code generator constructs identifiers for variables and functions in the generated code. For ERT targets, you can customize the naming of identifiers in the generated code by specifying parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box. You can also specify parameters that control identifiers generated from Simulink data objects. For detailed information about these parameters, see “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder).

Apply Naming Rules to Identifiers Globally

Goal	Specify
Set the maximum number of characters that the code generator uses for function, `typedef`, and variable names (default 31) .	An integer value for the “Maximum identifier length” (Simulink Coder) parameter. For more information, see “Specify Identifier Length to Avoid Naming Collisions” (Simulink Coder). If you expect your model to generate lengthy identifiers (due to use of long signal or parameter names, for example), or if identifiers are mangled more than you expect, increase the value of this parameter.
Define a macro that specifies certain text included within generated identifiers for: • Global variables • Global types • Field names of global types • Subsystem methods • Subsystem method arguments • Local temporary variables • Local block output variables	A macro for the **Identifier format control** parameters. For more information, see “Identifier Format Control” on page 36-22. See also “Exceptions to Identifier Formatting Conventions” on page 36-33 and “Identifier Format Control Parameters Limitations” on page 36-34.

Goal	Specify
• Constant macros • Shared utilities	
Set the minimum number of characters that the code generator uses for the mangling text.	An integer value for the "Minimum mangle length" (Simulink Coder) parameter. For more information, see "Control Name Mangling in Generated Identifiers" on page 36-28
Control whether the software uses shortened names for system-generated identifiers.	`Shortened` for the "System-generated identifiers" (Simulink Coder) parameter. This setting: • Provides more space for user names. • Provides a more predictable and consistent naming system that uses camel case. • Does not include underscores or plurals. • Provides consistent abbreviations for both a type and a variable.
Control whether the generated code expresses scalar inlined parameter values as literal values or as macros.	The value `Literals` or `Macros` for the "Generate scalar inlined parameters as" (Simulink Coder) parameter. • `Literals`: If you set **Default parameter behavior** to `Inlined`, parameters are expressed as numeric constants. • `Macros`: Parameters are expressed as variables (with `#define` macros). This setting makes code more readable.

Apply Naming Rules to Simulink Data Objects

When your model uses Simulink data objects from the `Simulink` package, identifiers in generated code copy the names of the objects by default. For example, a `Simulink.Signal` object named `Speed` appears as the identifier `Speed` in generated code.

You can control these identifiers by specifying naming rules that are specific to Simulink data objects. On the **Code Generation > Symbols** pane of the Configuration

Parameters dialog box, adjust the settings in the **Simulink data object naming rules** section .

When you specify naming rules for generated code, follow ANSI C[5]/C++ rules for naming identifiers.

Specify Naming Rule Using a Function

This example shows how to customize identifiers in generated code by defining a MATLAB function.

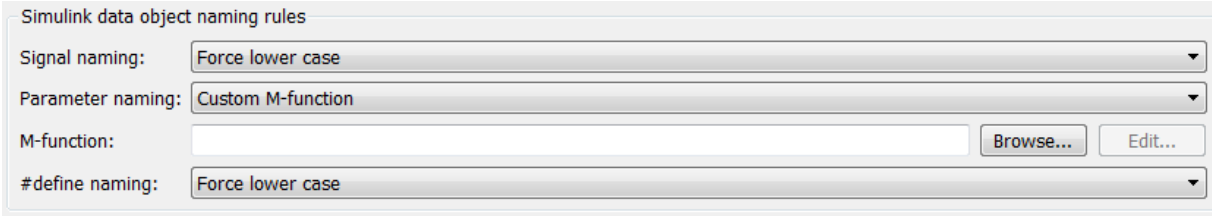
1. Write a MATLAB function that returns an identifier by modifying a data object name, and save the function in your working folder. For example, the following function returns an identifier name by appending the text `_param` to a data object name.

```
function revisedName = append_text(name, object)
% APPEND_TEXT: Returns an identifier for generated
% code by appending text to a data object name.
%
% Input arguments:
% name: data object name as spelled in model
% object: target data object
%
% Output arguments:
% revisedName: altered identifier returned for use in
% generated code.
%
%
text = '_param';

revisedName = [name,text];
```

2. Open the model `rtwdemo_namerules`.
3. Double-click the yellow box labeled **View Symbols Configuration** to open the **Code Generation** > **Symbols** pane in the Configuration Parameters dialog box.
4. From the **Parameter naming** (Simulink Coder) drop-down list, select **Custom M-function**.

5. ANSI is a registered trademark of the American National Standards Institute, Inc.



5 In the **M-function** field, type the name of the file that defines the MATLAB function, `append_text.m`.

6 Click **Apply**.

7 Generate code for the model.

8 Inspect the code generation report to confirm the parameter object naming rule. For example, the generated file `rtwdemo_namerules.h` represents the parameter objects `G1`, `G2`, and `G3` with the variables `G1_param`, `G2_param`, and `G3_param`.

Specify Naming Rule for Storage Class `Define`

You can specify a naming rule that applies only to Simulink data objects whose storage class you set to `Define`. For these data objects, the specified naming rule overrides the other parameter and signal object naming rules. On the **Code Generation > Symbols** pane in the Configuration Parameters dialog box, adjust the **#define naming** (Simulink Coder) setting.

Override Data Object Naming Rules

This example shows how to override a data object naming rule for a single data object.

You can override data object naming rules by specifying the `Alias` property of an individual Simulink data object. Generated code uses the text that you specify as the identifier to represent the data object, regardless of naming rules.

1 Open the model `rtwdemo_namerules`.
