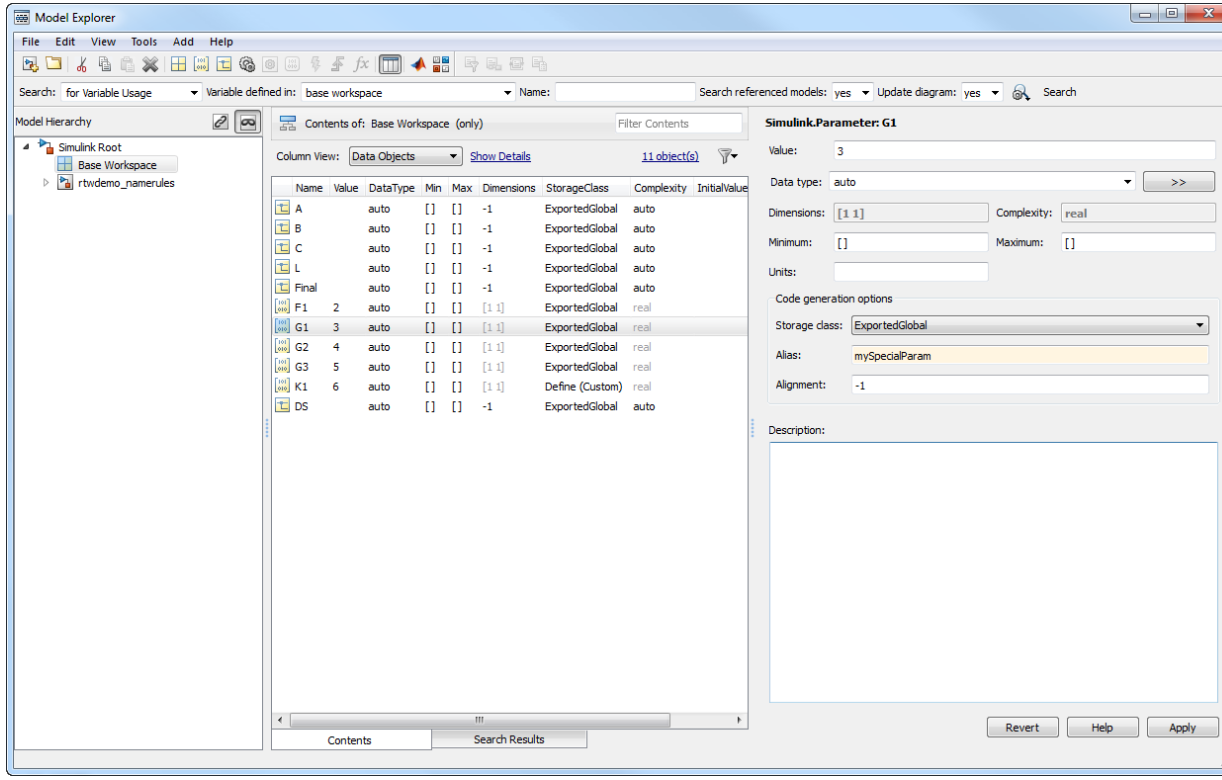
2 Open Model Explorer and navigate to the base workspace.

3 Click the parameter object `G1` and specify the `Alias` property as `mySpecialParam`. Click **Apply**.



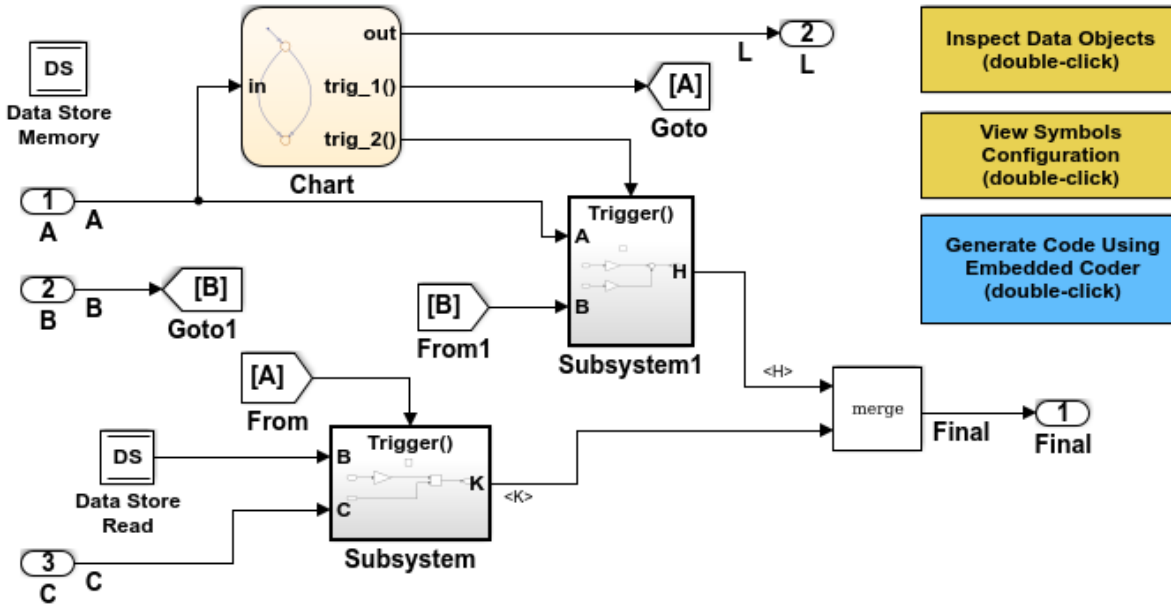
4 Generate code for the model.

5 In the code generation report, confirm the alias for the parameter object `G1`. The generated file `rtwdemo_namerules.h` represents `G1` with the variable `mySpecialParam`.

Apply Custom Naming Conventions to Identifiers

This example shows how to apply uniform naming rules for Simulink® data objects, including signals, parameters, and data store memory variables.

```
model='rtwdemo_namerules';
open_system(model)
```



Description
Many organizations employ coding standards that include naming rules for variables. This model shows how to apply uniform naming rules for Simulink data objects, including signals, parameters, and data store memory variables. Predefined conventions exist to apply upper and lower case naming, and arbitrary custom rules can be defined in a user-supplied MATLAB script.

Instructions
1. Double-click the yellow View Symbols Configuration button to inspect the "Simulink data object naming rules."
2. Double-click the yellow Inspect Data Objects button to inspect the data objects for this model.
3. Generate code using the blue button in the upper right of the diagram. An HTML report automatically appears.
4. Inspect the data that is defined toward the top of rtwdemo_namerules.c.

Note
The model is configured to "Force lower case." Therefore, the variables in the code are defined in lower case even though the data is declared upper case in the model.

```
% Cleanup
rtwdemoclean;
```

```
close_system(model,0)
```

Identifier Format Control

You can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box. For each parameter, you can enter a macro that specifies whether, and in what order, certain text is included within generated identifiers. For example, you can specify that the root model name be inserted into each identifier using the `$R` token.

The macro can include:

- Valid tokens, which are listed in Identifier Format Tokens. You can use or omit tokens depending on what you want to include in the identifier name. The **Shared utilities** parameter requires you to specify the checksum token, `$C` . The other parameters require the mangling token, `$M`. For more information, see "Control Name Mangling in Generated Identifiers" on page 36-28. The mangling token is subject to the use and ordering restrictions noted in Identifier Format Control Parameter Values.
- Token decorators, which are listed in "Control Case with Token Decorators" on page 36-25. You can use token decorators to control the case of generated identifiers for each token.
- Valid C or C++ language identifier characters (`a-z, A-Z, _ , 0-9`).

The build process generates each identifier by expanding tokens and inserting the resultant text into the identifier. The tokens are expanded in the order listed in Identifier Format Tokens. Groups of characters are inserted in the positions that you specify around tokens directly into the identifier. Contiguous token expansions are separated by the underscore (_) character.

Identifier Format Tokens

Token	Description
`$C`	This token is required for **Shared utilities**. If the identifier exceeds the **Maximum identifier length**, the code generator inserts an 8-character checksum to avoid naming collisions. The position of the `$C` token in the **Identifier format control** parameter specification determines the position of the checksum in the generated identifier. For example, if you use the specification `$N$C`, the checksum is appended to the end of the identifier. This token is available only for shared utilities.
`$M`	This token is required. If necessary, the code generator inserts name-mangling text to avoid naming collisions. The position of the `$M` token

Token	Description
	in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifier. For example, if you use the specification `$R$N$M`, the name-mangling text is appended (if required) to the end of the identifier. For more information, see "Control Name Mangling in Generated Identifiers" on page 36-28 .
`$U`	Insert text that you specify for the `$U` token. Use the **Custom token text** parameter to specify this text. This parameter is on the **All Parameters** tab of the Configuration Parameters dialog box. See "Custom token text".
`$F`	Insert method name (for example, `_Update` for update method). This token is available only for subsystem methods.
`$N`	Insert name of object (block, signal or signal object, state, parameter, shared utility function or parameter object) for which identifier is being generated.
`$R`	Insert root model name into identifier, replacing unsupported characters with the underscore (_) character. When you use referenced models, this token is required in addition to `$M` (see "Avoid Identifier Name Collisions with Referenced Models" on page 36-30). **Note:** This token replaces the **Prefix model name to global identifiers** option in previous releases.
`$H`	Insert tag indicating system hierarchy level. For root-level blocks, the tag is the text `root_`. For blocks at the subsystem level, the tag is of the form `sN_`. `N` is a unique system number assigned by the Simulink software. This token is available only for subsystem methods and field names of global types. **Note:** This token replaces the **Include System Hierarchy Number in Identifiers** option in previous releases.
`$A`	Insert data type acronym (for example, `i32` for integers) to signal and work vector identifiers. This token is available for local block output variables, local temporary variables, and field names of global types. **Note:** This token replaces the **Include data type acronym in identifier** option in previous releases.
`$I`	• Insert `u` if the argument is an input.

Token	Description
	• Insert `y` if the argument is an output. • Insert `uy` if the argument is an input and output. For example, `rtu_` for an input argument, `rty_` for an output argument, and `rtuy_` for an input and output argument. This token is available only for subsystem method arguments.

Identifier Format Control Parameter Values lists the default macro value, the supported tokens, and the applicable restrictions for each **Identifier format control** parameter.

Identifier Format Control Parameter Values

Parameter	Default Value	Supported Tokens	Restrictions
Global variables (Simulink Coder)	`rt$N$M`	`$R`, `$N`, `$M`,`$U`	`$F`, `$H`, `$A`, and `$I` are not allowed.
Global types (Simulink Coder)	`$N$R$M_T`	`$N`, `$R`, `$M`, `$U`	`$F`, `$H`, `$A`, and `$I` are not allowed.
Field name of global types (Simulink Coder)	`$N$M`	`$N`, `$M`, `$H`, `$A`, `$U`	`$R`, `$F`, and `$I` are not allowed.
Subsystem methods (Simulink Coder)	`$F$N$M`	`$R`, `$N`, `$M`, `$F`, `$H`, `$U`	`$F` and `$H` are empty for Stateflow functions; `$A` and `$I` are not allowed.
Subsystem method arguments (Simulink Coder)	`rt$I$N$M`	`$N`, `$M`, `$I`, `$U`	`$R`, `$F`, `$H`, and `$A` are not allowed.
Local temporary variables (Simulink Coder)	`$N$M`	`$N`, `$M`, `$R`, `$A`, `$U`	`$F`, `$H`, and `$I` are not allowed.
Local block output variables (Simulink Coder)	`rtb_$N$M`	`$N`, `$M`, `$A`, `$U`	`$R`, `$F`, `$H`, and `$I` are not allowed.
Constant macros (Simulink Coder)	`$R$N$M`	`$R`, `$N`, `$M`, `$U`	`$F`, `$H`, `$A`, and `$I` are not allowed.

Parameter	Default Value	Supported Tokens	Restrictions
Shared utilities	`$N$C`	`$N`, `$C`, `$N`, `$U`	`$C` is required. `$M`, `$F`, `$H`, `$A` , and `$I` are not allowed.
EMX array utility functions identifier format (Simulink Coder)	`emx$M$N`	`$M`, `$N`,`$R`	`$C`, `$U`, `$F`, `$H`, `$A` , and `$I` are not allowed.
EMX array types identifier format (Simulink Coder)	`emxArray_ $M$N`	`$M`, `$N`,`$R`	`$C`, `$U`, `$F`, `$H`, `$A` , and `$I` are not allowed.

Non-ERT-based targets (such as the GRT target) implicitly use a default `$R$N$M` specification. This default specification consists of the root model name, followed by the name of the generating object (signal, parameter, state, and so on), followed by name-mangling text.

For limitations that apply to **Identifier format control** parameters, see "Exceptions to Identifier Formatting Conventions" on page 36-33 and "Identifier Format Control Parameters Limitations" on page 36-34.

Control Case with Token Decorators

On the **Code Generation > Symbols** pane, you can use token decorators to control the case of generated identifiers. Place a decorator immediately after the target token and enclose the decorator in square brackets `[ ]`. For example, you can set **Global variables** to `$R[uL]$N$M`, which capitalizes the first letter of the model name and forces the remaining characters in the model name to lowercase.

The table shows how to manipulate the expansion of the `$R` token for a model whose name is `modelName`.

Desired Expansion	Description	Token and Decorator
`ModelName`	First letter of model name is uppercase. Remaining characters are not modified.	`$R[u]`

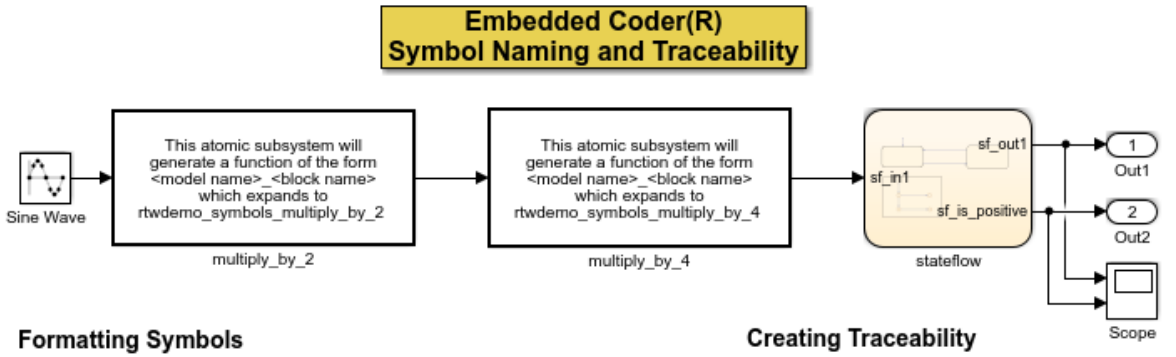
Desired Expansion	Description	Token and Decorator
`Modelname`	First letter of model name is uppercase. Remaining characters are lowercase.	`$R[uL]`
`MODELNAME`	All characters are uppercase.	`$R[U]`
`modelname`	All characters are lowercase.	`$R[L]`
`mODELNAME`	First letter of model name is lowercase. Remaining characters are uppercase.	`$R[lU]`
`modelName`	First letter of model name is lowercase. Remaining characters are not modified.	`$R[l]`

When you use a decorator, the code generator removes the underscore character (_) that appears between tokens by default. However, you can append each decorator with an underscore: `$R[U_]$N`. For example, if you set the **Global variables** parameter to `$R[u_]$N[uL]$M` for a model named `modelName` and a `DWork` structure represented by `DW`, the result is `ModelName_Dw`.

Control Formatting of Identifiers

This example shows how you can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box.

```
model='rtwdemo_symbols';
open_system(model)
```



Formatting Symbols

Symbols in Embedded Coder(R) can be formatted via the "Identifier format control" option group. These options can be composed of predefined macros and C-language literal characters.

Common macros include
- **$R** = Root model name
- **$N** = Name of object (block, signal, state, etc.)
- **$M** = Mangle used to uniquify symbol

For a complete list of macros and the rules by which they are expanded, see the Symbol format help link below.

Different identifier format control strings control different types of identifiers. Double-click the yellow buttons at the bottom to modify the format control strings for global variable names and global type names. Double-click the blue button to generate and inspect code for the change.

Double-click to view symbol format

Double-click to view symbol format help

Global variable names contain model name. (double-click to toggle)

Global structure type names contain model name. (double-click to toggle)

Creating Traceability

One aspect of traceability is making sure that incremental revisions to a model have minimal impact on the symbol names that appear in generated code. There are two ways of achieving this in Simulink:

1) Name objects in Simulink (blocks, signals, states, etc.) as uniquely as possible.
2) Make use of name mangling when conflicts cannot be avoided.

For a complete discussion of how name mangling can be used to create traceable code, see the help link below.

Double-click to view mangle settings

Double-click to view traceability help

Generate Code Using Embedded Coder (double-click)

```
% Cleanup
rtwdemoclean;
close_system(model,0)
```

Control Name Mangling in Generated Identifiers

The position of the `$M` token in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifiers. For example, if you use the specification `$R$N$M`, the name-mangling text is appended (if required) to the end of the identifier. For more information, see "Identifier Format Control" on page 36-22.

Name-Mangling Text Per Object

Object Type	Source of Mangling Text
Block diagram	Name of block diagram
Simulink block	Simulink identifier (for details, see "Locate Diagram Components Using Simulink Identifiers" (Simulink))
Simulink parameter	Full name of parameter owner (model or block) and parameter name
Simulink signal	Signal name, full name of source block, and port number
Stateflow objects	Complete path to Stateflow block and Stateflow computed name (unique within chart)

The length of the name-mangling text is specified by the **Minimum mangle length** (Simulink Coder) parameter. The default value is `1`, but this automatically increases during code generation as a function of the number of collisions. To minimize disturbance to the generated code during development, specify a larger **Minimum mangle length**. A **Minimum mangle length** of `4` is a conservative value. A value of `4` allows for over 1.5 million collisions for a particular identifier before the mangle length is increased.

Minimize Name Mangling

The length of generated identifiers is limited by the **Maximum identifier length** (Simulink Coder) parameter. When a name collision exists, the `$M` token is expanded to the minimum number of characters required to avoid the collision. Other tokens are expanded in the order listed in Identifier Format Tokens. If the **Maximum identifier length** is not large enough to accommodate full expansions of the other tokens, partial expansions are used. To avoid partial expansions, it is good practice to:

- Avoid name collisions. One way to avoid name collisions is to not use default block names (for example, `Gain1`, `Gain2...`) when there are many blocks of the same type in the model.

- Where possible, increase the **Maximum identifier length** to accommodate the length of the identifiers that you expect to generate.
- Set the **Maximum identifier length** parameter to reserve at least three characters for the name-mangling text. The length of the name-mangling text increases as the number of name collisions increases.

  If changes to the model create more or fewer collisions, existing name-mangling text increases or decreases in length. If the length of the name-mangling text increases, additional characters are appended to the existing text. For example, the mangling text `'xyz'` can change to `'xyzQ'`. For fewer collisions, the name-mangling text `'xyz'` changes to `'xy'`.

Avoid Identifier Name Collisions with Referenced Models

Within a model that uses referenced models, collisions between the names of the models are not allowed. When generating code from a model that uses model referencing:

- You must include the `$R` token in the **Identifier format control** parameter specifications (in addition to the `$M` token).
- The **Maximum identifier length** must be large enough to accommodate full expansions of the `$R` and `$M` tokens. If **Maximum identifier length** is too small, a code generation error occurs.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

If your model contains two referenced models with the same input or output port names, and one of the referenced models contains an atomic subsystem with "Function packaging" (Simulink) set to `Nonreuseable function`, a name conflict can occur and the build process produces an error.

Use Model Advisor to Detect Identifier Names Changed During Code Generation

For a referenced model, if the following **Configuration Parameters > Code Generation > Symbols** parameters have settings that do not contain a `$R` token (which represents the name of the reference model), code generation prepends the `$R` token to the identifier format.

- **Global variables**
- **Global types**
- **Subsystem methods**
- **Constant macros**

You can use the Model Advisor to identify referenced models in a model referencing hierarchy for which code generation changes these configuration parameter settings.

1. In the Simulink Editor, select **Analysis > Model Advisor**.
2. Select **By Task**.

3 Run the **Check code generation identifier formats used for model reference** check.

Maintain Traceability for Generated Identifiers

To verify your model, you can trace back and forth between generated identifiers and corresponding entities within the model. To maintain traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in generated code. There are two ways to minimally impact the identifier names:

- Choose unique names for Simulink objects (blocks, signals, states, and so on) as much as possible.
- Use name mangling when conflicts cannot be avoided.

The position of the name-mangling text is specified by the placement of the `$M` token in the **Identifier format control** parameters. Mangle characters consist of alphanumeric characters that are unique to each object. For more information, see “Control Name Mangling in Generated Identifiers” on page 36-28.

Exceptions to Identifier Formatting Conventions

There are some exceptions to the identifier formatting conventions described in "Identifier Format Control" on page 36-22.

- Type name generation: name mangling conventions do not apply to type names (that is, `typedef` statements) generated for global data types. If the `$R` token is included in the **Identifier format control** parameter specification, the model name is included in the `typedef`. When generating type definitions, the **Maximum identifier length** parameter is not respected.
- Non-`Auto` storage classes: the **Identifier format control** parameters specification does not affect objects (such as signals and parameters) that have a storage class other than `Auto` (such as `ImportedExtern` or `ExportedGlobal`).
- For shared utilities, code generation inserts the checksum specified by `$C` to prevent name collisions in the following situations:
  - `$C` is specified without `$N`.
  - The length of `$N` plus the length of the text that you specify exceeds the **Maximum identifier length**. Code generation truncates `$N` and inserts an 8-character checksum where you specified `$C` in the formatting scheme.

.

Identifier Format Control Parameters Limitations

The following limitations apply to the **Identifier format control** parameters:

- The following autogenerated identifiers currently do not fully comply with the setting of the **Maximum identifier length** parameter on the **Code Generation > Symbols** pane of the Configuration Parameters dialog box.
  - Model methods
    - The applicable format scheme is `$R$F`, and the longest `$F` is `_derivatives`, which is 12 characters long. The model name can be up to 19 characters without exceeding the default **Maximum identifier length** of 31.
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - `DW` identifiers generated by S-functions in referenced models
  - Fixed-point shared utility macros or shared utility functions
  - Simulink `rtm` macros
    - Most are within the default **Maximum identifier length** of 31, but some exceed the limit. Examples are `RTMSpecAccsGetStopRequestedValStoredAsPtr`, `RTMSpecAccsGetErrorStatusPointer`, and `RTMSpecAccsGetErrorStatusPointerPointer`.
  - Define protection guard macros
    - Header file guards, such as `_RTW_HEADER_$(filename)_h_`, which can exceed the default **Maximum identifier length** of 31 given a filename such as `$R_private.h`.
    - Include file guards, such as `_$R_COMMON_INCLUDES_`.
    - `typedef` guards, such as `_CSCI_$R_CHARTSTRUCT_`.
- In some situations, the following identifiers potentially can conflict with others.
  - Model methods
  - Reentrant model function arguments

  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Fixed-point shared utility macros or shared utility functions
  - Include header guard macros
- The following external identifiers that are unknown to the Simulink software might conflict with autogenerated identifiers.
  - Identifiers defined in custom code
  - Identifiers defined in custom header files
  - Identifiers introduced through a non-ANSI C standard library
  - Identifiers defined by custom TLC code
- Identifiers generated for simulation targets might exceed the **Maximum identifier length**. Simulation targets include the model reference simulation target, the accelerated simulation target, the RSim target, and the S-function target.
- Identifiers generated using a model name and bus object data type name, which are both long names, might exceed the **Maximum identifier length**. For example, a ground value variable name is generated as <*model_name*>`_rtZ`<*bus_name*>. If the *model_name* and *bus_name* are close to the maximum identifier length, the name exceeds the maximum identifier length.

Control Code Style

In this section...

You can change the code style, cast expressions, and indentation of your generated code to conform to certain coding standards. Modify style options by setting parameters on the **Code Generation > Code Style** pane.

In the generated code, you can control the following style aspects:

- Level of parenthesization, see “Control Parentheses in Generated Code” on page 36-37.
- Order of operands in expressions, see “Optimize Code by Reordering Commutable Operands” on page 36-39.
- Empty primary condition expressions in `if` statements, see “Preserve condition expression in if statement”.
- Whether to generate code for `if-elseif-else` decision logic as `switch-case` statements, see “Convert if-elseif-else patterns to switch-case statements”.
- Whether to include the `extern` keyword in function declarations, see “Preserve extern keyword in function declarations”.
- Whether to generate `default` cases for `switch-case` statements in the code for Stateflow charts, see “Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements” on page 36-40.
- Whether to replace multiplications by powers of two with signed bitwise shifts, see “Replace Multiplication by Powers of Two with Signed Bitwise Shifts” on page 36-43. Whether to allow right shifts on signed integers, see “Generate Code with Right Shifts on Signed Integers” on page 36-45. Some coding standards, such

as MISRA, do not allow bitwise operations on signed integers. Clearing this option increases the likelihood of generating MISRA C:2012 compliant code.

- Cast expressions, see “Control Cast Expressions in Generated Code” on page 36-48.
- Indentation style, see “Control Indentation Style in Generated Code” on page 36-46.

Control Parentheses in Generated Code

C code contains some syntactically required parentheses, and can contain additional parentheses that change semantics by overriding default operator precedence. C code can also contain optional parentheses that have no functional significance, but only increase the readability of the code. Optional C parentheses vary between two stylistic extremes:

- Include the minimum parentheses required by C syntax and precedence overrides so that C precedence rules specify all semantics unless overridden by parentheses.
- Include the maximum parentheses that can exist without duplication so that C precedence rules become irrelevant. Parentheses alone completely specify all semantics.

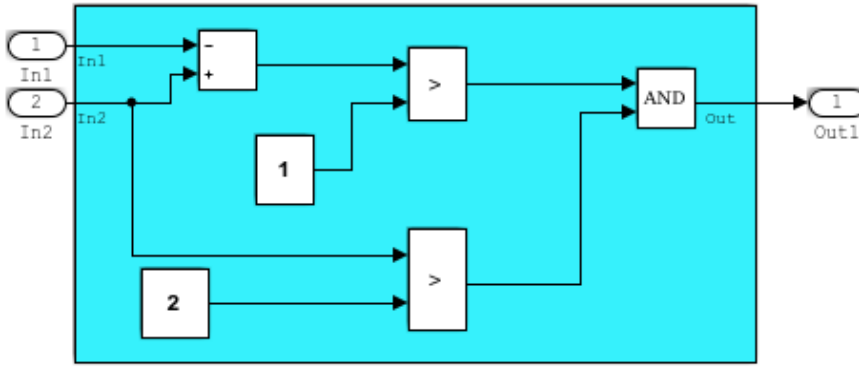
Understanding code with minimum parentheses can require applying nonobvious precedence rules. Maximum parentheses can hinder code reading by belaboring obvious precedence rules. Various parenthesization standards exist that specify one or the other extreme, or define an intermediate style useful to people who read code.

For more information on this parameter, see “Parentheses level”.

Control Use of Parentheses

This example shows that Embedded Coder® provides three levels of control for parentheses in the generated code.

```
model='rtwdemo_parentheses';
open_system(model)
```



View Code Style Configuration (double-click)

Generate Code Using Embedded Coder (double-click)

Parentheses level "Minimum": `Out = In2 - In1 > 1.0 && In2 > 2.0;`

Parentheses level "Nominal": `Out = ((In2 - In1 > 1.0) && (In2 > 2.0));`

Parentheses level "Maximum": `Out = (((In2 - In1) > 1.0) && (In2 > 2.0));`

Description
Embedded Coder(R) provides three levels of control for parentheses in the generated code. The control level "Minimum" generates the most compact code, with the smallest number of parentheses allowed under C syntax rules. The control level "Nominal" adds parentheses as needed to optimize readability. The control level "Maximum" generates the largest number of parentheses. The parentheses explicitly define the sequence of operations in an expression without relying on C precedence rules. Specifying control level "Maximum" provides full compliance with the MISRA-C(TM) standard.

Instructions
1. View and set the parentheses level by double-clicking the yellow button to the right.
2. Generate code by double-clicking the blue button to the right.
   An HTML report is displayed automatically.
3. Inspect the generated source files, comparing them with the three code examples above.

```
rtwdemoclean;
```

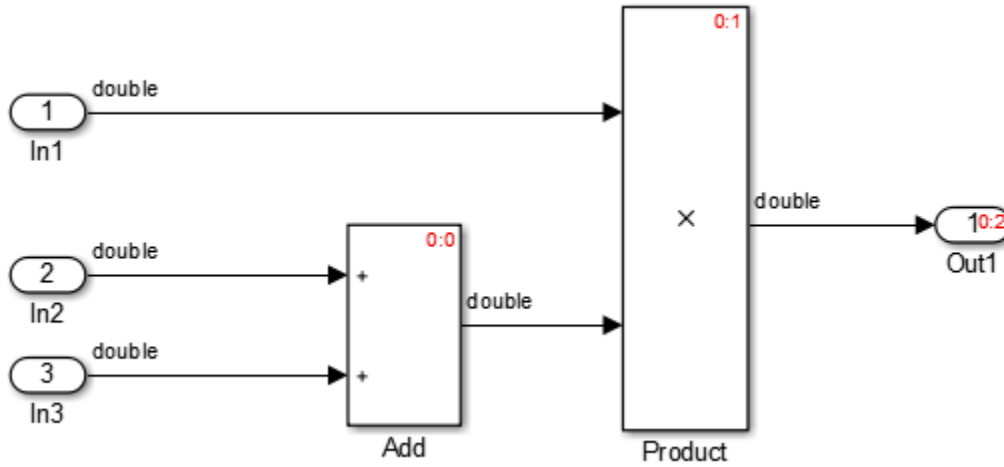
```
close_system(model,0)
```

Optimize Code by Reordering Commutable Operands

This example shows how to reorder commutable operands to make expressions left-recursive. This optimization improves code efficiency.

Example Model

To reorder commutable operands, create the following model and name it `operand_order`. In this model, the output signal is the result of multiplying the signal from Inport block `In1` by the sum of the signals from Inport blocks `In2` and `In3`.



Generate Code

1. Open the Model Configuration Parameters dialog box. On the **Code Style** tab, select the **Preserve operand order in expression** parameter.
2. Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```
operand_order_Y.Out1 = operand_order_U.In1 * (operand_order_U.In2 +
```

```
    operand_order_U.In3);
```

The code generator preserves the specified expression order in the model. Preserving the specified expression order increases the readability of the code for code traceability purposes.

Generate Code with Optimization

1. Open the Model Configuration Parameters dialog box. On the **Code Style** tab, clear the **Preserve operand order in expression** parameter.
2. Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```
operand_order_Y.Out1 = (operand_order_U.In2 + operand_order_U.In3) *
    operand_order_U.In1;
```

The code generator optimizes the code by reordering the commutable operands to make the expression left-recursive. Left-recursive expressions improve code efficiency.

For more information on the **Preserve operand order in expression** parameter, see "Preserve operand order in expression".

Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements

This example shows how to specify whether to generate default cases for switch-case statements in the code for Stateflow charts. Generated code that does not contain default cases conserves ROM consumption and enables better code coverage because every branch in the generated code is falsifiable.

Some coding standards, such as MISRA, require the default case for switch-case statements. If you want to increase your chances of producing MISRA C compliant code, generate default cases for unreachable Stateflow switch statements.

Example

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The Air-fuel rate controller logic is a Stateflow chart that specifies the different operation modes.

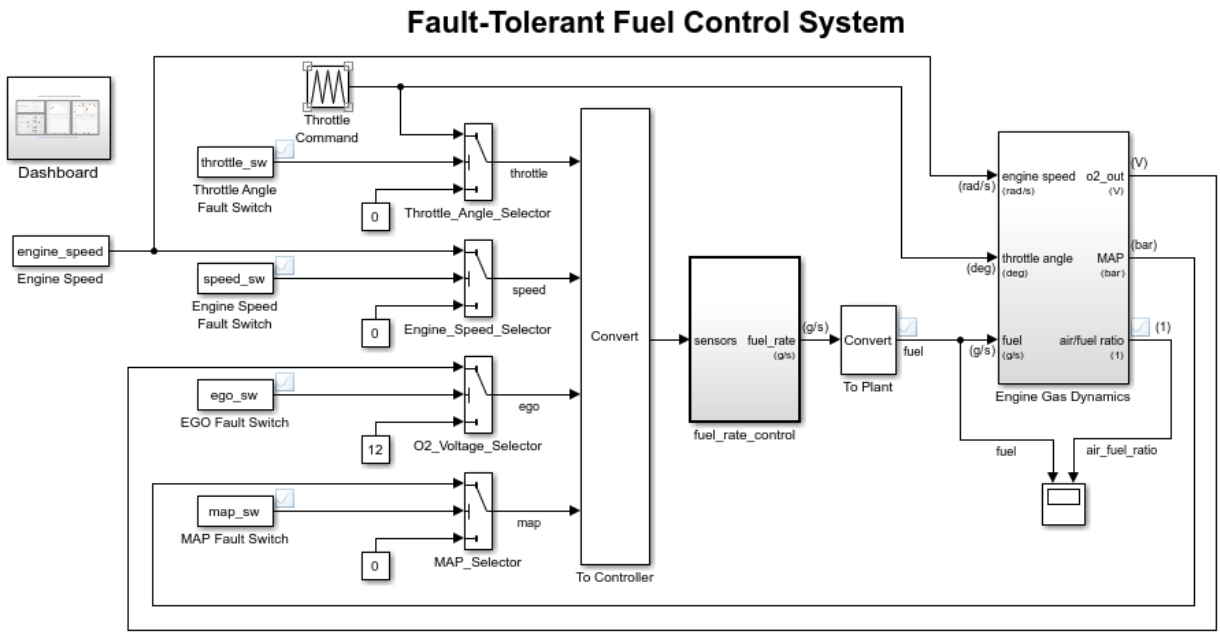


Figure 1: Top-level model of the plant and controller

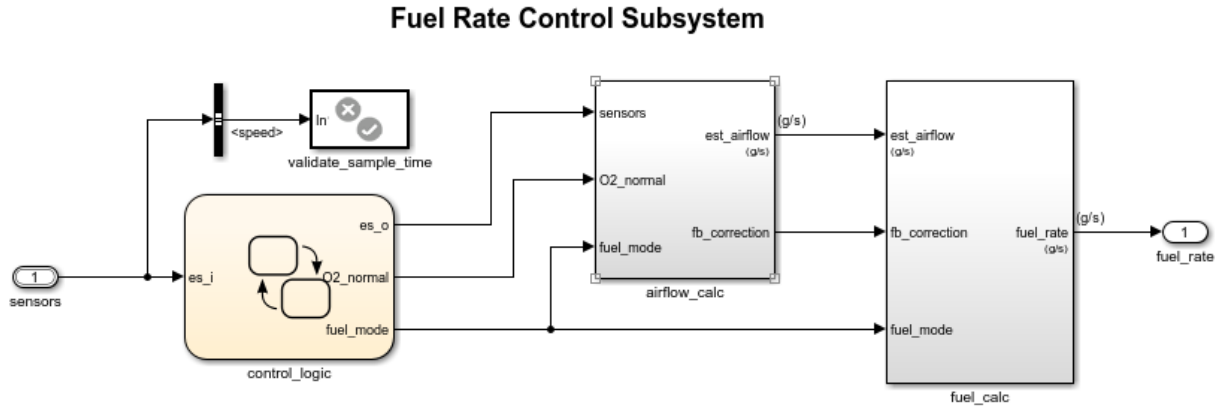

Figure 2: Fuel rate controller subsystem

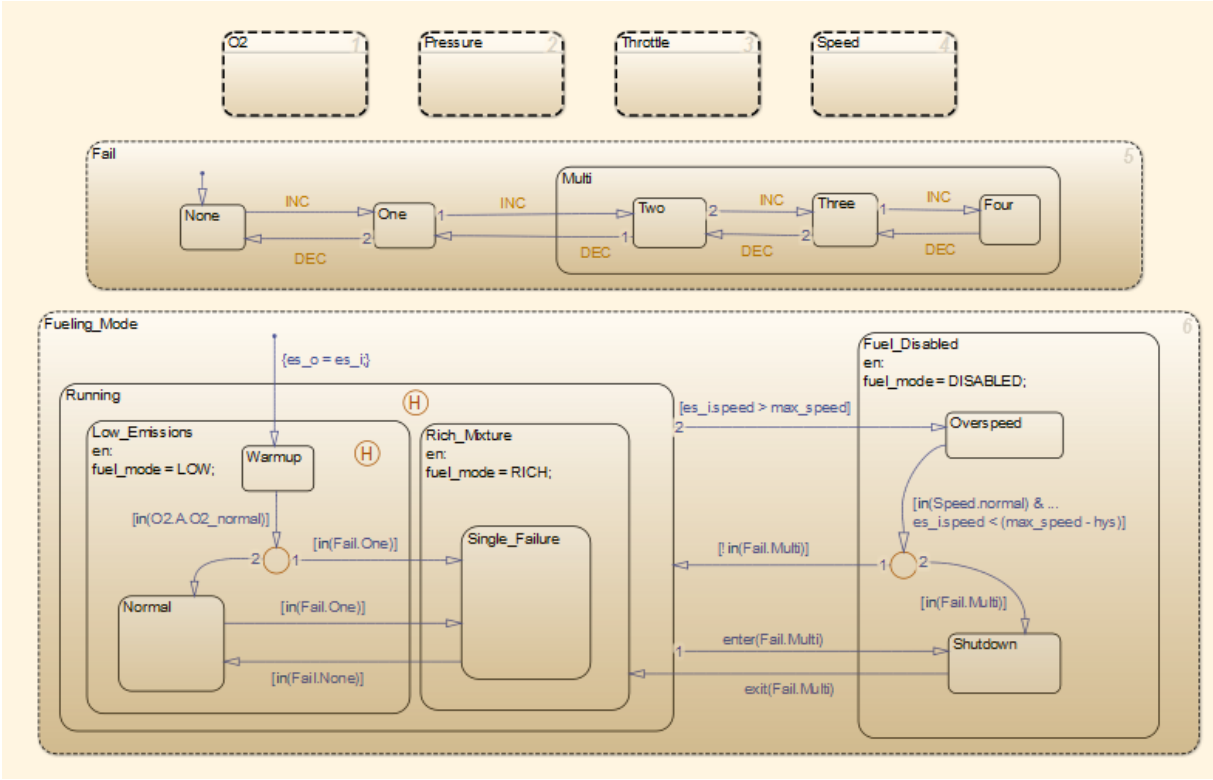

Figure 3: Fuel rate controller logic

Generate Code with Default Cases for Unreachable Stateflow Switch Statements

1. In the MATLAB Command Window, to open `sldemo_fuelsys` via `rtwdemo_fuelsys` enter:

   ```
   rtwdemo_fuelsys
   ```

2. Open the Model Configuration parameters dialog box. On the **Code Generation** > **Code Style** tab, clear the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.

3. In the MATLAB Command Window, to build the model, enter:

   ```
   rtwbuild('sldemo_fuelsys/fuel_rate_control');
   ```

For the different operation modes, the `fuel_rate_control.c` file contains default cases for unreachable switch statements. For example, for the Shutdown operation mode, the generated code contains this default statement:

```
default:
 /* Unreachable state, for coverage only */
 rtDWork.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
 break;
```

For the Warmup operation mode, the generated code contains this default statement:

```
default:
 /* Unreachable state, for coverage only */
 rtDWork.bitsForTID0.is_Low_Emissions = IN_NO_ACTIVE_CHILD;
 break;
```

Suppress Default Cases for Unreachable Stateflow Switch Statements

1. Open the Configuration Parameters dialog box. On the **Code Generation** > **Code Style** tab, select the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.
2. Build the model.

Read through the `fuel_rate_control.c` file. The default cases for unreachable switch statements are not in the generated code.

For more information on the **Suppress generation of default cases for Stateflow statements if unreachable** parameter, see "Suppress generation of default cases for Stateflow switch statements if unreachable".

Replace Multiplication by Powers of Two with Signed Bitwise Shifts

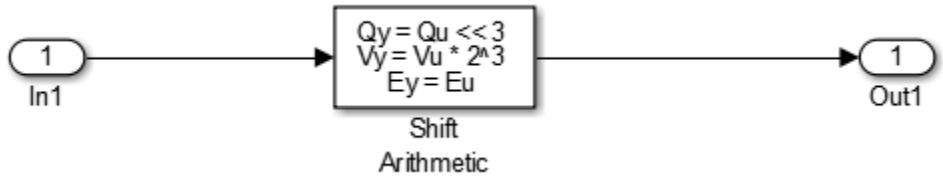
This example shows how to generate code that replaces multiplication by powers of two with signed bitwise shifts. Code that contains bitwise shifts is more efficient than code that contains multiplication by powers of two.

Some coding standards, such as MISRA, do not allow bitwise operations on signed integers. If you want to increase your chances of producing MISRA C compliant code, do not replace multiplication by powers of two with bitwise shifts.

Example

To replace multiplication by powers of two with bitwise shifts, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the

Shift Arithmetic Block Parameters dialog box, the **Bits to shift** > **Direction** parameter is set to `Left`. The **Bits to shift** > **Number** parameter is set to `3`. This parameter corresponds to a value of 8, or raising 2 to the power of 3.



Generate Code with Signed Bitwise Shifts

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Replace multiplications by powers of two with signed bitwise shifts** parameter is on by default.
2. Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 << 3);
```

The signed integer, `bitwise_multiplication_U.In1`, is shifted three bits to the left.

Generate Code with Multiplication by Powers of Two

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab.
2. Clear the **Replace multiplications by powers of two with signed bitwise shifts** parameter.
3. Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 * 8);
```

The signed integer `bitwise_multiplication_U.In1` is multiplied by `8`.

For more information on the **Replace multiplications by powers of two with signed bitwise shifts** parameter, see "Replace multiplications by powers of two with signed bitwise shifts".

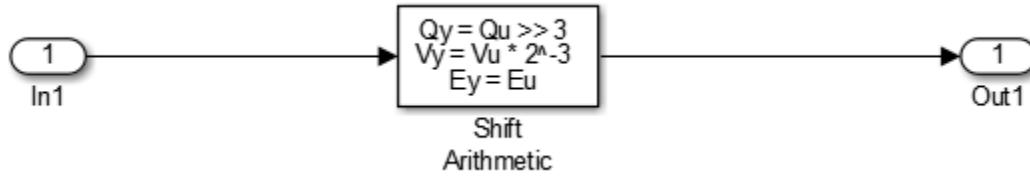
Generate Code with Right Shifts on Signed Integers

This example shows how to control whether the generated code contains right shifts on signed integers. Generated code that does not contain right shifts on signed integers first casts the signed integers to unsigned integers, and then right shifts the unsigned integers.

Some coding standards, such as MISRA, do not allow right shifts on signed integers because different hardware can store negative integers differently. For negative integers, you can get different answers depending on the hardware. If you want to increase your chances of producing MISRA C compliant code, do not allow right shifts on signed integers.

Example Model

To generate code with right shifts on signed integers, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift** > **Direction** parameter is set to `Right`. The **Bits to shift** > **Number** parameter is set to `3`.



Generate Code with Right Shifts on Signed Integers

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Allow right shifts on signed integers** parameter is on by default.
2. Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)(rightshift_U.In1 >> 3);
```

The signed integer `rightshift_U.In1` is shifted three bits to the right.

Generate Code That Does Not Allow Right Shifts on Signed Integers

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. Clear the **Allow right shifts on signed integers** parameter.
2. Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)asr_s32(rightshift_U.In1, 3U);
```

When you clear the **Allow right shifts on signed integers** parameter, the generated code contains a function call instead of a right shift on a signed integer. The function `asr_s32` contains this code:

```
int32_T asr_s32(int32_T u, uint32_T n)
{
  int32_T y;
  if (u >= 0) {
    y = (int32_T)((uint32_T)u >> n);
  } else {
    y = -(int32_T)((uint32_T)-(u + 1) >> n) - 1;
  }

  return y;
}
```

The `asr_s32` function casts a signed integer to an unsigned integer, and then right shifts the unsigned integer.

For more information on the **Allow right shifts on signed integers** parameter, see "Allow right shifts on signed integers".

Control Indentation Style in Generated Code

For code indentation, you can set the following parameters:

- "Indent style" controls the placement of braces in generated code.

- "Indent size" controls the number of characters per indent level in generated code (2–8 characters).

You can set **Indent style** to `K&R` or `Allman` style.

K&R

K&R stands for Kernighan and Ritchie. Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening braces are on the same line as the control statement. Closing braces are on a new line at the same level of indentation as the control statement. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to `K&R` with an **Indent size** of `2`:

```
void rt_OneStep(void)
{
  static boolean_T OverrunFlag = 0;
  if (OverrunFlag) {
    rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
    return;
  }

  OverrunFlag = TRUE;
  rtwdemo_counter_step();
  OverrunFlag = FALSE;
}
```

Allman

Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening and closing braces for control statements are on a new line at the same level of indentation as the control statement. This is the key difference between `K&R` and `Allman` styles. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to `Allman` with an **Indent size** of `4`:

```
void rt_OneStep(void)
{
    static boolean_T OverrunFlag = 0;
    if (OverrunFlag)
    {
        rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
        return;
    }

    OverrunFlag = TRUE;
    rtwdemo_counter_step();
    OverrunFlag = FALSE;
}
```

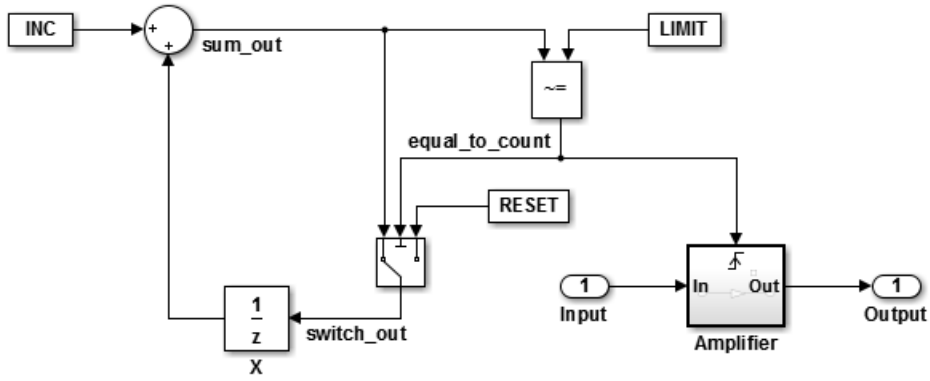
Control Cast Expressions in Generated Code

You can choose how the code generator specifies data type casts in the generated code. In the Configuration Parameters dialog box, select **Code Generation > Code Style**. From the **Casting modes** drop-down list, three parameter options control how the code generator casts data types.

- `Nominal` instructs the code generator to generate code that has minimal data type casting. When you do not have special data type information requirements, choose `Nominal`.
- `Standards Compliant` instructs the code generator to cast data types to conform to MISRA standards when it generates code. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations.

  For more information, see “MISRA C Guidelines” on page 12-5.
- `Explicit` instructs the code generator to cast data type values explicitly when it generates code. You can see how a value is stored, which tells you how much memory space the code uses for the variable. The data type informs you how much precision is possible in calculations involving the variable.

Open the example model `rtwdemo_rtwecintro`.



Enable Nominal Casting Mode and Generate Code

When you choose `Nominal` casting mode, the code generator does not create data type casts for variables in the generated code.

1. On the **Code Generation** > **Code Style** pane, from the **Casting modes** drop-down list, select `Nominal`.
2. On the **Code Generation** > **Report** pane, select **Create code generation report**.
3. On the **Code Generation** pane, select **Generate code only**.
4. Click **Apply**.
5. In the model window, press **Ctrl+B** to generate code.
6. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
  boolean_T rtb_equal_to_count;

  /* Sum: 'XRootX/Sum' incorporates:
   *  Constant: 'XRootX/INC'
   *  UnitDelay: 'XRootX/X'
   */
  rtDWork.X++;

  /* RelationalOperator: 'XRootX/RelOpt' incorporates:
   *  Constant: 'XRootX/LIMIT'
   */
```

```
  rtb_equal_to_count = (rtDWork.X != 16);

  /* Outputs for Triggered SubSystem: 'XRootX/Amplifier' incorporates:
   *  TriggerPort: 'XS1X/Trigger'
   */
  if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
  {
    /* Outport: 'XRootX/Output' incorporates:
     *  Gain: 'XS1X/Gain'
     *  Inport: 'XRootX/Input'
     */
    rtY.Output = rtU.Input << 1;
  }

  rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
    POS_ZCSIG : (int32_T)ZERO_ZCSIG);

  /* End of Outputs for SubSystem: 'XRootX/Amplifier' */

  /* Switch: 'XRootX/Switch' */
  if (!rtb_equal_to_count) {
    /* Update for UnitDelay: 'XRootX/X' incorporates:
     *  Constant: 'XRootX/RESET'
     */
    rtDWork.X = OU;
  }

  /* End of Switch: 'XRootX/Switch' */
}
```

Enable Standards Compliant Casting Mode and Generate Code

When you choose `Standards Compliant` casting mode, the code generator creates MISRA standards compliant data type casts for variables in the generated code.

1. On the **Code Style** pane, from the **Casting modes** drop-down list, select `Standards Compliant`.
2. On the **Code Generation** pane, click **Apply**.
3. In the model window, press **Ctrl+B** to generate code.
4. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
void rtwdemo_rtwecintro_step(void)
```

```
{
  boolean_T rtb_equal_to_count;

  /* Sum: '<Root>/Sum' incorporates:
   *  Constant: '<Root>/INC'
   *  UnitDelay: '<Root>/X'
   */
  rtDWork.X++;

  /* RelationalOperator: '<Root>/RelOpt' incorporates:
   *  Constant: '<Root>/LIMIT'
   */
  rtb_equal_to_count = (boolean_T)(int32_T)((int32_T)rtDWork.X != (int32_T)16);

  /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
   *  TriggerPort: '<S1>/Trigger'
   */
  if (((int32_T)rtb_equal_to_count) && (rtPrevZCSigState.Amplifier_Trig_ZCE !=
       POS_ZCSIG)) {
    /* Outport: '<Root>/Output' incorporates:
     *  Gain: '<S1>/Gain'
     *  Inport: '<Root>/Input'
     */
    rtY.Output = (int32_T)(uint32_T)((uint32_T)rtU.Input << (uint32_T)(int8_T)1);
  }

  rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(int32_T)(rtb_equal_to_count ?
    (int32_T)(uint8_T)POS_ZCSIG : (int32_T)(uint8_T)ZERO_ZCSIG);

  /* End of Outputs for SubSystem: '<Root>/Amplifier' */

  /* Switch: '<Root>/Switch' */
  if (!rtb_equal_to_count) {
    /* Update for UnitDelay: '<Root>/X' incorporates:
     *  Constant: '<Root>/RESET'
     */
    rtDWork.X = OU;
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Enable Explicit Casting Mode and Generate Code

When you choose `Explicit` casting mode, the code generator creates explicit data type casts for variables in the generated code.

1. On the **Code Style** pane, from the **Casting modes** drop-down list, select `Explicit`.
2. On the **Code Generation** pane, click **Apply**.
3. In the model window, press **Ctrl+B** to generate code.
4. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
  boolean_T rtb_equal_to_count;

  /* Sum: '<Root>/Sum' incorporates:
   *  Constant: '<Root>/INC'
   *  UnitDelay: '<Root>/X'
   */
  rtDWork.X = (uint8_T)(1U + (uint32_T)(int32_T)rtDWork.X);

  /* RelationalOperator: '<Root>/RelOpt' incorporates:
   *  Constant: '<Root>/LIMIT'
   */
  rtb_equal_to_count = (boolean_T)((int32_T)rtDWork.X != 16);

  /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
   *  TriggerPort: '<S1>/Trigger'
   */
  if (((int32_T)rtb_equal_to_count) && ((int32_T)((int32_T)
        rtPrevZCSigState.Amplifier_Trig_ZCE != (int32_T)POS_ZCSIG))) {
    /* Outport: '<Root>/Output' incorporates:
     *  Gain: '<S1>/Gain'
     *  Inport: '<Root>/Input'
     */
    rtY.Output = rtU.Input << 1;
  }

  rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
     POS_ZCSIG : (int32_T)ZERO_ZCSIG);

  /* End of Outputs for SubSystem: '<Root>/Amplifier' */
```

```
  /* Switch: '<Root>/Switch' */
  if (!(int32_T)rtb_equal_to_count) {
    /* Update for UnitDelay: '<Root>/X' incorporates:
     *  Constant: '<Root>/RESET'
     */
    rtDWork.X = 0U;
  }

  /* End of Switch: '<Root>/Switch' */
}
```

- "Model Configuration Parameters: Code Generation Code Style"

Customize Code Organization and Format

In this section...

Custom file processing (CFP) tools allow you to customize the organization and formatting of your generated code. With these tools, you can:

- Generate a source (`.c` or `.cpp`) or header (`.h`) file. Using a *custom file processing template* (CFP template), you can control how code emits to the standard generated model files (for example, *`model`*`.c` or `.cpp`, *`model`*`.h`) or generate files that are independent of model code.
- Organize generated code into sections (such as includes, `typedef`s, functions, and more). Your CFP template can emit code (for example, functions), directives (such as `#define` or `#include` statements), or comments into each section.
- Generate custom *file banners* (comment sections) at the start and end of generated code files and custom *function banners* that precede functions in the generated code.
- Generate code to call model functions, such as *`model`*`_initialize`, *`model`*`_step`, and so on.
- Generate code to read and write model inputs and outputs.
- Generate a main program module.
- Obtain information about the model and the generated files from the model.

Custom File Processing Components

The custom file processing features are based on the following interrelated components:

- *Code generation template* (CGT) files: a CGT file defines the top-level organization and formatting of generated code. See "Code Generation Template (CGT) Files" on page 36-57.
- The *code template API*: a high-level Target Language Compiler (TLC) API that provides functions with which you can organize code into named sections and subsections of generated source and header files. The code template API also provides utilities that return information about generated files, generate standard model calls, and perform other functions. See "Code Template API Summary" on page 36-79.

- *Custom file processing (CFP) templates*: a CFP template is a TLC file that manages the process of custom code generation. A CFP template assembles code to be generated into buffers. A CFP template also calls the code template API to emit the buffered code into specified sections of generated source and header files. A CFP template interacts with a CGT file, which defines the ordering of major sections of the generated code. See "Custom File Processing (CFP) Templates" on page 36-63.

To use CFP templates, you must understand TLC programming, for more information, see "Target Language Compiler" (Simulink Coder).

Custom File Processing Configuration

Customize generated code by specifying code and data templates on the **Code Generation > Templates** pane:

Goal	Action
Specify a template that defines the top-level organization and formatting of generated source code (`.c` or `.cpp`) files	Enter a code generation template (CGT) file for the **Source file (*.c) template** parameter.
Specify a template that defines the top-level organization and formatting of generated header (`.h`) files	Enter a CGT file for the **Header file (*.h) template** parameter. This template file can be the same template file that you specify for **Source file (.c) template**. If you use the same template file, source and header files contain identical banners. The default template is *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
Specify a template that organizes generated code into sections (such as includes, `typedefs`, functions, and more)	Enter a custom file processing (CFP) template file for the "File customization template" parameter. A CFP template can emit code, directives, or comments into each section. For more information, see "Custom File Processing (CFP) Templates" on page 36-63.
Generate a model-specific example main program module	Select **Generate an example main program**. For more information, see "Generate a Standalone Program" on page 49-2.

Note: Place the template files that you specify on the MATLAB path.

Specify Templates For Code Generation

To use custom file processing features, create CGT files and CFP templates. These files are based on default templates provided by the code generation software. Once you have created your templates, you must integrate them into the code generation process.

Select and edit CGT files and CFP templates, and specify their use in the code generation process in the **Code Generation** > **Templates** pane of a model configuration set. The following figure shows options configured for their defaults.

The options related to custom file processing are:

- The **Source file (.c) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating source (`.c` or `.cpp`) files. You must place this file on the MATLAB path.
- The **Header file (.h) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating header (`.h`) files. You must place this file on the MATLAB path.

  By default, the template for both source and header files is matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.
- The **File customization template** edit field in the **Custom templates** section. This field specifies the name of a CFP template file to use when generating code files. You must place this file on the MATLAB path. The default CFP template is matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc.

In each of these fields, click **Browse** to navigate to and select an existing CFP template or CGT file. Click **Edit** to open the specified file into the MATLAB editor where you can customize it.

Code Generation Template (CGT) Files

Code Generation Template (CGT) files define the top-level organization and formatting of generated source code and header files. CGT files have the following applications:

- Generation of custom banners (comments sections) in code files. See "Generate Custom File and Function Banners" on page 36-82.
- Generation of custom code using a CFP template requires a CGT file. To use CFP templates, you must understand the CGT file structure. In many cases, however, you can use the default CGT file without modifying it.

Default CGT file

The code generation software provides a default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt. Base your custom CGT files on the default file.

CGT File Structure

A CGT file consists of one required section and four optional sections:

Code Insertion Section

(Required) This section contains tokens that define an ordered partitioning of the generated code into a number of sections (such as `Includes` and `Defines` sections). Tokens have the form of:

```
%<SectionName>
```

For example,

```
%<Includes>
```

The code generation software defines a minimal set of required tokens. These tokens generate C or C++ source or header code. They are *built-in* tokens (see "Built-In Tokens and Sections" on page 36-58). You can also define custom tokens and custom sections.

Each token functions as a placeholder for a corresponding section of generated code. The ordering of the tokens defines the order in which the corresponding sections appear in the generated code. If you do not include a token, then the corresponding section is not

generated. To generate code into a given section, explicitly call the code template API from a CFP template, as described in "Custom File Processing (CFP) Templates" on page 36-63.

The CGT tokens define the high-level organization of generated code. Using the code template API, you can partition each code section into named subsections, as described in "Subsections" on page 36-60.

In the code insertion section, you can also insert C or C++ comments between tokens. Such comments emit directly into the generated code.

File Banner Section

(Optional) This section contains comments and tokens you use in generating a custom file banner.

Function Banner Section

(Optional) This section contains comments and tokens for use in generating a custom function banner.

Shared Utility Function Banner Section

(Optional) This section contains comments and tokens for use in generating a custom shared utility function banner.

File Trailer Section

(Optional) This section contains comments for use in generating a custom trailer banner.

For more information on these sections, see "Generate Custom File and Function Banners" on page 36-82.

Built-In Tokens and Sections

The following code extract shows the required code insertion section of the default CGT file with the required built-in tokens.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Code insertion section (required)
%%   These are required tokens. You can insert comments and other tokens in
%% between them, but do not change their order or remove them.
%%
```

```
%<Includes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Note the following requirements for customizing a CGT file:

- Do not remove required built-in tokens.
- Built-in tokens must appear in the order shown because each successive section has dependencies on previous sections.
- Only one token per line.
- Do not repeat tokens.
- You can add custom tokens and comments to the code insertion section as long as you do not violate the previous requirements.

Note: If you modify a CGT file and then rebuild your model, the code generation process does not force a top model build. To regenerate the code, see "Force Regeneration of Top Model Code" (Simulink Coder).

The following table summarizes the built-in tokens and corresponding section names, and describes the code sections.

Built-In CGT Tokens and Corresponding Code Sections

Token and Section Name	Description
`Includes`	`#include` directives section
`Defines`	`#define` directives section
`Types`	`typedef` section.`Typedefs` can depend on a previously defined type
`Enums`	Enumerated types section
`Definitions`	Data definitions (for example, `double x = 3.0;`)
`Declarations`	Data declarations (for example, `extern double x;`)
`Functions`	C or C++ functions

Subsections

You can define one or more named subsections for any section. Some of the built-in sections have predefined subsections summarized in table Subsections Defined for Built-In Sections.

Note: Sections and subsections emit to the source or header file in the order listed in the CGT file.

Using the custom section feature, you can define additional sections. See "Generate a Custom Section" on page 36-72.

Subsections Defined for Built-In Sections

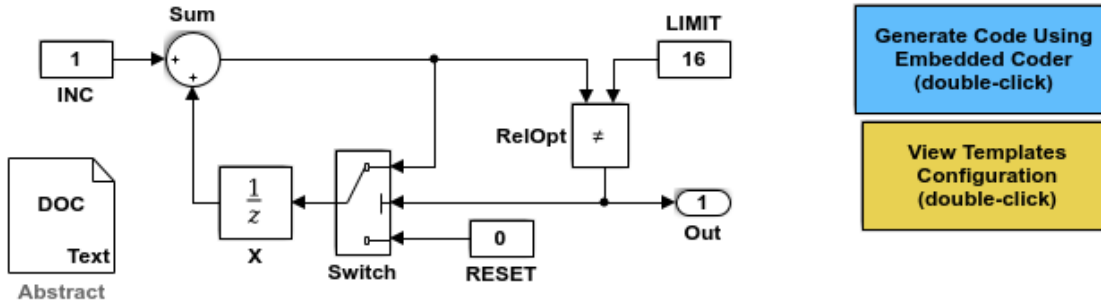
Section	Subsections	Subsection Description
`Includes`	N/A	
`Defines`	N/A	
`Types`	`IntrinsicTypes`	Intrinsic `typedef` section. Intrinsic types depend only on intrinsic C or C++ types.
`Types`	`PrimitiveTypedefs`	Primitive `typedef` section. Primitive `typedef`s depend only on intrinsic C or C++ types and on `typedef`s previously defined in the `IntrinsicTypes` section.
`Types`	`UserTop`	You can place any type of code in this section, including code that has dependencies on the previous sections.
`Types`	`Typedefs`	`typedef` section. `Typedef`s can depend on previously defined types
`Enums`	N/A	
`Definitions`	N/A	
`Declarations`	N/A	
`Functions`		C or C++ functions
`Functions`	`CompilerErrors`	`#error` directives
`Functions`	`CompilerWarnings`	`#warning` directives

Section	Subsections	Subsection Description
`Functions`	`Documentation`	Documentation (comment) section
`Functions`	`UserBottom`	You can place any code in this section.

Format Generated Code Files Using Templates

This example shows how to use code generation templates to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files.

```
model='rtwdemo_codetemplate';
open_system(model)
```



<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

Description
This model extracts text from the Model Description, a DOC block, and a Simulink annotation. The Simulink annotation maps to the code template %<Note> symbol. Many symbols are available that extract information from a model automatically. Refer to Module Packaging Features in the Embedded Coder documentation to see a complete list.

Many organizations employ coding standards that include consistent file layout and elaboration. Embedded Coder provides extensible code generation templates for formatting generated code. The layout and format of the code template file controls the output of the generated code.

Code generation templates (.cgt files) allow you to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files. Code generation templates are picked up automatically from the MATLAB path and employed during the code generation process. For this model, the code generation template "rtwdemocodetemplate.cgt" is used.

Instructions
1. Double-click the yellow View Templates Configuration button to view the templates configuration.
2. Click the Edit button to the right of the "rtwdemocodetemplate.cgt" template, and inspect the code template.
3. Double-click the blue button in the upper right to generate code. An HTML report appears automatically.
4. Open rtwdemo_codetemplate.c to inspect the generated code for this model.

```
rtwdemoclean;
close_system(model,0)
```

Custom File Processing (CFP) Templates

The files provided to support custom file processing are:

- matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc: A TLC function library that implements the code template API. `codetemplatelib.tlc` also provides the comprehensive documentation of the API in the comments headers preceding each function.
- matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc: An example custom file processing (CFP) template, which you should use as the starting point for creating your own CFP templates. Guidelines and examples for creating a CFP template are provided in "Generate Source and Header Files with a Custom File Processing (CFP) Template" on page 36-67.
- TLC files supporting generation of single-rate and multirate main program modules (see "Customizing Main Program Module Generation" on page 36-71).

Once you have created a CFP template, you must integrate it into the code generation process, using the **File customization template** edit field. See "Specify Templates For Code Generation" on page 36-56.

Custom File Processing (CFP) Template Structure

A custom file processing (CFP) template imposes a simple structure on the code generation process. The template, a code generation template (CGT) file, partitions the code generated for each file into a number of sections. These sections are summarized in Built-In CGT Tokens and Corresponding Code Sections and Subsections Defined for Built-In Sections.

Code for each section is assembled in buffers and then emitted, in the order listed, to the file being generated.

To generate a file section, your CFP template must first assemble the code to be generated into a buffer. Then, to emit the section, your template calls the TLC function

```
LibSetSourceFileSection(fileH, section, tmpBuf)
```

where

- `fileH` is a file reference to a file being generated.
- `section` is the code section or subsection to which code is to be emitted. section must be one of the section or subsection names listed in Subsections Defined for Built-In Sections.

Determine the `section` argument as follows:

- If Subsections Defined for Built-In Sections does not define subsections for a given section, use the section name as the `section` argument.
- If Subsections Defined for Built-In Sections defines one or more subsections for a given section, you can use either the section name or a subsection name as the `section` argument.
- If you have defined a custom token denoting a custom section, do not call `LibSetSourceFileSection`. Special API calls are provided for custom sections (see "Generate a Custom Section" on page 36-72).

- `tmpBuf` is the buffer containing the code to be emitted.

There is no requirement to generate all of the available sections. Your template need only generate the sections you require in a particular file.

Note that legality or syntax checking is not performed on the custom code within each section.

See "Generate Source and Header Files with a Custom File Processing (CFP) Template" on page 36-67, for typical usage examples.

Change the Organization of a Generated File

The files created during code generation are organized according to the general code generation template. This template has the filename `ert_code_template.cgt`, and is specified by default in **Code Generation** > **Templates** pane of the Configuration Parameters dialog box.

The following fragment shows the `rtwdemo_basicsc.c` file header that is generated using this default template:

```
/*
* File: rtwdemo_basicsc.c
*
* Code generated for Simulink model 'rtwdemo_basicsc'.
*
* Model version                  : 1.299
* Simulink Coder version         : 8.11 (R2017a) 01-Aug-2016
* C/C++ source code generated on : Fri Aug 19 12:45:59 2016
*
* Target selection: ert.tlc
* Embedded hardware selection: Intel->x86-64 (Windows64)
* Code generation objectives: Unspecified
* Validation result: Not run
*/
```

You can change the organization of generated files using code templates and data templates. Code templates organize the files that contain functions, primarily. Data templates organize the files that contain identifiers. In this procedure, you organize the generated files, using the supplied code and data templates:

1. Display the active **Templates** configuration parameters.
2. In the **Code templates** section of the **Templates** pane, type `code_c_template.cgt` into the **Source file (*.c) templates** text box.
3. Type `code_h_template.cgt` into the **Header file (*.h) templates** text box.
4. In the **Data templates** section, type `data_c_template.cgt` into the **Source file (*.c) templates** text box.
5. Type `data_h_template.cgt` into the **Header file (*.h) templates** text box, and click **Apply**.
6. In the model window, press **Ctrl+B**. Now the files are organized using the templates you specified. For example, the `rtwdemo_basicsc.c` file header now is organized like this:

```
/**
 ***************************************************************************
 **  FILE INFORMATION:

Generate Source and Header Files with a Custom File Processing (CFP) Template

In this section...

This example shows you the process of generating a simple source (`.c` or `.cpp`) and header (`.h`) file using the example CFP template. Then, it examines the template and the code generated by the template.

The example CFP template, matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc, demonstrates some of the capabilities of the code template API, including

- Generation of simple source (`.c` or `.cpp`) and header (`.h`) files
- Use of buffers to generate file sections for includes, functions, and so on
- Generation of includes, defines, into the standard generated files (for example, *`model`*`.h`)
- Generation of a main program module

Generate Code with a CFP Template

This section sets up a CFP template and configures a model to use the template in code generation. The template generates (in addition to the standard model files) a source file (`timestwo.c` or `.cpp`) and a header file (`timestwo.h`).

Follow the steps below to become acquainted with the use of CFP templates:

1. Copy the example CFP template, matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc, to a folder outside of the MATLAB folder structure (that is, not under *`matlabroot`*). If the folder is not on the MATLAB path or the TLC path, then add it to the MATLAB path. It is good practice to locate the CFP template in the same folder as your system target file, which is on the TLC path.

2. Rename the copied `example_file_process.tlc` to `test_example_file_process.tlc`.
3. Open `test_example_file_process.tlc` into the MATLAB editor.
4. Uncomment the following line:

   ```
   %%  %assign ERTCustomFileTest = TLC_TRUE
   ```

   It now reads:

   ```
     %assign ERTCustomFileTest = TLC_TRUE
   ```

   If `ERTCustomFileTest` is not assigned as shown, the CFP template is ignored in code generation.
5. Save your changes to the file. Keep `test_example_file_process.tlc` open, so you can refer to it later.
6. Open the rtwdemo_udt model.
7. Open the Simulink Model Explorer. Select the active configuration set of the model, and open the **Code Generation** pane of the active configuration set.
8. On the **Templates** tab, in the **File customization template** field, specify `test_example_file_process.tlc`. This is the file you previously edited and is now the specified CFP template for your model.
9. On the **General** tab, select the **Generate code only** check box.
10. Click **Apply**.
11. In the model window, press **Ctrl+B**. During code generation, notice the following message in the **Diagnostic Viewer**:

    ```
    Warning:  Overriding example ert_main.c!
    ```

    This message is displayed because `test_example_file_process.tlc` generates the main program module, overriding the default action of the ERT target. This is explained in greater detail below.
12. The `rtwdemo_udt` model is configured to generate an HTML code generation report. After code generation is complete, view the report.

    Notice that the **Generated Code** list contains the following files:

    - Under **Main file**, `ert_main.c`.
    - Under **Other files**, `timestwo.c` and `timestwo.h`.

The files were generated by the CFP template. The next section examines the template to learn how this was done.

13 Keep the model, the code generation report, and the `test_example_file_process.tlc` file open so you can refer to them in the next section.

Analysis of the Example CFP Template and Generated Code

This section examines excerpts from `test_example_file_process.tlc` and some of the code it generates. Refer to the comments in matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc while reading the following discussion.

Generating Code Files

Source (`.c` or `.cpp`) and header (`.h`) files are created by calling `LibCreateSourceFile`, as in the following excerpts:

```
%assign cFile = LibCreateSourceFile("Source", "Custom", "timestwo")
...
%assign hFile = LibCreateSourceFile("Header", "Custom", "timestwo")
```

Subsequent code refers to the files by the file reference returned from `LibCreateSourceFile`.

File Sections and Buffers

The code template API lets you partition the code generated to each file into sections, tagged as `Definitions`, `Includes`, `Functions`, `Banner`, and so on. You can append code to each section as many times as required. This technique gives you a great deal of flexibility in the formatting of your custom code files.

Subsections Defined for Built-In Sections describes the available file sections and their order in the generated file.

For each section of a generated file, use `%openfile` and `%closefile` to store the text for that section in temporary buffers. Then, to write (append) the buffer contents to a file section, call `LibSetSourceFileSection`, passing in the desired section tag and file reference. For example, the following code uses two buffers (`typesBuf` and `tmpBuf`) to generate two sections (tagged `"Includes"` and `"Functions"`) of the source file `timestwo.c` or `.cpp` (referenced as `cFile`):

```
%openfile typesBuf

#include "rtwtypes.h"

%closefile typesBuf

%<LibSetSourceFileSection(cFile,"Includes",typesBuf)>

 %openfile tmpBuf

 /* Times two function */
 real_T timestwofcn(real_T input) {
   return (input * 2.0);
}

%closefile tmpBuf

%<LibSetSourceFileSection(cFile,"Functions",tmpBuf)>
```

These two sections generate the entire `timestwo.c` or `.cpp` file:

```
#include "rtwtypes.h"

/* Times two function */
FLOAT64 timestwofcn(FLOAT64 input)
{
  return (input * 2.0);
}
```

Adding Code to Standard Generated Files

The `timestwo.c` or `.cpp` file generated in the previous example was independent of the standard code files generated from a model (for example, *`model`*`.c` or `.cpp`, *`model`*`.h`, and so on). You can use similar techniques to generate custom code within the model files. The code template API includes functions to obtain the names of the standard models files and other model-related information. The following excerpt calls `LibGetMdlPubHdrBaseName` to obtain the name for the *`model`*`.h` file. It then obtains a file reference and generates a definition in the `Defines` section of *`model`*`.h`:

```
%% Add a #define to the model's public header file model.h

%assign pubName = LibGetMdlPubHdrBaseName()
%assign modelH  = LibCreateSourceFile("Header", "Simulink", pubName)

%openfile tmpBuf
```

```
 #define ACCELERATION 9.81

 %closefile tmpBuf

%<LibSetSourceFileSection(modelH,"Defines",tmpBuf)>
```

Examine the generated `rtwdemo_udt.h` file to see the generated `#define` directive.

Customizing Main Program Module Generation

Normally, the ERT target determines whether and how to generate an `ert_main.c` or `.cpp` module based on the settings of the **Generate an example main program** and **Target operating system** options on the **Templates** pane of the Configuration Parameters dialog box. You can use a CFP template to override the normal behavior and generate a main program module customized for your target environment.

To support generation of main program modules, two TLC files are provided:

- `bareboard_srmain.tlc`: TLC code to generate an example single-rate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnSingleTaskingMain`.
- `bareboard_mrmain.tlc`: TLC code to generate a multirate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnMultiTaskingMain`.

In the example CFP template file matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc, the following code generates either a single- or multitasking `ert_main.c` or `.cpp` module. The logic depends on information obtained from the code template API calls `LibIsSingleRateModel` and `LibIsSingleTasking`:

```
%% Create a simple main.  Files are located in MATLAB/rtw/c/tlc/mw.

 %if LibIsSingleRateModel() || LibIsSingleTasking()
   %include "bareboard_srmain.tlc"
   %<FcnSingleTaskingMain()>
 %else
   %include "bareboard_mrmain.tlc"
   %<FcnMultiTaskingMain()>
 %endif
```

Note that `bareboard_srmain.tlc` and `bareboard_mrmain.tlc` use the code template API to generate `ert_main.c` or `.cpp`.

When generating your own main program module, you disable the default generation of `ert_main.c` or `.cpp`. The TLC variable `GenerateSampleERTMain` controls generation

of `ert_main.c` or `.cpp`. You can directly force this variable to `TLC_FALSE`. The examples `bareboard_mrmain.tlc` and `bareboard_srmain.tlc` use this technique, as shown in the following excerpt from `bareboard_srmain.tlc`.

```
%if GenerateSampleERTMain
    %assign CompiledModel.GenerateSampleERTMain = TLC_FALSE
    %warning Overriding example ert_main.c!
%endif
```

Alternatively, you can implement a `SelectCallback` function for your target. A `SelectCallback` function is a MATLAB function that is triggered during model loading, and also when the user selects a target with the System Target File browser. Your `SelectCallback` function should deselect and disable the **Generate an example main program** option. This prevents the TLC variable `GenerateSampleERTMain` from being set to TLC_TRUE.

See the "rtwgensettings Structure" (Simulink Coder) section for information on creating a `SelectCallback` function.

The following code illustrates how to deselect and disable the **Generate an example main program** option in the context of a `SelectCallback` function.

```
slConfigUISetVal(hDlg, hSrc, 'GenerateSampleERTMain', 'off');
slConfigUISetEnabled(hDlg, hSrc, 'GenerateSampleERTMain',0);
```

Note Creation of a main program for your target environment requires some customization; for example, in a bareboard environment you need to attach `rt_OneStep` to a timer interrupt. It is expected that you will customize either the generated code, the generating TLC code, or both. See "Guidelines for Modifying the Main Program" on page 49-4 and "Guidelines for Modifying rt_OneStep" on page 49-9 for further information.

Generate a Custom Section

You can define custom tokens in a CGT file and direct generated code into an associated built-in section. This feature gives you additional control over the formatting of code within each built-in section. For example, you could add subsections to built-in sections that do not already define subsections. Custom sections must be associated with one of the built-in sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`. To create custom sections, you must

- Add a custom token to the code insertion section of your CGT file.
- In your CFP file:
  - Assemble code to be generated to the custom section into a buffer.
  - Declare an association between the custom section and a built-in section, with the code template API function `LibAddSourceFileCustomSection`.
  - Emit code to the custom section with the code template API function `LibSetSourceFileCustomSection`.

The following code examples illustrate the addition of a custom token, `Myincludes`, to a CGT file, and the subsequent association of the custom section `Myincludes` with the built-in section `Includes` in a CFP file.

Note: If you have not already created custom CGT and CFP files for your model, copy the default template files matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt and matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc to a work folder that is outside the MATLAB folder structure but on the MATLAB or TLC path, rename them (for example, add the prefix `test_` to each file), and update the **Templates** pane of the Configuration Parameters dialog box to reference them.

First, add the token `Myincludes` to the code insertion section of your CGT file. For example:

```
%<Includes>
%<Myincludes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Next, in the CFP file, add code to generate `include` directives into a buffer. For example, in your copy of the example CFP file, you could insert the following section between the `Includes` section and the `Create a simple main` section:

```
%% Add a custom section to the model's C file model.c

%openfile tmpBuf
#include "moretables1.h"
```

```
#include "moretables2.h"
%closefile tmpBuf

%<LibAddSourceFileCustomSection(modelC,"Includes","Myincludes")>
%<LibSetSourceFileCustomSection(modelC,"Myincludes",tmpBuf)>
```

The `LibAddSourceFileCustomSection` function call declares an association between the built-in section `Includes` and the custom section `Myincludes`. `Myincludes` is a subsection of `Includes`. The `LibSetSourceFileCustomSection` function call directs the code in the `tmpBuf` buffer to the `Myincludes` section of the generated file. `LibSetSourceFileCustomSection` is syntactically identical to `LibSetSourceFileSection`.

In the generated code, the include directives generated to the custom section appear after other code directed to `Includes`.

```
#include "rtwdemo_udt.h"
#include "rtwdemo_udt_private.h"

/* #include "mytables.h" */
#include "moretables1.h"
#include "moretables2.h"
```

Note: The placement of the custom token in this example CGT file is arbitrary. By locating `%<Myincludes>` after `%<Includes>`, the CGT file specifies only that the `Myincludes` code appears after `Includes` code.

Custom Tokens

Custom tokens are automatically translated to TLC syntax as a part of the build process. To escape a token, that is to prepare it for normal TLC expansion, use the '!' character. For example, the token `%<!TokenName>` is expanded to `%<TokenName>` by the template conversion program. You can specify valid TLC code, including TLC function calls: `%<!MyTLCFcn()>`.

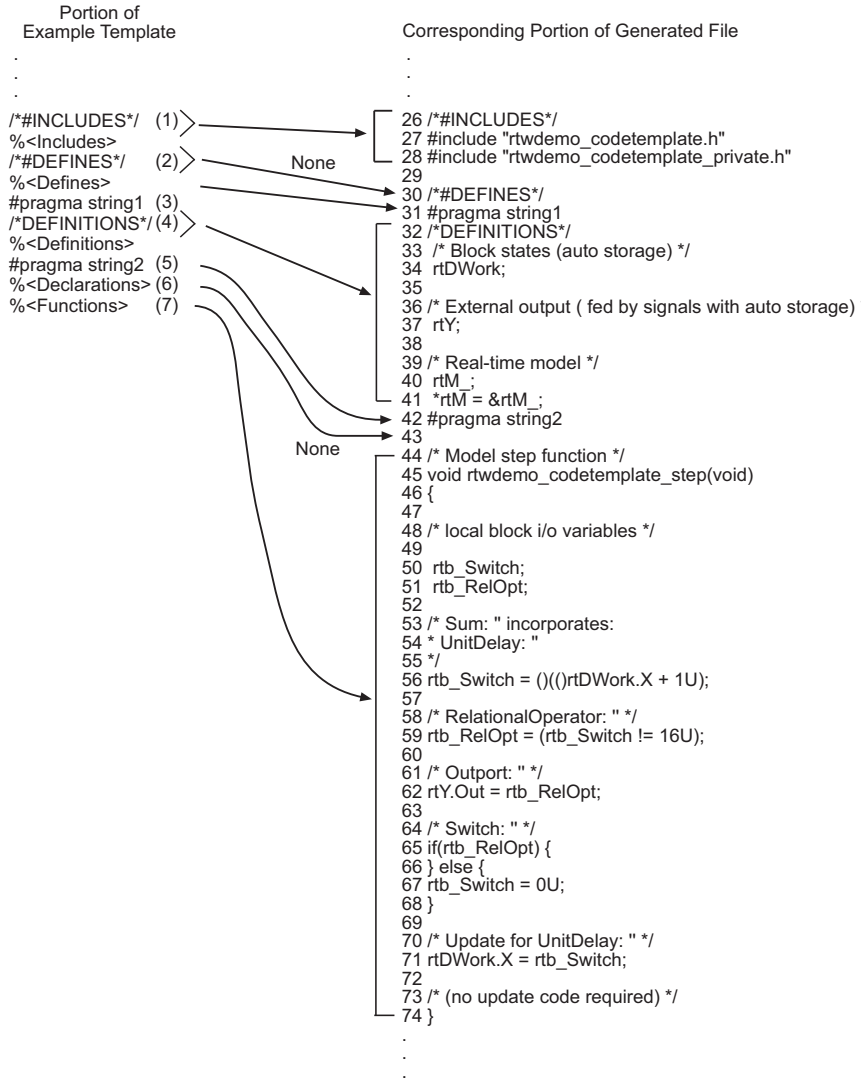
Comparison of a Template and Its Generated File

This figure shows part of a user-modified custom file processing (CFP) template and the resulting generated code. The figure illustrates how you can use a template to:

- Define what code the code generation software should add to the generated file
- Control the location of code in the file
- Optionally insert comments in the generated file

Notice `%<Includes>`, for example, on the template. The term `Includes` is a symbol name. A percent sign and brackets (`%< >`) must enclose every symbol name. You can add the desired symbol name (within the `%< >` delimiter) at a particular location in the template. This is how you control where the code generator places an item in the generated file.

Template and Generated File



Mapping Template Specification to Code Generation

This part of the template...		Generates in the file...		Explanation
		Line	Description	
(1)	`/*#INCLUDES*/` `%<Includes>`	26–28	An `/*#INCLUDES*/` comment, followed by `#include` statements	The code generator adds the C/C++ comment as a header, and then interprets the `%<Includes>` template symbol to list the required `#include` statements in the file. This code is first in this section of the file because the template entries are first.
(2)	`/*#DEFINES*/` `%<Defines>`	30	A `/*#DEFINES*/` comment, but no `#define` statements	Next, the code generator places the comment as a header for `#define` statements, but the file does not need `#define`. No code is added.
(3)	`#pragma string1`	31	`#pragma` statements	While the code generator requires `%<>` delimiters for template symbols, it can also interpret C/C++ statements in the template without delimiters. In this case, the generator adds the specified statements to the code, following the order in which the statements appear in the template.
(5)	`#pragma string2`	42		
(4)	`/*DEFINITIONS*/` `%<Definitions>`	32–41	`/*DEFINITIONS*/` comment, followed by definitions	The code generator places the comment and definitions in the file between the `#pragma` statements, according to the order in the template. It also inserts comments (lines 33 and 36) that are preset in the model's Configuration Parameters dialog box.
(6)	`%<Declarations>`	43	No declarations	The file needs no declarations, so the code generator does not generate declarations for this file. The template does not have

This part of the template...		Generates in the file...		Explanation
		Line	Description	
				a comment to provide a header. Line 43 is left blank.
(7)	`%<Functions>`	44–74	Functions	Finally, the code generator adds functions from the model, plus comments that are preset in the Configuration Parameters dialog box. But it adds no comments as a header for the functions, because the template does not have one. This code is last because the template entry is last.

For a list of template symbols and the rules for using them, see “Template Symbol Groups” on page 36-90, “Template Symbols” on page 36-93, and “Rules for Modifying or Creating a Template” on page 36-96. To set comment options, from the **Simulation** menu, select **Model Configuration Parameters**. On the Configuration Parameters dialog box, select the **Code Generation > Comments** pane. For details, see “Configure Code Comments” (Simulink Coder).

Code Template API Summary

Code Template API Functions summarizes the code template API. See the source code in matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc for detailed information on the arguments, return values, and operation of these calls.

Code Template API Functions

Function	Description
`LibClearFileSectionContents`	Clears a file section with custom values before writing file to disk.
`LibGetNumSourceFiles`	Returns the number of created source files (`.c` or `.cpp` and `.h`).
`LibGetSourceFileTag`	Returns `<filename>_h` and `<filename>_c` for header and source files, respectively, where `filename` is the name of the model file.
`LibCreateSourceFile`	Creates a new C or C++ file and returns its reference. If the file already exists, simply returns its reference.
`LibGetFileRecordName`	Returns a model file name (including the path) without the extension.
`LibGetSourceFileFromIdx`	Returns a model file reference based on its index. This is useful for a common operation on all files, such as to set the leading file banner of all files.
`LibSetSourceFileSection`	Adds to the contents of a specified section within a specified file (see also “Custom File Processing (CFP) Template Structure” on page 36-63).
`LibIndentSourceFile`	Indents a file (from within the TLC environment).
`LibCallModelInitialize`	Returns code for calling the model's *`model`*`_initialize` function (valid for ERT only).

Function	Description
`LibCallModelStep`	Returns code for calling the model's *`model`*`_step` function (valid for ERT only).
`LibCallModelTerminate`	Returns code for calling the model's *`model`*`_terminate` function (valid for ERT only).
`LibCallSetEventForThisBaseStep`	Returns code for calling the model's set events function (valid for ERT only).
`LibWriteModelData`	Returns data for the model (valid for ERT only).
`LibSetRTModelErrorStatus`	Returns the code to set the model error status.
`LibGetRTModelErrorStatus`	Returns the code to get the model error status.
`LibIsSingleRateModel`	Returns true if model is single rate and false otherwise.
`LibGetModelName`	Returns name of the model (without an extension).
`LibGetMdlSrcBaseName`	Returns the name of model's main source file (for example, *`model`*`.c` or `.cpp`).
`LibGetMdlPubHdrBaseName`	Returns the name of model's public header file (for example, *`model`*`.h`).
`LibGetMdlPrvHdrBaseName`	Returns the name of the model's private header file (for example, *`model`*`_private.h`).
`LibIsSingleTasking`	Returns `true` if the model is configured for single-tasking execution.
`LibWriteModelInput`	Returns the code to write to a particular root input (that is, a model inport block). (valid for ERT only).
`LibWriteModelOutput`	Returns the code to write to a particular root output (that is, a model outport block). (valid for ERT only).

Function	Description
`LibWriteModelInputs`	Returns the code to write to root inputs (that is, all model inport blocks). (valid for ERT only)
`LibWriteModelOutputs`	Returns the code to write to root outputs (that is, all model outport blocks). (valid for ERT only).
`LibNumDiscreteSampleTimes`	Returns the number of discrete sample times in the model.
`LibSetSourceFileCodeTemplate`	Set the code template to be used for generating a specified source file.
`LibSetSourceFileOutputDirectory`	Set the folder into which a specified source file is to be generated.
`LibAddSourceFileCustomSection`	Add a custom section to a source file. The custom section must be associated with one of the built-in (required) sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`.
`LibSetSourceFileCustomSection`	Adds to the contents of a specified custom section within a specified file. The custom section must have been previously created with `LibAddSourceFileCustomSection`.

Generate Custom File and Function Banners

Using code generation template (CGT) files, you can specify custom file banners and function banners for the generated code files. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. Use these banners to add a company copyright statement, specify a special version symbol for your configuration management system, remove time stamps, and for many other purposes. These banners can contain characters, which propagate to the generated code.

To specify banners, create a custom CGT file with customized banner sections. The build process creates an executable TLC file from the CGT file. The code generation process then invokes the TLC file.

You do not need to be familiar with TLC programming to generate custom banners. You can modify example files that are supplied with the ERT target.

Note Prior releases supported direct use of customized TLC files as banner templates. You specified these with the **Source file (.c) banner template** and **Header file (.h) banner template** options of the ERT target. You can still use a custom TLC file banner templates, however, you can now use CGT files instead.

ERT template options on the **Code Generation > Templates** pane of a configuration set, in the **Code templates** section, support banner generation.

The options for function and file banner generation are:

- "Code templates: Source file (*.c) template": CGT file to use when generating source (`.c` or `.cpp`) files. Place this file on the MATLAB path.
- "Code templates: Header file (*.h) template": CGT file to use when generating header (`.h`) files. You must place this file on the MATLAB path. This file can be the same template specified in the **Code templates: Source file (*.c) template** field, in which case identical banners are generated in source and header files.

  By default, the template for both source and header files is matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.
- In each of these fields, click **Browse** to navigate to and select an existing CGT file for use as a template. Click **Edit** to open the specified file into the MATLAB editor, where you can customize it.

Create a Custom File and Function Banner Template

To customize a CGT file for custom banner generation, make a local copy of the default code template and edit it, as follows:

1. Activate the configuration set that you want to work with.
2. Open the **Code Generation** pane of the active configuration set.
3. Click the **Templates** tab.
4. By default, the code template specified in the **Code templates: Source file (*.c) template** and **Code templates: Header file (*.h) template** fields is matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.
5. If you want to use a different template as your starting point, click **Browse** to locate and select a CGT file.
6. Click **Edit** button to open the CGT file into the MATLAB editor.
7. Save a local copy of the CGT file. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If required, add the folder to the MATLAB path.
8. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder.
9. Rename your local copy of the CGT file. When you rename the CGT file, update the associated **Code templates: Source file (*.c) template** or **Code templates: Header file (*.h) template** field to match the new file name.
10. Edit and customize the local copy of the CGT file for banner generation, using the information provided in "Customize a Code Generation Template (CGT) File for File and Function Banner Generation" on page 36-84.
11. Save your changes to the CGT file.
12. Click **Apply** to update the configuration set.
13. Save your model.
14. Generate code. Examine the generated source and header files to confirm that they contain the banners specified by the template or templates.

Customize a Code Generation Template (CGT) File for File and Function Banner Generation

This section describes how to edit a CGT file for custom file and function banner generation. For a description of CGT files, see "Code Generation Template (CGT) Files" on page 36-57.

Components of the File and Function Banner Sections in the CGT file

In a CGT file, you can modify the following sections: file banner, function banner, shared utility function banner, and file trailer. Each section is defined by open and close tags. The tags specific to each section are shown in the following table.

CGT File Section	Open Tag	Close Tag
File Banner	`<FileBanner>`	`</FileBanner>`
Function Banner	`<FunctionBanner>`	`</FunctionBanner>`
Shared-utility Banner	`<SharedUtilityBanner>`	`</SharedUtilityBanner>`
File Trailer	`<FileTrailer>`	`</FileTrailer>`

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example `<ModelVersion>`, which are replaced with values in the generated code.

Note: Including C comment indicators, '/*' or a '*/', in the contents of your banner might introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is as follows:

```
<OpenTag style = "style_value" width = "num_width">
```

Note: If the **Configuration Parameters > Code Generation > Language** parameter is set to `C++`, to select a comment style that uses C comment notation (`/*...*/`), you must also set the **Configuration Parameters > All Parameters > Comment style** parameter to `Multi-line`. For more information, see "Specify Comment Style" on page 36-14.

The built-in style options for the `style` attribute are:

- `classic`

```
/* single line comments */
/*
 * multiple line comments
 * second line
 */
```

- `classic_cpp`

```
// single line comments
//
// multiple line comments
// second line
//
```

- `box`

```
/*********************************************************/
/* banner contents                                       */
/*********************************************************/
```

- `box_cpp`

```
///////////////////////////////////////////////////////////
// banner contents                                       //
///////////////////////////////////////////////////////////
```

- `open_box`

```
/*********************************************************
 * banner contents
 *********************************************************/
```

- `open_box_cpp`

```
///////////////////////////////////////////////////////////
// banner contents
```

```
////////////////////////////////////////////////////////////
```

- `doxygen`

```
/** single line comments */

/**
 * multiple line comments
 * second line
 */
```

- `doxygen_cpp`

```
/// single line comments

///
/// multiple line comments
/// second line
///
```

- `doxygen_qt`

```
/*! single line comments */

/*!
 * multiple line comments
 * second line
 */
```

- `doxygen_qt_cpp`

```
//! single line comments

//!
//! multiple line comments
//! second line
//!
```

File Banner

This section contains comments and tokens for use in generating a custom file banner. The file banner precedes C or C++ code generated by the model. If you omit the file banner section from the CGT file, then no file banner emits to the generated code.

Note: If you customize your file banner, the software does not emit the customized banner for the file `const_params.c`.

The following section is the file banner section provided with the default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file banner section (optional)
%%
<FileBanner style="classic">
File: %<FileName>

Code generated for Simulink model %<ModelName>.

Model version                        : %<ModelVersion>
Simulink Coder version               : %<RTWFileVersion>
TLC version                          : %<TLCVersion>
C/C++ source code generated on       : %<SourceGeneratedOn>
%<CodeGenSettings>
</FileBanner>
```

Summary of Tokens for File Banner Generation

`FileName`	Name of the generated file (for example, `"rtwdemo_udt.c"`).
`FileType`	Either `"source"` or `"header"`. Designates whether generated file is a `.c` or `.cpp` file or an `.h` file.
`FileTag`	Given file names `file.c` or `.cpp` and `file.h`; the file tags are `"file_c"` and `"file_h"`, respectively.
`ModelName`	Name of generating model.
`ModelVersion`	Version number of model.
`RTWFileVersion`	Version number of *`model`*`.rtw` file.
`RTWFileGeneratedOn`	Timestamp of *`model`*`.rtw` file.
`TLCVersion`	Version of Target Language Compiler.
`SourceGeneratedOn`	Timestamp of generated file.
`CodeGenSettings`	Code generation settings for model: target language, target selection, production hardware selection, test hardware selection, code generation objectives (in priority order), and Code Generation Advisor validation result.

Function Banner

This section contains comments and tokens for use in generating a custom function banner. The function banner precedes C or C++ function generated during the build

process. If you omit the function banner section from the CGT file, the default function banner emits to the generated code. The following section is the default function banner section provided with the default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom function banner section (optional)
%%   Customize function banners by using the following predefined tokens:
%% %<ModelName>, %<FunctionName>, %<FunctionDescription>, %<Arguments>,
%% %<ReturnType>, %<GeneratedFor>, %<BlockDescription>.
%%
<FunctionBanner style="classic">
%<FunctionDescription>
%<BlockDescription>
</FunctionBanner>
```

Summary of Tokens for Function Banner Generation

`FunctionName`	Name of function
`Arguments`	List of function arguments
`ReturnType`	Return type of function
`ModelName`	Name of generating model
`FunctionDescription`	Short abstract about the function
`GeneratedFor`	Full block path for the generated function
`BlockDescription`	User input from the **Block Description** parameter of the block properties dialog box. `BlockDescription` contains an optional token attribute, `style`. The only valid value for`style` is `content_only`, which is case-sensitive and enclosed in double quotes. Use the `content_only` style when you want to include only the block description content that you entered in the block parameter dialog. The syntax for the token attribute `style` is: `%<BlockDescription style = ”content_only”>`

Shared Utility Function Banner

The shared utility function banner section contains comments and tokens for use in generating a custom shared utility function banner. The shared utility function banner precedes C or C++ shared utility function generated during the build process. If you omit the shared utility function banner section from the CGT file, the default shared utility function banner emits to the generated code. The following section is the default shared

utility function banner section provided with the default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom shared utility function banner section (optional)
%%   Customize banners for functions generated in shared location by using the
%% following predefined tokens: %<FunctionName>, %<FunctionDescription>,
%% %<Arguments>, %<ReturnType>.
%%
<SharedUtilityBanner style="classic">
%<FunctionDescription>
</SharedUtilityBanner>
```

Summary of Tokens for Shared Utility Function Banner Generation

`FunctionName`	Name of function
`Arguments`	List of function arguments
`ReturnType`	Return type of function
`FunctionDescription`	Short abstract about function

File Trailer

The file trailer section contains comments for generating a custom file trailer. The file trailer follows C or C++ code generated from the model. If you omit the file trailer section from the CGT file, no file trailer emits to the generated code. The following section is the default file trailer provided in the default CGT file.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
%%
<FileTrailer style="classic">
File trailer for generated code.

[EOF]
</FileTrailer>
```

Tokens available for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

Template Symbols and Rules

In this section...

Introduction

"Template Symbol Groups" on page 36-90 and "Template Symbols" on page 36-93 describe custom file processing (CFP) template symbols and rules for using them. The location of a symbol in one of the supplied template files (`code_c_template.cgt`, `code_h_template.cgt`, `data_c_template.cgt`, or `data_h_template.cgt`) determines where the items associated with that symbol are located in the corresponding generated file. "Template Symbol Groups" on page 36-90 identifies the symbol groups, starting with the parent ("Base") group, followed by the children of each parent. "Template Symbols" on page 36-93 lists the symbols alphabetically.

Note: If you are using custom CGT sections, for files generated to the `_sharedutils` folder, you can only use symbol names in the Base symbol group.

Template Symbol Groups

Symbol Group	Symbol Names in This Group

Base (Parents)	`Declarations`
	`Defines`
	`Definitions`
	`Documentation`
	`Enums`
	`Functions`

Symbol Group	Symbol Names in This Group
	`Includes` `Types`

Declarations	`ExternalCalibrationLookup1D`
	`ExternalCalibrationLookup2D`
	`ExternalCalibrationScalar`
	`ExternalVariableScalar`

Defines	`LocalDefines` `LocalMacros`

Definitions	`FilescopeCalibrationLookup1D`
	`FilescopeCalibrationLookup2D`
	`FilescopeCalibrationScalar`
	`FilescopeVariableScalar`
	`GlobalCalibrationLookup1D`
	`GlobalCalibrationLookup2D`
	`GlobalCalibrationScalar`
	`GlobalVariableScalar`

Symbol Group	Symbol Names in This Group

Documentation	`Abstract`
	`Banner`
	`Created`
	`Creator`
	`Date`
	`Description`
	`FileName`
	`History`
	`LastModifiedDate`
	`LastModifiedBy`
	`ModelName`
	`ModelVersion`
	`ModifiedBy`
	`ModifiedComment`
	`ModifiedHistory`

	`Notes` `ToolVersion`
Functions	`CFunctionCode`
Types	This parent has no children.

Template Symbols

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`Abstract`	Documentation	N/A	User-supplied description of the model or file. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
`Banner`	Documentation	N/A	Comments located near top of the file. Contains information that includes model and software versions, and date file was generated.
`CFunctionCode`	Functions	File	C/C++ functions. Must be at the bottom of the template.
`Created`	Documentation	N/A	Date when model was created. From **Created on** field on Model Properties dialog box.
`Creator`	Documentation	N/A	User who created model. From **Created by** field on Model Properties dialog box.
`Date`	Documentation	N/A	Date file was generated. Taken from computer clock.
`Declarations`	Base		Data declaration of a signal or parameter. For example, `extern real_T globalvar;`.
`Defines`	Base	File	Required `#defines` of `.h` files.
`Definitions`	Base	File	Data definitions of signals or parameters.
`Description`	Documentation	N/A	Description of model. From **Model description** field on Model Properties dialog box.**

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`Documentation`	Base	N/A	Comments about how to interpret the generated files.
`Enums`	Base	File	Enumerated data type definitions.
`ExternalCalibrationLookup1D`	Declarations	External	***
`ExternalCalibrationLookup2D`	Declarations	External	***
`ExternalCalibrationScalar`	Declarations	External	***
`ExternalVariableScalar`	Declarations	External	***
`FileName`	Documentation	N/A	Name of the generated file.
`FilescopeCalibrationLookup1I`	Definitions	File	***
`FilescopeCalibrationLookup2I`	Definitions	File	***
`FilescopeCalibrationScalar`	Definitions	File	***
`FilescopeVariableScalar`	Definitions	File	***
`Functions`	Base	File	Generated function code.
`GlobalCalibrationLookup1D`	Definitions	Global	***
`GlobalCalibrationLookup2D`	Definitions	Global	***
`GlobalCalibrationScalar`	Definitions	Global	***
`GlobalVariableScalar`	Definitions	Global	***
`History`	Documentation	N/A	User-supplied revision history of the generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
`Includes`	Base	File	`#include` preprocessor directives.
`LastModifiedDate`	Documentation	N/A	Date when model was last saved. From **Last saved on** field on Model Properties dialog box.

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`LastModifiedBy`	Documentation	N/A	User who last saved model. From **Last saved by** field on Model Properties dialog box.
`LocalDefines`	Defines	File	`#define` preprocessor directives from code-generation data objects.
`LocalMacros`	Defines	File	C/C++ macros local to the file.
`ModelName`	Documentation	N/A	Name of the model.
`ModelVersion`	Documentation	N/A	Version number of the Simulink model. From **Model version** field on Model Properties dialog box.
`ModifiedBy`	Documentation	N/A	Name of user who last modified the model.
`ModifiedComment`	Documentation	N/A	Comment user enters in the **Modified Comment** field on the Log Change dialog box. For more information, see "Log Comments History" (Simulink).
`ModifiedHistory`	Documentation	N/A	Text from **Model history** field on Model Properties dialog box.**
`Notes`	Documentation	N/A	User-supplied miscellaneous notes about the model or generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
`ToolVersion`	Documentation	N/A	A list of the versions of the toolboxes used in generating the code.
`Types`	Base		Data types of generated code.

* Symbol names must be enclosed between `%< >`. For example, `%<Functions>`.

** This symbol can be used to add a comment to the generated files. See "Add Global Comments" on page 36-8. The code generator places the comment in each generated file whose template has this symbol name. The code generator places the comment at the location that corresponds to where the symbol name is located in the template file.

*** The description can be deduced from the symbol name. For example, `GlobalCalibrationScalar` is a symbol that identifies a scalar. It contains data of global scope that you can calibrate .

Rules for Modifying or Creating a Template

The following are the rules for creating a MPF template. "Comparison of a Template and Its Generated File" on page 36-75 illustrates several of these rules.

1. Place a symbol on a template within the `%< >` delimiter. For example, the symbol named `Includes` should look like this on a template: `%<Includes>`. *Note that symbol names are case sensitive.*
2. Place a symbol on a template where desired. Its location on the template determines where the item associated with this symbol is located in the generated file. If no item is associated with it, the symbol is ignored.
3. Place a C/C++ statement outside of the `%< >` delimiter, and on a different line than a `%< >` delimiter, for that statement to appear in the generated file. For example, `#pragma message ("my text")` in the template results in `#pragma message ("my text")` at the corresponding location in the generated file. Note that the statement must be compatible with your C/C++ compiler.
4. Use the `.cgt` extension for every template filename. ("`cgt`" stands for *c*ode *g*eneration *t*emplate.)
5. Note that `%% $Revision: 1.1.4.10.4.1 $` appears at the top of the MathWorks supplied templates. This is for internal MathWorks use only. It does not need to be placed on a user-defined template and does not show in a generated file.
6. Place a comment on the template between `/* */` as in standard ANSI C[6]. This results in `/*comment*/` on the generated file.
7. Each MPF template must have all of the Base group symbols, in predefined order. They are listed in "Template Symbol Groups" on page 36-90. Each symbol in the Base group is a parent. For example, `Declarations` is a parent symbol.

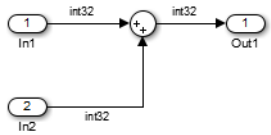
6. ANSI is a registered trademark of the American National Standards Institute, Inc.

8. Each symbol in a non-Base group is a child. For example, `LocalMacros` is a child.
9. Except for Documentation children, children must be placed after their parent, before the next parent, and before the `Functions` symbol.
10. Documentation children can be located before or after their parent in any order anywhere in the template.
11. If a non-Documentation child is missing from the template, the code generator places the information associated with this child at its parent location in the generated file.
12. If a Documentation child is missing from the template, the code generator omits the information associated with that child from the generated file.

Annotate Code for Justifying Polyspace Checks

With the Polyspace Code Prover product you can apply Polyspace verification to Embedded Coder generated code. The software detects run-time errors in the generated code and helps you to locate and fix model faults.

Polyspace might highlight overflows for certain operations that are legitimate because of the way the code generator implements these operations. Consider the following model and the corresponding generated code.



```
32 /* Sum: '<Root>/Sum' incorporates:
33   *  Inport: '<Root>/In1'
34   *  Inport: '<Root>/In2'
35   */
36  qY_0 = sat_add_U.In1 + sat_add_U.In2;
37  if ((sat_add_U.In1 < 0) && ((sat_add_U.In2 < 0) && (qY_0 >= 0))) {
38    qY_0 = MIN_int32_T;
39  } else {
40   if ((sat_add_U.In1 > 0) && ((sat_add_U.In2 > 0) && (qY_0 <= 0))) {
41      qY_0 = MAX_int32_T;
42    }
43  }
```

The code generator recognizes that the largest built-in data type is 32-bit. It is not possible to saturate the results of the additions and subtractions using `MIN_INT32` and `MAX_INT32` and a bigger single-word integer data type. Instead the software detects the results overflow and the direction of the overflow, and saturates the result.

If you do not provide justification for the addition operator on line 36, Polyspace verification generates an orange check that indicates a potential overflow. The verification does not take into account the saturation function of lines 37 to 43. In addition, the trace-back functionality of Polyspace Code Prover does not identify the reason for the orange check.

To justify overflows from operators that are legitimate, on the **Configuration Parameters > Code Generation > Comments** pane:

- Under **Overall control**, select the **Include comments** check box.
- Under **Auto generate comments**, select the **Operator annotations check box**.

The code generator annotates generated code with comments for Polyspace. For example:

```
32 /* Sum: '<Root>/Sum' incorporates:
33   *  Inport: '<Root>/In1'
34   *  Inport: '<Root>/In2'
35   */
36  qY_0 = sat_add_U.In1 +/*MW:OvOk*/ sat_add_U.In2;
```

When you run a verification using Polyspace Code Prover, the Polyspace software uses the annotations to justify the operator-related orange checks and assigns the `Not a defect` classification to the checks.

Manage Placement of Data Definitions and Declarations

In this section...

Overview of Data Placement

This chapter focuses on module packaging features (MPF) settings that are interdependent. Their combined values, along with Simulink partitioning, determine the file placement of data definitions and declarations, or *data placement*. This includes

- The number of files generated.
- Whether or not the generated files contain definitions for a model's global identifiers. And, if a definition exists, the settings determine the files in which MPF places them.
- Where MPF places global data declarations (`extern`).

The following six MPF settings are distributed among the main procedures and form an important interdependency:

- The **Data definition** field on the **Code Placement** pane of the Configuration Parameters dialog box.
- The **Data declaration** field on the **Code Placement** pane of the Configuration Parameters dialog box.
- The **Owner** field of the data object in the Model Explorer and the checkbox for **Use owner from data object for data definition placement** on the **Code Placement** pane of the Configuration Parameters dialog box. The term "ownership settings" refers to these fields together.
- The **Definition file** field of the data object on the Model Explorer.
- The **Header file** field of the data object on the Model Explorer.

- The **Memory section** field of the data object on the Model Explorer.

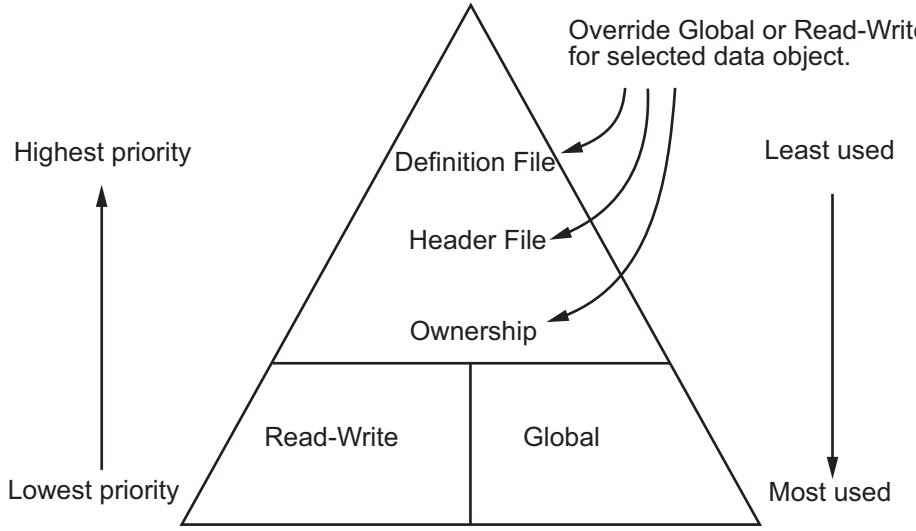
Priority and Usage

Overview

There is a priority order among interdependent MPF settings. From highest to lowest, the priorities are

- Definition File priority
- Header File priority
- Ownership priority
- Read-Write priority or Global priority

Priority order varies inversely with frequency of use, as illustrated below. For example, Definition File is highest priority but least used.



MPF Settings Priority and Usage

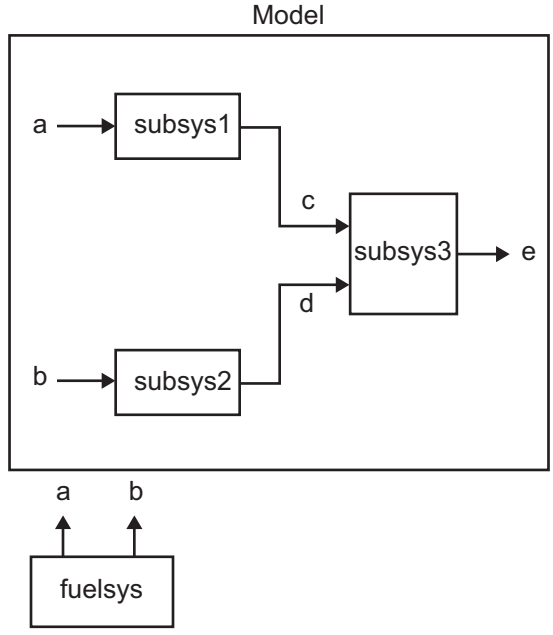
Unless they are overridden, the Read-Write and Global priorities place in the generated files all of the model's MPF-derived data objects that you selected using Data Object Wizard. (See “Create Data Objects for Code Generation with Data Object Wizard” on page 24-2 for details.) Before generating the files, you can use the higher priority Definition file, Header file, and Ownership, as desired, to override Read-Write or Global priorities for single data objects. Most users will employ Read-Write or Global, without an override. A few users, however, will want to do an override for certain data objects. We expect that those users whose applications include multiple modules will want to use the Ownership priority.

The priorities are used only for those data objects that are derived from `Simulink.Signal` and `Simulink.Parameter`, and whose custom storage classes are specified using the Custom Storage Class Designer. (For details, see “Design Custom Storage Classes and Memory Sections” on page 23-34.) Otherwise, the build process determines the data placement.

Read-Write Priority

This is the lowest priority. Consider that a model consists of one or more Simulink blocks or Stateflow diagrams. There can be subsystems within these. For the purpose of illustration, think of a model with one top-level block called `fuelsys`. You double-clicked the block and now see three subsystems labeled `subsys1`, `subsys2` and `subsys3`, as shown in the next figure. Signals `a` and `b` are outputs from the top-level block (`fuelsys`). Signal `a` is an input to `subsys1` and `b` is input to `subsys2`. Signal `c` is an output from `subsys1`. Notice the other inputs and outputs (`d` and `e`). Signals `a` through `e` have corresponding data objects.

As explained in “Data Definition and Declaration Management”, MPF provides you with the means of selecting a data object that you want defined as an identifier in the generated code. MPF also allows you to specify property values for each data object.

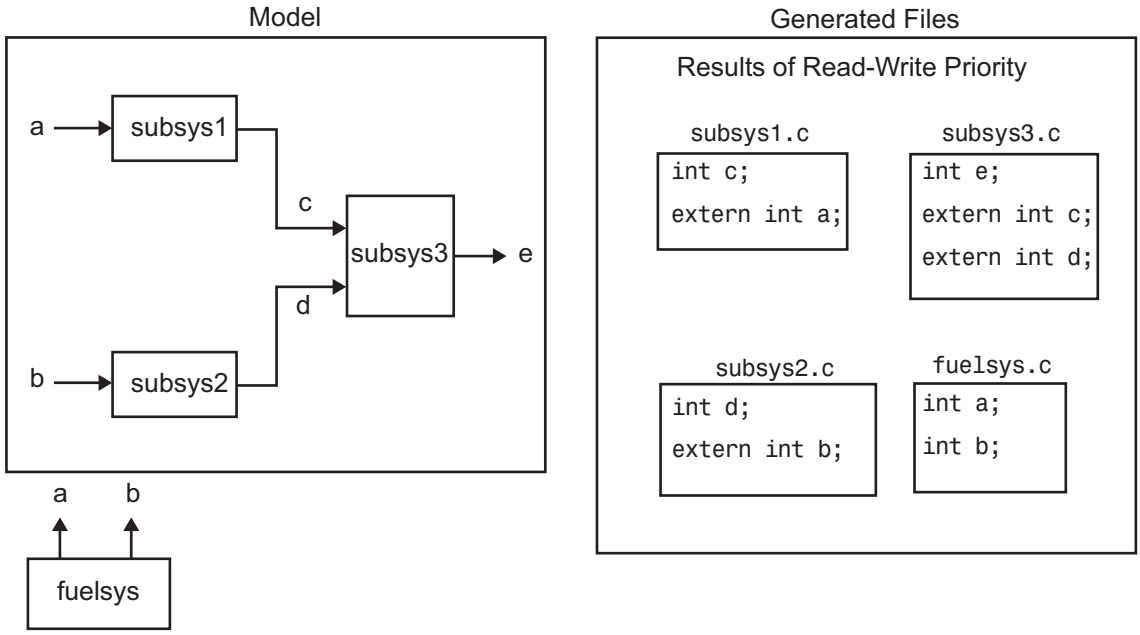


The Generated Files

We generate code for this model. As shown in the figure below, this results in a `.c` source file corresponding to each of the subsystems. (In actual applications, there could be more than one `.c` source file for a subsystem. This is based on the file partitioning previously selected for the model. But for our illustration, we only need to show one for each subsystem.) Data objects `a` through `e` have corresponding identifiers in the generated files.

A `.c` source file has one or more functions in it, depending on the internal operations (functions) of its corresponding subsystem. An identifier in a generated `.c` file has local scope when it is used only in one function of that `.c` file. An identifier has file scope when more than one function in the same `.c` file uses it. An identifier has global scope when more than one of the generated files uses it.

A subsystem's source file contains the definitions for that subsystem's data objects that have local scope or file scope. (These definitions are not shown in the figure.) But where are the definitions and declarations for data objects of global scope? These are shown in the next figure.



For the Read-Write priority, this source file contains the definitions for the subsystem's global data objects, if this is the file that first writes to the data object's address. Other files that read (use) that data object only include a reference to it. This is why this priority is called Read-Write. Since a read and a write of a file are analogous to input and output of a model's block, respectively, there is another way of saying this. The definitions of a block's global data objects are located in the corresponding generated file, if that data object is an output from that block. The declarations (`extern`) of a block's global data objects are located in the corresponding generated file, if that data object is an input to that block.

Settings for Read-Write Priority

The generated files and what they include, as just described, occur when the Read-Write priority is used. For this to be the case, the other priorities are turned off. That is,

- The **Data definition** field on the **Code Placement** pane is set to `Data defined in source file`.
- The **Data declaration** field on the **Code Placement** pane is set to `Data declared in source file`.

- The **Owner** field on the Model Explorer is blank, and the checkbox for the **Use owner from data object for data definition placement** field on the **Code Placement** pane is not checked.
- **Definition file** and **Header file** on the Model Explorer are blank.

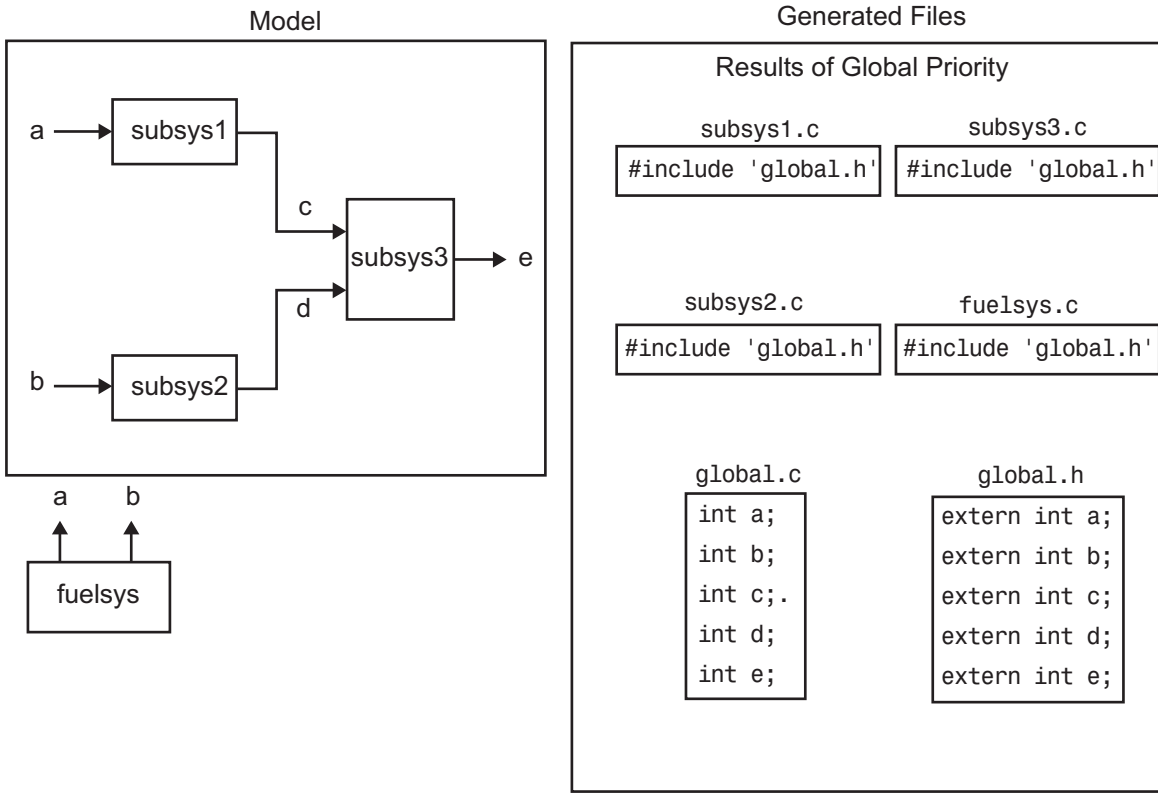
Global Priority

This has the same priority as Read-Write (the lowest) priority. The settings for this are the same as for Read-Write Priority, except

- The **Data definition** field on the **Code Placement** pane is set to `Data defined in single separate source file`.
- The **Data declaration** field on the **Code Placement** pane is set to `Data declared in single separate header file`.

The generated files that result are shown in the next figure. A subsystem's data objects of local or file scope are defined in the `.c` source file where the subsystem's functions are located (not shown). The data objects of global scope are defined in another `.c` file (called `global.c` in the figure). The declarations for the subsystem's data objects of global scope are placed in a `.h` file (called `global.h`).

For example, data objects of local and file scope for `subsys1` are defined in `subsys1.c`. Signal `c` in the model is an output of `subsys1` and an input to `subsys2`. So `c` is used by more than one subsystem and thus is a global data object. Because of the global priority, the definition for `c` (`int c;`) is in `global.c`. The declaration for `c` (`extern int c;`) is in `global.h`. Since `subsys2` uses (reads) `c`, `#include "global.h"` is in `subsys2.c`.



Definition File, Header File, and Ownership Priorities

While the Read-Write and Global priorities operate on all MPF-derived data objects that you want defined in the generated code, the remaining priorities allow you to override the Read-Write or Global priorities for one or more particular data objects. There is a high-to-low priority among these remaining priorities — Definition File, Header File, and Ownership — for a particular data object, as shown in MPF Settings Priority and Usage

Ownership Settings

Ownership settings refers to the `on` or `off` setting specified using the **Use owner from data object for data definition placement** checkbox on the **Code Placement** pane of the Configuration Parameters dialog box, and the **Owner** field of a data object in the Model Explorer. These settings control the file placement of data definition and

initialization by specifying a model that owns the data. The settings do not control what files are generated. There are four possible configurations, as shown in "Ownership Settings" on page 36-116.

Memory Section Settings

Memory sections allow you to specify storage directives for a data object. As shown in Parameter and Signal Property Values, the possible values for the **Memory section** property of a parameter or signal object are `Default`, `MemConst`, `MemVolatile` or `MemConstVolatile`.

If you specify a filename for **Definition file**, and select `Default`, `MemConst`, `MemVolatile` or `MemConstVolatile` for the **Memory section** property, the code generation software generates a `.c` file and an `.h` file. The `.c` file contains the definition for the data object with the `pragma` statement or qualifier associated with the **Memory section** selection. The `.h` file contains the declaration for the data object. The `.h` file can be included, using the preprocessor directive `#include`, in files that need to reference the data object.

You can add more memory sections. For more information, see "Design Custom Storage Classes and Memory Sections" on page 23-34 and "Control Data and Function Placement in Memory by Inserting Pragmas" on page 27-2.

Data Placement Rules

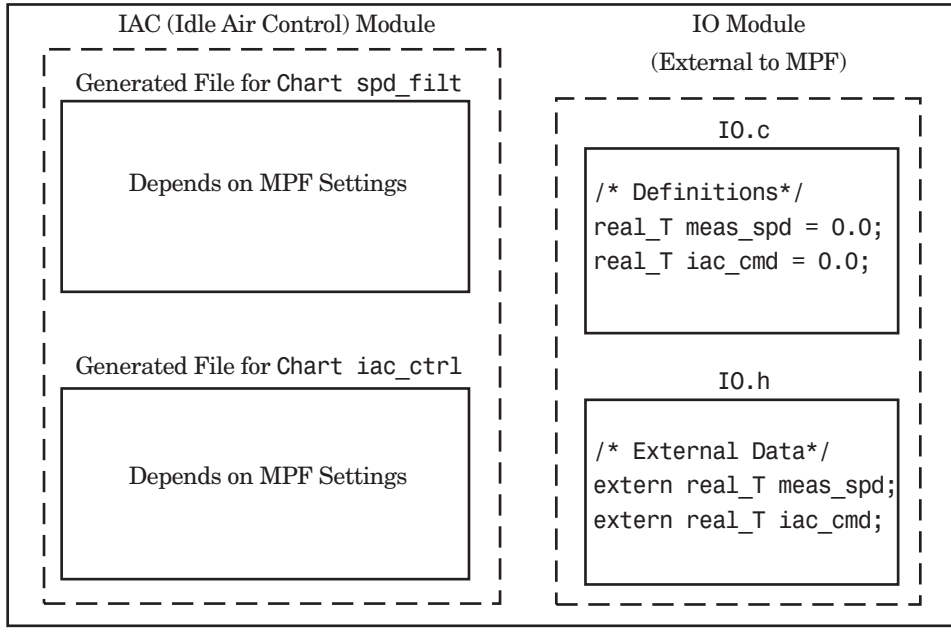
For a complete set of data placement rules in convenient tabular form, based on the priorities discussed in this chapter, see "Data Placement Rules and Results" on page 36-115.

Settings for a Data Object

Introduction

"Settings and Resulting Generated Files" on page 36-116 provides example settings for one data object of a model. Eight examples are listed so that you can see the generated files that result from a wide variety of settings. Four examples from this table are discussed below in more detail. These discussions provide information for understanding settings you might choose. For illustration purposes, the four examples assume that we are dealing with an overall system that controls engine idle speed.

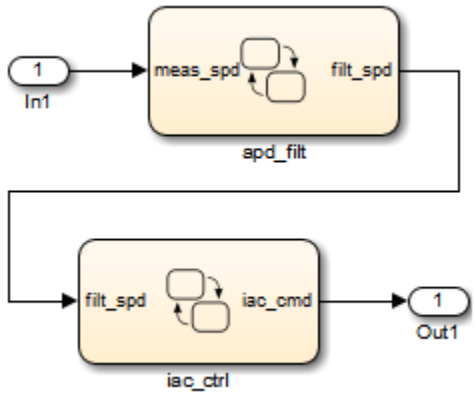
The next figure shows that the software component of this example system consists of two modules, IAC (Idle Air Control), and IO (Input-Output).



Engine Idle Speed Control System

The code in the IO module controls the system's IO hardware. Code is generated only for the IAC module. (Some other means produced the code for the IO module, such as hand-coding.) So the code in IO is external to MPF, and can illustrate legacy code. To simplify matters, the IO code contains one source file, called `IO.c`, and one header file, called `IO.h`.

The IAC module consists of two Stateflow charts, `spd_filt` and `iac_ctrl`. The `spd_filt` chart has two signals (`meas_spd`) and `filt_spd`), and one parameter (`a`). The `iac_ctrl` chart also has two signals (`filt_spd` and `iac_cmd`) and a parameter (`ref_spd`). (The parameters are not visible in the top-level charts.) One file for each chart is generated. This example system allows us to illustrate referencing from file to file within the MPF module, and model to external module. It also illustrates the case where there is no such referencing.



Proceed to the discussion of the desired example settings:

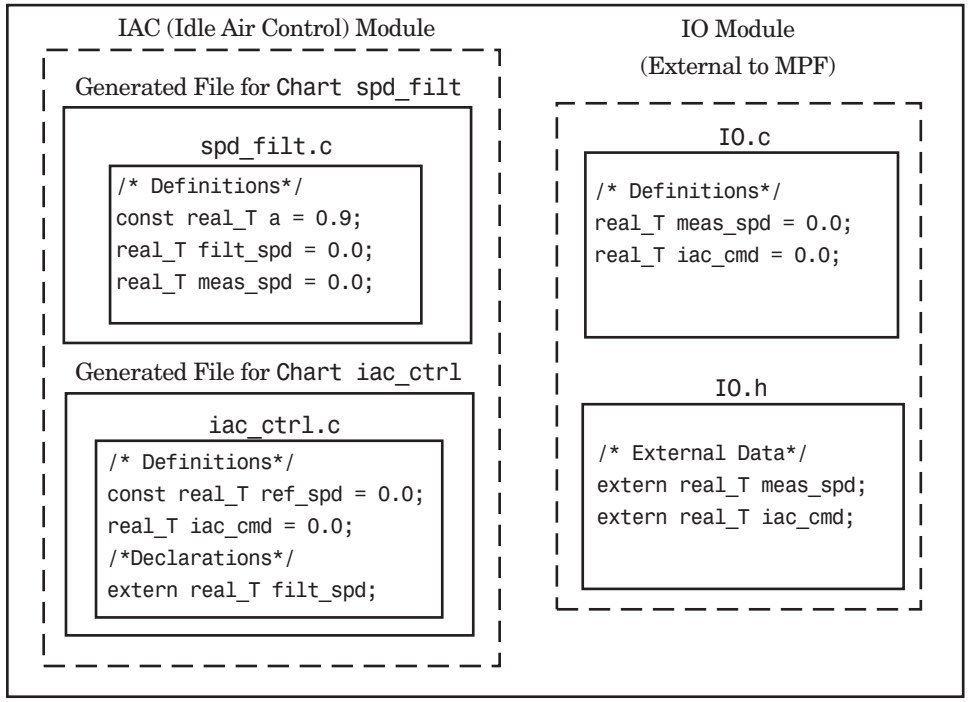
- "Read-Write" on page 36-109
- "Ownership" on page 36-111
- "Header File" on page 36-112
- "Definition File" on page 36-114

Read-Write

These settings and the generated files that result are shown as Example Settings 1 in "Settings and Resulting Generated Files" on page 36-116. As you can see from the table, this example illustrates the case in which only one `.c` source file (for each chart) is generated.

So, for the IAC model, select the following settings. Accept the `Data defined in source file` in the **Data definition** field and the `Data declared in source file` in the **Data declaration** field on the **Code Placement** pane of the Configuration

Parameters dialog box. Accept the default unchecked **Use owner from data object for data definition placement** field. Accept the default blank settings for the **Owner**, **Definition file** and **Header file** fields on the Model Explorer. For **Memory section**, accept `Default`. Now the Read-Write priority is active. Generate code. The next figure shows the results in terms of definition and declaration statements.



Engine Idle Speed Control System (Read-Write Example)

The code generator generated a `spd_filt.c` for the `spd_filt` chart and `iac_ctrl.c` for the `iac_ctrl` chart. As you can see, MPF placed definitions of data objects for the `spd_filt` chart in `spd_filt.c`. It placed definitions of data objects for the `iac_ctrl` chart in `iac_ctrl.c`.

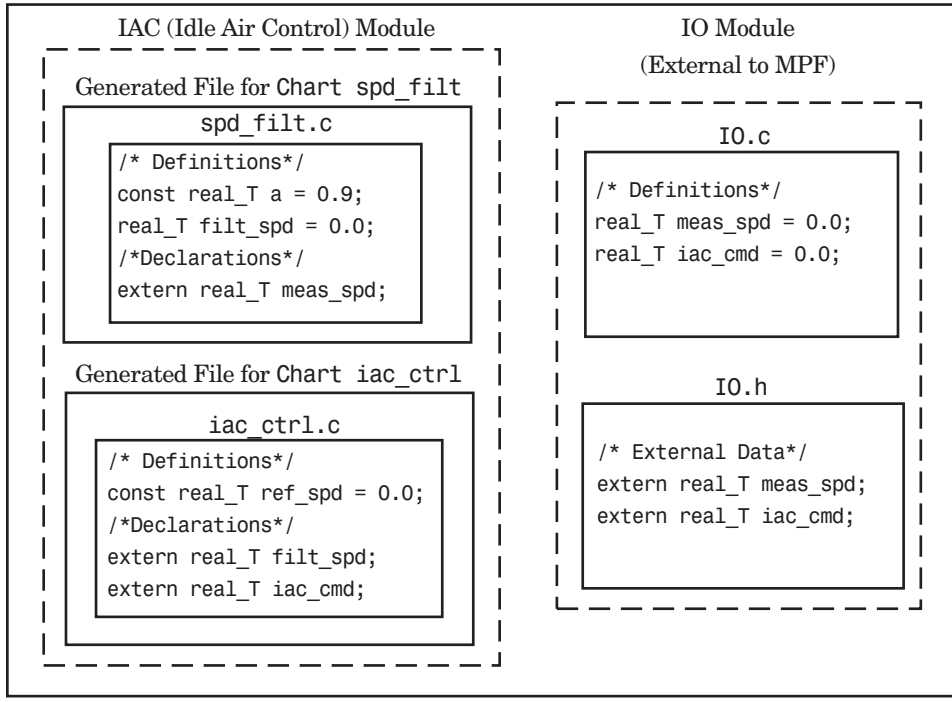
However, notice `real_T filt_spd`. This data object is defined in `spd_filt.c` and declared in `iac_ctrl.c`. That is, since the Read-Write priority is active, `filt_spd` is defined in the file that first writes to its address. And, it is declared in the file that reads (uses) it. Further, `real_T meas_spd` is defined in both `spd_filt.c` and the external `IO.c`. And, `real_T iac_cmd` is defined in both `iac_ctrl.c` and `IO.c`.

Ownership

See tables "Ownership Settings" on page 36-116 and "Settings and Resulting Generated Files" on page 36-116. In the "Read-Write" on page 36-109, there are several instances where the same data object is defined in more than one `.c` source file, and there is no declaration (`extern`) statement. This would result in compiler errors during link time. But in this example, we configure MPF Ownership rules so that linking can take place. Notice the Example Settings 2 row in "Settings and Resulting Generated Files" on page 36-116. Except for the ownership settings, assume these are the settings you made for the model in the IAC module. Since this example has no **Definition file** or **Header file** specified, now Ownership takes priority. (If you specified a **Definition file** or **Header file**, MPF ignores the ownership settings.)

On the **Code Placement** pane of the Configuration Parameters dialog box, check the box for the **Use owner from data object for data definition placement** field. Open the Model Explorer (by issuing the MATLAB command `daexplr`) and, for all data objects except `meas_spd` and `iac_cmd`, type IAC in the **Owner** field (case sensitive). Then, only for the `meas_spd` and `iac_cmd` data objects, type IO as their **Owner** (case sensitive). Generate code.

The results are shown in the next figure. Notice the `extern real_T meas_spd` statement in `spd_filt.c`, and `extern real_T iac_cmd` in `iac_ctrl.c`. MPF placed these declaration statements in the files where these data objects are used. This allows the generated source files (`spd_filt.c` and `iac_ctrl.c`) to be compiled and linked with `IO.c`.



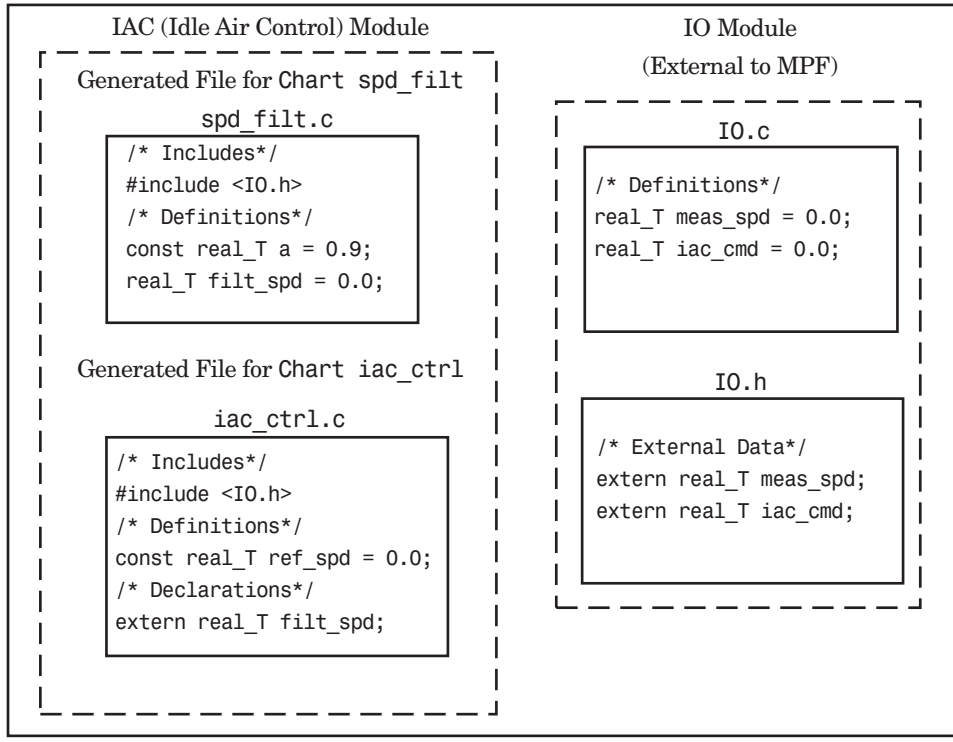
Engine Idle Speed Control System (Ownership Example)

Header File

These settings and the generated files that result are shown as Example Settings 3 in "Settings and Resulting Generated Files" on page 36-116. This example has no **Definition file** specified. If you specified a **Definition file**, MPF ignores the **Header file** setting. The focus of this example is to show how the **Header file** settings result in the linking of the two chart source files to the external IO files, shown in the next figure. (Also, ownership settings will be used to link the two chart files with each other.)

As you can see in the figure, the `meas_spd` and `iac_cmd` identifiers are defined in `IO.c` and declared in `IO.h`. Both of these identifiers are external to the generated `.c` files. You open the Model Explorer and select both the `meas_spd` and `iac_cmd` data objects. For each of these data objects, in the **Header file** field, specify `IO.h`, since this is where these two objects are declared. This setting allows the `spd_filt.c` source file to compile and link with the external `IO.c` file.

Now we configure the ownership settings. In the Model Explorer, select the `filt_spd` data object and set its **Owner** field to `IAC`. Then, on the **Code Placement** pane of the Configuration Parameters dialog box, check the box for the **Use owner from data object for data definition placement** field. Now the `spd_filt` source file links to the `iac_ctrl` source file. Generate code. See the figure below.



Engine Idle Speed Control System (Header File Example)

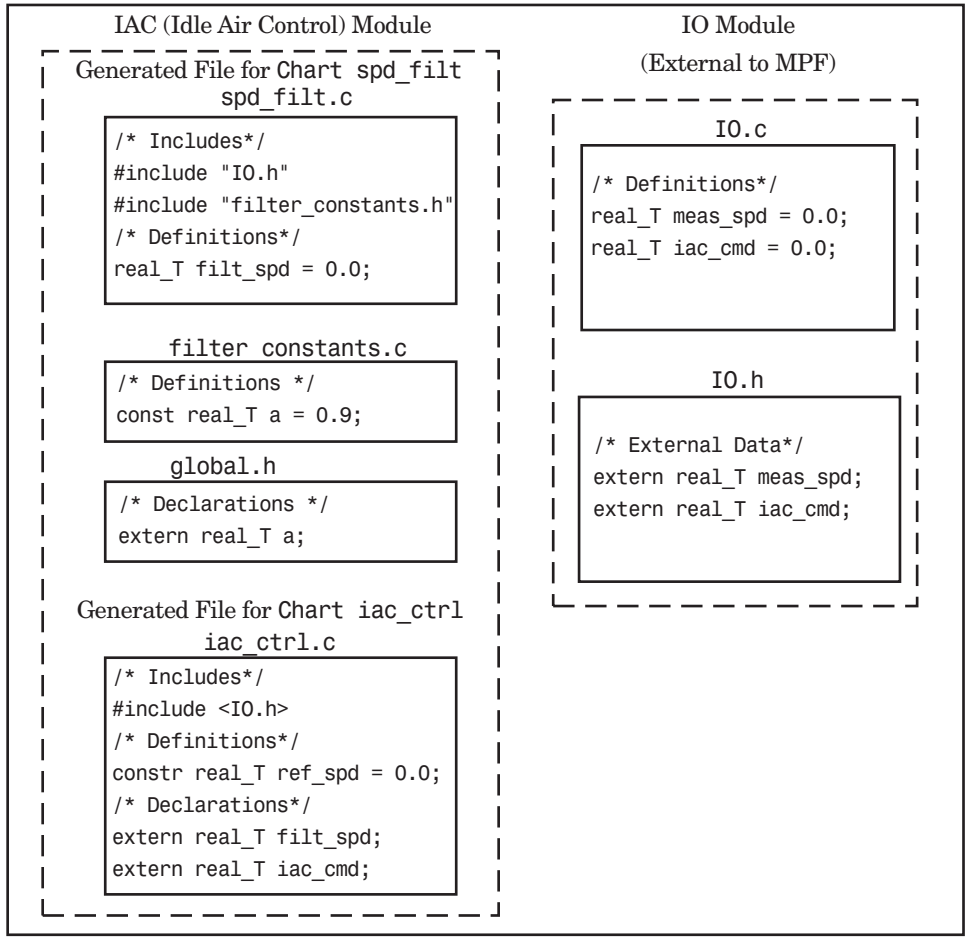
Since you specified the `IO.h` filename for the **Header file** field for the `meas_spd` and `iac_ctrl` objects, the code generator assumed that their declarations are in `IO.h`. So the code generator placed `#include IO.h` in each source file: `spd_filt.c` and `iac_ctrl.c`. So these two files will link with the external IO files. Also, due to the ownership settings that were specified, the code generator places the `real_T filt_spd = 0.0;` definition in `spd_filt.c` and declares the `filt_spd` identifier in `iac_ctrl.c` with `extern real_T iac_cmd;`. Consequently, the two source files will link together.

Definition File

These settings and the generated files that result are shown as Example Settings 4 in "Settings and Resulting Generated Files" on page 36-116. Notice that a definition filename is specified. The settings in the table only apply to the data object called `a`. You have decided that you do not want this object defined in `spd_filt.c`, the generated source file for the `spd_filt` chart. (There are many possible organizational reasons one might want an object declared in another file. It is not important for this example to specify the reason.)

For this example, assume the settings for all data objects are the same as those indicated in "Header File" on page 36-112, except for the data object `a`. The description below identifies only the differences that result from this.

Open the Model Explorer, and select data object `a`. In the **Definition file** field specify a filename. Choose `filter_constants.c`. Generate code. The results are shown in the next figure.



Engine Idle Speed Control System (Definition File Example)

The code generator generates the same files as in the “Header File” on page 36-112, and adds a new file, `filter_constants.c`. Data object `a` now is defined in `filter_constants.c`, rather than in the source file `spd_filt.c`, as it is in the example. This data object is declared with an `extern` statement in `global.h`

Data Placement Rules and Results

- “Ownership Settings” on page 36-116

- "Settings and Resulting Generated Files" on page 36-116
- "Data Placement Rules" on page 36-118

Ownership Settings

Row Number	Enable Data Ownership Checkbox	Owner Setting	Result*
1	`Off**`	Blank**	The code generator determines whether the current model defines and initializes data.
2	`Off**`	A name is specified.	The code generator determines whether the current model defines and initializes data.
3	`On`	Blank**	The code generator determines whether the current model defines and initializes data.
4	`On`	A name is specified.	The model specified in the **Owner** setting defines and initializes data.

* See also "Ownership Settings" on page 36-106.** Default.

Settings and Resulting Generated Files

	Data Defined In...	Data Declared In...	Owner-ship*	Defined File**	Header File	Generated Files
Example Settings 1 (Rd-Write Example)	Source file	Source file	Blank	Blank	Blank	`.c/.cpp` source file
Example Settings 2 (Owner- ship Example)	Source file	Source file	Name of module specified	Blank	Blank	`.c/.cpp` source file
Example Settings 3 (Header File Example)	Source file	Source file	Blank	Blank	Desired include filename specified.	`.c/.cpp` source file `.h` definition file

	Data Defined In...	Data Declared In...	Owner-ship*	Defined File**	Header File	Generated Files
Example Settings 4 (Def. File Example)	Source file	Source file	Blank	Desired definition filename specified.	Desired include filename specified.	`.c/.cpp` source file `.c/.cpp` definition file* `.h` definition file*
Example Settings 5	Single separate source file	Source file	Blank	Blank	Blank	`.c/.cpp` source file global `.c/.cpp`
Example Settings 6	Single separate source file	Single separate header file	Blank	Blank	Blank	`.c/.cpp` source file `global .c/.cpp` `global.h`
Example Settings 7	Single separate source file	Single separate header file	Name of module specified	Blank	Blank	`.c/.cpp` source file `global.c/.cppglobal.h`
Example Settings 8	Single separate source file	Single separate header file	Blank	Blank	Desired include filename specified.	`.c/.cpp` source file `global.c/.cppglobal.h` `.h` definition file

* "Blank" in ownership setting means that the check box for the **Use owner from data object for data definition placement** field on the **Code Placement** pane is `Off` and the **Owner** field on the Model Explorer is blank. "Name of module specified" can be a variety of ownership settings as defined in “Ownership Settings” on page 36-116.

** The code generator generates a definition `.c/.cpp` file for every data object for which you specified a definition filename (unless you selected `#DEFINE` for the **Memory section** field). For example, if you specify the same definition filename for all data objects, only one definition `.c/.cpp` file is generated. The code generator places declarations in *`model`*`.h` by default, unless you specify `Data declared in single separate header file` for the **Data declaration** option on the **Code Generation** > **Code Placement** pane of the Configuration Parameter dialog box. If you select that data placement option, the code generator places declarations in `global.h`. If you specify a definition filename for each data object, the code generator generates one definition `.c/.cpp` file for each data object and places declarations in *`model`*`.h` by default, unless you specify `Data declared in single separate header file` for **Data declaration**. If you select that data placement option, the code generator places declarations in `global.h`.

Note: If you generate C++ rather than C code, the `.c` files listed in the following table will be `.cpp` files.

Data Placement Rules

	Global Settings:		Override Settings for Specific Data Object:			Results in Generated Files:

Notes

In the previous table:

- A Declaration Inclusion Approach is a file in which the header file that contains the data declarations is included.
- D/C stands for don't care.
- Dec stands for declaration.
- Def stands for definition.
- `gbl` stands for global.
- `hdr` stands for header.
- N/A stands for not applicable.
- null stands for field is blank.
- `sep` stands for separate.

Note 1: `model.h` is included directly in all source files.

Note 2: `model_private.h` is included directly in all source files.

Note 3: `extern` is included in `model_private.h`, which is in `source.c`.

Note 4: `header.h` is included in `model_private.h`, which is in `source.c`.

Note 5: `model.h` is included directly in all source files that use `#define`.

Note 6: `header.h` is included in `model.h`, which is in source files that use `#define`.

Note 7: `model.h` is included in all `source.c` files.

Note 8: `extern` is inlined in source files where data is used.

Note 9: `global.h` is included in `model.h`, which is in all source files.

Note 10: When you specify a definition filename for a data object, a header file is not generated for that data object. The code generator declares the data object according to the data placement priorities.

Note 11: `header.h` is included in `model.h`, which is in all source files.

Note 12: Signal: Either not defined because it is expression folded, or local data, or defined in a structure in `model.c`, all depending on model's code generation settings. Parameter: Either inlined in the code, or defined in `model_data.c`.

Note 13: Signal: In a structure that is defined in `model.c`. Parameter: In a structure that is defined in `model_data.c`.

Specify Default `#include` Syntax for Data Header Files

To control the file placement of a data item such as a signal line or block state in the generated code, you can apply a custom storage class to the data item (see "Introduction to Custom Storage Classes" on page 23-2). You then use the `HeaderFile` custom attribute to specify the generated or custom header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify `HeaderFile`, you can omit delimiters (`"` or `<>`) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters** > **Code Generation** > **Code Placement** > **#include file delimiters** to `#include <header.h>`.

Enhance Readability of Code for Flow Charts

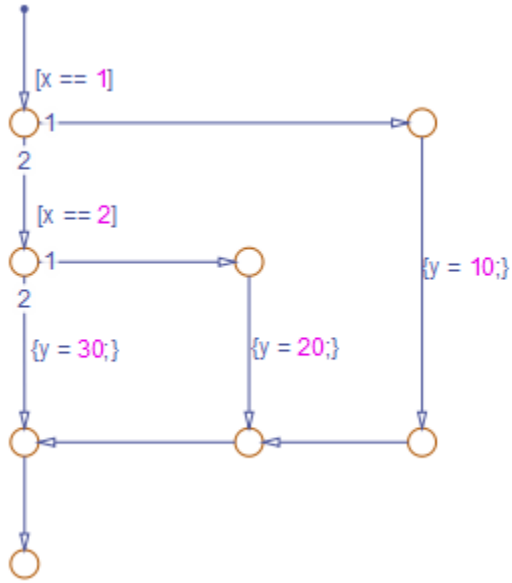
In this section...

Appearance of Generated Code for Flow Charts

If you have an Embedded Coder license and you generate code for models that include Stateflow objects, the code from a flow chart resembles the samples that follow.

The following characteristics apply:

- By default, the generated code uses `if-elseif-else` statements to represent `switch` patterns. To convert the code to use `switch-case` statements, see “Convert If-Elseif-Else Code to Switch-Case Statements” on page 36-130.
- By default, variables that appear in the flow chart do not retain their names in the generated code. Modified identifiers make sure that no naming conflicts occur.
- Traceability comments for the transitions appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Trace Stateflow Objects in Generated Code” on page 61-10.

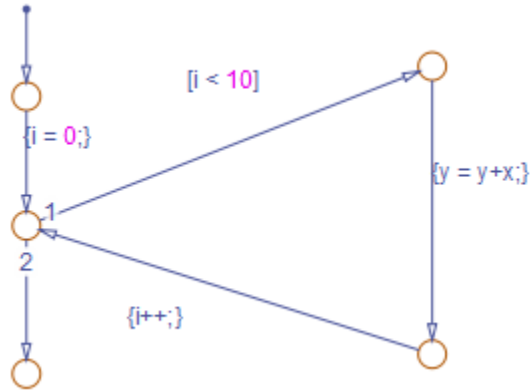


```
if (modelname_U.In1 == 1.0) {
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  modelname_Y.Out1 = 10.0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
} else {
  /* Transition: '<S1>:10' */
  if (modelname_U.In1 == 2.0) {
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    modelname_Y.Out1 = 20.0;

    /* Transition: '<S1>:16' */
  } else {
    /* Transition: '<S1>:17' */
    modelname_Y.Out1 = 30.0;
  }
}
```

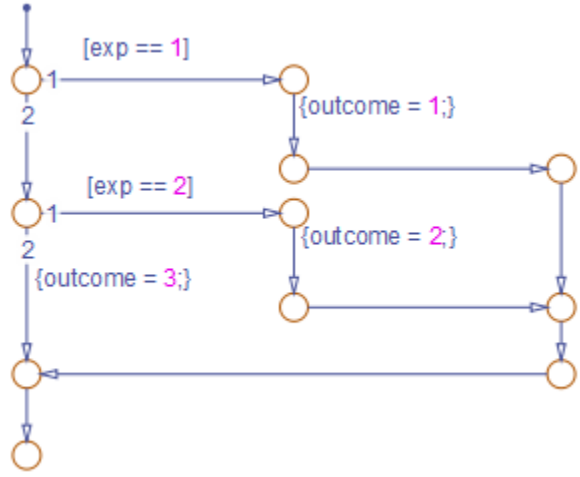
Sample Code for a Decision Logic Pattern



```
for (sf_i = 0; sf_i < 10; sf_i++) {
  /* Transition: '<S1>:40' */
  /* Transition: '<S1>:41' */
  modelname_B.y = modelname_B.y +
    modelname_U.In1;

  /* Transition: '<S1>:39' */
}
```

Sample Code for an Iterative Loop Pattern



```
if (modelname_U.In1 == 1.0) {
  /* Transition: '<S1>:149' */
  /* Transition: '<S1>:150' */
  modelname_Y.Out1 = 1.0;

  /* Transition: '<S1>:151' */
  /* Transition: '<S1>:152' */
  /* Transition: '<S1>:158' */
  /* Transition: '<S1>:159' */
} else {
  /* Transition: '<S1>:156' */
  if (modelname_U.In1 == 2.0) {
    /* Transition: '<S1>:153' */
    /* Transition: '<S1>:154' */
    modelname_Y.Out1 = 2.0;

    /* Transition: '<S1>:155' */
    /* Transition: '<S1>:158' */
    /* Transition: '<S1>:159' */
  } else {
    /* Transition: '<S1>:161' */
    modelname_Y.Out1 = 3.0;
  }
}
```

Sample Code for a Switch Pattern

Convert If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` code to `switch-case` statements. This conversion can enhance readability of the code. For example, when a flow chart contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the flow chart from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your flow chart follows the rules for conversion.	"Verify the Contents of the Flow Chart" on page 36-134
2	Enable the conversion.	"Enable the Conversion" on page 36-135
3	Generate code for your model.	"Generate Code for Your Model" on page 36-136
4	Troubleshoot the generated code. • If you see `switch-case` statements for your flow chart, you can stop. • If you see `if-elseif-else` statements for your flow chart, update the chart and repeat the previous step.	"Troubleshoot the Generated Code" on page 36-136

Rules of Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
Flow chart	Must have two or more *unique* conditions, in addition to a default. For more information, see "How the Conversion Handles Duplicate Conditions" on page 36-132.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS. **Note:** You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Cannot have any side effects on simulation.

Construct	Rules to Follow
	For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

How the Conversion Handles Duplicate Conditions

If a flow chart has duplicate conditions, the conversion preserves only the first condition. The code discards the other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. If not, the conversion does not occur and the code contains all duplicate conditions.

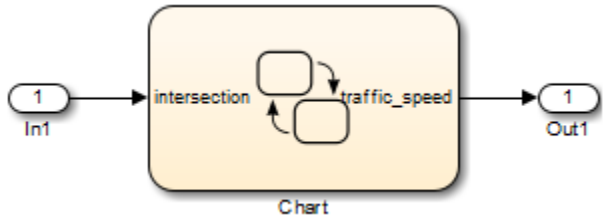
Example of Generated Code	Code After Conversion

`if (x == 1) {`
`  block1`
`} else if (x == 2) {`
`  block2`
`} else if (x == 1) {  // duplicate`
`  block3`
`} else if (x == 3) {`
`  block4`
`} else if (x == 1) {  // duplicate`
`  block5`
`} else {`
`  block6`
`}`
	`switch (x) {`
	`  case 1:`
	`  block1; break;`
	`  case 2:`
	`  block2; break;`
	`  case 3:`
	`  block4; break;`
	`  default:`
	`  block6; break;`
	`}`

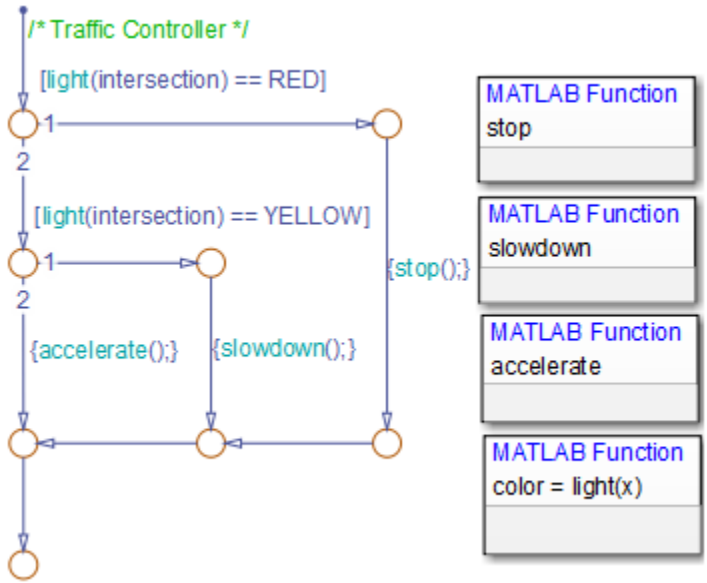
`if (x == 1) {`
`  block1`
`} else if (x == 1) {  // duplicate`
`  block2`
`} else {`
`  block3`
`}`
	No change, because only one unique condition exists

Example of Converting Code to Switch-Case Statements

Suppose that you have the following model with a single chart.



The chart contains a flow chart and four MATLAB functions:



The MATLAB functions in the chart contain the code in the following table. In each case, the **Function Inline Option** is `Auto`. For more information about function inlining, see "Specify Graphical Function Properties" (Stateflow).

MATLAB Function	Code

`stop`	`function stop`
	`%#codegen`
	`coder.extrinsic('disp');`
	`disp('Not moving.')`

MATLAB Function	Code
	`traffic_speed = 0;`

`slowdown`	`function slowdown`
	`%#codegen`
	`coder.extrinsic('disp')`
	`disp('Slowing down.')`
	
	`traffic_speed = 1;`

`accelerate`	`function accelerate`
	`%#codegen`
	`coder.extrinsic('disp');`
	`disp('Moving along.')`
	
	`traffic_speed = 2;`

`light`	`function color = light(x)`
	`%#codegen`
	`if (x < 20)`
	`    color = TrafficLights.GREEN;`
	`elseif (x >= 20 && x < 25)`
	`    color = TrafficLights.YELLOW;`
	`else`
	`    color = TrafficLights.RED;`
	`end`

The output `color` of the function `light` uses the enumerated type `TrafficLights`. The enumerated type definition in `TrafficLights.m` is:

```
classdef TrafficLights < Simulink.IntEnumType
  enumeration
    RED(0)
    YELLOW(5)
    GREEN(10)
  end
end
```

For more information, see "Define Enumerated Data in a Chart" (Stateflow).

Verify the Contents of the Flow Chart

Check that the flow chart in your chart follows the rules in "Rules of Conversion" on page 36-131.

Construct	How the Construct Follows the Rules
Flow chart	Two unique conditions exist, in addition to the default: • `[light(intersection) == RED]` • `[light(intersection) == YELLOW]`
Each condition	Each condition: • Tests equality • Uses the same function call `light(intersection)` for the LHS
Each LHS	Each LHS: • Contains a single expression • Is the output of a function call and therefore not a constant • Is of enumerated type `TrafficLights`, which you define in `TrafficLights.m` on the MATLAB path (see "Define Enumerated Data in a Chart" (Stateflow)) • Uses a function call that does not have side effects
Each RHS	Each RHS: • Is an enumerated value and therefore a constant • Is of enumerated type `TrafficLights`

Enable the Conversion

1. Open the Model Configuration Parameters dialog box.
2. In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

   This step specifies an ERT-based target for your model.
3. In the **Code Generation** > **Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

Tip: This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- Flow charts in all charts of a model
- MATLAB functions in all charts of a model

- All MATLAB Function blocks in that model

Generate Code for Your Model

In the model, select **Code > C/C++ Code > Build Model** to generate source code from the model.

Troubleshoot the Generated Code

The generated code for the flow chart appears something like this:

```
if (sf_color == RED) {
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  /* MATLAB Function 'stop': '<S1>:23' */
  /* '<S1>:23:6' */
  rtb_traffic_speed = 0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
} else {
  /* Transition: '<S1>:10' */
  /* MATLAB Function 'light': '<S1>:19' */
  if (ifelse_using_enums_U.In1 < 20.0) {
    /* '<S1>:19:3' */
    /* '<S1>:19:4' */
    sf_color = GREEN;
  } else if ((ifelse_using_enums_U.In1 >= 20.0) &&
             (ifelse_using_enums_U.In1 < 25.0)) {
    /* '<S1>:19:5' */
    /* '<S1>:19:6' */
    sf_color = YELLOW;
  } else {
    /* '<S1>:19:8' */
    sf_color = RED;
  }

  if (sf_color == YELLOW) {
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    /* MATLAB Function 'slowdown': '<S1>:24' */
    /* '<S1>:24:6' */
    rtb_traffic_speed = 1;
```

```
    /* Transition: '<S1>:16' */
  } else {
    /* Transition: '<S1>:17' */
    /* MATLAB Function 'accelerate': '<S1>:25' */
    /* '<S1>:25:6' */
    rtb_traffic_speed = 2;
  }
}
```

Because the MATLAB function `light` appears inlined, inequality comparisons appear in these lines of code:

```
if (ifelse_using_enums_U.In1 < 20.0) {
....
} else if ((ifelse_using_enums_U.In1 >= 20.0) &&
             (ifelse_using_enums_U.In1 < 25.0)) {
....
```

Because inequalities appear in the body of the `if-elseif-else` code for the flow chart, the conversion to `switch-case` statements does not occur. To prevent this behavior, do one of the following:

- Specify that the function `light` does not appear inlined. See "Change the Inlining Property for the Function" on page 36-137.
- Modify the flow chart. See "Modify the Flow Chart to Ensure Switch-Case Statements" on page 36-139.

Change the Inlining Property for the Function

If you do not want to modify your flow chart, change the inlining property for the function `light`:

1. Right-click the function box for `light` and select **Properties**.

   The properties dialog box appears.
2. For **Function Inline Option**, select `Function`.
3. Click **OK** to close the dialog box.

Note: You do not have to change the inlining property for the other three MATLAB functions in the chart. Because the flow chart does not call those functions during evaluation of conditions, the inlining property for those functions can remain `Auto`.

When you regenerate code for your model, the code for the flow chart now appears something like this:

```
switch (ifelse_using_enums_light(ifelse_using_enums_U.In1)) {
 case RED:
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  /* MATLAB Function 'stop': '<S1>:23' */
  /* '<S1>:23:6' */
  ifelse_using_enums_Y.Out1 = 0.0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
  break;

 case YELLOW:
  /* Transition: '<S1>:10' */
  /* Transition: '<S1>:13' */
  /* Transition: '<S1>:14' */
  /* MATLAB Function 'slowdown': '<S1>:24' */
  /* '<S1>:24:6' */
  ifelse_using_enums_Y.Out1 = 1.0;

  /* Transition: '<S1>:16' */
  break;

 default:
  /* Transition: '<S1>:17' */
  /* MATLAB Function 'accelerate': '<S1>:25' */
  /* '<S1>:25:6' */
  ifelse_using_enums_Y.Out1 = 2.0;
  break;
}
```

Because the MATLAB function `light` no longer appears inlined, the conversion to `switch-case` statements occurs. The `switch-case` statements provide the following benefits to enhance readability:

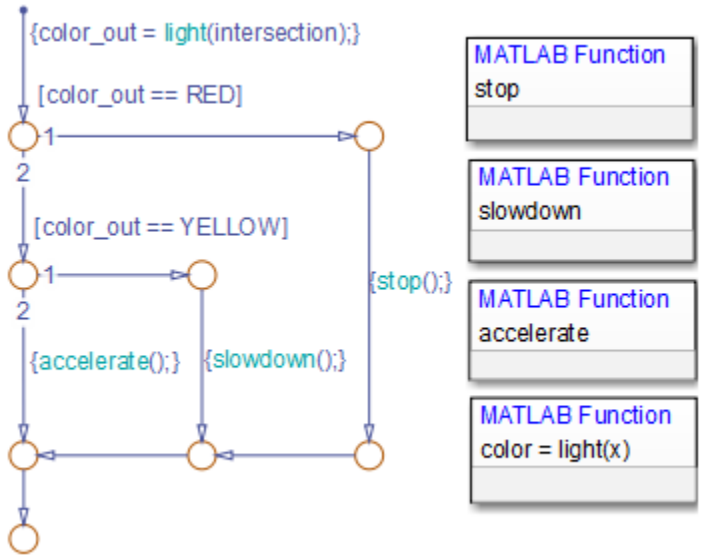
- The code reduces the use of parentheses and braces.
- The LHS expression `ifelse_using_enums_light(ifelse_using_enums_U.In1)` appears only once, minimizing repetition in the code.

Modify the Flow Chart to Ensure Switch-Case Statements

If you do not want to change the inlining property for the function `light`, modify your flow chart:

1. Add chart local data `color_out` with the enumerated type `TrafficLights`.
2. Replace each instance of `light(intersection)` with `color_out`.
3. Add the action `{color_out = light(intersection)}` to the default transition of the flow chart.

The chart should now look something like this:



When you regenerate code for your model, the code for the flow chart uses `switch-case` statements.

Generate Inlined Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, the **Function packaging** parameter specifies the format of the subsystem's generated code. This parameter has four settings: `Auto`, `Inline`, `Nonreusable function`, and `Reusable function`. The code generator can generate inlined code for the `Auto` or `Inline` settings.

The `Inline` setting explicitly directs the code generator to inline the subsystem code unconditionally.

The default `Auto` setting directs the code generator to generate the most efficient code for the subsystem based on the type and number of instances of the subsystem that exist in the model. When there is only one instance of a subsystem, the `Auto` setting inlines the subsystem code. When there are multiple instances of a subsystem, that is not too complex, the `Auto` setting inlines the code for each subsystem. Otherwise, the `Auto` setting generates a single copy of the function (as a reusable function). For a function-call subsystem with multiple callers, the `Auto` setting generates subsystem code that is consistent with the `Nonreusable function` setting.

Configure Subsystem to Inline Code

To configure your subsystem for inlining:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.
3. Click the **Code Generation** tab and select `Auto` or `Inline` from the **Function packaging** parameter.
4. Click **Apply** and close the dialog box.

   The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within *`model`*`.c` or *`model`*`.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though you select the `Inline` setting.

- If a noninlined S-function calls a function-call subsystem, the code generator ignores the `Inline` setting. Because noninlined S-functions use function pointers to make function calls, the code generator must generate a function with all arguments present.
- In a feedback loop involving function-call subsystems, the code generator generates a function instead of inlined code for one of the subsystems. Based on the internal, sorted order of the subsystems, the code generator selects which subsystem to generate a function.
- If an S-function, an Async Interrupt, or a Task Sync block with the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` set to `TRUE` calls a subsystem, the code generator generates a function instead of inlined code for the subsystem. The VxWorks block library (`vxlib1`), contains the user-defined Async Interrupt and Task Sync blocks.[7]

Code Replacement in Simulink Coder

What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from the following libraries that MathWorks provides:

- GNU C99 extensions—GNU[8] gcc math library, which provides C99 extensions as defined by compiler option `-std=gnu99`.
- AUTOSAR 4.0—Produces code that more closely aligns with the AUTOSAR standard. Requires an Embedded Coder license.
- Intel IPP for x86-64 (Windows)—Generates calls to the Intel® Performance Primitives (IPP) library for the x86-64 Windows platform.
- Intel IPP/SSE for x86-64 (Windows)—Generates calls to the IPP and Streaming SIMD Extensions (SSE) libraries for the x86-64 Windows platform.
- Intel IPP for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP library for the x86-64 Windows platform and MinGW compiler.

8. GNU is a registered trademark of the Free Software Foundation.

- Intel IPP/SSE for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP and SSE libraries for the x86-64 Windows platform and MinGW compiler.
- Intel IPP for x86/Pentium (Windows)—Generates calls to the IPP library for the x86/Pentium Windows platform.
- Intel IPP/SSE for x86/Pentium (Windows)—Generates calls to the Intel Performance IPP and SSE libraries for the x86/Pentium Windows platform.
- Intel IPP for x86-64 (Linux)—Generates calls to the IPP library for the x86-64 Linux platform.
- Intel IPP/SSE with GNU99 extensions for x86-64 (Linux)—Generates calls to the GNU libraries for IPP and SSE, with GNU C99 extensions, for the x86-64 Linux platform.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available . If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

Code Replacement Libraries

A *code replacement library* consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A *code replacement table* contains one or more *code replacement entries*, with each entry representing a potential replacement for a function or operator. Each entry maps a *conceptual representation* of a function or operator to an *implementation representation* and priority.

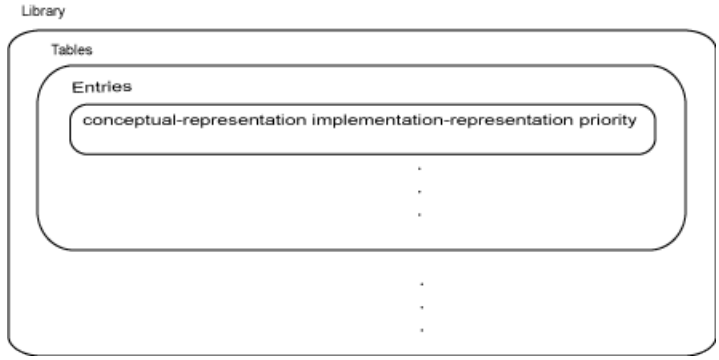

Table Entry Component	Description
Conceptual representation	Identifies the table entry and contains match criteria for the code generator. Consists of: • Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name `'cos'` and operator key `'RTW_OP_ADD'`. • Conceptual arguments that observe code generator naming (`'y1'`, `'u1'`, `'u2'`, ...), with corresponding I/O types (output or input) and data types. • Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.
Implementation representation	Specifies replacement code. Consists of: • Function name. For example, `'cos_dbl'` or `'u8_add_u8_u8'`. • Implementation arguments, with corresponding I/O types (output or input) and data types. • Parameters that provide additional implementation details, such as header and source file names and paths of build resources.

Table Entry Component	Description
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a *call site object* with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions

Term	Definition
	and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: • Function or operator name or key • Conceptual arguments with type, dimension, and complexity specification for inputs and output • Attributes, such as an algorithm and fixed-point saturation and rounding modes
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: • Function name (for example, `'cos_dbl'` or `'u8_add_u8_u8'`) • Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output • Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key `RTW_OP_ADD` identifies the addition operator.
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

Choose a Code Replacement Library

In this section...

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in "What Is Code Replacement?" on page 38-2.
   - See "Explore Available Code Replacement Libraries" on page 37-9.
2. Explore the contents of the library. See "Explore Code Replacement Library Contents" on page 37-9.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

Select the "Code replacement library" (Simulink Coder) to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2. In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
3. In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
4. In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

   If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that MATLAB, Simulink, Simulink Coder, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can also require Embedded Coder.

   To install MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver` .
2. Identify an existing or create a Simulink model for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore the available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

   - In the Configuration Parameters dialog box, on the **Code Generation** > **Interface** pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
   - Set the `CodeReplacementLibrary` parameter at the command line or programmatically.
2. Configure the code generator to produce code only (not build an executable) so you can verify your code replacements before building an executable. Do one of the following:

   - In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only” (Simulink Coder).
   - Set the `GenCodeOnly` parameter at the command line or programmatically.

Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select "Create code generation report" (Simulink Coder). Consider having the report open automatically. Select "Open report automatically" (Simulink Coder).
2. Include the code replacement section in the report. On the **All Parameters** tab, select "Summarize which blocks triggered code replacements" (Simulink Coder).

Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Code Replacement for Simulink Models in Embedded Coder

What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from the following libraries that MathWorks provides:

- GNU C99 extensions—GNU[9] gcc math library, which provides C99 extensions as defined by compiler option `-std=gnu99`.
- AUTOSAR 4.0—Produces code that more closely aligns with the AUTOSAR standard. Requires an Embedded Coder license.
- Intel IPP for x86-64 (Windows)—Generates calls to the Intel Performance Primitives (IPP) library for the x86-64 Windows platform.
- Intel IPP/SSE for x86-64 (Windows)—Generates calls to the IPP and Streaming SIMD Extensions (SSE) libraries for the x86-64 Windows platform.
- Intel IPP for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP library for the x86-64 Windows platform and MinGW compiler.

9. GNU is a registered trademark of the Free Software Foundation.

- Intel IPP/SSE for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP and SSE libraries for the x86-64 Windows platform and MinGW compiler.
- Intel IPP for x86/Pentium (Windows)—Generates calls to the IPP library for the x86/Pentium Windows platform.
- Intel IPP/SSE for x86/Pentium (Windows)—Generates calls to the Intel Performance IPP and SSE libraries for the x86/Pentium Windows platform.
- Intel IPP for x86-64 (Linux)—Generates calls to the IPP library for the x86-64 Linux platform.
- Intel IPP/SSE with GNU99 extensions for x86-64 (Linux)—Generates calls to the GNU libraries for IPP and SSE, with GNU C99 extensions, for the x86-64 Linux platform.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available . If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

Code Replacement Libraries

A *code replacement library* consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A *code replacement table* contains one or more *code replacement entries*, with each entry representing a potential replacement for a function or operator. Each entry maps a *conceptual representation* of a function or operator to an *implementation representation* and priority.

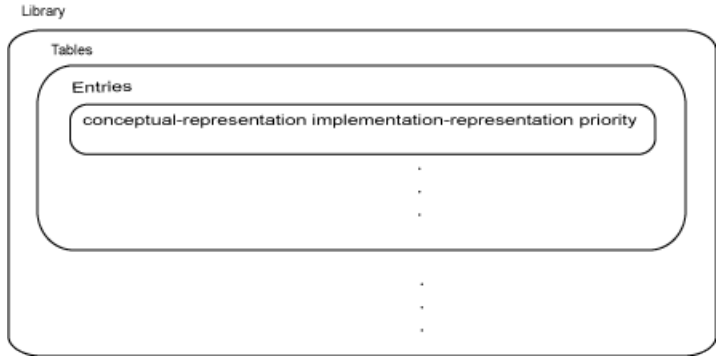

Table Entry Component	Description
Conceptual representation	Identifies the table entry and contains match criteria for the code generator. Consists of: • Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name `'cos'` and operator key `'RTW_OP_ADD'`. • Conceptual arguments that observe code generator naming (`'y1'`, `'u1'`, `'u2'`, ...), with corresponding I/O types (output or input) and data types. • Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.
Implementation representation	Specifies replacement code. Consists of: • Function name. For example, `'cos_dbl'` or `'u8_add_u8_u8'`. • Implementation arguments, with corresponding I/O types (output or input) and data types. • Parameters that provide additional implementation details, such as header and source file names and paths of build resources.

Table Entry Component	Description
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a *call site object* with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions

Term	Definition
	and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: • Function or operator name or key • Conceptual arguments with type, dimension, and complexity specification for inputs and output • Attributes, such as an algorithm and fixed-point saturation and rounding modes
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: • Function name (for example, `'cos_dbl'` or `'u8_add_u8_u8'`) • Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output • Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key `RTW_OP_ADD` identifies the addition operator.
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

Related Examples

- “Choose a Code Replacement Library” on page 38-9
- “Replace Code Generated from Simulink Models” on page 38-11

Choose a Code Replacement Library

In this section...

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in "What Is Code Replacement?" on page 38-2.
   - See "Explore Available Code Replacement Libraries" on page 37-9.
2. Explore the contents of the library. See "Explore Code Replacement Library Contents" on page 37-9.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

Select the "Code replacement library" (Simulink Coder) to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2. In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
3. In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
4. In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

   If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that MATLAB, Simulink, Simulink Coder, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can also require Embedded Coder.

   To install MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver` .
2. Identify an existing or create a Simulink model for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore the available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

   - In the Configuration Parameters dialog box, on the **Code Generation** > **Interface** pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
   - Set the `CodeReplacementLibrary` parameter at the command line or programmatically.
2. Configure the code generator to produce code only (not build an executable) so you can verify your code replacements before building an executable. Do one of the following:

   - In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only” (Simulink Coder).
   - Set the `GenCodeOnly` parameter at the command line or programmatically.

Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select "Create code generation report" (Simulink Coder). Consider having the report open automatically. Select "Open report automatically" (Simulink Coder).
2. Include the code replacement section in the report. On the **All Parameters** tab, select "Summarize which blocks triggered code replacements" (Simulink Coder).

Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Deployment

External Code Integration in Simulink Coder

The code generator includes multiple approaches for integrating legacy or custom code with generated code. *Legacy code* is existing handwritten code or code for environments that you integrate with code produced by the code generator. *Custom code* is legacy code or other user-specified lines of code that you include in the code generator build process. Collectively, legacy and custom code are called *external code*.

You integrate external code by importing existing external code into code produced by the code generator, exporting generated code into an existing external code base, or you can do both. For example, you can import code by calling an external function, by using the Legacy Code Tool, or place external code at specific locations in generated code by including Custom Code blocks in a model. When you import external code, the resulting generated code interfaces with generated scheduling code.

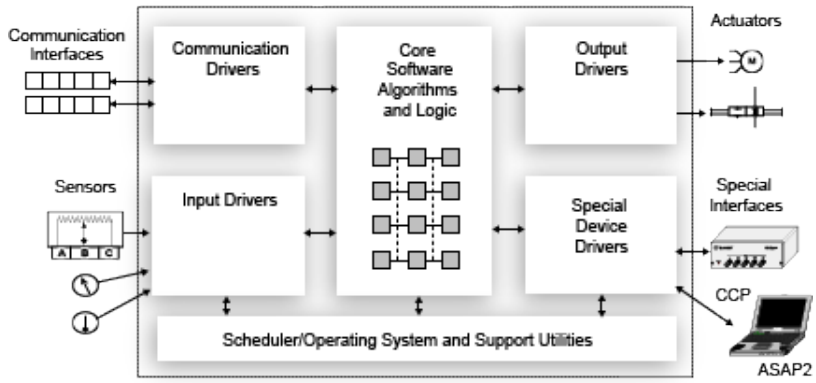
You can export generated code as a plug-in function for use in an external development environment. When you export generated code, you intend to interface that code manually with a scheduling mechanism in your application run-time environment.

For guidance on choosing an approach based on your application, see “Choose an External Code Integration Workflow” (Simulink Coder) .

What Is External Code Integration?

Software projects typically involve combining code from multiple sources. A typical system structure for a code generation application consists of a framework that combines code from multiple sources, including external code and code generated from Simulink models.

This figure shows an application that requires integration of existing driver code for hardware devices. The core software algorithms and logic can be a combination of code modules for external reusable algorithms integrated into the Simulink environment and code generated as part of an overall model design.



Several workflows and tools are available for you to integrate external and generated code. Each workflow identifies tooling for generating code that aligns interfaces, code appearance, and other factors, such as optimization between external and generated code.

More About

- “Choose an External Code Integration Workflow” on page 39-4

Choose an External Code Integration Workflow

In this section...

Completing these tasks helps you choose external code integration workflows and tooling that align with your project.

Task	Action	More Information
1	Partition your application, map algorithms to components, and identify integration points.	"Design Models for Generated Embedded Code Deployment" on page 1-2
2	Determine whether you can rely on scheduling code that the code generator produces, or whether you must integrate generated code with scheduling mechanisms that are specific to your run-time environment.	"Choose a Software Execution Framework" on page 39-4
3	Evaluate the characteristics of the external code that you are importing or to which you are exporting generated code.	"Evaluate Characteristics of External Code" on page 39-7
4	Identify integration requirements, which assists with choosing optimal tooling for your integration.	"Identify Integration Requirements" on page 39-8
5	Based on the results of tasks 1–4, choose a workflow.	"Choose a Workflow" on page 39-10

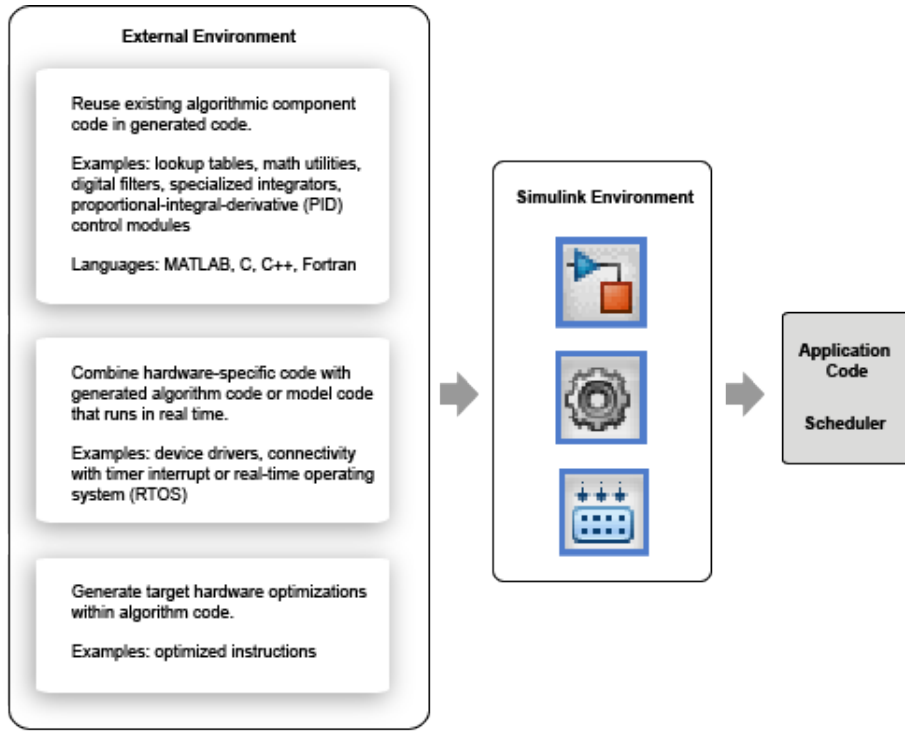
Choose a Software Execution Framework

The code generator supports two types of software execution frameworks—single top model and multiple top-level, as described in "Design Models for Generated Embedded

Code Deployment" on page 1-2. The first question to answer concerns which of the two frameworks applies to your project.

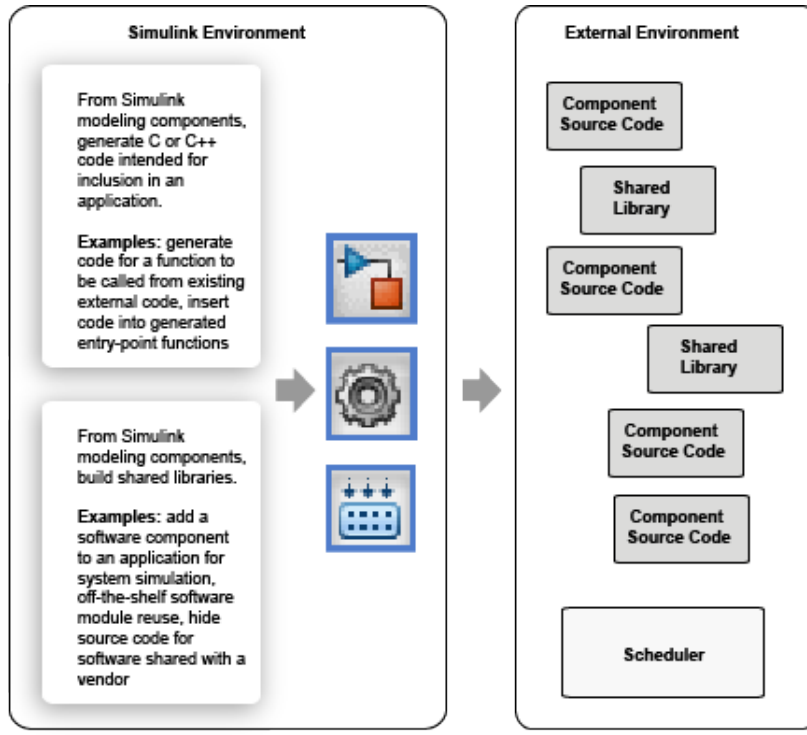
- Single top model

  Generate one set of application code files from external code and code that the Simulink C/C++ code generator produces. The generated code includes a scheduler. In this case, you *import* code into the Simulink code generation environment.



- Single top model or multiple top-level models

  Integrate C or C++ code that the code generator produces from model components with external application code and an external scheduler. You *export* generated code from the Simulink code generation environment.



Importing calls to external device driver code into a model and generating code for that model for export involves importing and exporting code.

Based on goals and requirements, external code integration is characterized in several ways, requiring different workflows and integration tooling:

- Import existing external code into generated code.
  - Call reusable external algorithm code for simulation and code generation.
  - Place external C/C++ code in generated code.
  - Call external device drivers.
  - Apply function and operator code replacements.
  - Interface with external timer interrupt or scheduler.
  - Generate replacement code for specific run-time environment.

- Export generated code for inclusion in external code base.
  - Generate component source code for export.
  - Generate shared library for export.

Next, see "Evaluate Characteristics of External Code" on page 39-7.

Evaluate Characteristics of External Code

Before choosing an external integration workflow, evaluate these characteristics of the external code. To interface with external code, generated C or C++ code handles one or more of the external code characteristics. An understanding of these characteristics and your requirements for modeling, simulation, and code generation helps you choose the optimal workflow for your integration scenario. (See "Identify Integration Requirements" on page 39-8.)

Characteristic	What to Consider
Hardware dependency	Is the external code hardware-dependent? Utility functions, lookup tables, and filters are examples of hardware-independent code. Device drivers interact directly with hardware. They depend on characteristics of the hardware. For example, a device driver for an analog-to-digital converter initializes, reads data from, and writes data to hardware registers. Hardware differences and dependencies concern data type size, endianess, shift operations, compiler directives, and optimized function and operator support. Other code interfaces with device drivers by using an API and data mapped to specific memory addresses. Typically, simulation on a development computer is not possible. Reading from and writing to a register during simulation on a development computer produces unexpected and unwanted results.
Reusable	Is the external code a reusable software module? Examples include utility functions, lookup tables, filters, specialized integrators, and proportional-integral-derivative (PID) control modules.
Dependency on data persistence between function calls	Does the external code require persistent data? For example, a call to a first order filter function uses the output of the previous call to the function to calculate a new output value. You have the option of defining the data as global or using shared memory outside the context of the function.

Characteristic	What to Consider
Data typing and interface	How complex is the data that the external code uses? What does the data interface look like? It consists of arguments, a return value, global variables, and access functions. What data types does the code use? Are the types limited to basic ANSI C integers, floating-point types, arrays of integers or floating-point types, and pointers to these types? Does the interface include structures or pointers to structures?
Fixed-point code	Is the external code designed to run on integer-only processors? If yes, the code exchanges and uses data represented as integers only. Data can be associated with fixed-point scaling or offsets.
External resource dependencies	Does the external code use data, functions, or macros defined outside the scope of the code? For example, the function can use a standard ANSI function, a shared library, or predefined constants. In these cases, you must inform the compiler and linker of the paths and file names of the external resources.
External solver required	Are you using the external function for advanced development or rapid prototyping to describe a system with a continuous transfer function or a set of differential equations? If yes, the external code relies on an external solver.

Next, see “Identify Integration Requirements” on page 39-8.

Identify Integration Requirements

Before choosing an external integration workflow, review these integration requirements. An understanding of these requirements and the characteristics of your external code helps you choose the optimal workflow for your integration scenario. (See “Evaluate Characteristics of External Code” on page 39-7.)

Requirement	What to Consider
Effort	What level of effort is planned for the integration project—low, medium, or high?
Learning effort	What is the programming experience of assigned project resources? How much experience do assigned resources have with Simulink and MathWorks C/C++ code generation products?

Requirement	What to Consider
Simulation and code generation behaviors	Do you want to take advantage of Model-Based Design? To take full advantage of Model-Based Design, convert code to modeling elements, which you can then use in the Simulink and Stateflow simulation environment. Then, simulate and generate code for the integrated component. Use software-in-the-loop (SIL) or processor-in-the-loop (PIL) testing to verify whether algorithm behavior is the same in both environments.
Data interface and typing	• Does your model or generated code need to exchange data with the external function? If so, map inputs, outputs, and parameters to the external function interface. Typical function interfaces involve function arguments and return values, global variables, and access functions, such as `getRPM`. • Do you want to represent arrays, structures, or enumerated types? In the Simulink environment, you can represent these types as vectors, buses, and `IntEnum`, respectively. • Is fixed-point support required? If you use the Simulink fixed-point interface, you can scale and specify offsets. • Does the external code use company-specific data types? If yes and you have Embedded Coder software, create alias types to represent those external types. The code generator uses the alias types in the code that it produces. For example, once defined, you can specify an alias type in a function prototype, for a temporary variable, or for block output. • Does the code exchange data with shared memory? If yes, define and use memory sections.
Direct function call	Do you want to call C external code directly from a model? You can choose from mechanisms, such as the Legacy Code Tool, Stateflow external code interface and chart action language, and the MATLAB Function block.
Insertion of external code into generated code	Do you want to control the placement of external code within generated code? Do you want to insert code into generated entry-point functions? You can place code within generated code by using model configuration parameters or custom code blocks.

Requirement	What to Consider
Code generation optimization support	Do you want to optimize the code that the code generator produces? If so, you can configure the model for the code generator to optimize the code it produces based on application objectives, such as execution, ROM, and RAM efficiency. You also have the option of using code replacement libraries.
Files required	Do you want to minimize the number of files that you maintain? Some external code integration tools require that you maintain separate files for defining simulation and code generation.

Next, see “Choose a Workflow” on page 39-10.

Choose a Workflow

To choose a workflow for each integration point, use the following flow diagram . The gray boxes identify common workflows and provide links to more information. Click the gray box that best addresses the requirements of an integration point.

Call Reusable External Algorithm Code for Simulation and Code Generation

Code reuse offers business and technological advantages. From a business perspective, code reuse saves time and resources. From a technological perspective, code reuse promotes consistency and reduces memory requirements. Other considerations include:

- Modularizing an application
- Reusing an optimized algorithm
- Interfacing with a predefined dataset
- Developing application variants

Examples of reusable hardware-independent algorithmic code to consider importing into the Simulink environment for simulation and code generation include:

- Utility functions
- Lookup tables
- Digital filters
- Specialized integrators
- Proportional-integral-derivative (PID) control modules

Workflow

To call reusable external algorithm code for simulation and code generation, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 39-4
2	Based on the programming language of the external code, choose an integration approach to add the external code to a Simulink model.	“Choose an Integration Approach” on page 39-14

Task	Action	More Information
3	Verify algorithm behavior and performance by simulating the model.	"Simulation" (Simulink)
4	Define the representation of model data for code generation.	"Exchange Data Between External C/C++ Code and Simulink Model or Generated Code" on page 39-86
5	Configure the model for code generation.	"Generate Code That Matches Appearance of External Code" on page 39-95 and "Model Configuration"
6	Generate code and a code generation report.	"Code Generation"
7	Review the generated code interface and static code metrics.	"Analyze the Generated Code Interface" on page 35-21 and "Static Code Metrics" on page 35-34
8	Build an executable program from the model.	"Build Integrated Code Within the Simulink Environment" on page 39-41
9	Verify that executable program behaves as expected.	"Numerical Equivalence Testing"
10	Verify that executable program performs as expected.	"Code Execution Profiling"

Choose an Integration Approach

Several approaches are available for integrating reusable algorithmic code into the Simulink environment for code generation. Some approaches integrate external code directly. Other approaches convert the external code to Simulink or Stateflow modeling elements for simulation, and later for code generation from the modeled design. The integration approach that you choose depends on:

- Programming language of the external code — MATLAB, C, C++, or Fortran
- Your programming language experience and preference
- Performance requirements
- Whether the algorithm must model continuous time dynamics or you are integrating the algorithm into an application that uses discrete and continuous time

- Whether you want to take advantage of Model-Based Design
- Level of control required over the code that the code generator produces

To choose an approach for a reusable algorithm, see the subsection that matches the programming language of your external algorithm code.

- "Integration Approaches for External MATLAB Code" on page 39-15
- "Integration Approaches for External C or C++ Code" on page 39-18
- "Integration Approaches for External Fortran Code" on page 39-24

Integration Approaches for External MATLAB Code

Multiple approaches are available for integrating external MATLAB code into the Simulink environment. The following diagram and table help you choose the best integration approach for your application based on integration requirements.

	Condition or Requirement	Action	More Information
1	The algorithm must model continuous state dynamics.	Write a MATLAB S-function and, for generating code, a corresponding TLC file for the algorithm. Add the S-function to your model.	• "MATLAB S-Functions" (Simulink) • "Write S-Function and TLC Files By Hand" on page 11-66 • "Target Language Compiler" (Simulink Coder)

	Condition or Requirement	Action	More Information
2	External code complies with the MATLAB code for code generation subset and you want to call MATLAB code from a Simulink model.	Add a MATLAB Function block to the model. Embed the MATLAB code in that block.	• "Integrate C Code Using the MATLAB Function Block" (Simulink) • MATLAB Function
3	External code complies with the MATLAB code for code generation subset, you want to call MATLAB code from a Simulink model, and your algorithm includes iterative computations that process large streams of data.	Add a MATLAB System block to the model. Embed the MATLAB code in that block as a System object™.	• "Integrate C Code Using the MATLAB Function Block" (Simulink) • MATLAB System
4	External code complies with the MATLAB code for code generation subset, you want to call MATLAB code from a Simulink model, and your algorithm includes design logic that is based on state machines and flow charts.	Add a Stateflow chart to the model. Call the external code from the chart, using MATLAB as the action language.	• "Chart Programming Basics" (Stateflow) • "Insert External Code into Stateflow Charts" on page 39-24
5	You want to use the `parfor` function for parallel computing or interface data types that are available to MATLAB Coder but are not available to Simulink Coder or Embedded Coder.	Use MATLAB Coder software to generate C code. Then, call that generated code as external C code.	• "C Code Generation Using the MATLAB Coder App" (MATLAB Coder) • "Getting Started with MATLAB Coder" (MATLAB Coder)

	Condition or Requirement	Action	More Information
6	You have C or C ++ programming experience and the external MATLAB code is compact and primarily uses C or C++ constructs.	Manually convert the MATLAB code to C or C++ code. Choose an integration approach for C or C++ code.	"Integration Approaches for External C or C++ Code" on page 39-18
7	Sections of the external MATLAB code map to built-in blocks.	Develop the algorithm in the context of a model, using the applicable built-in blocks.	• "Model Editing Fundamentals" (Simulink) and "Component-Based Modeling" (Simulink) • "Supported Products and Block Usage" (Simulink Coder)

To embed external MATLAB code in a MATLAB Function block or generate C or C++ code from MATLAB code with the MATLAB Coder software, the MATLAB code must use functions and classes supported for C/C++ code generation.

- "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" (MATLAB Coder)
- "Functions and Objects Supported for C/C++ Code Generation — Category List" (MATLAB Coder)

Integration Approaches for External C or C++ Code

Under most circumstances, you can integrate external code written in C or C++ into the Simulink environment by generating S-functions and TLC files with the Legacy Code Tool. This tool uses specifications that you supply as MATLAB code to transform existing MATLAB functions into C MEX S-functions that you can include in Simulink models and call from generated code. For details, see "Legacy Code Integration" (Simulink) and "Import Calls to External Code into Generated Code with Legacy Code Tool" on page 11-7.

In comparison to alternative approaches, Legacy Code Tool is the easiest to use and generates code optimized enough for embedded systems. Consider alternative approaches if one or more of the following conditions exist:

- The external code uses global variables to exchange data.
- Programming experience is limited.

- The algorithm must model discrete and continuous state dynamics.
- You want to include the integrated external code in a Stateflow chart.
- The external code requires a fixed-point interface.
- You want maximum flexibility for controlling what code the code generator produces.
- You quickly want to embed a call to the external code in a call to the `coder.ceval` function that is embedded in the MATLAB Function block, and performance is not an issue.

This diagram and table help you choose the best integration approach based on your integration requirements.

	Condition or Requirement	Action	More Information
1	You want to integrate external C code with generated C++ code or conversely	Match the language choice for the generated code by modifying the	"Modify Programming Language of External Code to Match Generated Code" on page 39-23

	Condition or Requirement	Action	More Information
		language of the external code.	
2	Your algorithm includes design logic that is based on state machines and flow charts. Or, a function that you want to integrate must exchange data with a model by using global variables. The function defines the global variables and uses them to write output rather than returning a value (return) or writing output to an argument.	Add a Stateflow chart to the model. Call the external code from the chart, using C as the action language. In the chart, write code that calls the external function and reads from and writes to the global variables. To perform calculations with output of the external code, the model must read from the global variable during execution.	"Insert External Code into Stateflow Charts" on page 39-24
3	You want to include external C or C++ code in a Stateflow chart for simulation and code generation.	Configure the model that contains the chart to apply the external C or C ++ code.	• "Custom Code Algorithm" (Stateflow) • "Call C Functions in C Charts" (Stateflow) • "Insert External Code into Stateflow Charts" on page 39-24
4	You quickly want to embed a call to external C or C++ code in a model. Performance is not an issue.	Call the C or C++ code with the `coder.ceval` function from within a MATLAB Function block.	• `coder.ceval` function • "Integrate C Code Using the MATLAB Function Block" (Simulink) • MATLAB Function block

	Condition or Requirement	Action	More Information
5	The application requires more entry-point functions than the code generator typically produces —for example, more than *model*_step, *model*_initialize, and *model*_terminate. You want maximum flexibility for controlling what code the code generator produces.	Manually write an S-function and TLC file.	• "S-Function Basics" (Simulink) • "S-Functions and Code Generation" on page 11-2 • "C S-Function Examples" (Simulink) and "C++ S-Function Examples" (Simulink)
6	You want to simulate and generate external code for a discrete time application. Optimizing generated code is essential. You want ease of use with moderate flexibility for controlling what code the code generator produces. You have C or C++ programming experience, but you prefer to generate the files for adding the code to a model.	Generate S-function and TLC files by using the Legacy Code Tool. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)	• "Integrate C Functions Using Legacy Code Tool" (Simulink) • "Import Calls to External Code into Generated Code with Legacy Code Tool" (Simulink Coder)

	Condition or Requirement	Action	More Information
7	The algorithm must model discrete and continuous state dynamics for simulation and rapid prototyping. The external code requires a fixed-point interface. Programming experience is limited. You want ease of use with basic flexibility for controlling what code the code generator produces for rapid prototyping.	Generate S-function and TLC files by using the S-Function Builder. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)	• "Build S-Functions Automatically" (Simulink) • "Automate S-Function Generation with S-Function Builder" on page 11-61

Modify Programming Language of External Code to Match Generated Code

To integrate external C code with generated C++ code or conversely, modify the language of the external code to match the programming language choice for the generated code. Options for making the programming language match include:

- Writing or rewriting the external code in the language choice for the generated code.
- If you are generating C++ code and the external code is C code, for each C function, create a header file that prototypes the function. Use this format:

  ```
  #ifdef __cplusplus
  extern "C" {
  #endif
  int my_c_function_wrapper();
  #ifdef __cplusplus
  }
  #endif
  ```

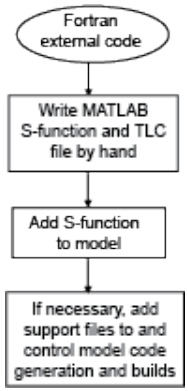
  The prototype serves as a function wrapper. If your compiler supports C++ code, the value `__cplusplus` is defined. The linkage specification `extern "C"` specifies C linkage without name mangling.
- If you are generating C code and the external code is C++ code, include an `extern "C"` linkage specification in each `.cpp` file. For example, the following example shows C++ code in the file `my_func.cpp`:

```
extern "C" {

int my_cpp_function()
{
  ...
}
}
```

Integration Approaches for External Fortran Code

To integrate external Fortran code, write an S-function and corresponding TLC file.



See “S-Function Basics” (Simulink), “Fortran S-Functions” (Simulink), “S-Functions and Code Generation” on page 11-2, and“Fortran S-Function Examples” (Simulink).

Insert External Code into Stateflow Charts

Integrate External Code for Library Charts

To integrate external code that applies only to Stateflow library charts for code generation, for each library model that contributes a chart to your main model, complete these steps. Then, generate code.

1 In the Stateflow Editor, select **Code > C/C++ Code > Code Generation Options**.

2. In the Model Configuration Parameters dialog box, select **Code Generation** > **Use local custom code settings (do not inherit from main model)**.

   The library model retains its own custom code settings during code generation.

3. Specify your custom code in the subpanes.

   Follow the guidelines in "Specify Relative Paths for Custom Code" (Stateflow).

   If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

4. Click **OK**.

After completing these steps for each library model, generate code.

Integrate External Code for All Charts

To integrate external code that applies to all charts for code generation:

1. Specify custom code options for code generation of your main model.

   a. In the Model Configuration Parameters dialog box, select **Code Generation** > **Custom Code**.

   b. In the custom code text fields, specify your custom code.

      Follow the guidelines in "Specify Relative Paths for Custom Code" (Stateflow).

      If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

2. Configure code generation for each library model that contributes a chart to your main model.

   a. In the Stateflow Editor, select **Code** > **C/C++ Code** > **Code Generation Options**.

   b. In the **Code Generation** pane, clear the **Use local custom code settings (do not inherit from main model)** check box.

      The library charts inherit the custom code settings of your main model.

   c. Click **OK**.

3 Generate code.

Place External C/C++ Code in Generated Code

In this section...

You can customize code that the code generator produces for a model by specifying external code with custom code blocks or model configuration parameters.

- Place code at the start and end of the generated code for the root model.
- Place declaration, body, and exit code in generated function code for blocks in the root model or nonvirtual subsystems.

The functions that you can augment with external code depends on the functions that the code generator produces for blocks that are in the model. For example, if a model or atomic subsystem includes blocks that have states, you can specify code for a disable function. Likewise, if you need the code for a block to save data, free memory, or reset target hardware, specify code for a terminate function. For more information, see "Block Target File Methods" (Simulink Coder).

Workflow

To place external C or C++ code at specific locations in code that the code generator produces for root models and subsystems, iterate through the tasks listed in this table.

Task	Action	More Information
1	If you want to integrate external C code with generated C++ code or conversely, modify the language of the external code to match the language choice for the generated code.	"Modify Programming Language of External Code to Match Generated Code" (Simulink Coder)

Choose an Integration Approach

Within the Simulink modeling environment, two approaches are available for placing external C or C++ code into sections of code that the code generator produces:

- Add blocks from the Custom Code library to a root model or atomic subsystem.
- Set model configuration parameters on the **Code Generation** > **Custom Code** pane.

The following table compares the two approaches. Choose the approach that aligns best with your integration requirements. For more information about how to apply each approach, see "Integrate External Code by Using Custom Code Blocks" on page

39-29 and "Integrate External Code by Using Model Configuration Parameters" on page 39-32.

Requirement	Blocks	Model Configuration Parameters
Include a representation of your external code in the modeling canvas	✓	
Place code in functions generated for root models	✓	✓
Place code in functions generated for atomic subsystems	✓	
Save code placement in a model configuration set		✓
Place code at the top and bottom of the header and source files generated for a model	✓	✓
Place code within declaration, execution, and exit sections of the `SystemInitialize` and`SystemTerminate` functions that the code generator creates	✓	✓
Place code within declaration, execution, and exit sections of the `SystemStart`, `SystemEnable`, `SystemDisable`, `SystemOutputs`, `SystemUpdate`, or`SystemDerivatives` functions that the code generator creates	✓	
Add preprocessor macro definitions to generated code		✓
Use the custom code settings that are specified for the simulation target		✓
Configure a library model to use custom code settings of the parent model to which the library is linked		✓

Integrate External Code by Using Custom Code Blocks

• "Add External Code to Generated Start Function" on page 39-31

Custom Code Block Library

The Custom Code block library contains blocks that you can use to place external C or C++ code into specific locations and functions within code that the code generator produces. The library consists of 10 blocks that add your code to the model header (*model*.h) and source (*model*.c or *model*.cpp) files that the code generator produces.

The Model Header and Model Source blocks add external code at the top and bottom of header and source files that the code generator produces for a root model. Theses blocks display two text fields into which you can type or paste code. One field specifies code that you want to place at the top of the generated header or source file. The second field specifies code that you want to place at the bottom of the file.

The remaining blocks add external code to functions that the code generator produces for the root model or atomic subsystem that contains the block. The blocks display text fields into which you can type or paste code that customizes functions that the code generator produces. The text fields correspond to the declaration, execution, and exit sections of code for a given function.

To Customize Code That	Use This Block
Computes continuous states	System Derivatives
Disables state	System Disable
Enables state	System Enable
Resets state	System Initialize
Produces output	System Outputs
Executes once	System Start
Saves data, free memory, reset target hardware	System Terminate
Requires updates at each major time step	System Update

The block and its location within a model determines where the code generator places the external code. For example, if the System Outputs block is at the root model level, the code generator places the code in the model `Outputs` function. If the block resides in a triggered or enabled subsystem, the code generator places the code in the subsystem `Outputs` function.

If the code generator does not need to generate a function that corresponds to a Custom Code block that you include in a model, the code generator does one of the following:

- Omits the external code that you specify in the Custom Code block.
- Returns an error, indicating that the model does not include a relevant block. In this case, remove the Custom Code block from the mode.

For more information, see "Block Target File Methods" (Simulink Coder).

Add Custom Code Blocks to the Modeling Canvas

To add the Custom Code library blocks to a model:

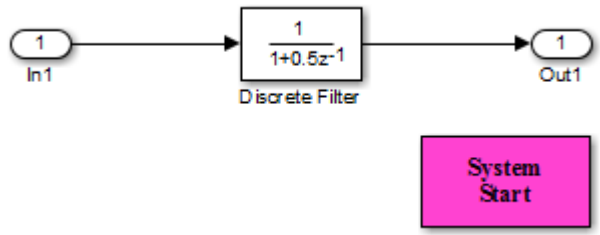
1. In the Simulink Library Browser, open the Custom Code block library. You can gain access to the library by:
   - Navigating to **Simulink Coder** > **Custom Code** in the browser.
   - Entering the MATLAB command `custcode`.
2. Drag the blocks that you want into your model or subsystem. Drag Model Header and Model Source blocks into root models only. Drag function-based Custom Code blocks into root models or atomic subsystems.

You can use models that contain Custom Code blocks as referenced models. The code generator ignores the blocks when producing code for a simulation target. When producing code for a code generation target, the code generator includes and compiles the custom code.

Add External Code to Generated Start Function

This example shows how to use the System Start block to place external C code in the code that the code generator produces for a model that includes a discrete filter.

1. Create the following model.



2. Configure the model for code generation.
3. Double-click the System Start block.
4. In the block parameters dialog box, in the **System Start Function Declaration Code** field, enter this code:

   ```
   unsigned int *ptr = 0xFFEE;
   ```

5. In the **System Start Function Execution Code** field, enter this code:

   ```
   /* Initialize hardware */
   *ptr = 0;
   ```

6. Click **OK**.
7. Generate code and a code generation report.
8. View the generated *model*`.c` file. Search for the string `start function`. You should find the following code, which includes the external code that you entered in steps 4 and 5.

   ```
   {
     {
       /* user code (Start function Header) */
       /* System '<Root>' */
       unsigned int *ptr = 0xFFEE;

       /* user code (Start function Body) */
       /* System '<Root>' */
       /* Initialize hardware */
       *ptr = 0;
     }
   }
   ```

For another example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 39-34.

Integrate External Code by Using Model Configuration Parameters

Model configuration parameters provide a way to place external C or C++ code into specific locations and functions within code that the code generator produces.

To	Select
Insert external code near the top of the generated *model*`.c` or *model*`.cpp` file	**Source file**, and enter the external code to insert. **Note:** If you generate subsystem code into separate files, that code does not have access to external code that you specify with the **Source file**

To	Select
	parameter. For example, if you specify an include file as a **Source file** setting, the code generator inserts the `#include` near the top of the *`model`*`.c` or *`model`*`.cpp` file. The subsystem code that the code generator places in a separate file does not have access to declarations inside your included file. In this case, consider specifying your external code with the **Header file** parameter.
Insert external code near the top of the generated *`model`*`.h` file	**Header file**, and enter the external code to insert.
Insert external code inside the model initialize function in the *`model`*`.c` or *`model`*`.cpp` file	**Initialize function**, and enter the external code to insert.
Insert external code inside the model terminate function in the *`model`*`.c` or *`model`*`.cpp` file	**Terminate function**, and enter the external code to insert. Also select the **Terminate function required** parameter on the **Interface** pane.
Add preprocessor macro definitions	**Defines**, and enter a space-separated list of preprocessor macro definitions to add to the generated code. The list can include simple definitions (for example, `-DEF1`) and definitions with a value (for example, `-DDEF2=1`). Definitions can omit the `-D` (for example, `-DFOO=1` and `FOO=1` are equivalent). If a definition includes `-D`, the toolchain can override the flag if the toolchain uses a different flag for defines.
Use the same custom code parameter settings as the settings specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	**Use the same custom code settings as Simulation Target** This parameter refers to the **Simulation Target** pane in the Configuration Parameters dialog box.

To	Select
Enable a library model to use custom code settings unique from the parent model to which the library is linked	**Use local custom code settings (do not inherit from main model)** This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.

To include a header file in an external header file, add `#ifndef` code. Using this code avoids multiple inclusions. For example, in `rtwtypes.h`, the following `#include` guards are added:

```
#ifndef RTW_HEADER_rtwtypes_h_
#define RTW_HEADER_rtwtypes_h_
...
#endif /* RTW_HEADER_rtwtypes_h_ */
```

For more information on how to add files names and locations of header, source, and shared library files to the build process, see "Build Integrated Code Within the Simulink Environment" on page 39-41.

Note The code generator includes external code that you include in a configuration set when generating code for software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations. However, the code generator ignores external code that you include in a configuration set when producing code with the S-function, rapid simulation, or simulation system target file.

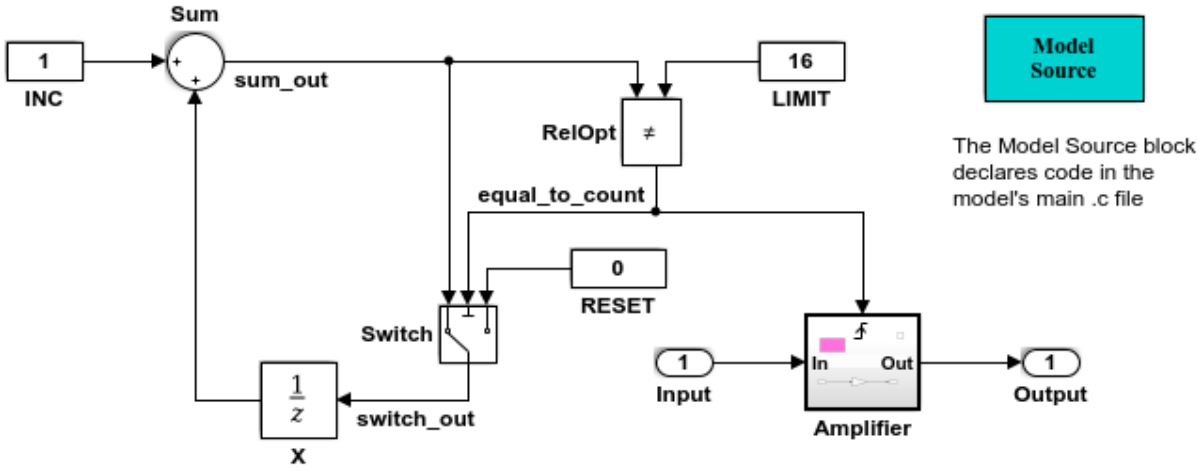
For more information about **Custom Code** parameters, see "Model Configuration Parameters: Code Generation Custom Code" (Simulink Coder). For an example, see "Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters" on page 39-34.

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```



Several techniques exist for incorporating custom code into Simulink Coder. This model shows the use of the Simulink Coder custom code blocks and the Configuration Parameters Code Generation Custom Code page:

1. The Model Source custom code block declares an integer GLOBAL_INT1 in <model>.c.
2. The Subsystem Outputs custom code block (inside subsystem Amplifier) uses GLOBAL_INT1.
3. The variable GLOBAL_INT2 is declared and set from the Configuration Parameters Code Generation Custom Code page, from the "Source file" and "Initialize function," respectively.

Some overlap exists between custom code blocks and custom code specified using configuration parameters, but custom code blocks provide much finer granularity of code placement, and have the advantage of being graphical.

Generate Code Using Simulink Coder (double-click) | **Generate Code Using Embedded Coder (double-click)** | **View Custom Code Configuration (double-click)** | **View Custom Code Library (double-click)**

2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** intializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem `Amplifier`. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the `Amplifier` subsystem. The external code:

- Declares the pointer variable `*intPtr` and intitializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;

int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Output block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;
```

```
*intPtr = -1;

rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;

*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

Call External Device Drivers

Device drivers for protocols and target hardware are essential to many real-time development projects. For example, you can have a working device driver that you want to integrate with algorithmic code that has to read data from and write data to the I/O device that the driver supports. The code generator can produce a single set of application source files from an algorithm model and integrated driver code written in C or C++.

To call external device driver code from the Simulink environment, iterate through the tasks in this table.

Task	Action	More Information

Apply Function and Operator Code Replacements

If your generated code must use functions and operators that are consistent with external code, configure the code generator to use a code replacement library (CRL). By default, the code generator does not apply a code replacement library. You can choose from several libraries that MathWorks provides, including GNU C99 extensions, AUTOSAR 4.0, and several Intel platform-specific IPP and IPP/SSE libraries. Depending on the products that you have, other libraries might be available. If you have Embedded Coder software, you can view and choose from additional libraries and you can create custom code replacement libraries.

Build Integrated Code Within the Simulink Environment

Workflow

To build executable programs that integrate generated code and external C or C++ code, iterate through the tasks in this table.

Task	Action	More Information
1	Choose whether to use the toolchain approach or template makefile approach build process.	"Choose and Configure Build Process" on page 40-14 For an example, see "Build Process Workflow for a Real-Time STF" on page 40-30.
2	Configuredbuild process support for your external code.	"Configure Parameters for Integrated Code Build Process" on page 39-42
3	Configure S-Function build support for your external code.	"Build Support for S-Functions" on page 39-44 "Use makecfg to Customize Generated Makefiles for S-Functions" on page 70-24 For examples, see "Call External C Code from Model and Generated Code" and "Call Reusable External Algorithm Code for Simulation and Code Generation" on page 39-13.
4	Configure build process to find the external code source, library, and header files.	"Manage Build Process File Dependencies" on page 33-52 "Control Library Location and Naming During Build" on page 70-7
5	Set up custom build processing required for your external code integration.	For the build process customization workflow, see "Customize Post-Code-Generation Build Processing" on page 70-14.

Task	Action	More Information
		To automate applying build customizations to a toolchain approach build, see "Customize Build Process with sl_customization.m" on page 70-38. To automate applying build customizations to a template makefile approach build, see "Customize Build Process with STF_make_rtw_hook File" on page 70-31.

Configure Parameters for Integrated Code Build Process

The table provides a guide to configuration parameters that support the build process for external code integration. For information about folders for your external code, see "Manage Build Process Folders" on page 33-37. If you choose to place your external code in the "Code generation folder" (Simulink), see "Preserve External Code Files in Build Folder" on page 39-43.

To	Select
Add include folders, which contain header files, to the build process	**Configuration Parameters > Code Generation > Custom Code > Additional build information > Include directories**, and enter the absolute or relative paths to the folders. If you specify relative paths, the paths must be relative to the folder containing your model files, not relative to the build folder. The order in which you specify the folders is the order in which they are searched for header, source, and library files.
Add source files to be compiled and linked	**Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files**, and enter the full paths or just the file names for the files. Enter just the file name if the file is in the current MATLAB folder or in one of the include folders. For each additional

To	Select

	source that you specify, the build process expands a generic rule in the template makefile for the folder in which the source file is located. For example, if a source file is located in folder `inc`, the build process adds a rule similar to the following:
	
	`%.obj: buildir\inc\%.c`
	`$(CC) -c -Fo$(@F) $(CFLAGS) $<`
	
	The build process adds the rules in the order that you list the source files.

Add libraries to be linked	**Configuration Parameters > Code Generation > Custom Code > Additional build information > Libraries**, and enter the full paths or just the file names for the libraries. Enter just the file name if the library is located in the current MATLAB folder or in one of the include folders.
Use the same custom code settings as those specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	**Configuration Parameters > All Parameters > Code Generation > Custom Code > Use the same custom code settings as Simulation Target** **Note** This parameter refers to the **Simulation Target** pane in the Configuration Parameters dialog box.
Enable a library model to use custom code settings unique from the parent model to which the library is linked	**Configuration Parameters > All Parameters > Code Generation > Custom Code > Use local custom code settings (do not inherit from main model)** **Note** This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.

Preserve External Code Files in Build Folder

By default, the build process deletes foreign source files. You can preserve foreign source files by following these guidelines.

If you put a `.c/.cpp` or `.h` source file in a build folder, and you want to prevent the code generator from deleting it during the TLC code generation process, insert the text `target specific file` in the first line of the `.c/.cpp` or `.h` file. For example:

```
/*  COMPANY-NAME target specific file
 *
 *   This file is created for use with the
 *   COMPANY-NAME target.
 *   It is used for ...
 */
...
```

Make sure that you spell the text "target specific file" as shown in the preceding example, and that the text is in the first line of the source file. Other text can appear before or after this text.

Flagging user files in this manner prevents postprocessing these files to indent them with generated source files. Auto-indenting occurred in previous releases to build folder files with names having the pattern *`model`*`_*.c/.cpp` (where `*` was text). The indenting is harmless, but can cause differences detected by source control software that can potentially trigger unnecessary updates.

Build Support for S-Functions

User-written S-Function blocks provide a powerful way to incorporate external code into the Simulink development environment. In most cases, you use S-functions to integrate existing external code with generated code. Several approaches to writing S-functions are available:

- "Write Noninlined S-Function and TLC Files" on page 11-66
- "Write Wrapper S-Function and TLC Files" on page 11-68
- "Write Fully Inlined S-Functions" on page 11-77
- "Write Fully Inlined S-Functions with mdlRTW Routine" on page 11-78
- "S-Functions That Support Code Reuse" on page 11-114
- "S-Functions for Multirate Multitasking Environments" on page 11-115

S-functions also provide the most flexible and capable way of including build information for legacy and custom code files in the build process.

There are different ways of adding S-functions to the build process.

Implicit Build Support

When building models with S-functions, the build process adds rules, include paths, and source file names to the generated makefile. The source files (`.h`, `.c`, and `.cpp`) for the S-function must be in the same folder as the S-function MEX-file. Whether using the toolchain approach or template makefile approach for builds, the build process propagates this information through the toolchain or template makefile.

- If the file *`sfcnname`*`.h` exists in the same folder as the S-function MEX-file (for example, *`sfcnname.mexext`*), the folder is added to the include path.
- If the file *`sfcnname`*`.c` or *`sfcnname`*`.cpp` exists in the same folder as the S-function MEX-file, the build process adds a makefile rule for compiling files from that folder.
- When an S-function is not inlined with a TLC file, the build process must compile the S-function source file. To determine the name of the source file to add to the list of files to compile, the build process searches for *`sfcnname`*`.cpp` on the MATLAB path. If the source file is found, the build process adds the source file name to the makefile. If *`sfcnname`*`.cpp` is not found on the path, the build process adds the file name *`sfcnname`*`.c` to the makefile, whether or not it is on the MATLAB path.

Note: For the Simulink engine to find the MEX-file for simulation and code generation, it must exist on the MATLAB path or exist in our current MATLAB working folder.

Specify Additional Source Files for an S-Function

If your S-function has additional source file dependencies, you must add the names of the additional modules to the build process. Specify the file names:

- In the **S-function modules** field in the S-Function block parameter dialog box
- With the `SFunctionModules` parameter in a call to the `set_param` function

For example, suppose you build your S-function with multiple modules.

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then add the modules to the build process by doing one of the following:

- In the S-function block dialog box, specify `sfun_main`, `sfun_module1`, and `sfun_module2` in the **S-function modules** field.
- At the MATLAB command prompt, enter:

```
set_param(sfun_block,'SFunctionModules','sfun_module1 sfun_module2')
```

Alternatively, you can define a variable to represent the parameter value.

```
modules = 'sfun_module1 sfun_module2'
          set_param(sfun_block,'SFunctionModules', modules)
```

The **S-function modules** field and `SFunctionModules` parameter do not support complete source file path specifications. To use the parameter, the code generator must find the additional source files when executing the makefile. For the code generator to locate the additional files, place them in the same folder as the S-function MEX-file. You can then leverage the implicit build support described in "Implicit Build Support" on page 39-45.

When you are ready to generate code, force the code generator to rebuild the top model, as described in "Control Regeneration of Top Model Code" (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in "Use rtwmakecfg.m API to Customize Generated Makefiles" on page 70-26.

Use TLC Library Functions

If you inline your S-function by writing a TLC file, you can add source file names to the build process by using the TLC library function `LibAddToModelSources`. For details, see "LibAddSourceFileCustomSection(file, builtInSection, newSection)" (Simulink Coder).

Note: This function does not support complete source file path specifications. The function assumes that the code generator can find the additional source files when executing the makefile.

Another useful TLC library function is `LibAddToCommonIncludes`. Use this function in a `#include` statement to include S-function header files in the generated *`model`*`.h` header file. For details, see "LibAddToCommonIncludes(incFileName)" (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in "Use rtwmakecfg.m API to Customize Generated Makefiles" on page 70-26.

Precompile S-Function Libraries

You can precompile new or updated S-function libraries (MEX-files) for a model by using the MATLAB language function `rtw_precompile_libs`. Using a specified model and a library build specification, this function builds and places the libraries in a precompiled library folder.

By precompiling S-function libraries, you can optimize system builds. Once your precompiled libraries exist, the build process can omit library compilation from subsequent builds. For models that use numerous libraries, the time savings for build processing can be significant.

To use `rtw_precompile_libs`:

1. Set the library file suffix, including the file type extension, based on your system platform.

   Consider determining the type of platform, and then use the `TargetLibSuffix` parameter to set the library suffix accordingly. For example, when applying a suffix for a GRT target, you can set the suffix to `_std.a` for a UNIX platform and `_vcx64.lib` for a Windows platform.

   ```
   if isunix
     suffix = '_std.a';
   else
     suffix = '_vcx64.lib';
   end

   set_param(my_model,'TargetLibSuffix', suffix);
   ```

   There are a number of factors that influence the precompiled library suffix and extension. The following table provides examples for typical selections of system target file, the compiler toolchain, and other options that affect your choice of suffix and extension. For more information, examine the template make files in the `matlab/rtw/c/grt` folder or `matlab/rtw/c/ert` folder.

TMF File	COMPILER _TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND _LIBRARY _NAME Value)	Library Suffix Integer- Only Code (EXPAND _LIBRARY _NAME Value)	Library Suffix Optimize for Speed (EXPAND _LIBRARY _NAME Value)	Library Extension (EXPAND _LIBRARY _NAME Value)
ert_lcc64.tmf	lcc	_rtwsfcn_lcc	_int_ert_lcc	_ert_lcc	.lib

TMF File	COMPILER_TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND_LIBRARY_NAME Value)	Library Suffix Integer- Only Code (EXPAND_LIBRARY_NAME Value)	Library Suffix Optimize for Speed (EXPAND_LIBRARY_NAME Value)	Library Extension (EXPAND_LIBRARY_NAME Value)
ert_vcx64.tmf	vcx64	_rtwsfcn_vcx64	_int_ert_vcx64	_ert_vcx64	.lib
ert_unix.tmf	unix	_rtwsfcn	_int_ert	_ert	.a
grt_lcc64.tmf	lcc	n/a	n/a	_lcc	.lib
grt_vcx64.tmf	vcx64	n/a	n/a	_vcx64	.lib
grt_unix.tmf	unix	n/a	n/a	_std	.a

2 Set the precompiled library folder.

Use one of the following methods to set the precompiled library folder:

- Set the `TargetPreCompLibLocation` parameter, as described in "Specify the Location of Precompiled Libraries" on page 70-9.
- Set the `makeInfo.precompile` field in an `rtwmakecfg.m` function file. (For more information, see "Use rtwmakecfg.m API to Customize Generated Makefiles" on page 70-26.)

If you set `TargetPreCompLibLocation` and `makeInfo.precompile`, the setting for `TargetPreCompLibLocation` takes precedence.

The following command sets the precompiled library folder for model `my_model` to folder `lib` under the current working folder.

```
set_param(my_model,'TargetPreCompLibLocation', fullfile(pwd,'lib'));
```

Note: If you set both the target folder for the precompiled library files and a target library file suffix, the build process detects whether any precompiled library files are missing while processing builds.

3 Define a build specification.

Set up a structure that defines a build specification. The following table describes fields that you can define in the structure. These fields are optional, except for `rtwmakecfgDirs`.

Field	Description
`rtwmakecfgDirs`	A cell array of character vectors that name the folders containing `rtwmakecfg` files for libraries to be precompiled. The function uses the `Name` and `Location` elements of `makeInfo.library`, as returned by `rtwmakecfg`, to specify the name and location of the precompiled libraries. If you set the `TargetPreCompLibLocation` parameter to specify the library folder, that setting overrides the `makeInfo.library.Location` setting. **Note:** The specified model must contain blocks that use precompiled libraries specified by the `rtwmakecfg` files because the TMF-to-makefile conversion generates the library rules only if the build process uses the libraries.
`libSuffix`	A character vector that specifies the suffix, including the file type extension, to be appended to the name of each library (for example, `.a` or `_vc.lib`). The character vector must include a period (.). You must set the suffix with either this field or the `TargetLibSuffix` parameter. If you specify a suffix with both mechanisms, the `TargetLibSuffix` setting overrides the setting of this field.
`intOnlyBuild`	A Boolean flag. When set to true, the flag indicates the libraries are to be optimized such that they are compiled from integer code only. This field applies to ERT targets only.
`makeOpts`	A character vector that specifies an option to be included in the `rtwMake` command line.
`addLibs`	A cell array of structures that specify libraries to be built that are not specified by an `rtwmakecfg` function. Each structure must be defined with two fields that are character arrays: • `libName` — the name of the library without a suffix • `libLoc` — the location for the precompiled library The target makefile (TMF) can specify other libraries and how those libraries are built. Use this field to precompile those libraries.

The following commands set up build specification `build_spec`, which indicates that the files to be compiled are in folder `src` under the current working folder.

```
build_spec = [];
```

```
build_spec.rtwmakecfgDirs = {fullfile(pwd,'src')};
```

4 Issue a call to `rtw_precompile_libs`.

The call must specify the model for which you want to build the precompiled libraries and the build specification. For example:

```
rtw_precompile_libs(my_model,build_spec);
```

Generate Component Source Code for Export to External Code Base

In this section...

If you have Embedded Coder software, you can generate function source code from modeling components to use in an external code base. The generated code does not include supporting scheduling code (for example, a step function). Controlling logic outside of the Simulink environment invokes the generated function code.

Modeling Options

You can generate function code to export for these modeling components:

- Export-function models (model containing functional blocks that consist exclusively of function-call subsystems, function-call model blocks, or other export-function models, as described in "Export-Function Models" (Simulink))
- Export-function subsystems (virtual subsystem that contains function-call subsystems)

To export code that the code generator produces for these modeling components, the modeling components must meet specific requirements on page 39-52.

For models designed in earlier releases, the code generator can export functions from triggered subsystems. The requirements stated for export-function subsystems also apply to exporting functions from triggered subsystems, with the following exceptions:

- Encapsulate triggered subsystems from which you intend to export functions in a top-level virtual subsystem.

- Triggered subsystems do not have to meet requirements and limitations identified for virtual subsystems that contain function-call subsystem.
- "Export Functions That Use Absolute or Elapsed Time" on page 39-53 does not apply to exporting functions from triggered subsystems.

Requirements

- Model solver must be a fixed-step discrete solver.
- You must configure each root-level Inport block that triggers a function-call subsystem to output a function-call trigger. These Inport blocks cannot connect to an Asynchronous Task Specification block.
- Model or subsystem, must contain only the following blocks at the root level:
  - Function-call blocks (such as Function-Call Subsystem, Simulink Function, S-Functions, and Function-Call Model blocks at the root level if the solver parameter **Tasking and sample time options > Periodic sample time constraint** is set to `Ensure sample time independent`)
  - Inport and Outport blocks (ports)
  - Constant blocks (including blocks that resolve to constants, such as Add)
  - Blocks with a sample time of Inf
  - Merge and data store memory blocks
  - Virtual connection blocks (such as, Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and virtual subsystems that contain these blocks)
  - Signal-viewer blocks, such as Scope blocks (export-function subsystems only)
- When a constant block appears at the top level of the model or subsystem, you must set the model configuration parameter **Optimization > Signals and Parameters > Default parameter behavior** for the model or containing model to `Inlined`.
- Blocks inside the model or subsystem must support code generation.
- Blocks that use absolute or elapsed time must be inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block. See "Export Functions That Use Absolute or Elapsed Time" on page 39-53.
- Data signals that cross the boundary of an exported system cannot be a virtual bus and cannot be implemented as a Goto-From connection. Data signals that cross the export boundary must be scalar, muxed, or a nonvirtual bus.

In addition, for export-function models, data logging and signal-viewer blocks, such as the Scope block, are not allowed at the root level or within the function-call blocks.

For export-function subsystems, the following additional requirements apply:

- A trigger signal that crosses the boundary of an export-function subsystem must be scalar. Input and output data signals that do not act as triggers do not have to be scalar.
- When a constant signal drives an output port of an export-function subsystem, the signal must specify a storage class.

Export Functions That Use Absolute or Elapsed Time

If you want to export function code for a modeling component with blocks that use absolute or elapsed time, those blocks must be inside a function-call subsystem that:

- You configure for periodic execution
- You configure the root-level Inport block with a discrete sample time

To configure a function-call subsystem for periodic execution:

1. In the function-call subsystem, right-click the Trigger block and choose **Block Parameters** from the context menu.
2. In the **Sample time type** field, specify `periodic`.
3. Set the **Sample time** to the same granularity specified (directly or by inheritance) in the function-call initiator.
4. Click **OK** or **Apply**.

For more information, see "Absolute and Elapsed Time Computation" (Simulink Coder).

Limitations for Export-Function Subsystems

- Subsystem block parameters do not control the names of the files containing the generated code. The file names begin with the name of the exported subsystem.
- Subsystem block parameters do not control the names of top-level functions in the generated code. Each function name reflects the name of the signal that triggers the function or (for an unnamed signal) reflects the block from which the signal originates.
- The code generator cannot export reusable code for export-function subsystems. The **Code interface packaging** value `Reusable function` does not apply for export-function subsystems.

- You can export function-call systems for the C++ class code interface packaging only when its function specification is set to **Default step method**. See "Control Generation of C++ Class Interfaces" on page 26-23. The exported function is compatible with single-threaded execution. To avoid potential data race conditions for shared signals, invoke all members for the class from the same execution thread.
- The code generator supports a SIL or PIL block in accelerator mode only if its function-call initiator is noninlined in accelerator mode. Examples of noninlined initiators include Stateflow charts.
- A Level-2 S-function initiator block, such as a Stateflow chart or the built-in Function-Call Generator block, must drive a SIL block.
- You can export an asynchronous (sample-time) function-call system, but the software does not support the SIL or PIL block for an asynchronous system.
- The software does not support MAT-file logging for export-function subsystems. Specifications that enable MAT-file logging are ignored.
- The use of the TLC function `LibIsFirstInit` has been removed for export-function subsystems.

Workflow

To generate code for an exported function, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	"Choose an External Code Integration Workflow" on page 39-4
2	Verify that the model or subsystem that you are exporting satisfies function exporting requirements.	"Requirements" on page 39-52
3	Address data interface requirements by modifying the model or subsystem.	"Exchange Data Between External C/C++ Code and Simulink Model or Generated Code" on page 39-86
4	If necessary, configure function prototype.	"Configure Simulink Function Code Interface" on page 26-67 and, for fixed-step rate-based models, "Control Generation of Function Prototypes" on page 26-2 or "Control Generation of C++ Class Interfaces" on page 26-23

Task	Action	More Information
5	If necessary , update the model to place external application-specific code in generated system functions.	"Place External C/C++ Code in Generated Code" on page 39-27
6	Verify that the functions behave and perform as expected during simulation by creating and using a test harness model. The test harness model schedules execution of the functions during simulation.	"Configure Model, Generate Code, and Simulate" on page 33-2 and, if you have Simulink Test software, "Tests in Models" (Simulink Test)
7	Configure the model or subsystem for code generation.	"Generate Code Using Embedded Coder®", "Generate Code That Matches Appearance of External Code" on page 39-95, and"Model Configuration"
8	Generate code and a code generation report.	"Code Generation"
9	Review the generated code interface and static code metrics.	"Analyze the Generated Code Interface" on page 35-21 and "Static Code Metrics" on page 35-34
10	Build an executable program that includes the exported function code.	"Build Integrated Code Outside the Simulink Environment" on page 39-79
11	Verify that executable program behaves and performs as expected.	

Choose an Integration Approach

Multiple approaches are available for generating function code for export to an external development environment. The following table compares approaches. Choose the approach that aligns best with your integration requirements. For more information on how to create export-function models, see "Export-Function Models" (Simulink). For more information on generating code for function call subsystems, see "Generate Component Source Code for Export to External Code Base" on page 39-51.

Generate C Function Code for Export-Function Model

This example shows how to generate function code for individual Simulink function blocks and function-call subsystems in a model without generating scheduling code.

To generate function code for export:

1. Create a model that contains the functions for export.
2. Create a test harness model that schedules execution of the functions during simulation.
3. Simulate the model that contains the functions by using the test harness model.
4. Generate code for the model that contains the functions.

Create Model That Contains Functions for Export

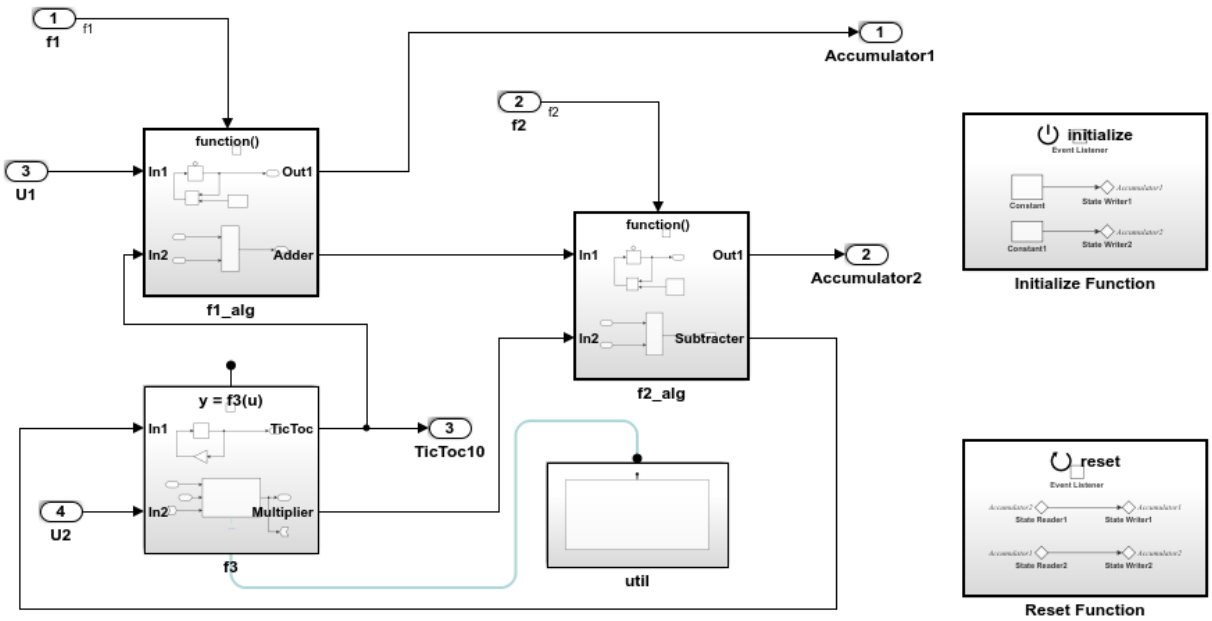
The model with functions for export must satisfy architectural constraints at the model root level. At the root level, valid blocks are:

- Inport
- Outport
- Function-Call Subsystem
- Simulink Function
- Goto
- From
- Merge

The code generator produces function code for Function-Call Subsystem and Simulink Function blocks and Initialize and Reset Function blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives. A Simulink Function block is executed in response to the execution of a corresponding Function Caller block or Stateflow chart. An Initialize Function block is executed on a model initialize event and a Reset Function block is executed on a user-defined reset event.

For exporting functions, model `rtwdemo_functions` contains two function-call subsystems (`f1_alg` and `f2_alg`) and a Simulink Function block (`f3`) for exporting functions. The model also contains an Initialize Function block (`Initialize Function`) and a Reset Function block (`Reset Function`). To calculate initial conditions for blocks with state in other parts of the model, the State Writer blocks are used inside the Initialize and Reset Function blocks.

```
open_system('rtwdemo_functions')
```



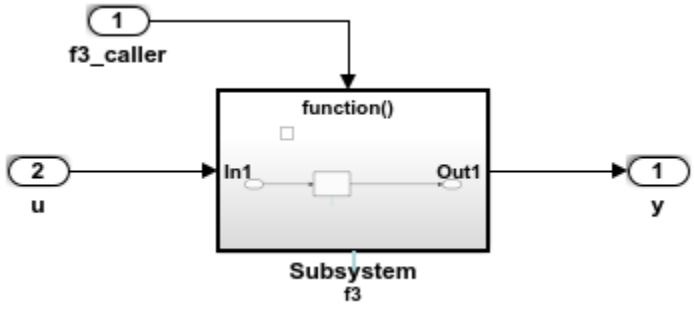
Create Model That Contains Function Caller Block

Use a Function Caller block to invoke a Simulink Function block. The Function Caller block can be in the same model or in a different model as the Simulink Function block.

Multiple Function Caller blocks can invoke a Simulink Function block. You can place the Function Caller block inside a function-call subsystem. During code generation, the code generator exports a function from the function-call subsystem.

The model `rtwdemo_caller` exports a function-call subsystem that contains a Function Caller block.

```
open_system('rtwdemo_caller')
```



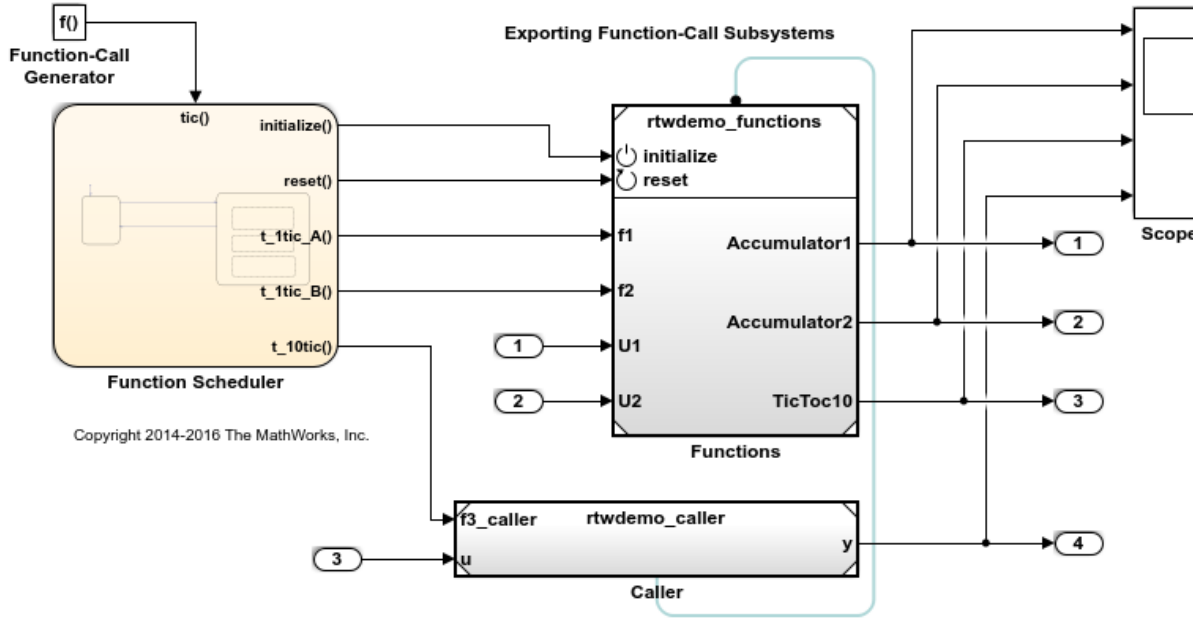
Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_export_functions` is a test harness. The model:

- Schedules the Simulink Function block with the Function Caller block in `rtwdemo_caller`.
- Provides function-call signals to other models in this example to schedule the model contents, including the model initialize and reset events.

```
open_system('rtwdemo_export_functions')
```



Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_export_functions`.

```
sim('rtwdemo_export_functions')
```

Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_functions`.

```
rtwbuild('rtwdemo_functions')
```

```
### Starting build procedure for model: rtwdemo_functions
### Successful completion of code generation for model: rtwdemo_functions
```

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_functions.c` calls the initialization function, including `Initialize Function`, and exported functions for model components `f1_alg`, `f2_alg`, and `f3`.
- `rtwdemo_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `f3.h` is a shared file that declares the call interface for the Simulink function `f3`.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

1. Include the generated header files by adding directives `#include rtwdemo_functions.h`, `#include f3.h`, and `#include rtwtypes.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_functions_initialize(void)`. At startup, call this function once.
- Reset entry-point function, `void rtwdemo_functions_reset(void)`. Call this function as needed.
- Exported function, `void f1(void)`. Call this function as needed.
- Exported function, `void f2(void)`. Call this function as needed.
- Simulink function, `void f3(real_T rtu_u, real_T *rty_y)`. Call this function as needed.

Output ports:

- `rtY.Accumulator1` of type `int8_T` with dimension [2]
- `rtY.Accumulator2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

bdclose('rtwdemo_functions')
bdclose('rtwdemo_caller')
```

Generate C++ Function and Class Code for Export-Function Model

This example shows how to generate function code for an export-function model that includes a function-call subsystem. The code generator produces function and class code that does not include scheduling code.

To generate function code for export:

1. Create a model that contains the functions for export.
2. Create a test harness model that schedules execution of the functions during simulation.
3. Simulate the model that contains the functions by using the test harness model.
4. Generate code for the model that contains the functions.

Create Model That Contains Functions and C++ Class Interface for Export

The model with functions for export with a C++ model class interface must satisfy architectural constraints at the model root level. For C++ class generation, blocks that are valid at the root level are:

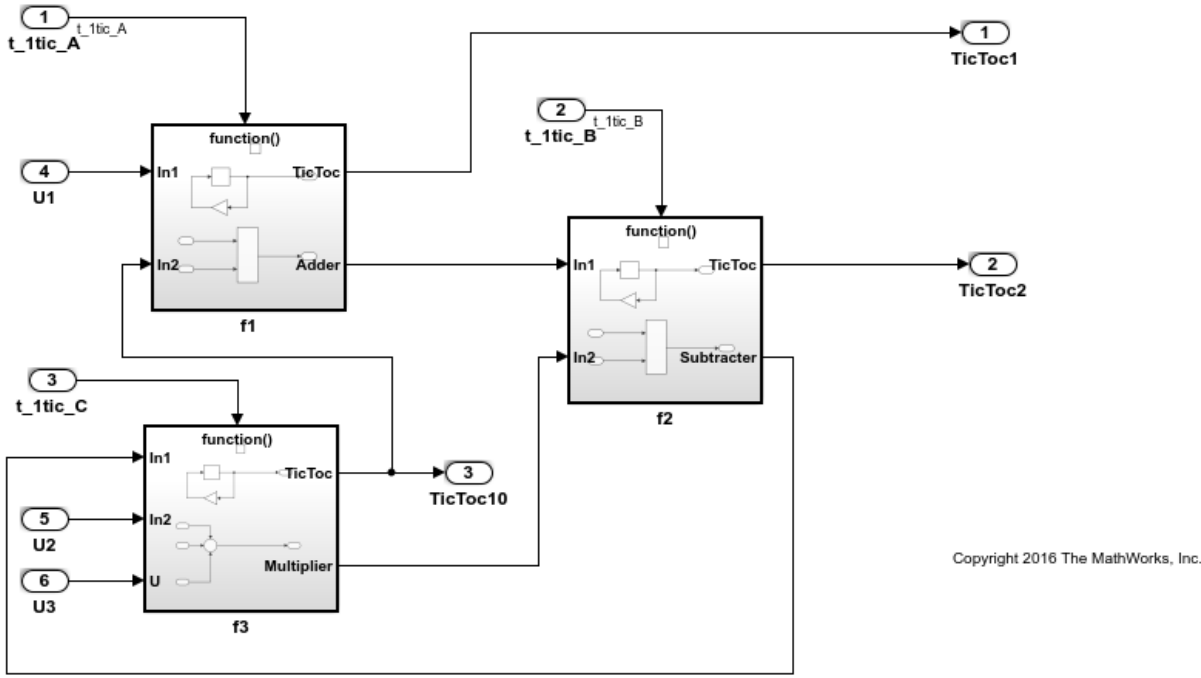
- Inport
- Outport
- Function-Call Subsystem
- Goto
- From
- Merge

Note: Export Function-Call Subsystem with C++ class interface does not support Simulink Function blocks.

The code generator produces function code for the Function-Call Subsystem block. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives.

Model `rtwdemo_cppclass_functions` contains function-call subsystems `f1`, `f2`, and `f3` for exporting functions.

```
open_system('rtwdemo_cppclass_functions')
```

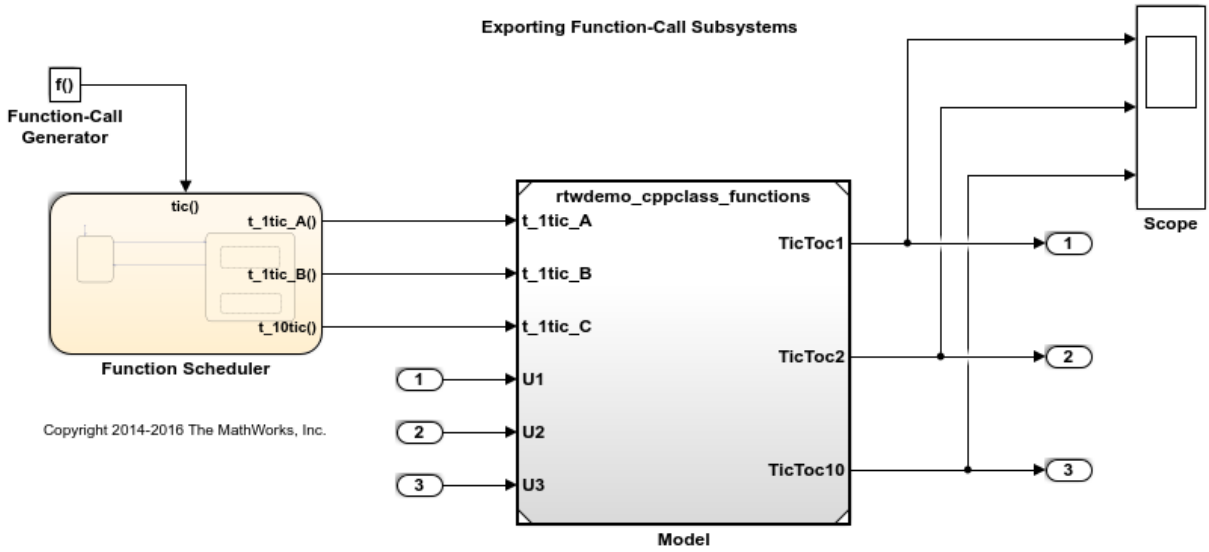


Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_cppclass_export_functions` is a test harness. The model provides function-call signals to other models in this example to schedule the model contents.

```
open_system('rtwdemo_cppclass_export_functions')
```



Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_cppclass_export_functions`.

```
sim('rtwdemo_cppclass_export_functions')
```

Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_cppclass_functions`.

```
rtwbuild('rtwdemo_cppclass_functions')

### Starting build procedure for model: rtwdemo_cppclass_functions
### Successful completion of build procedure for model: rtwdemo_cppclass_functions
```

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.cpp` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_cppclass_functions.cpp` calls the initialization function, including `Initialize Function`, and exported functions for model subsystem components `f1`, `f2`, and `f3`.
- `rtwdemo_cppclass_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

1. Include the generated header files by adding directives `#include rtwdemo_cppclass_functions.h` and `#include rtwtypes.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1
- `rtU.U3` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void initialize(void)`. At startup, call this function once.
- Exported function, `void t_1tic_A(void)`. Call this function as needed.
- Exported function, `void t_1tic_B(void)`. Call this function as needed.
- Exported function, `void t_1tic_C(void)`. Call this function as needed.

Output ports:

- `rtY.TicToc1` of type `int8_T` with dimension [2]

- `rtY.TicToc2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

Generate Code for Export-Function Subsystems

- "Specify a Custom Initialize Function Name" on page 39-69
- "Specify a Custom Description" on page 39-69
- "Optimize Code Generated for Export-Function Subsystems" on page 39-70

To generate code for an export-function subsystem:

1. Verify that the subsystem for which you are generating code satisfies exporting requirements on page 39-52.
2. In the Configuration Parameters dialog box:
   a. On the **Code Generation** pane, specify an ERT-based system target file, such as `ert.tlc`.
   b. If you want a SIL block with the generated code, for verification purposes, from the **Configuration Parameters** > **All Parameters** > **Create block** drop-down list, select `SIL`.
   c. Click **OK** or **Apply**.
3. Right-click the subsystem block and choose **C/C++ Code** > **Export Functions** from the context menu.

The `Build code for subsystem: Subsystem` dialog box is not specific to export-function subsystems. Generating code does not require entering information in the dialog box.

4 Click **Build**.

The code generator produces code and places it in the working folder.

If you set **Create block** to `SIL` in step 2b, Simulink opens a new window that contains an S-function block that represents the generated code. This block has the same size, shape, and connectors as the original subsystem.

Code generation and optional block creation are now complete. You can test and use the code and optional block as you do for generated ERT code and S-function block. For optional workflow tasks, see "Specify a Custom Initialize Function Name" on page 39-69 and "Specify a Custom Description" on page 39-69.

Specify a Custom Initialize Function Name

You can specify a custom name for the initialize function of your exported function as an argument to the `rtwbuild` command. The command takes the following form:

```
blockHandle = rtwbuild('subsystem', 'Mode', 'ExportFunctionCalls',..
            'ExportFunctionInitializeFunctionName', 'fcnname')
```

`fcnname` specifies the function name. For example, if you specify the name `'myinitfcn'`, the build process emits code similar to:

```
/* Model initialize function */
void myinitfcn(void){
...
}
```

Specify a Custom Description

You can enter a custom description for an exported function by using the Block Properties dialog box of an Inport block.

1 Right-click the Inport block that drives the control port of the subsystem for which you are exporting code.

2 Select **Properties**.

3 In the **General** tab, in the **Description** field, enter your descriptive text.

During function export, the text you enter is emitted to the generated code in the header for the Inport block. For example, if you open the example program `rtwdemo_exporting_functions` and enter a description in the Block Properties dialog box for port `t_1tic_A`, the code generator produces code that is similar to:

```
/*
 * Output and update for exported function: t_1tic_A
 *
 *  My custom description of the exported function
*/
void t_1tic_A(void)
{
...
}
```

Optimize Code Generated for Export-Function Subsystems

To optimize the code generated for an export-function subsystem, specify a separate storage class for each input signal and output signal that crosses the boundary of the subsystem.

For each function-call subsystem that you are exporting:

1. Right-click the subsystem.
2. From the context menu, choose **Block Parameters (Subsystem)**.
3. Select the **Code Generation** tab.
4. Set **Function packaging** to `Auto`.
5. Click **OK** or **Apply**.

Generate Shared Library for Export to External Code Base

In this section...

About Generated Shared Libraries

If you have Embedded Coder software, you can generate a shared library—Windows dynamic link library (`.dll`), UNIX shared object (`.so`), or Macintosh OS X dynamic library (`.dylib`)— from a model component. You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. Uses of shared libraries include:

- Adding a software component to an application for system simulation
- Reusing software modules among applications on a development computer
- Hiding intellectual property associated with software that you share with vendors

When producing a shared library, the code generator exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (*`model`*`_M`) as data
- Functions essential to executing the model code

Workflow

To generate a shared library from a model component and use the library, complete the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	• "Choose an External Code Integration Workflow" on page 39-4 • "Shared Library Limitations" on page 47-7
2	Configure the model for code generation.	"Generate Code That Matches Appearance of External Code" on page 39-95 and "Model Configuration"
3	Configure the model for the code generator to produce a shared library and initiate code generation.	"Generate Shared Libraries" on page 39-73
4	Verify that the generated shared library meets requirements. For example, review the code generation report and view the list of symbols in the library. • On Windows, use the Dependency Walker utility, downloadable from www.dependencywalker.com • On UNIX, use `nm -D model.so` • On Macintosh OS X, use `nm -g model.dylib`	
5	Use the shared library in application code.	"Create Application Code That Uses Generated Shared Libraries" on page 39-73
6	Compile and link application code that loads and uses the generated shared library.	"Build Integrated Code Outside the Simulink Environment" on page 39-79
7	Verify that executable program behaves and performs as expected.	

Generate Shared Libraries

1. When configuring the model for code generation, select the system target file `ert_shrlib.tlc`.
2. Build the model. The code generator produces source code for the model and a shared library version of the code. The code generator places the source code in the code generation folder and the shared library (`.dll`, `.so`, or `.dylib` file) in your current working folder. The code generator also produces and retains a `.lib` file to support implicit linking.

Create Application Code That Uses Generated Shared Libraries

This example application code is generated for the example "Interface to a Development Computer Simulator By Using a Shared Library" on page 39-76.

1. Create an application header file that contains type declarations for model external input and output. For example:

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

#endif /*_APP_MAIN_HEADER_*/
```

2. In the application C source code, dynamically load the shared library. Use preprocessing conditional statements to invoke platform-specific commands. For example:

```
#if (defined(_WIN32)||defined(_WIN64)) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
```

```
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

#endif

int main()
{
    void* handleLib;
...
#if defined(_WIN64)
    handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
#else #if defined(_WIN32)
    handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
#else /* UNIX */
    handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
#endif
#endif
...
    return(CLOSELIB(handleLib));
}
```

3 From the application C source code, access exported data and functions generated from the model. The code uses hooks to add user-defined initialization, step, and termination code.

```
   int32_T i;
 ...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);

    uint8_T (*sum_outptr);
...

    }
    else {
        printf("Cannot locate the specified reference(s) in the shared
          library.\n");
        return(-1);
    }
```

Limitations

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (*`model`*_M)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is unavailable on the **Code Generation** pane in the Configuration Parameters dialog box.
- To reconstruct a model simulation by using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing must be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables model configuration parameters **Support: continuous time** and **Single output/update function**. For more information, see Single output/update function (Simulink Coder) dependencies.

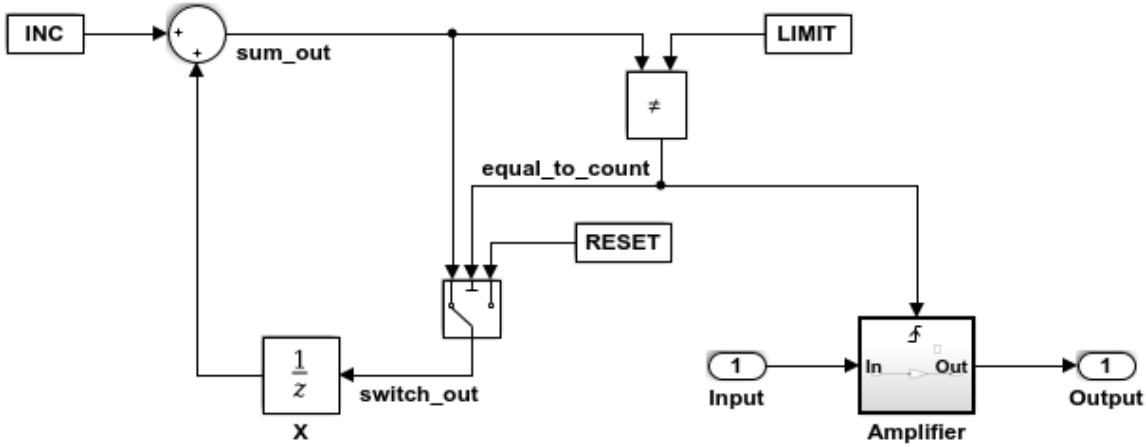
Interface to a Development Computer Simulator By Using a Shared Library

This example generates a shared library for interfacing to a simulator that runs on your development computer. Generate the shared library by using the system target file `ert_shrlib.tlc`.

To build a shared library from the model and use the library in an appplication:

1. Develop your model. For this example, open the model `rtwdemo_shrlib`.

```
open_system('rtwdemo_shrlib');
```



Description
This example shows the use of a shared library generated using the system target file ert_shrlib.tlc for a single-rate discrete-time model. An 8-bit counter feeding a triggered subsystem is parameterized with constants INC=1, LIMIT=4, and RESET=0. The I/O for the model is Input and Output. The Amplifier subsystem amplifies the input signal by a gain factor K=3. The output signal is updated whenever signal equal_to_count is true. The shared library generated from this example can be dynamically loaded from another application. See rtwdemo_shrlib_app.c for an application example written in C language.

Instructions
1. View the Code Generation configuration by clicking the yellow button below.
2. Double-click the blue button to build and run an example application that uses the generated shared library. Click the white buttons to view source code.

matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.h

matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.c

matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\run_rtwdemo_shrlib_app.m

Run script run_rtwdemo_shrlib_app.m (double-click)

View Code Generation Configuration (double-click)

The model is a single-rate, discrete-time model. An 8-bit counter feeds the triggered subsystem named `Amplifier`. Parameters `INC`, `LIMIT`, and `RESET` are set to constant

values 1, 4, and 0, respectively. When signal `equal_to_count` is true, the subsystem amplifies its input signal by a gain factor `K=3` and the output signal is updated.

2. Configure the model for code generation, specifying `ert_shrlib.tlc` as the system target file. Click the yellow button on the model to view the configuration settings on the **Code Generation** pane in the Configuration Parameters dialog box.

3. Build the shared library file. The file that the code generator produces depends on your development platform. For example, on a Windows system, the code generator produces the library file `rtwdemo_shrlib_win64.dll`.

4. Create application code that uses the shared library. This example uses application code that is available in the these files:

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.h
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.c
```

To view the source code in these files, in the model, click the white buttons for the `.h` and `.c` files.

5. Compile and link the file application and shared library files to produce an executable program. The following script compiles, builds, and runs the program.

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.m
```

To view the script code, in the model, click the white button for the `.m` file.

To build the model and run the application that uses the generated shared library, in the model, double-click the blue button.

For more information about using a shared library, see “Package Generated Code as Shared Libraries”.

- “Model Protection”

Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see "Generate C Code from a Control Algorithm for an Embedded System".

Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, and a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the *`model`*`_ert_rtw` folder.

Open the example model, rtwdemo_PCG_Eval_P5.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

1. Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
2. At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler does not require all of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

Integrating the Generated Code into an Existing System

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to all integration environments.

Overview of Integration Environment

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View example_main.c.

```
int_T main(void)
{
  /* Initialize model */
  rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
  rtwdemo_PCG__Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
  defineImportData();                /* Defines the memory and values of inputs */

  do /* This is the "Schedule" loop.
      Functions would be called based on a scheduling algorithm */
  {
    /* HARDWARE I/O */

    /* Call control algorithms */
    PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
    PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
    pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
    pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

    rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                    &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines `extern` data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

Match System Interfaces

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View defineImportedData.c.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
    pos_rqst = &dummy_pos_value;
}
```

View rtwdemo_PCG_Eval_P5_Private.h.

```
/* Imported (extern) block signals */
extern real_T fbk_1;                   /* '<Root>/fbk_1' */
extern real_T fbk_2;                   /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst;               /* '<Root>/pos_rqst' */
```

Connect Output Data

In this example, you do not access the output data of the system. The example "Test Generated Code" shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View rtwdemo_PCG_Eval_P5.h.

Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, some or all of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

```
Data Type      Data Name     Data Purpose

Constants      |model_cP|    Constant parameters
Constants      |model_cB|    Constant block I/O
Output         |model_U|     Root and atomic subsystem input
Output         |model_Y|     Root and atomic subsystem output
Internal data  |model_B|     Value of block output
Internal data  |model_D|     State information vectors
Internal data  |model_M|     Time and other system level data
Internal data  |model_Zero|  Zero-crossings
Parameters     |model_P|     Parameters
```

Match Function Call Interfaces

By default, functions that the code generator generates have a `void` *`Func`*`(void)` interface. If you configure the model or atomic subsystem to generate reentrant code,

the code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with the correct input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

1. Create a build folder (`Eclipse_Build_P5`).
2. Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
3. Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse”.

To exercise the model with input data, see “Test Generated Code”.

Exchange Data Between External C/C++ Code and Simulink Model or Generated Code

Whether you import your external code into a Simulink model (for example, by using the Legacy Code Tool) or export the generated code to an external environment, the model or the generated code can exchange data (signals, states, and parameters) with your code.

Functions in C or C++ code, including your function, can exchange data with a caller or a called function through:

- Arguments (formal parameters) of functions. When a function exchanges data through arguments, a caller can call the function multiple times. Each instance of the called function can manipulate its own independent set of data so that the instances do not interfere with each other.
- Direct access to global variables. Global variables can:
  - Enable different algorithms (functions) and instances of the same algorithm to share data such as calibration parameters and error status.
  - Enable the different rates (functions) of a multitasking system to exchange data.
  - Enable different algorithms to exchange data asynchronously.

In Simulink, you can organize and configure data so that a model uses these exchange mechanisms to provide, extract, and share data with your code.

Before you attempt to match data interfaces, to choose an integration approach, see “Choose an External Code Integration Workflow” on page 39-4.

In this section...

Import External Code into Model

To exchange data between your model and your external function, choose an exchange mechanism based on the technique that you chose to integrate the function.

- To exchange data through the arguments of your external function, construct and configure your model to create and package the data according to the data types of the arguments. Then, you connect and configure the block that calls or represents your function to accept, produce, or refer to the data from the model.

  For example, if you use the Legacy Code Tool to generate an S-Function block that calls your function, the ports and parameters of the block correspond to the arguments of the function. You connect the output signals of upstream blocks to the input ports and set parameter values in the block mask. Then, you can create signal lines from the output ports of the block and connect those signals to downstream blocks.
- To exchange data through global variables that your external code already defines, a best practice is to use a Stateflow chart to call your function and to access the variables. You write algorithmic C code in the chart so that during simulation or execution of the generated code the model reads and writes to the variables.

  To use such a global variable as an item of parameter data (not signal or state data) elsewhere in a model, you can create a numeric MATLAB variable or `Simulink.Parameter` object that represents the variable. If you change the value of the C-code variable in between simulation runs, you must manually synchronize the value of the Simulink variable or object. If your algorithmic code (function) changes the value of the C-code variable during simulation, the corresponding Simulink variable or object does not change.

  If you choose to create a Simulink representation of the C-code variable, you can configure the Simulink representation so that the generated code reads and writes to the variable but does not duplicate the variable definition. Apply a storage class to the Simulink representation.

Technique for Integrating External Function	Mechanism to Exchange Data with Model	Examples and More Information
S-Function block	Function arguments	To call your function through an S-function that you create by using the Legacy Code Tool, see “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).
Stateflow chart	Function arguments and direct access to global variables	To call your function and access global variables in a Stateflow chart, see “Integrate Custom C/C++ Code for Simulation” (Stateflow). For information about

Technique for Integrating External Function	Mechanism to Exchange Data with Model	Examples and More Information
		creating data items in a chart (which you can pass to your function as arguments), see "Add Stateflow Data" (Stateflow).
`coder.ceval` in MATLAB Function block	Function arguments	To call your function in a MATLAB Function block by using `coder.ceval`, see "Integrate C Code Using the MATLAB Function Block" (Simulink). For information about creating data items in a MATLAB Function block (which you can pass to your function as arguments), see "Ports and Data Manager" (Simulink).

Export Generated Code to External Environment

To export the generated code into your external code so that you can later compile and deploy the code, you configure the generated code to match the data interface of your external code. For example, if your external code defines some global variables for storing input data and expects the generated code to calculate that input data, you can construct the model and configure Outport blocks so that the generated code interacts with the variables.

- You can generate reentrant code from a model, which means that the generated entry-point functions exchange data through arguments. If you have Embedded Coder, you can control the prototypes of the entry-point functions. For example, you can make root-level Inport blocks appear in the generated code as arguments of the entry-point functions, which enables your external code to call the functions multiple times. For more information about generating reentrant code from a model, see "Generate Reentrant Code from Top-Level Models" on page 25-4. For more information about function prototype control, see "Control Generation of Function Prototypes" on page 26-2.

  Similarly, when you generate code from a subsystem, you can generate reentrant code and configure the function prototypes by using parameters of the Subsystem block. For more information, see "Generate Reusable Function for Identical Subsystems Within a Model" on page 3-11 and `RTW.configSubsystemBuild`.
- You can exchange data between the generated code and your code through global variables. You can generate variable definitions for your code to use, or you can share and reuse existing variables that your code already defines.

To make the generated code read or write to an item of signal, state, or parameter data as a global variable, apply a storage class or custom storage class to the data. The storage class also determines whether the generated code exports the variable definition (memory allocation) to your external code or imports the definition from your code. For information about controlling a data interface by applying storage classes in a model, see "Design Data Interface by Configuring Inport and Outport Blocks" on page 19-134 and "Configure Data Interface by Applying Custom Storage Classes".

Simulink Representations of C Data Types and Constructs

To model and reuse your custom C data types such as structures, enumerations, and `typedef` aliases, use the information in these tables.

Modeling Patterns for Matching C-Code Data

C Data Type or Construct	Example External Code	Simulink Equivalent	More Information
Primitive type alias (`typedef`)	`typedef float mySinglePrec_T`	Create a `Simulink.AliasType` object. Use the object to: • Set the data types of signals and block parameters in a model. • Configure data type replacements for code generation. Generating code that uses an alias requires Embedded Coder.	For information about defining custom data types for your model, see `Simulink.AliasType` and "What Are User-Defined Data Types?" on page 21-2. For an example that shows how to export the generated code into your external code, see "Conform to Coding Standards by Replacing and Renaming Data Types" on page 21-22.
Array	`int myArray[6];`	Specify signal and parameter dimensions	For information about how the generated code

C Data Type or Construct	Example External Code	Simulink Equivalent	More Information
		as described in "Signal Dimensions" (Simulink).	stores nonscalar data (including limitations), see "Code Generation of Matrices and Arrays" (Simulink Coder). For an example that shows how to export the generated code into your external code, see "Reuse Parameter Data from Custom Code in the Generated Code" on page 23-17. To model lookup tables, see Simulink.LookupTable.

Enumeration	`typedef enum myColorsType {`
	`  Red = 0,`
	`  Yellow,`
	`  Blue`
	`} myColorsType;`
		Define a Simulink enumeration that corresponds to your enumeration definition. Use the Simulink enumeration to set data types in a model.	To use enumerated data in a Simulink model, see "Use Enumerated Data in Simulink Models" (Simulink).
			
			For an example that shows how to export the generated code into your external code, see "Exchange Structured and Enumerated Data Between Generated and External Code" on page 21-28.

C Data Type or Construct	Example External Code	Simulink Equivalent	More Information

Structure	`typedef struct myStructType {`
	`  int count;`
	`  double coeff;`
	`} myStructType;`
		Create a `Simulink.Bus` object that corresponds to your structure type.
		
		To create structured signal or state data, package multiple signal lines in a model into a single nonvirtual bus signal.
		
		To create structured parameter data, create a parameter object (such as `Simulink.Parameter`) that stores a MATLAB structure. Use the bus object as the data type of the parameter object.
		
		To package lookup table data into a structure, use `Simulink.LookupTable` and, optionally, `Simulink.Breakpoint` objects.
			For information about bus signals, see "Getting Started with Buses" (Simulink). For information about structures of parameters, see "Organize Related Block Parameter Definitions in Structures" (Simulink).
			
			For an example that shows how to import your external code into a model by using the Legacy Code Tool, see "Integrate C Function Whose Arguments Are Pointers to Structures" (Simulink).
			
			For examples that show how to export the generated code into your external code, see "Exchange Structured and Enumerated Data Between Generated and External Code" on page 21-28 and "Access Structured Data Through

C Data Type or Construct	Example External Code	Simulink Equivalent	More Information
			a Pointer That External Code Defines" on page 23-27. To package lookup table data into a structure, Simulink.LookupTable.

Additional Modeling Patterns for Code Generation

C Data Type or Construct	Example External C Code	Simulink Equivalent	More Information

Bit field	`typedef struct myBitField {`
	`  unsigned short int MODE : 1;`
	`  unsigned short int FAIL : 1;`
	`  unsigned short int OK : 1;`
	`} myBitField`
		Apply the custom storage class `BitField` to signals, states, and parameters whose data type is `boolean`.
		
		Use a model configuration parameter to aggregate Boolean data into bit fields.
		
		This technique requires Embedded Coder.
			"Bitfields" on page 13-95
			
			"Optimize Generated Code By Packing Boolean Data Into Bitfields" on page 57-14

Macro	`#define myParam 9.8`	Apply the custom storage classes `Define` and `ImportedDefine` to parameters.	"Macro Definitions (#define)" on page 13-77

C Data Type or Construct	Example External C Code	Simulink Equivalent	More Information
		This technique requires Embedded Coder.	
Storage type qualifiers such as `const` and `volatile`	`const volatile int countLimit;`	Apply the custom storage classes `Const`, `Volatile`, or `ConstVolatile` to signals (`volatile`), states, and parameters (`const`, `volatile`, or `const volatile`). This technique requires Embedded Coder.	"Type Qualifiers" on page 13-15

Function call that reads or writes to data	`/* Call this function to acquire the value of the signal. */`
	`double get_inSig(void)`
	`{`
	`  return myBigStruct.inSig;`
	`}`
		Apply the custom storage class `GetSet` to signals, states, and parameters. Each data item appears in the generated code as a call to your custom functions that read and write to the target data.
		
		This technique requires Embedded Coder.
			"Access Data Through Functions with Custom Storage Class `GetSet`" on page 23-92

Generate Code That Matches Appearance of External Code

A key aspect of code integration, especially for larger projects, is adherence to guidelines and standards for code appearance. If code appearance requirements apply to your project, review the requirements in this table. To learn more, see the relevant information.

Requirement	More Information
Thoroughly document code or document code in a specific way.	• "Configure Code Comments" on page 28-14 • "Specify Comment Style" on page 36-14 • "Add Custom Comments to Generated Code" on page 36-3 • "Add Custom Comments for Variables in the Generated Code" on page 36-5 • "Add Global Comments" on page 36-8 • "Annotate Code for Justifying Polyspace Checks" on page 36-98
Control the length and naming of code identifiers (symbols), including the use of reserved names.	• "Identifier Format Control" on page 36-22 • "Specify Identifier Length to Avoid Naming Collisions" on page 28-17 • "Specify Reserved Names for Generated Identifiers" on page 28-18 • "Customize Generated Identifier Naming Rules" on page 36-15 • "Avoid Identifier Name Collisions with Referenced Models" on page 36-30 • "Control Name Mangling in Generated Identifiers" on page 36-28 • "Specify Boolean and Data Type Limit Identifiers" on page 21-43
Control style aspects of code: • Level of parenthesization • Order of operations in expressions	"Control Code Style" on page 36-36

Requirement	More Information
• Empty primary condition expressions `in` if statements • `if-elseif-else` or `switch-case` statements for decision logic • Use of `extern` keyword in function declarations • Use of `default` cases for `switch-case` statements • Use multiplications by powers of two or signed bitwise shifts • Cast expressions • Indent style (Kernighan and Ritchie or Allman) and size	
Placement of data definitions and declarations, including location of global identifiers and global data declarations (`extern`)	"Manage Placement of Data Definitions and Declarations" on page 36-100
Appearance of code for flow charts	"Enhance Readability of Code for Flow Charts" on page 36-127
Apply code templates to control organization of code and use of banners	• "Customize Code Organization and Format" on page 36-54 • "Template Symbols and Rules" on page 36-90 • "Specify Templates For Code Generation" on page 36-56 • "Generate Custom File and Function Banners" on page 36-82 • "Change the Organization of a Generated File" on page 36-65 • "Generate Source and Header Files with a Custom File Processing (CFP) Template" on page 36-67

Program Building, Interaction, and Debugging in Simulink Coder

Select C or C++ Programming Language

After the steps in "Select a Solver That Supports Code Generation" (Simulink Coder) and "Select a System Target File from STF Browser" (Simulink Coder), an optional step is to change the programming language selection for code generation. The default selection is C language for code generation.

To change the programming language setting:

1. From **Configuration Parameters** > **Code Generation** > **Language**, select `C` or `C++` for the code generation language. Alternatively, set the `TargetLang` parameter at the command line.

   The code generator produces `.c` or `.cpp` files, depending on your selection, and places the generated files in your build folder.

   For more information, see "Language" (Simulink Coder).
2. Check whether you must choose and configure a compiler. If you select C++, you must choose and configure a compiler. For details, see "Select and Configure C or C++ Compiler or IDE" (Simulink Coder).
3. Check whether the standard math library is configured for your compiler. By default, the code generator uses the ISO/IEC 9899:1999 C (`C99 (ISO)`) library for the C language and the ISO/IEC 14882:2003 C++ (`C++03 (ISO)`) library for the C++ language.

   For more information, see "Standard math library" (Simulink Coder).

More About

- "Select and Configure C or C++ Compiler or IDE" (Simulink Coder)
- "Troubleshoot Compiler Issues" (Simulink Coder)

Select and Configure C or C++ Compiler or IDE

The build process requires a supported compiler. *Compiler*, in this context, refers to a development environment (IDE) containing a linker and make utility, and a high-level language compiler. For details on supported compiler versions, see:

`http://www.mathworks.com/support/compilers/current_release`

When creating an executable program, the build process must be able to access a supported compiler. The build process can find a compiler to use based on your default MEX compiler.

The build process also requires the selection of a toolchain or template makefile. The toolchain or template makefile determines which compiler runs, during the make phase of the build. For more information, see "Choose and Configure Build Process" (Simulink Coder)

To determine which templates makefiles are available for your compiler and system target file, see "Compare System Target File Support" (Simulink Coder).

For both generated files and user-supplied files, the file extension, `.c` or `.cpp`, determines whether the build process uses a C or a C++ compiler. If the file extension is `.c`, the build process uses C compiler to compile the file, and the symbols use the C linkage convention. If the file extension is `.cpp`, the build process uses a C++ compiler to compile the file, and the symbols use the C++ linkage specification.

In this section...

Language Standards Compliance

The code generator produces code that is compliant with the following standards:

Language	Supported Standard
C	ISO/IEC 9899:1990, also known as C89/C90
C++	ISO/IEC 14882:2003

Code that the code generator produces from these sources is ANSI C/C++ compliant:

- Simulink built-in block algorithmic code
- Generated system-level code (task ID [TID] checks, management, functions, and so on)
- Code from other blocksets, including the Fixed-Point Designer product and the Communications System Toolbox product
- Code from other code generators, such as MATLAB functions

Also, the code generator can incorporate code from:

- Embedded system target files (for example, startup code, device driver blocks)
- Custom S-functions or TLC files

Note: Coding standards for these two sources are beyond the control of the code generator. These standards can be a source for compliance problems, such as code that uses C99 features not supported in the ANSI C, C89/C90 subset.

Programming Language Considerations

The code generator produces C and C++ code. Consider the following as you choose a programming language:

- Does your project require you to configure the code generator to use a specific compiler? C/C++ code generation on Windows requires this selection.
- Does your project require you to change the default language configuration setting for the model? See “Select C or C++ Programming Language” on page 40-2.
- Does your project require you to integrate legacy or custom code with generated code? For a summary of integration options, see “What Is External Code Integration?” on page 39-3.
- Does your project require you to integrate C and C++ code? If so, see “What Is External Code Integration?” on page 39-3.

Note: You can mix C and C++ code when integrating generated code with custom code. However, you must be aware of the differences between C and default C++ linkage conventions, and add the `extern "C"'` linkage specifier where required. For the details of the differing linkage conventions and how to apply `extern "C"`, refer to a C++ programming language reference book.

- Does your project require code generation support from other products? See "C++ Language Support Limitations" on page 40-5.

For C++ code generations examples with Stateflow, see the sfcndemo_cppcount model or sf_cpp model.

C++ Language Support Limitations

To use C++ language support, you could need to configure the code generator to use a specific compiler. For example, if a supported compiler is not installed on your Microsoft Windows computer, the default compiler is the `lcc` C compiler shipped with the MATLAB product. This compiler does not support C++. If you do not configure the code generator to use a C++ compiler before you specify C++ for code generation, the software produces an error message.

Code generator limitations on C++ support include:

- The code generator does not support C++ code generation for the following:
  Simscape Driveline
  Simscape Multibody First Generation (Simscape Multibody Second Generation is supported)
  Simscape Power Systems
  Simulink Real-Time
- For ERT and ERT-based system target files with **Configuration Parameters** > **Data Placement** > **Interface** > **Code interface packaging** set to `Nonreusable function`, the following fields currently do not accept the `.cpp` extension. If you specify a file name with a `.c` extension or without an extension and specify C++ for the code generation language, the code generator produces a `.cpp` file.
  - **Configuration Parameters** > **Code Placement** > **Data definition filename** field (available when **Configuration Parameters** > **Code Placement** > **Data definition** is set to `Data defined in a single separate source file`)

- **Definition file** field for a data object in Model Explorer. Data objects are objects of the class `Simulink.Signal`, `Simulink.Parameter`, and subclasses.

Code Generator Assumes Wrap on Signed Integer Overflows

The code generator reduces memory usage and enhances generated code execution by assuming signed integer C operations wrap on overflow. A signed integer overflow occurs when the result of an arithmetic operation is outside the range of values that the output data type can represent. The C programming language does not define the results of such operations. Some C compilers aggressively optimize signed operations for in-range values at the expense of overflow conditions. Other compilers preserve the full wrap-on-overflow behavior. For example, the gcc and MinGW compilers provide an option to wrap on overflow reliably for signed integer overflows. The generated program image for a model can produce results that differ from model simulation results because the handling of overflows varies, depending on your compiler.

When you generate code, if you use a supported compiler with the default options configured by the code generator, the compiler preserves the full wrap-on-overflow behavior. If you change the compiler options or compile the code in another development environment, it is possible that the compiler does not preserve the full wrap-on-overflow behavior. In this case, the executable program can produce unpredictable results.

If this issue is a concern for your application, consider one or more of the following actions:

- Verify that the compiled code produces expected results.
- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, configure the build process to use the compiler option `-fwrapv`.
- Choose a compiler that wraps on integer overflow.
- If you have Embedded Coder installed, develop and apply a custom code replacement library to replace code generated for signed integers. For more information, see “Code Replacement Customization”.

Choose and Configure Compiler

The compiler for your model build appears in the build process parameters in **Configuration Parameters > Code Generation**. To view the installed compilers and select the default compiler, in the Command Window type:

```
mex -setup
```

On a Windows computer, you can install supported compilers and select a default compiler.

On a UNIX platform, the default compiler is GNU `gcc/g++` for GNU or Xcode for Mac.

Unless the build approach configuration selects a specific compiler, the code generator uses the default compiler for the build process.

Primarily, the specified system target file determines the compiler that the code generator requires:

- If you select a toolchain-based system target file such as `grt.tlc` (Generic Real-Time Target), `ert.tlc` (Embedded Coder), or `autosar.tlc` (Embedded Coder for AUTOSAR), the **Build process** subpane displays toolchain parameters for configuring the build process. Use the **Toolchain** parameter to select a compiler and associated tools for your model build. To validate the selected toolchain, click the **Validate** button for the **Configuration Parameters** > **All Parameters** > **Code Generation** > **Toolchain** box.
- If you select a template makefile (TMF) based system target file, such as `rsim.tlc`, the **Build process** subpane displays template makefile parameters for configuring the build process. The **Template makefile** parameter displays the default TMF file for the selected system target file. If the system target file supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function system target files), you can set **Template makefile** to a compiler-specific TMF, such as `rsim_lcc.tmf` or `rsim_unix.tmf`. (See "Compare System Target File Support" (Simulink Coder) for valid TMF names.)

Include S-Function Source Code

When the code generator builds models with S-functions, source code for the S-functions can be either in the current folder or in the same folder as their MEX-file. The code generator adds an include path to the generated makefiles whenever it finds a file named *`sfncname`*`.h` in the same folder as the S-function MEX-file. This folder must be on the MATLAB path.

Similarly, the code generator adds a rule for the folder when it finds a file *`sfncname`*`.c` (or `.cpp`) in the same folder as the S-function MEX-file is in.

Troubleshoot Compiler Issues

In this section...

Compiler Version Mismatch Errors

Description

The build process produces a compiler version mismatch error.

Action

1. Check the list of supported and compatible compilers available at www.mathworks.com/support/compilers/current_release/.
2. Upgrade or change your compiler. For more information, see "Choose and Configure Compiler" on page 40-6.
3. Rebuild the model.

Results for Model Simulation and Program Execution Differ

Description

The program generated for the model produces different results from model simulation results. The generated source code includes an arithmetic operation that produces a signed integer overflow. It is possible that your compiler does not implement wrapping behavior for signed integer overflow conditions. Or, if you are using a compiler that supports wrapping, it is possible that you did not configure it to use the `-fwrapv` option.

For more information, see "Code Generator Relies on Undefined Behavior of C Language for Integer Overflows."

Action

- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, specify the compiler option `-fwrapv`.
- Choose a compiler that checks for integer overflows.
- If you have Embedded Coder, develop and apply a code replacement library to replace code generated for signed integers.

Generates Expected Code and Produces Unexpected Results

Description

The build process generates expected source code, but the executable program produces unexpected results. The generated source code appears as expected. However, the executable program produces unexpected results.

Action

Do one of the following:

- Lower the compiler optimization level.
  1. Select `Custom` for the Model Configuration parameter **Code Generation** > **Compiler optimization level**.
  2. In the **Custom compiler optimization flags** field, specify a lower optimization level.
  3. Rebuild the model.
- Disable compiler optimizations.
  1. Select `Optimizations off (faster builds)` for the Model Configuration parameter **Code Generation** > **Compiler optimization level**.
  2. Rebuild the model.

For more information, see "Control Compiler Optimizations" (Simulink Coder) and your compiler documentation.

Compile-Time Issues

Issue	Action
Error is present in the compiler configuration.	Make sure that MATLAB supports the compiler and version that you want to use. For a list of currently supported and compatible compilers, see www.mathworks.com/support/compilers/current_release/. If necessary, upgrade or change your compiler (see "Choose and Configure Compiler" on page 40-6 or "Choose and Configure Compiler" on page 40-6).
Environment variables are incorrectly set up for your make utility, compiler, or linker. For example, installation of Cygwin tools on a Windows platform affects environment variables used by other compilers.	Review the environment variable settings for your system by using the `set` command on a Windows platform or `setenv` on a UNIX platform. Make sure that the settings match what is required for the tools you are using.
Error is present in custom code specified as an S-function block or in **Configuration Parameters** > **Code Generation** > **Custom Code**. For example, the code refers to a header file that the compiler cannot find.	To isolate the source of the problem, remove the custom code from the model, debug, and rebuild the model.
The model includes a block, such as a device driver block, which is not intended for use with the currently selected system target file.	Remove the system target file-specific block or configure the model for use with another system target file.
A linker error about an undefined reference to the data appears when the model build generates an executable from the model reference hierarchy and all these conditions are true: • You represent signal, state, or parameter data by creating a data object such as `Simulink.Signal`.	To resolve the issue, choose one of these methods: • In the data object, clear the `Owner` property. Alternatively, set the owner to a model that directly accesses the data. • Use a different toolchain, such as `gcc`, instead of `lcc`.

Issue	Action
You use the object in a model reference hierarchy. • You use a custom storage class with the data object. Custom storage classes require Embedded Coder. • You set the owner of the object to a model that does not directly access the data. • You use the toolchain `lcc-win64`.	

LCC Compiler Does Not Support Ampersands in Source Folder Paths

Description

If you use the LCC compiler and your model folder path contains an ampersand (`&`), the build process produces an error.

Action

Remove the ampersand from the model folder path. Then, rebuild the model.

LCC Compiler Might Not Support Line Lengths of Rapid Accelerator Code

Description

If you are compiling Rapid Accelerator code, the LCC compiler might produce an error related to line limits. Rapid Accelerator code can have longer line lengths due to obfuscation.

Action

Compile your Rapid Accelerator code using a compiler that supports longer code lines.

Choose and Configure Build Process

The code generator supports two processes for building code generated from Simulink models:

- *Toolchain approach* — A newer build process that generates optimized makefiles and supports custom toolchains. The benefits of this approach include:
  - Provide control of your build process with toolchain information objects. You can define these objects using MATLAB scripts.
  - Supports model referencing, PIL, SIL, and Rapid Accelerator builds.
  - Supported by MATLAB Coder.
  - Provides added flexibility to configure the build process for individual models.
- *Template makefile approach* — An older build process that uses template makefiles

The "System target file" (Simulink Coder) parameter, located in the **Configuration Parameters > Code Generation** pane, determines the build process for a model. When the **System target file** is set to:

- `ert.tlc`, `ert_shrlib.tlc`, `grt.tlc`, or any toolchain-compliant system target file, the build process uses the *toolchain approach*. For more information, see "Toolchain Approach" on page 40-14 and see "Support Toolchain Approach with Custom Target" on page 71-81.
- Any non-toolchain-compliant system target files. The build process uses the *template makefile approach*. For more information, see "Template Makefile Approach" on page 40-20.

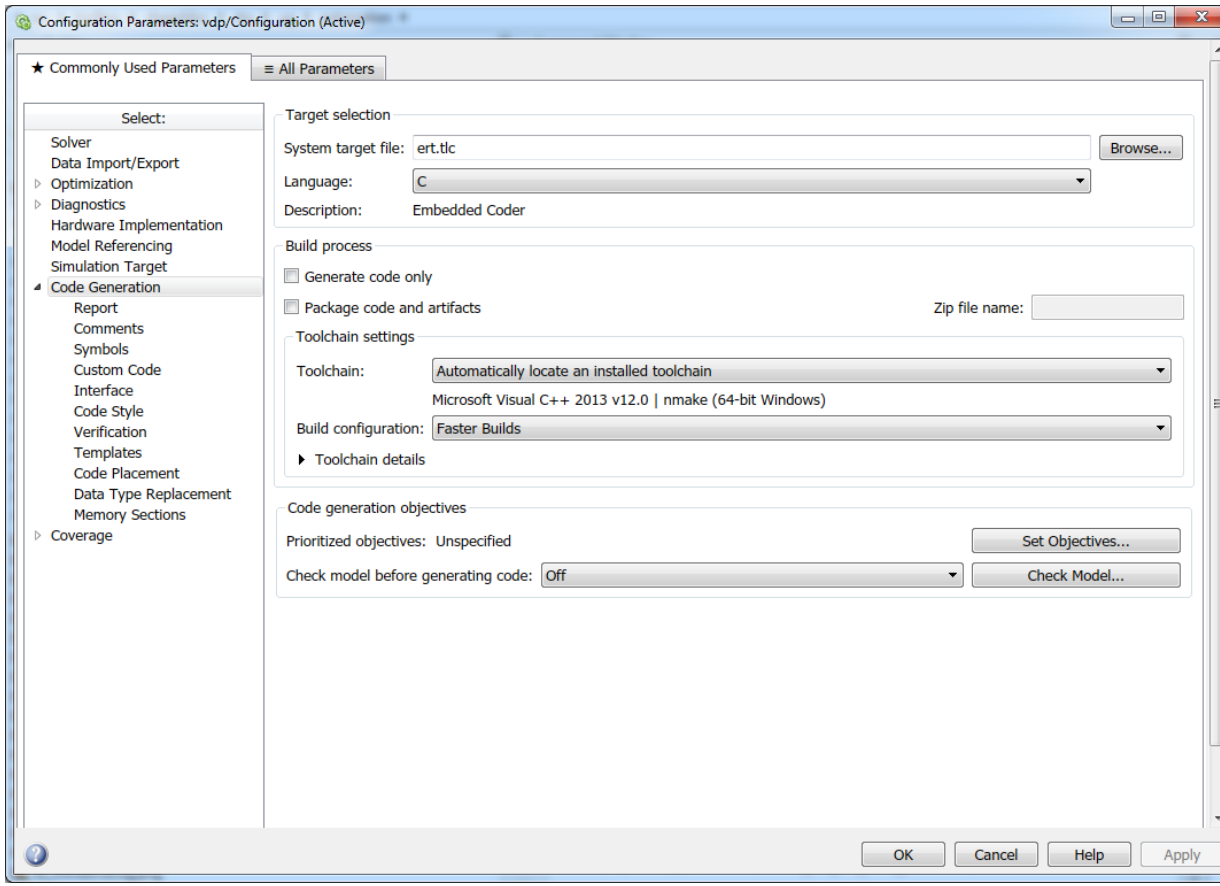
In this section...

Toolchain Approach

The *toolchain approach* is named for the **Toolchain settings** that appear under **Build process** when you set **System target file** to:

- `grt.tlc` — `Generic Real-Time Target`
- `ert.tlc` — `Embedded Coder` (requires the Embedded Coder product)
- `ert_shrlib.tlc` — `Embedded Coder (host-based shared library target)` (requires the Embedded Coder product)
- Any toolchain-compliant system target file (If ERT-based, requires the Embedded Coder product)

For more information about toolchain-compliant system target files, see "Support Toolchain Approach with Custom Target" (Simulink Coder).



The **Toolchain settings** include:

- The "Toolchain" (Simulink Coder) parameter specifies the collection of third-party software tools that builds the generated code. A toolchain can include a compiler, linker, archiver, and other prebuild or postbuild tools that download and run the executable on the target hardware.

  The default value of **Toolchain** is `Automatically locate an installed toolchain`. The **Toolchain** parameter displays name of the located toolchain just below `Automatically locate an installed toolchain`.

  Click the **Validate** button for the **Configuration Parameters** > **All Parameters** > **Code Generation** > **Toolchain** parameter to check that the toolchain is present and validate that the code generator has the information required to use the toolchain. The resulting Validation Report gives a pass/fail for the selected toolchain, and identifies issues to resolve.
- The "Build configuration" (Simulink Coder) parameter lets you choose or customize the optimization settings. By default, **Build Configuration** is set to `Faster Builds`. You can also select `Faster Runs`, `Debug`, and `Specify`. When you select `Specify` and click **Apply**, you can customize the toolchain options for each toolchain. These custom toolchain settings only apply to the current model.

Note: The following system target files, which use the template makefile approach, have the same names but different descriptions from system target files that use the toolchain approach:

- `ert.tlc – Create Visual C/C++ Solution File for Embedded Coder`
- `grt.tlc – Create Visual C/C++ Solution File for Simulink Coder`

To avoid confusion, click **Browse** to select the system target file and look at the description of each file.

Upgrade Model to Use Toolchain Approach

When you open a model created before R2013b that uses the following system target files, the software tries to upgrade the model. The upgrade changes the configuration from using template makefile settings to using the toolchain settings:

- `ert.tlc – Embedded Coder`
- `ert_shrlib.tlc – Embedded Coder (host-based shared library target)`

- `grt.tlc — Generic Real-Time Target`

Note: To upgrade models using a custom system target file to use the toolchain approach, see "Support Toolchain Approach with Custom Target" on page 71-81.

Some model configuration parameter values prevent the software from upgrading a model to use toolchain settings. The following instructions show you ways to complete the upgrade process.

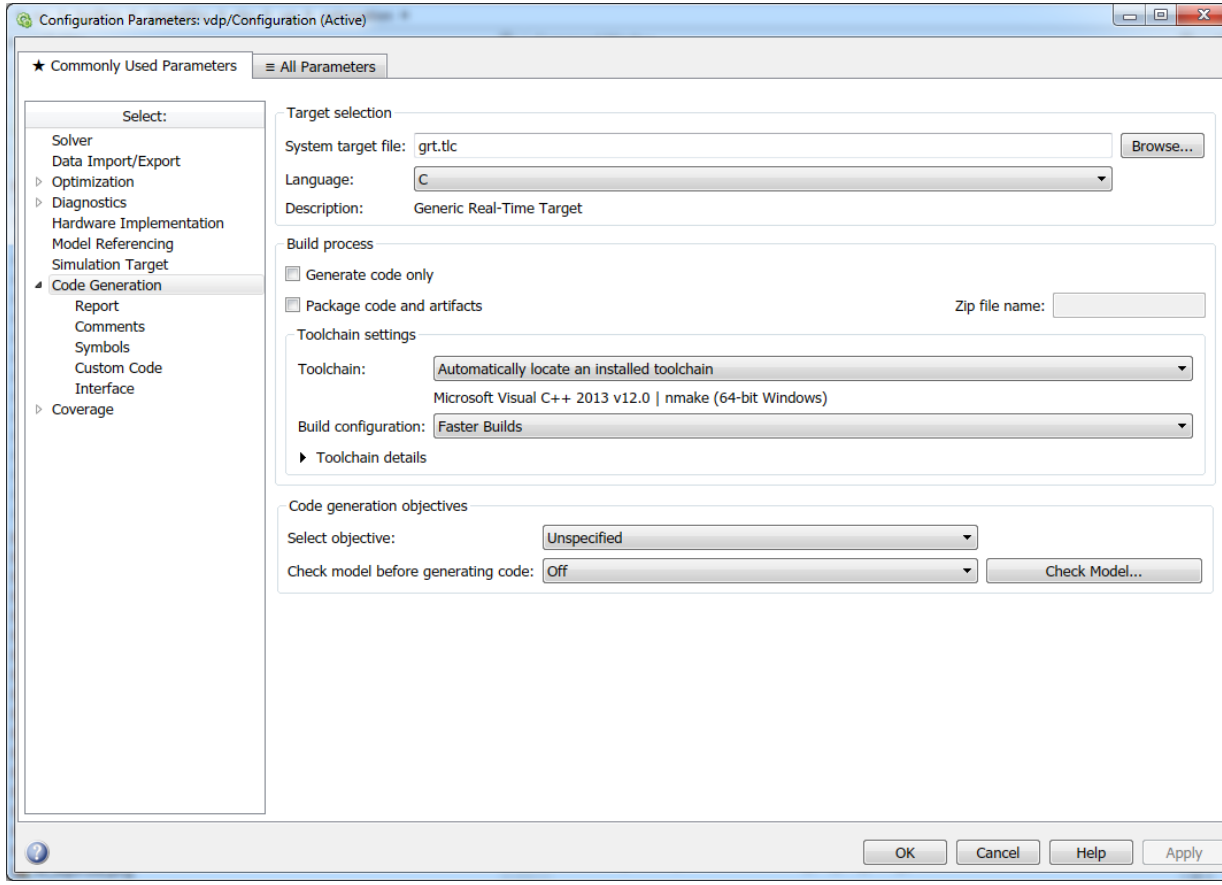
Consider upgrading your models and use the toolchain build approach. Doing so is not required. You can continue generating code from a model that has not been upgraded.

Note: The software does not upgrade models that use the following system target files:

- `ert.tlc — Create Visual C/C++ Solution File for Embedded Coder`
- `grt.tlc — Create Visual C/C++ Solution File for Simulink Coder`

To see if a model was upgraded:

1. Open the model configuration parameters by pressing **Ctrl+E**.
2. Select **Configuration Parameters** > **Code Generation**.
3. If the **Build process** subpane contains the **Toolchain** and **Build configuration** parameters, the model has already been upgraded.



If the **Build process** area displays **Makefile configuration** parameters, such as **Generate makefile**, **Make command**, and **Template makefile**, the software has not upgraded the model.

Start by creating a working copy of the model using **File** > **Save As**. This action preserves the original model and configuration parameters for reference.

Try to upgrade the model using Upgrade Advisor:

1 In your model, select **Analysis** > **Model Advisor** > **Upgrade Advisor**.

2. In Upgrade Advisor, select **Check and update model to use toolchain approach to build generated code** and click **Run This Check**.
3. Perform the suggested actions and/or click **Update Model**.

When you cannot upgrade the model using Upgrade Advisor, one or more of the following parameters is not set to its default value, shown here:

- **Compiler optimization level** — `Optimizations off (faster builds)`
- **Generate makefile** — Enabled
- **Template makefile** — System target file-specific template makefile
- **Make command** — `make_rtw` without arguments

Sometimes, a model cannot be upgraded. Try the following procedure:

- If **Generate makefile** is disabled, this case cannot be upgradable. However, you can try enabling it and try upgrading the model using Upgrade Advisor.
- If **Compiler optimization level** is set to `Optimizations on (faster runs)`:

  1. Set **Compiler optimization level** is to `Optimizations off (faster builds)`.
  2. Upgrade the model using Upgrade Advisor.
  3. Set **Build configuration** to `Faster Runs`.
- If **Compiler optimization level** is set to `Custom`:

  1. Copy the **Custom compiler optimization flags** to a text file.
  2. Set **Compiler optimization level** to `Optimizations off (faster builds)`.
  3. Upgrade the model using Upgrade Advisor.
  4. Set **Build configuration** to `Specify`.
  5. To perform the same optimizations, edit the compiler options.
- If **Template makefile** uses a customized template makefile, this case cannot be upgradable. However, you can try the following:

  1. Update **Template makefile** to use the default makefile for the system target file.

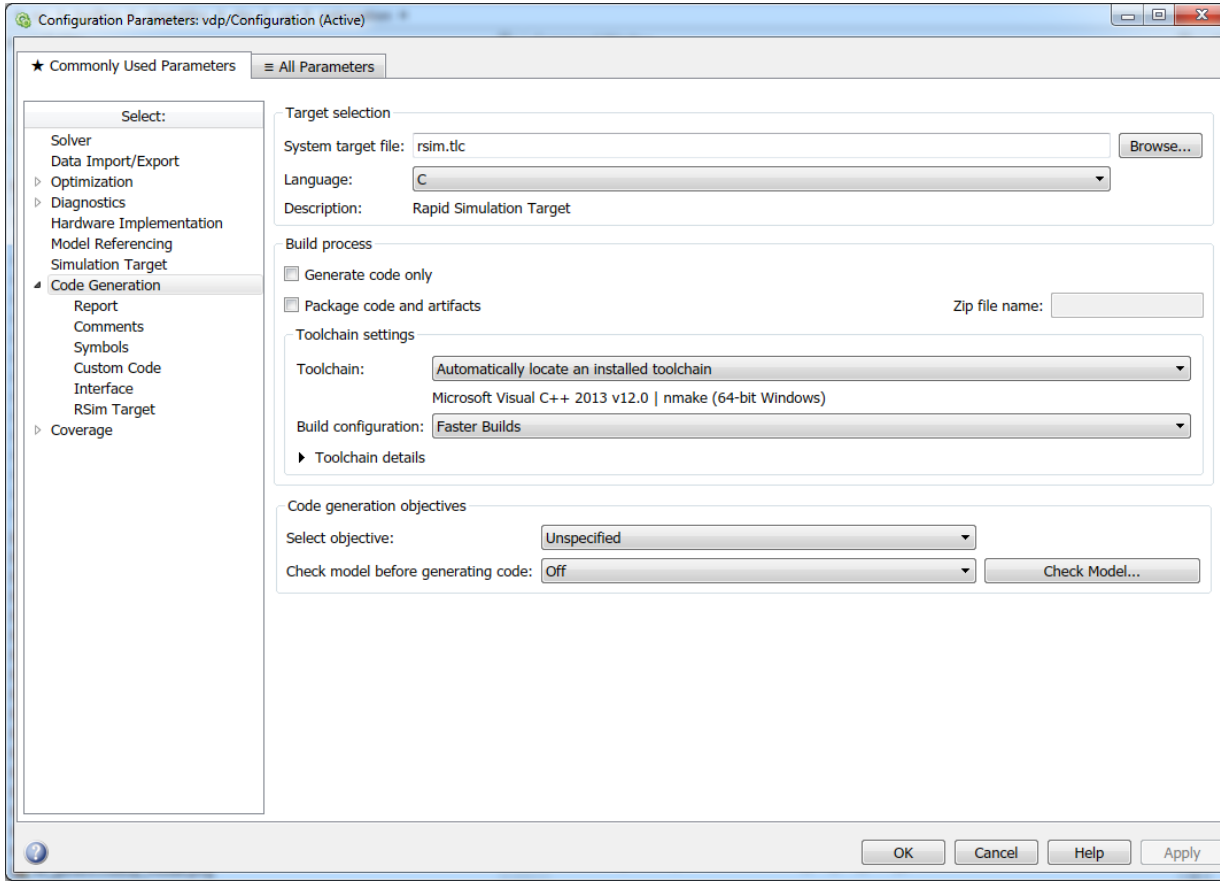
     Note: To get the default makefile name, change the **System target file**, click **Apply**, change it back, and click **Apply** again.

2. Upgrade the model using Upgrade Advisor.
3. If the template makefile contains build tool options, such as compiler optimization flags, set **Build configuration** to `Specify` and update the options.
4. If the template makefile uses custom build tools, create and register a custom toolchain, as described in "Custom Toolchain Registration" (MATLAB Coder) . Then, set the **Toolchain** parameter to use the custom toolchain.

   Note: After registering the custom toolchain, update **Toolchain** to use the custom toolchain.
5. If the template makefile contains custom rules and logic, these customizations cannot be applied to the upgraded model.

Template Makefile Approach

When the **System target file** is set to a `tlc` file that uses the template makefile approach, the software displays **Compiler optimization level**, **Generate makefile**, **Make command**, and **Template makefile** parameters.



Specify Whether to Generate a Makefile

The **Generate makefile** option specifies whether the build process is to generate a makefile for a model. By default, the build process generates a makefile. Suppress generation of a makefile, for example in support of custom build processing that is not based on makefiles, by clearing **Generate makefile**. When you clear this parameter:

- The **Make command** and **Template makefile** options are unavailable.
- Set up post code generation build processing using a user-defined command, as explained in "Customize Post-Code-Generation Build Processing" (Simulink Coder).

Specify a Make Command

Each template makefile-based system target file has an associated `make` command. The code generator uses this internal MATLAB command to control the build process. The command appears in the **Make command** field and runs when you start a build.

Most system target files use the default command, `make_rtw`. Third-party system target files could supply another `make` command. See the documentation from the vendor.

In addition to the name of the `make` command, you can supply makefile options in the **Make command** field. These options could include compiler-specific options, include paths, and other parameters. When the build process invokes the `make` utility, these options are passed on the `make` command line, which adds them to the overall flags passed to the compiler.

"Template Makefiles and Make Options" on page 40-24 lists the **Make command** options you can use with each supported compiler.

Specify the Template Makefile

The **Template makefile** field has these functions:

- If you selected a system target file with the System Target File Browser, this field displays the name of a MATLAB language file that selects a template makefile for your development environment. For example, in "Model Configuration Parameters: Code Generation" (Simulink Coder), the **Template makefile** field displays `grt_default_tmf`, indicating that the build process invokes `grt_default_tmf.m`.

  "Template Makefiles and Make Options" on page 40-24 gives a detailed description of the logic by which the build process selects a template makefile.
- Alternatively, you can explicitly enter the name of a specific template makefile (including the extension) or a MATLAB language file that returns a template makefile in this field. Use this approach if you are using a system target file that does not appear in the System Target File Browser. For example, use this approach if you have written your own template makefile for a custom system target file.

If you specify your own template makefile, be sure to include the file name extension. If you omit the extension, the build process attempts to find and execute a file with the extension `.m` (that is, a MATLAB language file). The template make file (or a MATLAB language file that returns a template make file) must be on the MATLAB path. To determine whether the file is on the MATLAB path, enter the following command in the MATLAB Command Window:

```
which tmf_filename
```

Specify TLC for Code Generation

You can specify Target Language Compiler (TLC) command-line options and arguments for code generation using the model parameter `TLCOptions` in a `set_param` function call. For example,

```
>> set_param(gcs,'TLCOptions','-p0 -aWarnNonSaturatedBlocks=0')
```

Some common uses of TLC options include the following:

- `-aVarName=1` to declare a TLC variable and/or assign a value to it
- `-IC:\Work` to specify an include path
- `-v` to obtain verbose output from TLC processing (for example, when debugging)

TLC options that you specify for code generation appear in the summary section of the generated HTML code generation report.

Specifying TLC command-line options does not add flags to the make command line.

For additional information, see "Target Language Compiler Overview" (Simulink Coder).

- "Executable Program Generation" on page 40-68

Template Makefiles and Make Options

The code generator includes a set of built-in template makefiles that build programs for specific system target files.

In this section...

Types of Template Makefiles

There are two types of template makefiles:

- *Compiler-specific* template makefiles are for a particular compiler or development system.

  By convention, compiler-specific template makefiles names correspond to the system target file and compiler (or development system). For example, `grt_vcx64.tmf` is the template makefile for building a generic real-time program under the Visual C++ compiler; `ert_lcc.tmf` is the template makefile for building an Embedded Coder program under the `lcc` compiler.
- *Default* template makefiles make your model designs more portable, by choosing the compiler-specific makefile and compiler for your installation. "Select and Configure C or C++ Compiler or IDE" on page 40-3 describes the operation of default template makefiles in detail.

  Default template makefiles have names that follow the pattern *`target`*`_default_tmf`. They are MATLAB language files that, when run, select the TMF for the specified system target file configuration. For example, `grt_default_tmf` is the default template makefile for building a generic real-time program; `ert_default_tmf` is the default template makefile for building an Embedded Coder program.

For details on the structure of template makefiles, see "Customize Template Makefiles" on page 71-62. This section describes compiler-specific template makefiles and common options you can use with each.

Specify Template Makefile Options

You can specify template makefile options by using the **Make command** box in **Configuration Parameters** > **Code Generation**. Append the options after `make_rtw` (or other `make` command), as in the following example:

```
make_rtw OPTS="-DMYDEFINE=1"
```

The syntax for `make` command options differs slightly for different compilers.

Note: To control compiler optimizations for a makefile build at the Simulink GUI level, use the **Compiler optimization level** parameter on the **All Parameters** tab of the Configuration Parameters dialog box. The **Compiler optimization level** parameter provides

- System target file-independent values `Optimizations on (faster runs)` and `Optimizations off (faster builds)`, which easily allow you to toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at Simulink GUI level (rather than at other levels of the build process)

If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

Template Makefiles for UNIX Platforms

The template makefiles for UNIX platforms are for the Free Software Foundation's GNU Make. These makefiles conform to the guidelines specified in the IEEE®[10] Std 1003.2-1992 (POSIX) standard.

- `ert_unix.tmf`
- `grt_unix.tmf`
- `rsim_unix.tmf`
- `rtwsfcn_unix.tmf`

10. IEEE is a registered trademark of The Institute of Electrical and Electronics Engineers, Inc.

You can supply options to makefiles using the **Make command** box in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

  ```
  OPTS="-DMYDEFINE=1"
  ```

- `OPT_OPTS`— Optimization options. Default is `-O`. To enable debugging, specify the option as `OPT_OPTS=-g`. Because of optimization problems in IBM_RS, the default is no optimization.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

Template Makefiles for the Microsoft Visual C++ Compiler

Visual C++ Executable Build

To build an executable using the Visual C++ compiler within the build process, use one of the *target*`_vcx64.tmf` template makefiles:

- `ert_vcx64.tmf`
- `grt_vcx64.tmf`
- `rsim_vcx64.tmf`
- `rtwsfcn_vcx64.tmf`

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPT_OPTS` — Optimization option. Default is `-O2`. To enable debugging, specify the option as `OPT_OPTS=-Zi`.
- `OPTS` — User-specific options.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

Visual C++ Code Generation Only

To create a Visual C++ project makefile (*`model`*`.mak`) without building an executable, use one of the *`target`*`_msvc.tmf` template makefiles:

- `ert_msvc.tmf`
- `grt_msvc.tmf`

These template makefiles are for `nmake`, which is bundled with the Visual C++ compiler.

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

  ```
  OPTS="/D MYDEFINE=1"
  ```

- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

Template Makefiles for the LCC Compiler

The code generator provides template makefiles to create an executable for the Windows platform using Lcc compiler Version 2.4 and GNU Make (`gmake`).

- `ert_lcc.tmf`
- `grt_lcc.tmf`
- `rsim_lcc.tmf`
- `rtwsfcn_lcc.tmf`

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

  ```
  OPTS="-DMYDEFINE=1"
  ```

- `OPT_OPTS` — Optimization options. Default is no options. To enable debugging, specify `-g4`:

  ```
  OPT_OPTS="-g4"
  ```

- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths. For example:

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

For `lcc`, use `/` as file separator before the file name instead of `\`, for example, `d:\work\proj1/myfile.c`.

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

More About

- "Customize System Target Files" (Simulink Coder)

Build Process Workflow for a Real-Time STF

Building a program means generating C or C++ code from an example model and then building an executable program from the generated code. This example can use a generic real-time (GRT) or an embedded real-time (ERT) system target file (STF) for code generation. The resulting standalone program runs on your desktop computer, independent of external timing and events.

In this section...

Working Folder

This example uses a local copy of the `slexAircraftExample` model, stored in its own folder, `aircraftexample`. Set up your *working folder* as follows:

1. In the MATLAB Current Folder browser, navigate to a folder to which you have write access.
2. To create the working folder, enter the following MATLAB command:

   ```
   mkdir aircraftexample
   ```
3. Make `aircraftexample` your working folder:

   ```
   cd aircraftexample
   ```
4. Open the `slexAircraftExample` model:

   ```
   slexAircraftExample
   ```

   The model appears in the Simulink Editor model window.

5 In the model window, choose **File** > **Save As**. Navigate to your working folder, `aircraftexample`. Save a copy of the `slexAircraftExample` model as `myAircraftExample`.

Build Folder and Code Generation Folders

While producing code, the code generator creates a *build folder* within your working folder. The build folder name is *`model_target`*`_rtw`, derived from the name of the source model and the chosen system target file. The build folder stores generated source code and other files created during the build process. Examine the build folder contents at the end of this example.

When a model contains Model blocks (references to other models), the model build creates special subfolders in your "Code generation folder" (Simulink) to organize code for the referenced models. These code generation folders exist alongside product build folders and are named `slprj`. "Generate Code for Referenced Models" on page 5-4 describes navigating code generation folder structures in Model Explorer.

Under the `slprj` folder, a subfolder named `_sharedutils` contains generated code that can be shared between models.

Set Simulation Parameters

To generate code from your model, you must change some of the simulation parameters. In particular, the generic real-time (GRT) system target file and most other system target files require that the model specifies a fixed-step solver.

Note The code generator produces code for models, using variable-step solvers, for rapid simulation (`rsim`) and S-function system target files only.

To set simulation parameters using the Configuration Parameters dialog box:

1 Open the `myAircraftExample` model if it is not already open.

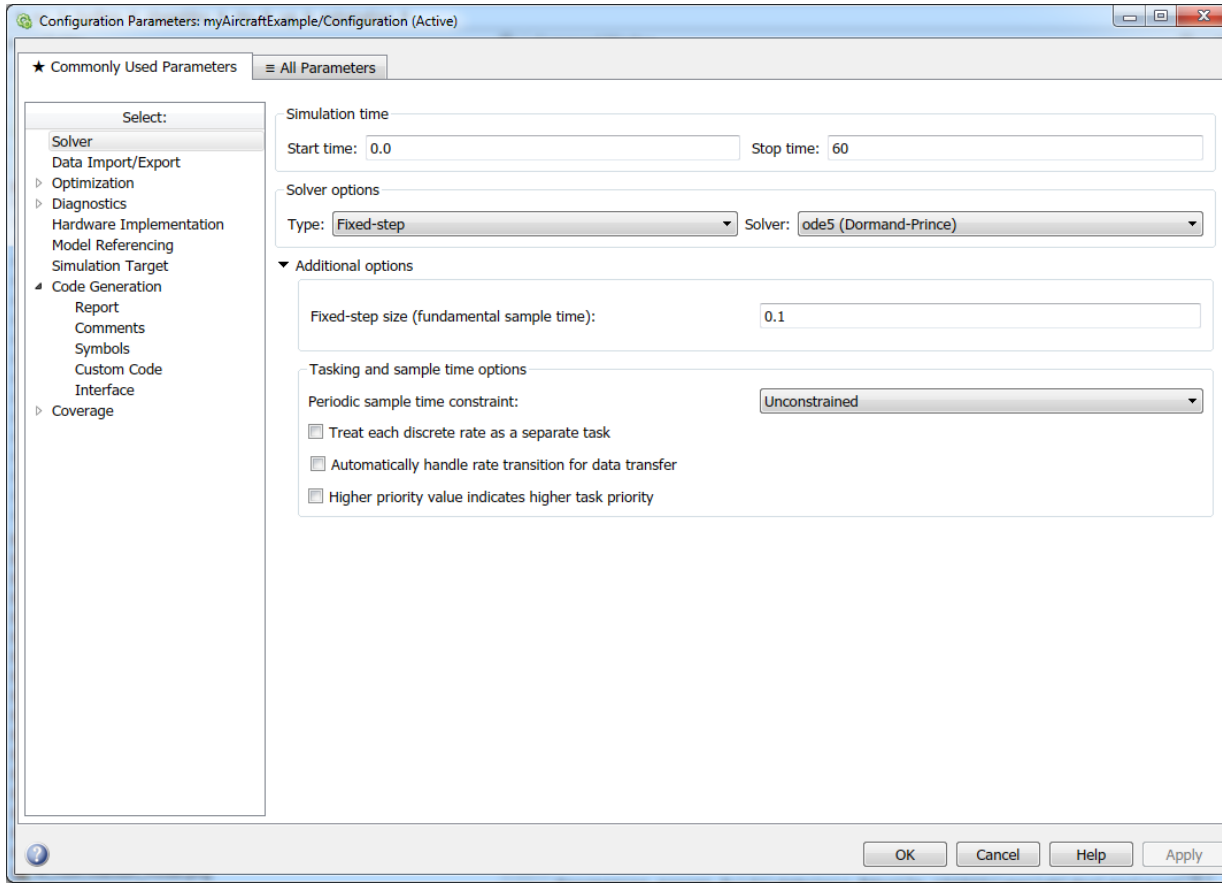
2 From the model window, open the Configuration Parameters dialog box by selecting **Simulation** > **Model Configuration Parameters**.

3 Select **Configuration Parameters** > **Solver**. Enter the following parameter values (some could already be set):

- **Start time**: `0.0`

- **Stop time**: `60`
- **Type**: `Fixed-step`
- **Solver**: `ode5 (Dormand-Prince)`
- **Fixed step size (fundamental sample time)**: `0.1`
- **Treat each discrete rate as a separate task**: `Off`

The background color of the controls you just changed is tan. The color also appears on fields as a reaction to your choices in other fields. Use this visual feedback to verify that what you set is what you intended. When you apply your changes, the background color reverts to white.



4 To register your changes, click **Apply**.

5 Save the model. Simulation parameters persist with the model for use in future sessions.

Configure Build Process

To configure the build process for your model, choose a system target file, a toolchain or template makefile, and a `make` command.

In these examples and in most applications, you do not need to specify these parameters individually. The examples use the ready-to-run generic real-time target (GRT) configuration. The GRT system target file builds a standalone executable program that runs on your desktop computer.

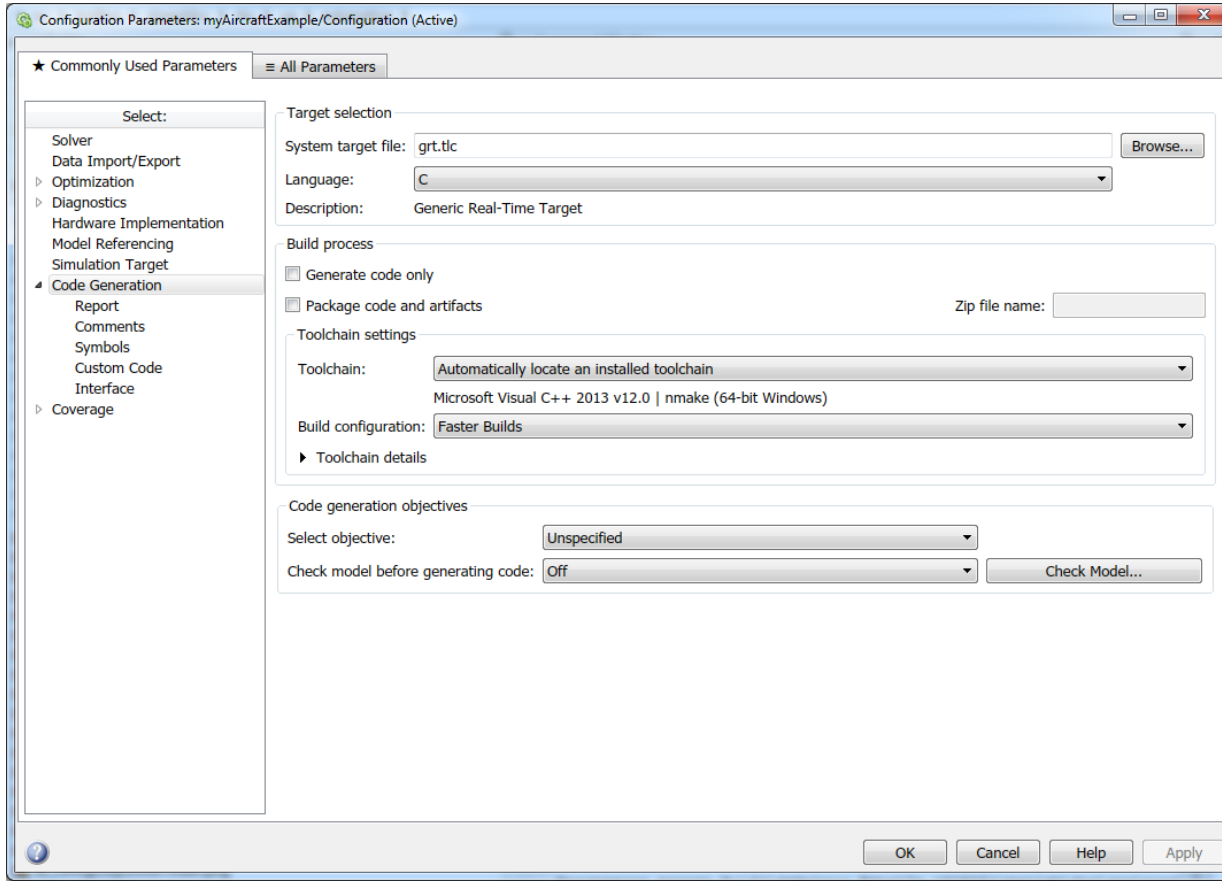
To select the GRT system target file using the Configuration Parameters dialog box:

1 With the `myAircraftExample` model open, select **Simulation** > **Model Configuration Parameters** to open the Configuration Parameters dialog box.

2 Select **Configuration Parameters** > **Code Generation**.

3 For **System target file**, enter `grt.tlc`, and click **Apply**.

The **Configuration Parameters** > **Code Generation** pane displays selections for the **System target file** (`grt.tlc`), **Toolchain** (`Automatically locate an installed toolchain`), and **Build Configuration** (`Faster Builds`).



Note If you click **Browse**, a System Target File Browser opens and displays the system target files on the MATLAB path. Some system target files require additional products. For example, `ert.tlc` requires Embedded Coder.

4 Save the model.

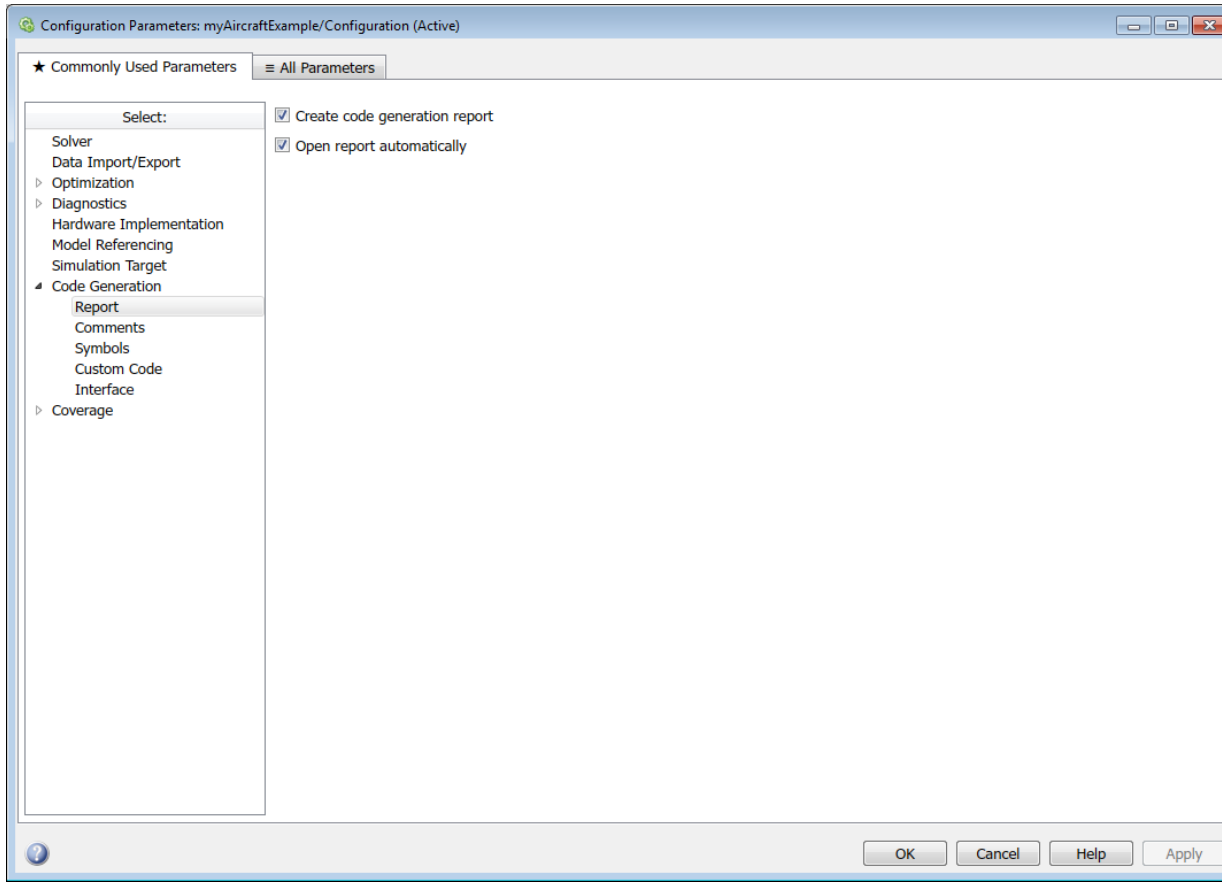
Set Code Generation Parameters

Before you generate code from your model for the first time, inspect the code generation parameters for the model. Some of the steps in this topic do not require you to change

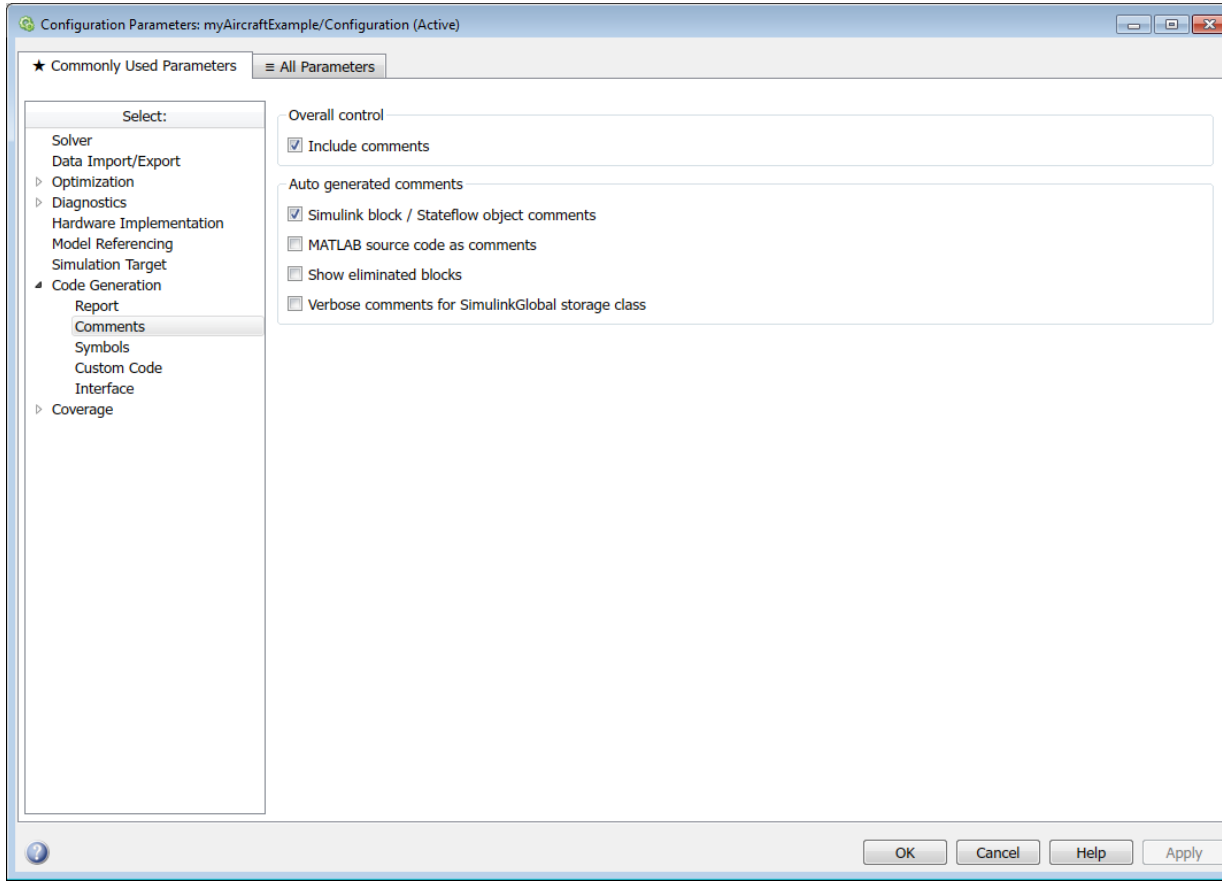
parameter values. These steps appear to help you familiarize yourself with the user interface. As you work with the model parameters, you can place the mouse pointer on a parameter to see a tool tip describing its function.

To set code generation parameters using the Configuration Parameters dialog box:

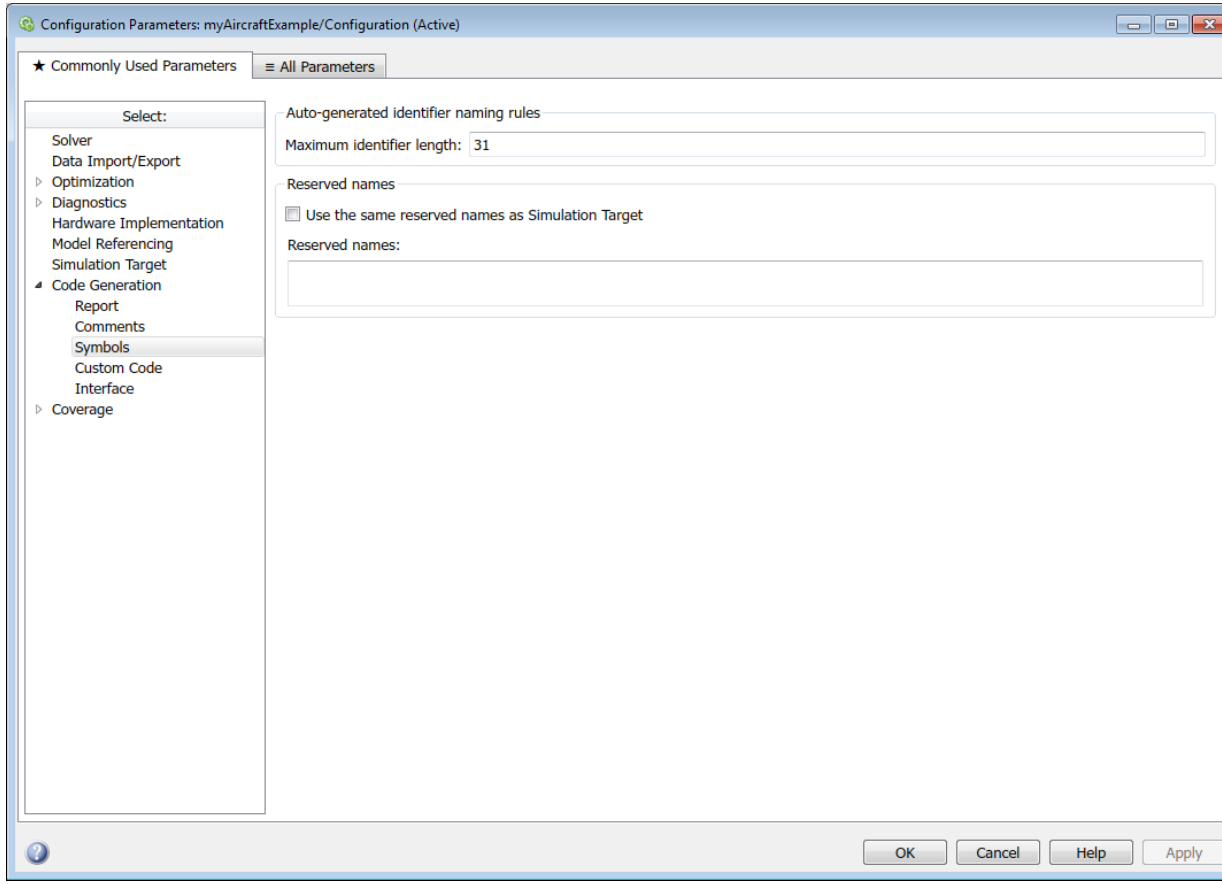
1. With the `myAircraftExample` model open, select **Simulation** > **Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. Select **Code Generation** > **Report** > **Create code generation report**. This action enables the software to create and display a code generation report for the `myAircraftExample` model.



3 Select **Code Generation** > **Comments**. The options displayed here control the types of comments included in generated code. Leave the options set to their defaults.



4 Select **Code Generation** > **Symbols**. These options control the look and feel of generated code.



5 Select the **All Parameters** tab. The following parameters in the **Code Generation** category control build verbosity and debugging support. These parameters are common to all system target file configurations.

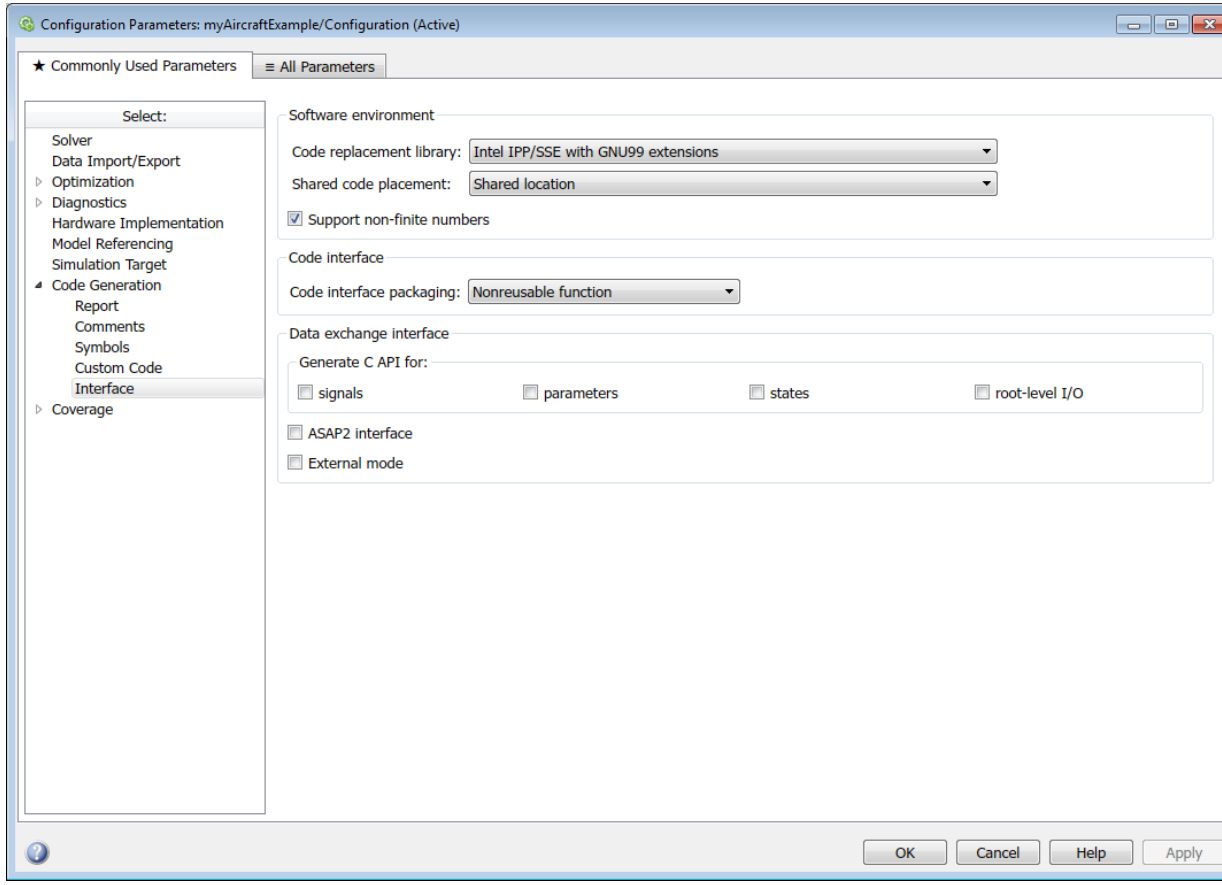
- **Verbose build** (`RTWVerbose` parameter)
- **Retain .rtw file** (`RetainRTWFile` parameter)
- **Profile TLC** (`ProfileTLC` parameter)
- **Start TLC debugger when generating code** (`TLCDebug` parameter)
- **Start TLC coverage when generating code** (`TLCCoverage` parameter)

- **Enable TLC assertion** (`TLCAssert` parameter)

Leave the options set to their defaults.

6 Select **Configuration Parameters** > **Code Generation** > **Interface**.

- For the **Shared code placement** parameter, select `Shared location`. The build process places generated code for utilities at a shared location within the `slprj` folder in your "Code generation folder" (Simulink).
- If it is not already cleared, switch to the **All Parameters** tab and clear the **Code Generation** > **Classic call interface** option.



7 Click **Apply** and save the model.

Build and Run a Program

The build process generates C code from the model. It then compiles and links the generated program to create an executable image. To build and run the program:

1 With the `myAircraftExample` model open, initiate code generation and the build process for the model by using any of the following options:

- Click the **Build Model** button.
- Press **Ctrl+B**.
- Select **Code** > **C/C++ Code** > **Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

Some messages concerning code generation and compilation appear in the Command Window. The initial message is:

```
### Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```
### Created executable myAircraftExample.exe
### Successful completion of build procedure for model: myAircraftExample
### Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in your "Code generation folder" (Simulink).

Note: After generating the code for the `myAircraftExample` model, the build process displays a code generation report. See "Report Generation" (Simulink Coder) for more information about how to create and use a code generation report.

---

2 To see the contents of the working folder after the build, enter the `dir` or `ls` command:

```
>> dir
```

```
.                              myAircraftExample.slx           slprj
..                             myAircraftExample.slx.autosave
myAircraftExample.exe          myAircraftExample_grt_rtw
```

3 To run the executable from the Command Window, type `!myAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `myAircraftExample` program.

```
>> !myAircraftExample

** starting the model **
** created myAircraftExample.mat **
```

4 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform:

```
>> dir myAircraftExample_grt_rtw

.                     rt_main.obj                 myAircraftExample_data.c
..                    rtmodel.h                   myAircraftExample_data.obj
buildInfo.mat         rtw_proj.tmw                myAircraftExample_private.h
codeInfo.mat          myAircraftExample.bat       myAircraftExample_ref.rsp
defines.txt           myAircraftExample.c         myAircraftExample_types.h
html                  myAircraftExample.h
modelsources.txt      myAircraftExample.mk
rt_logging.obj        myAircraftExample.obj
```

Contents of the Build Folder

The build process creates a build folder and names it *`model`*`_`*`target`*`_rtw`, where *`model`* is the name of the source model and *`target`* is the system target file selected for the model. In this example, the build folder is named `myAircraftExample_grt_rtw`.

The build folder includes the following generated files.

File	Description
`myAircraftExample.c`	Standalone C code that implements the model
`myAircraftExample.h`	An include header file containing definitions of parameters and state variables
`myAircraftExample_private.h`	Header file containing common include definitions
`myAircraftExample_types.h`	Forward declarations of data types used in the code

File	Description
`rtmodel.h`	Master header file for including generated code in the static main program (its name does not change, and it simply includes `myAircraftExample.h`)

The code generation report that you created for the `myAircraftExample` model displays a link for each of these files. You can click the link explore the file contents.

The build folder contains other files used in the build process. They include:

- `myAircraftExample.mk` — Makefile for building executable using the specified Toolchain.
- Object (`.obj`) files
- `myAircraftExample.bat` — Batch control file
- `rtw_proj.tmw` — Marker file
- `buildInfo.mat` — Build information for relocating generated code to another development environment
- `defines.txt` — Preprocessor definitions required for compiling the generated code
- `myAircraftExample_ref.rsp` — Data to include as command-line arguments to `mex` (Windows systems only)

The build folder also contains a subfolder, `html`, which contains the files that make up the code generation report. For more information, see "Reports for Code Generation" (Simulink Coder).

Customized Makefile Generation

After producing code, the code generator produces a customized makefile, *`model`*`.mk`. The generated makefile instructs the `make` system utility to compile and link source code generated from the model, any required harness program, libraries, or user-provided modules. The code generator produces the file *`model`*`.mk` whether you are using the toolchain approach or template makefile approach for build process control. For more information about these approaches, see "Choose and Configure Build Process" on page 40-14.

If you are using the toolchain approach, the code generator creates *`model`*`.mk` based on the model **Toolchain settings**. You can modify generation of the makefile through the `rtwmakecfg.m` API. For more information, see "Toolchain Approach" on page 40-14.

If you are using the template makefile approach, the code generator creates *model*.mk from a system template file, *system*.tmf (where *system* stands for the selected system target file name). The system template makefile is designed for your system target file. You have the option of modifying the template makefile to specify compilers, compiler options, and additional information used during the creation of the executable. For more information, see "Template Makefile Approach" on page 40-20.

More About

- "Choose and Configure Build Process" on page 40-14
- "Build and Run a Program" on page 40-43
- "Reports for Code Generation" (Simulink Coder)
- "Select and Configure C or C++ Compiler or IDE" on page 40-3

Build and Run a Program

The build process generates C code from a model, then compiles and links the generated program to create an executable image. To build and run a sample program, use the example model `slexAircraftExample`.

1. In the Command Window, enter `slexAircraftExample` to open the model.
2. Save a copy of the model to your working folder and name it `myAircraftExample`.
3. Open the Configuration Parameters dialog box by selecting **Simulation** > **Model Configuration Parameters**. Set the following parameters.

   - Select **Configuration Parameters** > **Solver**. Enter the following parameter values for the **Solver** (some could already be set):

     - **Start time**: `0.0`
     - **Stop time**: `60`
     - **Type**: `Fixed-step`
     - **Solver**: `ode5 (Dormand-Prince)`
     - **Fixed step size (fundamental sample time)**: `0.1`
     - **Treat each discrete rate as a separate task**: `Off`

   - Select **Configuration Parameters** > **Code Generation** > **Report**, and select the **Create code generation report** parameter. This option causes the build process to display a code generation report after generating the code for the `myAircraftExample` model.
   - Select **Configuration Parameters** > **Code Generation** > **Interface**. For the **Shared code placement** parameter, select `Shared location`. This option causes generated code for utilities to be placed at a shared location within the `slprj` folder in the "Code generation folder" (Simulink).
   - Select the **All Parameters** tab.

     - If it is not already cleared, clear the **Classic call interface** option.
     - If it is not already set, set the **Single output/update function** option.

   Click **Apply** and **OK**.
4. With the model open, initiate code generation and the build process for the model by using any of the following options:

- Click the **Build Model** button.
- Press **Ctrl+B**.
- Select **Code** > **C/C++ Code** > **Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

Some messages concerning code generation and compilation appear in the MATLAB Command Window. The initial message is:

```
### Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```
### Created executable slexAircraftExample.exe
### Successful  completion of build procedure for model: myAircraftExample
### Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in the "Code generation folder" (Simulink) .

Note: The build process displays a code generation report after generating the code for the `myAircraftExample` model. See "Report Generation" (Simulink Coder) for more information about how to create and use a code generation report.

---

5 To observe the contents of the working folder after the build, type the `dir` or `ls` command from the Command Window.

```
>> dir

.                   myAircraftExample.exe      myAircraftExample_grt_rtw
..                  myAircraftExample.slx      slprj
```

6 To run the executable from the Command Window, type `!slexAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `slexAircraftExample` program.

```
>> !myAircraftExample

** starting the model **
** created myAircraftExample.mat **
```

7 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform.

```
>> dir myAircraftExample_grt_rtw

.                     rt_main.obj                 myAircraftExample_data.c
..                    rtmodel.h                   myAircraftExample_data.obj
buildInfo.mat         rtw_proj.tmw                myAircraftExample_private.h
codeInfo.mat          myAircraftExample.bat       myAircraftExample_ref.rsp
defines.txt           myAircraftExample.c         myAircraftExample_types.h
html                  myAircraftExample.h
modelsources.txt      myAircraftExample.mk
rt_logging.obj        myAircraftExample.obj
```

Tip: For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

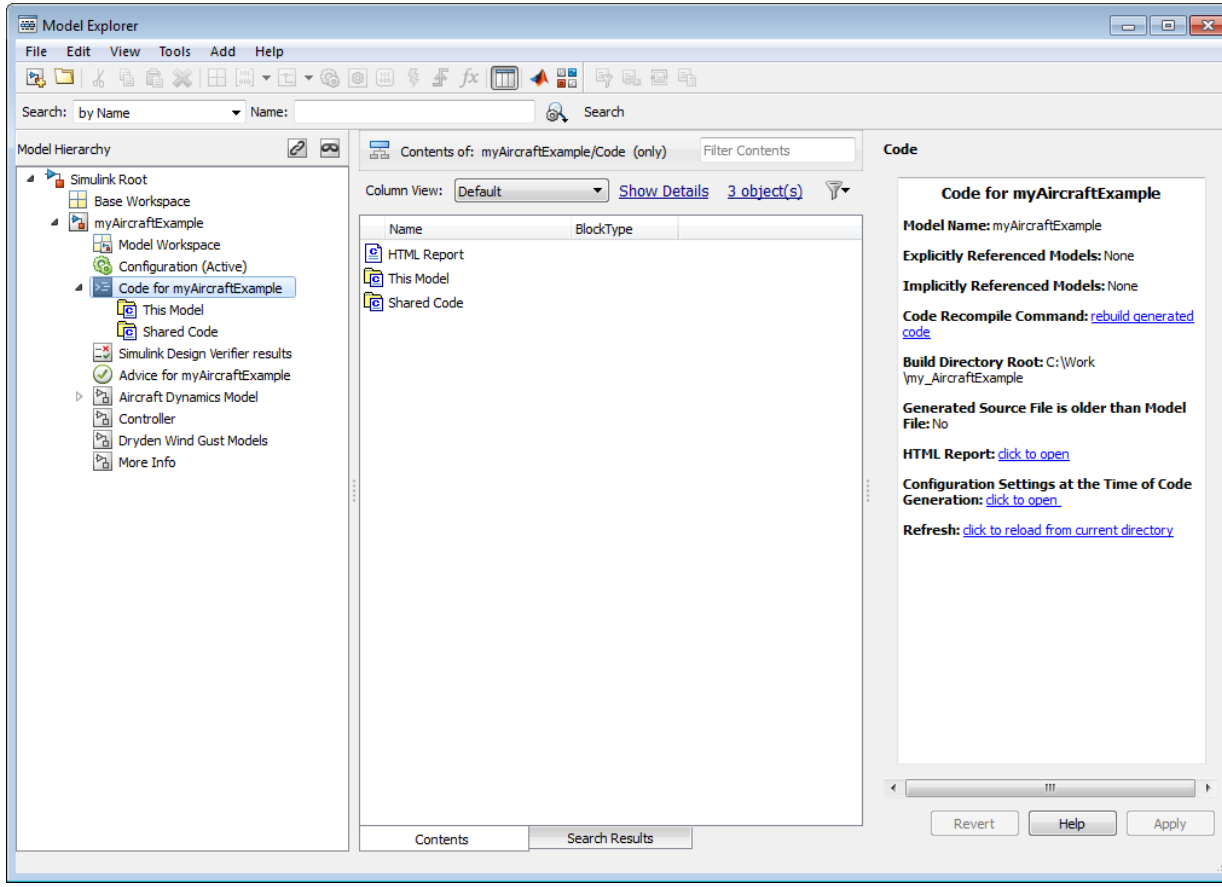
More About

- "Run External Commands, Scripts, and Programs" (MATLAB)
- "Build and Run a Program" on page 40-39
- "Rebuild a Model" on page 40-46
- "Report Generation" (Simulink Coder)

Rebuild a Model

If you update generated source code or makefiles manually to add customizations, you can rebuild the files with the `rtwrebuild` command. This command recompiles the modified files by invoking the generated makefile. Alternatively, you can use this command from the Model Explorer:

1. Open the top model. To open the Model Explorer window, select **View > Model Explorer**.
2. In the **Model Hierarchy** pane, expand the node for the model.
3. Click the **Code for *`model`*** node.
4. In the **Code** pane, next to **Code Recompile Command**, click **rebuild generated code**.



More About

- rtwrebuild (Simulink Coder)
- “Build and Run a Program” on page 40-43

Control Regeneration of Top Model Code

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. The model build regenerates top model code if any of the following conditions is true:

- The structural checksum of the model has changed.
- The top-model-only checksum has changed. The top-model-only checksum provides information about top model parameters, such as application lifespan, maximum stack size, make command, verbose and `.rtw` file debug settings, and `TLCOptions`.
- Any of the following TLC debugging model options, on the **All Parameters** tab of the Configuration Parameters dialog box, is `on`:
  - **Start TLC debugger when generating code** (`TLCDebug`)
  - **Start TLC coverage when generating code** (`TLCCoverage`)
  - **Enable TLC assertion** (`TLCAssert`)
  - **Profile TLC** (`ProfileTLC`)

Whether the top model code is regenerated, the build process calls the build process hooks and reruns the makefile. The hooks include the *`STF`*`_make_rtw_hook` functions and the post code generation command. This process recompiles and links the external dependencies.

System target file authors can perform actions related to code regeneration in the *`STF`*`_make_rtw_hook` functions that the build process calls. These actions include forcing or reacting to code regeneration. For more information, see “Control Code Regeneration Using STF_make_rtw_hook.m” on page 70-36.

Regeneration of Top Model Code

If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. An example check is whether previously generated code is not current due to a model update.

The build process omits regeneration of the top model code when the checks indicate both:

- The top model generated code is current for the model.

- No model settings require full regeneration,

This omission can significantly reduce model build times.

With an Embedded Coder license, if you modify a code generation template (CGT) file then rebuild your model, the code generation process does not force a top model build. In this case, see "Force Regeneration of Top Model Code" on page 40-49.

Force Regeneration of Top Model Code

If you want to control or override the default top model build behavior, use one of the following command-line options:

- To ignore the checksum and force regeneration of the top model code:
  - `rtwbuild(`*`model`*`,'ForceTopModelBuild',true)`
  - `slbuild(`*`model`*`,'StandaloneRTWTarget','ForceTopModelBuild',true)`
- To clean the model build area enough to trigger regeneration of the top model code at the next build (`slbuild` only):
  ```
  slbuild(model,'CleanTopModel')
  ```

You can force regeneration of the top model code by deleting the `slprj` folder or the generated model code folder from the "Code generation folder" (Simulink) .

More About

- rtwrebuild (Simulink Coder)
- "Control Code Regeneration Using STF_make_rtw_hook.m" on page 70-36
- "Choose and Configure Build Process" on page 40-14
- "Rebuild a Model" on page 40-46
- "Reduce Build Time for Referenced Models" on page 40-50

Reduce Build Time for Referenced Models

In a parallel computing environment, you can increase the speed of code generation and compilation for models containing large model reference hierarchies. Achieve the speed by building referenced models in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox™ software, code generation and compilation for each referenced model can be distributed across the cores of a multicore host computer. If you also have MATLAB Distributed Computing Server™ software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Distributed Computing Server configuration.

In this section...

Parallel Building for Large Model Reference Hierarchies

The performance gain realized by using parallel builds for referenced models depends on several factors. These factors include how many models can be built in parallel for a given model referencing hierarchy, the size of the referenced models, and parallel computing resources. The resources include the number of local and/or remote workers available and the hardware attributes of the local and remote machines. Examples of hardware attributes are the amount of RAM and number of cores.

For configuration requirements that could apply to your parallel computing environment, see "Parallel Building Configuration Requirements" on page 40-51.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see "Build Models in a Parallel Computing Environment" on page 40-51.

For information on how to configure a custom embedded system target file to support parallel builds, see "Support Model Referencing" (Simulink Coder).

Note: In a MATLAB Distributed Computing Server parallel computing configuration, parallel building is designed to work interactively with the software. You can initiate

builds from the Simulink user interface or from the MATLAB Command Window using commands such as `slbuild`. You cannot initiate builds using `batch` or other batch mode workflows.

Parallel Building Configuration Requirements

The following requirements apply to configuring your parallel computing environment for building model reference hierarchies in parallel whenever conditions allow:

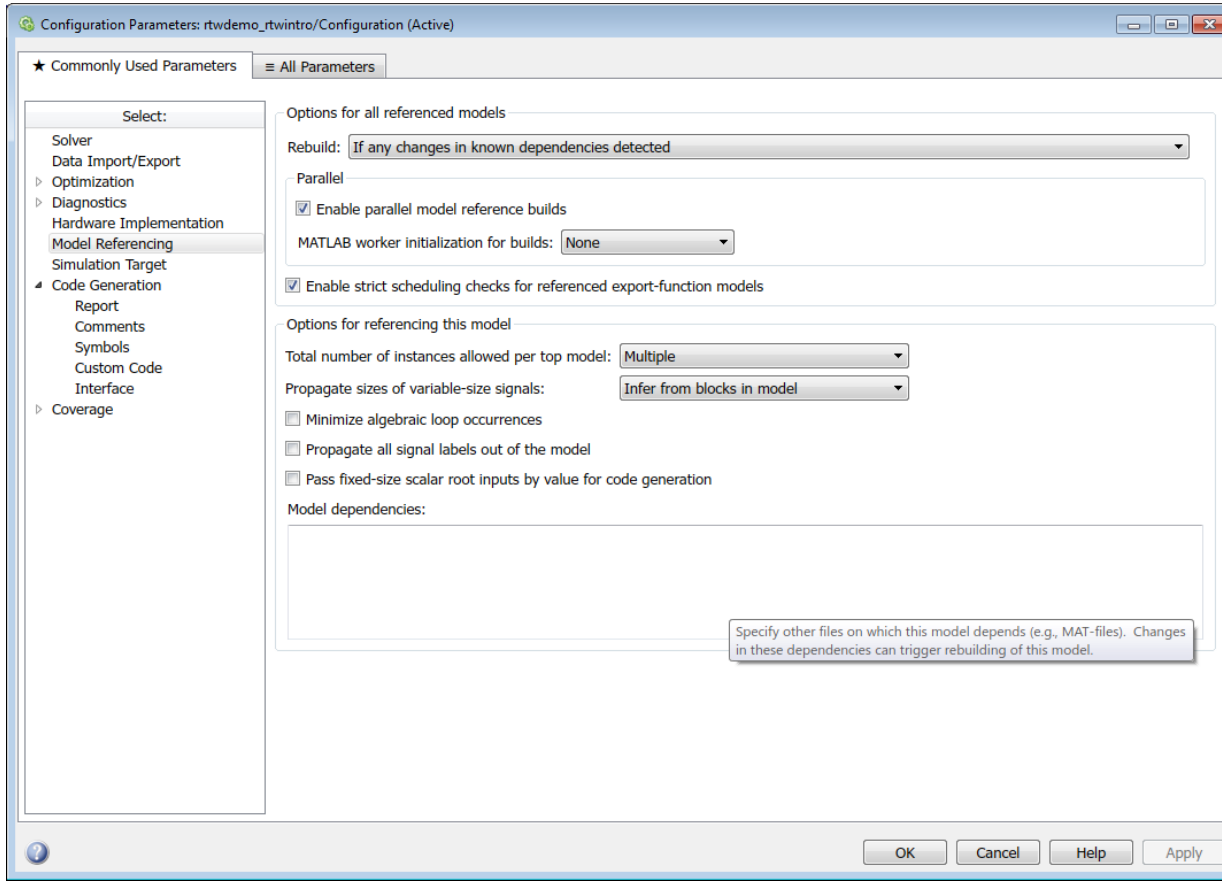
- For local pools, the host machine must have enough RAM to support the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine. Each pool uses the amount of memory required for MATLAB and the code generator at startup. For memory requirements, see System Requirements for MATLAB & Simulink.
- Remote MATLAB Distributed Computing Server workers participating in a parallel build and the client machine must use a common platform and compiler.
- A consistent MATLAB environment must be set up in each MATLAB worker session as in the MATLAB client session — for example, shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.

Build Models in a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

1. Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
   a. Make sure that Parallel Computing Toolbox software is licensed and installed.
   b. To use remote workers, make sure that MATLAB Distributed Computing Server software is licensed and installed.
   c. Issue MATLAB commands to set up the parallel pool, for example, `parpool(4)`.
2. From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Go to the **Model Referencing** pane and select the **Enable**

parallel model reference builds (Simulink) option. This selection enables the parameter **MATLAB worker initialization for builds** (Simulink).



For **MATLAB worker initialization for builds**, select one of the following values:

- `None` if it is preferable that the software does not perform special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up. An example is a model load function.

- `Copy base workspace` if it is preferable that the software attempts to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.
- `Load top model` if it is preferable that the software loads the top model on each worker. Specify this value if the top model in the model reference hierarchy handles the base workspace setup. An example is a model load function.

Note: Only set **Enable parallel model reference builds** for the top model of the model reference hierarchy to which it applies.

3 Optionally, turn on verbose messages for simulation builds, code generation builds, or both. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model.

- To turn on verbose messages in model builds for simulation, go to **Configuration Parameters > All Parameters > Optimization** and select **Verbose accelerator builds**.
- To turn on verbose messages in model builds for code generation, go to **Configuration Parameters > All Parameters > Code Generation** and select **Verbose build**.

Verbose options control the build messages in the MATLAB Command Window and in parallel build log files.

4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models are built in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.

5 Build your model. Messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. The order in which referenced models build is nondeterministic. They could build in a different order each time the model is built.

If you need more information about a parallel build, for example, if a build fails, see "Locate Parallel Build Logs" on page 40-53.

Locate Parallel Build Logs

If verbose builds are turned on when you build a model for which referenced models are built in parallel, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model002'
### Starting parallel model reference SIM build for 'bot_model003'
### Starting parallel model reference SIM build for 'bot_model004'
### Finished parallel model reference SIM build for 'bot_model001'
### Finished parallel model reference SIM build for 'bot_model002'
### Finished parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model004'
### Starting parallel model reference RTW build for 'bot_model001'
### Starting parallel model reference RTW build for 'bot_model002'
### Starting parallel model reference RTW build for 'bot_model003'
### Starting parallel model reference RTW build for 'bot_model004'
### Finished parallel model reference RTW build for 'bot_model001'
### Finished parallel model reference RTW build for 'bot_model002'
### Finished parallel model reference RTW build for 'bot_model003'
### Finished parallel model reference RTW build for 'bot_model004'
```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *`model`*`_buildlog.txt`, where *`model`* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model `bot_model004`, look for the build log file `bot_model004_buildlog.txt` in a referenced model subfolder such as *`build_folder`*`/slprj/grt/bot_model004`, *`build_folder`*`/slprj/ert/bot_model004`, or *`build_folder`*`/slprj/sim/bot_model004`. The build log (diagnostic viewer) provides a relative path to the location of each build log file.

If a parallel builds fails, you could see output similar to the following:

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
...
### Starting parallel model reference RTW build for 'bot_model002'
### Starting parallel model reference RTW build for 'bot_model003'
### Finished parallel model reference RTW build for 'bot_model002'
### Finished parallel model reference RTW build for 'bot_model003'
### Starting parallel model reference RTW build for 'bot_model001'
### Starting parallel model reference RTW build for 'bot_model004'
### Finished parallel model reference RTW build for 'bot_model004'
### The following error occurred during the parallel model reference RTW build for
'bot_model001':

Error(s) encountered while building model "bot_model001"

### Cleaning up parallel workers.
```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder `/par_mdl_ref/`*`model`*. For example, for a failed parallel build of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in a subfolder such as *`build_folder`*`/par_mdl_ref/bot_model001/slprj/grt/bot_model001`, *`build_folder`*`/par_mdl_ref/bot_model001/slprj/ert/bot_model001`, or *`build_folder`*`/par_mdl_ref/bot_model001/slprj/sim/bot_model001`.

Relocate Code to Another Development Environment

If you require relocating the static and generated code files for a model to another development environment, use the pack-and-go utility. This condition occurs when your system or integrated development environment (IDE) does not include MATLAB and Simulink products.

In this section...

Code Relocation

The pack-n-go utility uses the tools for customizing the build process after code generation and a `packNGo` function to find and package files for building an executable image. The files are packaged in a compressed file that you can relocate and unpack using a standard `zip` utility.

To package model code files, you can do either of the following:

- Use the model option **Package code and artifacts** (Simulink Coder) in the **Configuration Parameters > Code Generation** pane. See "Package Code Using the User Interface" on page 40-56.
- Use MATLAB commands to configure a `PostCodeGenCommand` parameter with a call to the `packNGo` function. See "Package Code Using the Command-Line Interface" on page 40-58. The command-line interface provides more control over the details of code packaging.

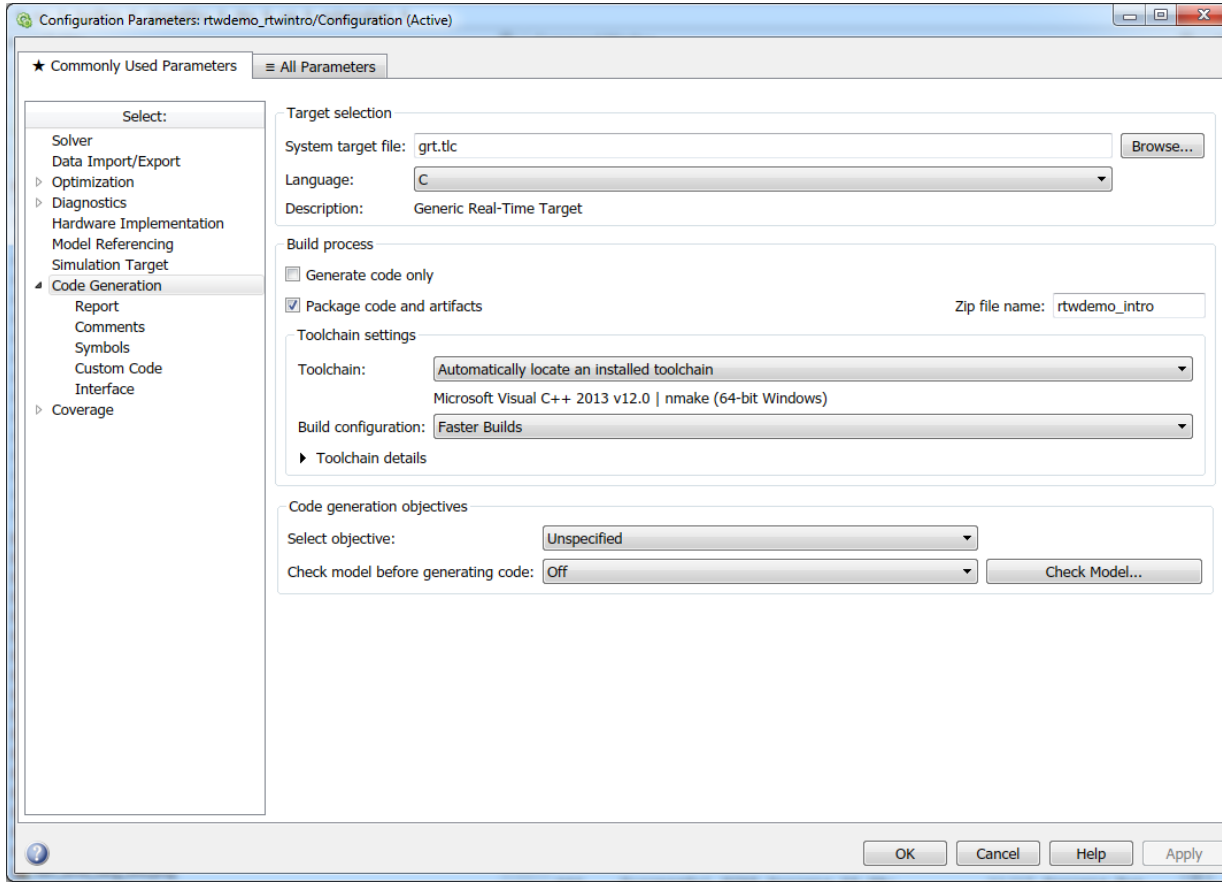
Package Code Using the User Interface

To package and relocate code for your model using the user interface:

1 Open **Configuration Parameters > Code Generation**.

2. Select the option **Package code and artifacts** (Simulink Coder). This option configures the build process to run the `packNGo` function after code generation to package generated code and artifacts for relocation.

3. In the **Zip file name** (Simulink Coder) field, enter the name of the `zip` file in which to package generated code and artifacts for relocation. You can specify the file name with or without the `.zip` extension. If you specify no extension or an extension other than `.zip`, the `zip` utility adds the `.zip` extension. If you do not specify a value, the build process uses the name *`model`*`.zip`, where *`model`* is the name of the top model for which code is being generated.



4 Apply changes and generate code for your model. To verify that it is ready for relocation, inspect the resulting `zip` file. Depending on the `zip` tool that you use, you could be able to open and inspect the file without unpacking it.

5 Relocate the `zip` file to the destination development environment and unpack the file.

Package Code Using the Command-Line Interface

To package and relocate code for your model using the command-line interface:

1 Select a structure for the `zip` file.

2 Select a name for the `zip` file.

3 Package the model code files in the `zip` file.

4 Inspect the generated `zip` file.

5 Relocate and unpack the `zip` file.

Select a Structure for the Zip File

Before you generate and package the files for a model build, decide whether you want the files to be packaged in a flat or hierarchical folder structure. By default, the `packNGo` function packages the files in a single, flat folder structure.

If...	Then Use a...
You are relocating files to an IDE that does not use the generated makefile, or the code is not dependent on the relative location of required static files	Single, flat folder structure
The destination development environment must maintain the folder structure of the source environment because it uses the generated makefile, or the code depends on the relative location of files	Hierarchical structure

If you use a hierarchical structure, the `packNGo` function creates two levels of `zip` files, a primary `zip` file, which in turn contains the following secondary `zip` files:

- `mlrFiles.zip` — files in your *`matlabroot`* folder tree

- `sDirFiles.zip` — files in and under your build folder where you initiated code generation for the model
- `otherFiles.zip` — required files not in the *`matlabroot`* or `start` folder trees

Paths for the secondary `zip` files are relative to the root folder of the primary `zip` file, maintaining the source development folder structure.

Select a Name for the Zip File

By default, the `packNGo` function names the primary `zip` file *`model`*. You have the option of specifying a different name. If you specify a file name and omit the file type extension, the function appends `.` to the name that you specify.

Package Model Code in a Zip File

Package model code files by using the `PostCodeGenCommand` configuration parameter, `packNGo` function, and build information object for the model. You can set up the packaging operation to use:

- A system generated build information object.

  In this case, before generating the model code, use `set_param` to set the configuration parameter `PostCodeGenCommand` to an explicit call to the `packNGo` function. For example:

  ```
  set_param(bdroot, 'PostCodeGenCommand', 'packNGo(buildInfo);');
  ```

  After generating and writing the model code to disk and before generating a makefile, this command instructs the build process to evaluate the call to `packNGo`. This command uses the system generated build information object for the currently selected model.

- A build information object that you construct programmatically.

  In this case, you could use other build information functions to include paths and files selectively in the build information object that you then specify with the `packNGo` function. For example:

  ```
  .
  .
  .
  myModelBuildInfo = RTW.BuildInfo;
  addSourceFiles(myModelBuildInfo, {'test1.c' 'test2.c' 'driver.c'});
  .
  ```

```
.
.
packNGo(myModelBuildInfo);
```

The following examples show how you can change the default behavior of `packNGo`.

To...	Specify...
Change the structure of the file packaging to hierarchical	`packNGo(buildInfo, {'packType' 'hierarchical'});`
Rename the primary `zip` file	`packNGo(buildInfo, {'fileName' 'zippedsrcs'});`
Change the structure of the file packaging to hierarchical and rename the primary `zip` file	`packNGo(buildInfo, {'packType' 'hierarchical'... 'fileName' 'zippedsrcs'});`
Include header files found on the include path in the `zip` file	`packNGo(buildInfo, {'minimalHeaders' false});`
Generate warnings for parse errors and missing files	`packNGo(buildInfo, {'ignoreParseError' true... 'ignoreFileMissing' true});`

Note: The `packNGo` function can potentially modify the build information passed in the first `packNGo` argument. As part of packaging model code, `packNGo` could find additional files from source and include paths recorded in build information for the model and add them to the build information.

Inspect a Generated Zip File

To verify that it is ready for relocation, inspect the generated `zip` file. Depending on the `zip` tool that you use, you could be able to open and inspect the file without unpacking it. If unpacking the file and you packaged the model code files as a hierarchical structure, unpacking requires you to unpack the primary and secondary `zip` files. When you unpack the secondary `zip` files, relative paths of the files are preserved.

Relocate and Unpack a Zip File

Relocate the generated `zip` file to the destination development environment and unpack the file.

Code Packaging Example

This example shows how to package code files generated for the example model `rtwdemo_rtwintro` using the command-line interface:

1. Set your working folder to a writable folder.
2. Open the model `rtwdemo_rtwintro` and save a copy to your working folder.
3. Enter the following MATLAB command:

   ```
   set_param('rtwdemo_rtwintro', 'PostCodeGenCommand',...
   'packNGo(buildInfo, {''packType'' ''hierarchical''})');
   ```

   You must double the single-quotes due to the nesting of character arrays `'packType'` and `'hierarchical'` within the character array that specifies the call to `packNGo`.
4. Generate code for the model.
5. Inspect the generated `zip` file, `rtwdemo_rtwintro.zip`. The `zip` file contains the two secondary `zip` files, `mlrFiles.zip` and `sDirFiles.zip`.
6. Inspect the `zip` files `mlrFiles.zip` and `sDirFiles.zip`.
7. Relocate the `zip` file to a destination environment and unpack it.

Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see “Generate C Code from a Control Algorithm for an Embedded System”.

Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files

that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, and a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the *`model`*`_ert_rtw` folder.

Open the example model, rtwdemo_PCG_Eval_P5.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

1. Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
2. At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler does not require all of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

Integrating the Generated Code into an Existing System

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to all integration environments.

Overview of Integration Environment

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides

hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View example_main.c.

```
int_T main(void)
{
  /* Initialize model */
  rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
  rtwdemo_PCG__Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
  defineImportData();                /* Defines the memory and values of inputs */

  do /* This is the "Schedule" loop.
      Functions would be called based on a scheduling algorithm */
  {
    /* HARDWARE I/O */

    /* Call control algorithms */
    PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
    PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
    pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
    pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

    rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                    &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines `extern` data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

Match System Interfaces

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View defineImportedData.c.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
    pos_rqst = &dummy_pos_value;
}
```

View rtwdemo_PCG_Eval_P5_Private.h.

```
/* Imported (extern) block signals */
extern real_T fbk_1;                   /* '<Root>/fbk_1' */
extern real_T fbk_2;                   /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst;               /* '<Root>/pos_rqst' */
```

Connect Output Data

In this example, you do not access the output data of the system. The example "Test Generated Code" shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View rtwdemo_PCG_Eval_P5.h.

Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, some or all of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

```
Data Type      Data Name     Data Purpose

Constants      |model_cP|    Constant parameters
Constants      |model_cB|    Constant block I/O
Output         |model_U|     Root and atomic subsystem input
Output         |model_Y|     Root and atomic subsystem output
Internal data  |model_B|     Value of block output
Internal data  |model_D|     State information vectors
Internal data  |model_M|     Time and other system level data
Internal data  |model_Zero|  Zero-crossings
Parameters     |model_P|     Parameters
```

Match Function Call Interfaces

By default, functions that the code generator generates have a `void Func(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with the correct input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

1 Create a build folder (`Eclipse_Build_P5`).

2. Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
3. Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example "Install and Use Cygwin and Eclipse".

To exercise the model with input data, see "Test Generated Code".

packNGo Function Limitations

The following limitations apply to the `packNGo` function:

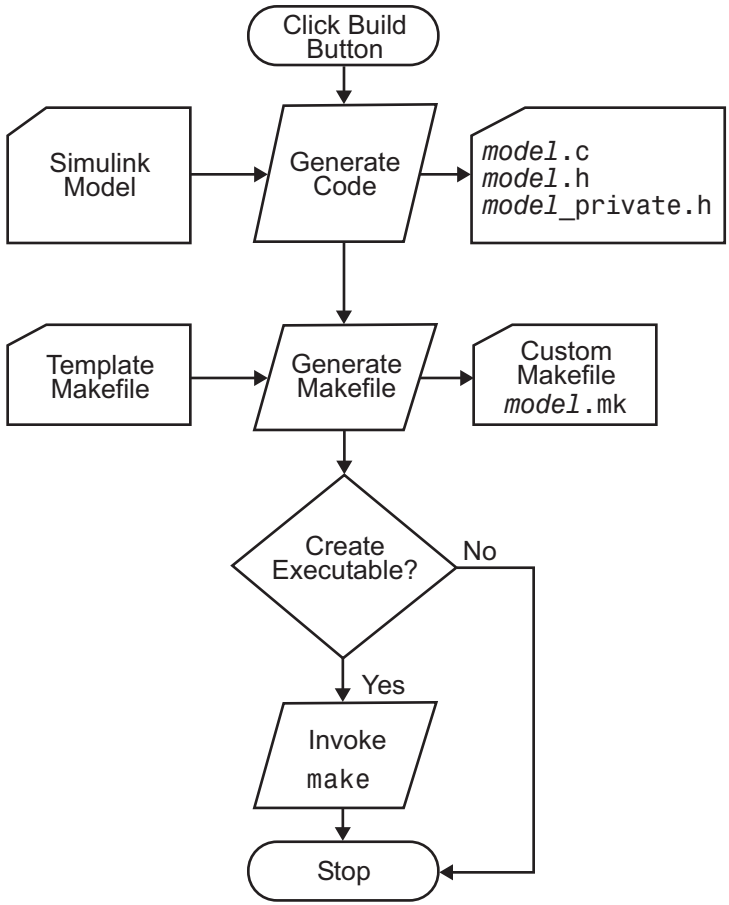
- The function operates on source files, such as `*.c`, `*.cpp`, and `*.h` files, only. The function does not support compile flags, defines, or makefiles.
- Unnecessary files could be included. The function could find additional files from source and include paths recorded in build information for the model and include them, even if they are not used.

More About

- packNGo (Simulink Coder)
- "Choose and Configure Build Process" on page 40-14
- "Build and Run a Program" on page 40-43
- "Executable Program Generation" on page 40-68

Executable Program Generation

The following figure shows how the process for program building.



During the final stage of processing, the build process invokes the generated makefile, *model*`.mk`, which in turn compiles and links the generated code. On PC platforms, a batch file is created to invoke the generated makefile. The batch file sets up the environment for invoking the `make` utility and related compiler tools. To avoid recompiling C files, the `make` utility performs date checking on the dependencies between the object and C files; only out-of-date source files are compiled. Optionally, the makefile can download the resulting executable image to your target hardware.

This stage is optional, as illustrated by the control logic in the preceding figure. You could choose to omit this stage (for example, if you are targeting an embedded microcontroller board).

To omit this stage of processing, select the **Configuration Parameters > Code Generation** pane and select the **Generate code only** check box. You can then cross-compile your code and download it to your target hardware.

If you select the **Configuration Parameters > Code Generation > Report** pane and select **Create code generation report**, the code generator produces a navigable summary of source files when the model is built. The report files occupy a folder called `html` within the build folder. The following display shows an example of an HTML code generation report for a generic real-time (GRT) system target file.

Profile Code Performance

By profiling the performance of generated code, you can help verify that the code meets performance requirements.

Profiling can be especially important early in the development cycle for identifying potential architectural issues that can be more expensive to address later in the process. Profiling can also identify bottlenecks and procedural issues that indicate a need for optimization, for example, with an inner loop or inline code.

Note: If you have an Embedded Coder license, see "Code Execution Profiling" for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

In this section...

Use the Profile Hook Function Interface

You can profile code generated with code generation technology by using a Target Language Compiler (TLC) hook function interface.

To use the profile hook function interface:

1. For your system target file, create a TLC file that defines the following hook functions. Write the functions so that they specify profiling code. The code generator adds the hook function code to code generated for atomic systems in the model.

Function	Input Arguments	Output Type	Description
`ProfilerHeaders`	`void`	Array of header file names	Return an array of the header file names to be included in the generated code.
`ProfilerTypedefs`	`void`	`typedefs`	Generate code statements for profiler type definitions.

Function	Input Arguments	Output Type	Description
`ProfilerGlobal-Data`	`system`	Global data for the specified `system`	Generate code statements that declare global data.
`ProfilerExtern-DataDecls`	`system`	`extern` declarations for the specified `system`	Generate code statements that create global `extern` declarations.
`ProfilerSystem-Decls`	`system`, `functionType`	Declarations for the specified `system` for the specified `functionType`	Generate code for required variable declarations within the scope of an atomic subsystem `Output`, `Update`, `OutputUpdate`, or `Derivatives` function.
`ProfilerSystem-Start`	`system`, `functionType`	Profiler start commands for the specified `system` and `functionType`	Generate code that starts the profiler within the scope of an atomic subsystem `Output`, `Update`, `OutputUpdate`, or `Derivatives` function.
`ProfilerSystem-Finish`	`system`, `functionType`	Profiler end commands for the specified `system` and `functionType`	Generate code that stops the profiler within the scope of the `Output`, `Update`, `OutputUpdate`, or `Derivatives` functions of an atomic subsystem.
`ProfilerSystem-Terminate`	`system`	Profiler termination code for the specified `system`	Generate code that terminates profiling (and possibly reports results) for an atomic subsystem.

For an example TLC file, see *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwdemo_profile_hook.tlc`.

2 In your *`target`*`.tlc` file, define the following global variables.

Define...	To Be...
`ProfileGenCode`	`TLC_TRUE` or 1 to turn on profiling (`TLC_FALSE` or 0 to turn off profiling)
`ProfilerTLC`	The name of the TLC file that you created in step 1

A quick way to define global variables is to define the parameters with the `-a` option. You can apply this option by using the `set_param` command to set the model configuration parameter `TLCOptions`. For example,

```
>> set_param(gcs,'TLCOptions','-aProfileGenCode=1 -aProfilerTLC="rtwdemo_profile_hook.tlc"')
```

3. Consider setting configuration parameters for generating a code generation report. You can then examine the profiling code in the context of the code generated for the model.
4. Build the model. The build process embeds the profiling code in the hook function locations in the generated code for the model.
5. Run the generated executable file. In the MATLAB Command Window, enter `!`*`model-name`*. You see the profiling report you programmed in the profiling TLC file that you created. For example, a profile report could list the number of calls made to each system in a model and the number of CPU cycles spent in each system.

For details on programming a `.tlc` file and defining TLC configuration variables, see "Target Language Compiler" (Simulink Coder).

Profile Hook Function Interface Limitation

The TLC hook function interface for profiling code performance does not support the S-function system target file (`rtwsfcn.tlc`).

Host/Target Communication in Simulink Coder

Set Up and Use Host/Target Communication Channel

External mode allows two separate systems, a *host* and a *target*, to communicate. The host is the computer where the MATLAB and Simulink environments execute. The target is the computer where the executable created by the code generation and build process runs.

The host (the Simulink environment) transmits messages requesting the target to accept parameter changes or to upload signal data. The target responds by executing the request. External mode communication is based on a *client/server* architecture, in which the Simulink environment is the client and the target is the server.

In this section...

What You Can Do with a Host/Target Communication Channel

You can use a host/target communication channel to:

- Modify, or *tune*, block parameters in real time. In external mode, whenever you change parameters in the block diagram, the Simulink engine downloads them to the executing target program. You can tune your program parameters without recompiling.
- View and log block outputs in many types of blocks and subsystems. You can monitor and store signal data from the executing target program, without writing special interface code. You can define the conditions under which data is uploaded from target to host. For example, data uploading can be triggered by a selected signal crossing zero in a positive direction. Alternatively, you can manually trigger data uploading.

External mode establishes a communication channel between the Simulink engine and generated code. The channel's low-level *transport layer* handles the physical transmission of messages. The Simulink engine and the generated model code are independent of this layer. The transport layer and the code directly interfacing to it are isolated in separate modules that format, transmit, and receive messages and data packets.

This design allows for different targets to use different transport layers. For example:

- ERT, GRT, and RSim targets support external mode host/target communication by using TCP/IP and serial (RS-232) communication.
- The Simulink Real-Time product uses a customized transport layer.
- The Simulink Desktop Real-Time product uses shared memory communication.
- Target hardware platforms supported by Simulink use serial or TCP/IP communication.

For an example of using external mode, see "Set Up an External Mode Communication Channel" on page 41-3.

Set Up an External Mode Communication Channel

External Mode Communication Channel Setup

External mode is a very useful environment for rapid prototyping. This example consists of four parts, each of which depends on completion of the preceding ones, in order. The four parts correspond to the steps that you follow in simulating, building, running, and tuning an actual real-time application.

1. Set up the model.
2. Build the target executable.
3. Run the external mode target program.
4. Tune parameters.

The example uses the GRT target. It does not require hardware other than the computer on which you run the Simulink and Simulink Coder software. The generated executable in this example runs on the host computer in a separate process from MATLAB and Simulink.

Set Up the Model

In this part of the example, you create a simple model, `ex_extModeExample`. You also create a folder called `ext_mode_example` to store the model and the generated executable.

To create the folder and the model:

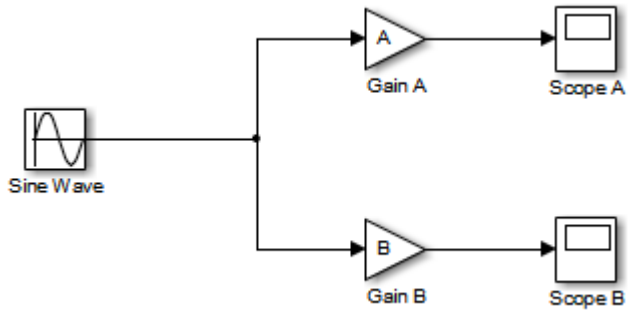
1. From the MATLAB command line, type:

   ```
   mkdir ext_mode_example
   ```

2. Make `ext_mode_example` your working folder:

   ```
   cd ext_mode_example
   ```

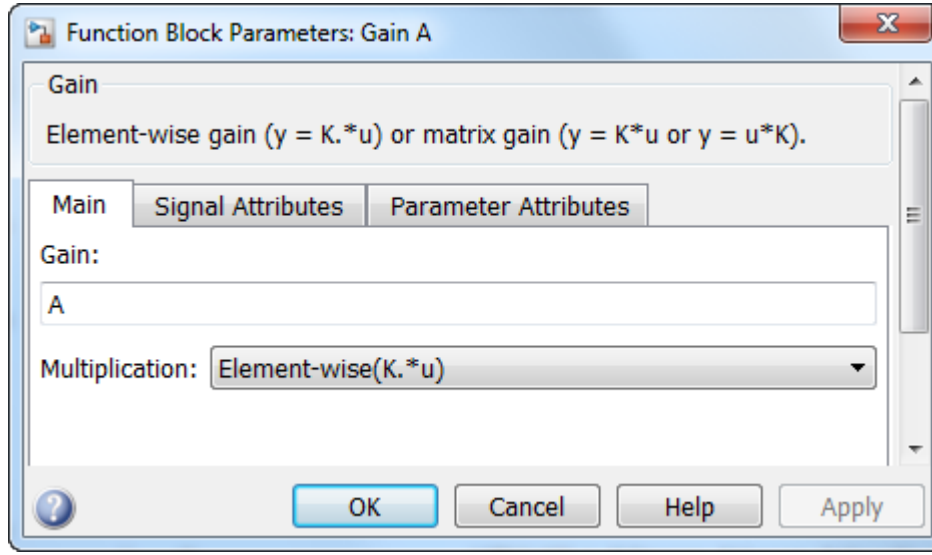
3. Create a model in Simulink with a Sine Wave block for the input signal, two Gain blocks in parallel, and two Scope blocks. Be sure to label the Gain and Scope blocks as shown.



4. Define and assign two MATLAB workspace variables, `A` and `B`:

   ```
   A = 2;
   B = 3;
   ```

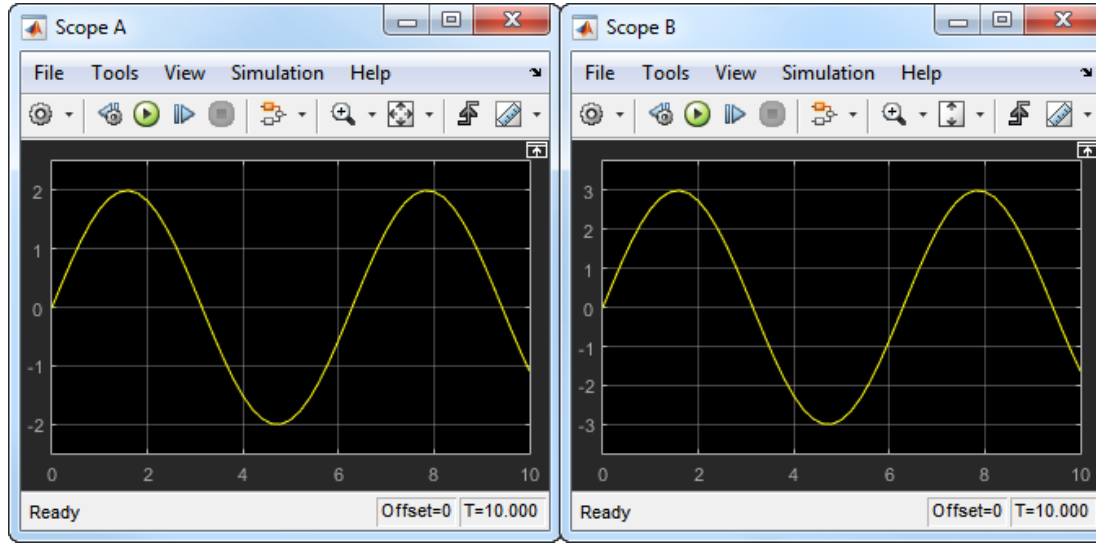
5. Open Gain block A and set its **Gain** parameter to the variable `A`.



6 Open Gain block B and set its **Gain** parameter to the variable `B`.

When the target program is built and connected to Simulink in external mode, you can download new gain values to the executing target program. To do this, you can assign new values to workspace variables `A` and `B`, or edit the values in the block parameters dialog box. For more information, see "Tune Parameters" on page 41-12.

7 Verify operation of the model. Open the Scope blocks and run the model. When `A = 2` and `B = 3`, the output appears as shown.



8 Save the model as `ex_extModeExample`.

Build the Target Executable

Set up the model and code generation parameters required for an external mode compatible target program. Then, generate code and build the target executable.

1 Open the Configuration Parameters dialog box by selecting **Simulation** > **Model Configuration Parameters**.

2 Select the **Solver** pane.

3 In the **Solver options** subpane:

   a In the **Type** field, select `Fixed-step`.

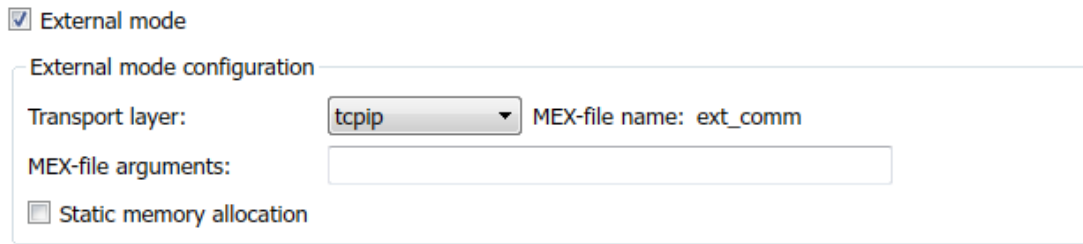
   b In the **Solver** field, select `discrete (no continuous states)`.

   c Open **Additional options**. In the **Fixed-step size** field, specify `0.1`. (Otherwise, when you generate code, the Simulink Coder build process posts a warning and supplies a value.)

   Leave **Start time** set to the default value of `0.0`.

   Click **Apply**.

4. Select the **Data Import/Export** pane, and clear the **Time** and **Output** check boxes. In this example, data is not logged to the workspace or to a MAT-file. Click **Apply**.
5. Select the **Optimization** > **Signals and Parameters** pane. Make sure that **Default parameter behavior** is set to `Tunable`. Inlined parameters are not part of this example. If you have made changes, click **Apply**.
6. Select the **Code Generation** pane. By default, the generic real-time (GRT) target is selected.
7. Select the **Code Generation** > **Interface** pane. In the **Data exchange interface** section, select **External mode**. This selection enables generation of external mode support code and displays additional external mode configuration parameters.
8. In the **External mode configuration** section, make sure that the default value `tcpip` is selected for the **Transport layer** parameter.



External mode supports communication via TCP/IP, serial, and custom transport protocols. The **MEX-file name** field specifies the name of a MEX-file that implements host and target communication on the host side. The default for TCP/IP is `ext_comm`, a MEX-file provided with the Simulink Coder software. You can override this default by supplying other files. If you need to support other transport layers, see "Create a Transport Layer for External Communication" (Simulink Coder).

The **MEX-file arguments** field lets you specify arguments, such as a TCP/IP server port number, to be passed to the external interface program. These arguments are specific to the external interface that you are using. For information on setting these arguments, see "MEX-File Optional Arguments for TCP/IP Transport" (Simulink Coder) and "MEX-File Optional Arguments for Serial Transport" (Simulink Coder).

This example uses the default arguments. Leave the **MEX-file arguments** field blank.

9. Click **Apply** to save the external mode settings.

10 Save the model.

11 Select the **Code Generation** pane. Make sure that **Generate code only** is cleared, and then, in the model window, press **Ctrl+B** to generate code and create the target program. The software creates the `ex_extModeExample` target executable in your working folder.

Run the External Mode Target Program

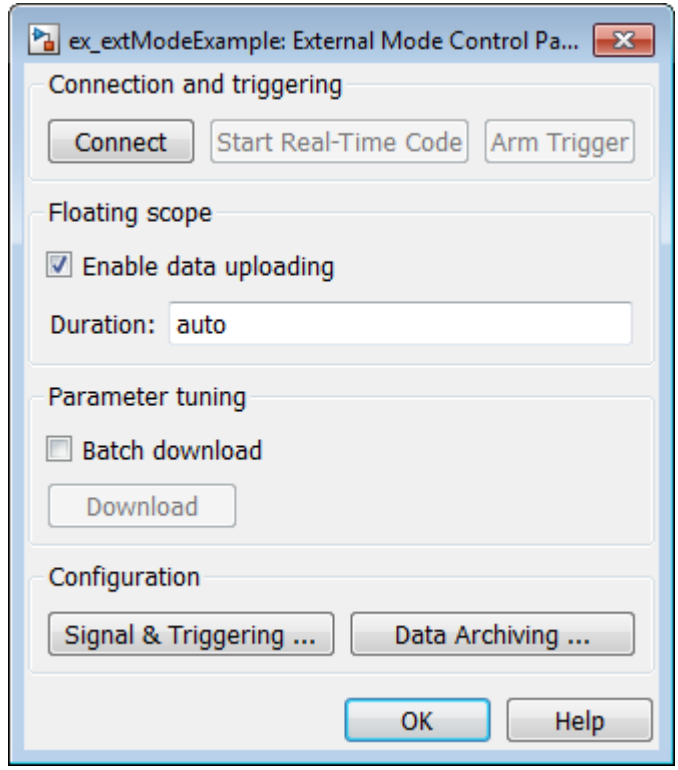
You now run the `ex_extModeExample` target executable and use Simulink as an interactive front end to the running target program. The executable file is in your working folder. Run the target program and establish communication between Simulink and the target.

Note: An external mode program like `ex_extModeExample` is a host-based executable. Its execution is not tied to a real-time operating system (RTOS) or a periodic timer interrupt, and it does not run in real time. The program just runs as fast as possible, and the time units it counts off are simulated time units that do not correspond to time in the world outside the program.

The External Signal & Triggering dialog box (accessed from the External Mode Control Panel) displays a list of blocks in your model that support external mode signal monitoring and logging. In the dialog box, you can configure the signals that are viewed, how they are acquired, and how they are displayed.

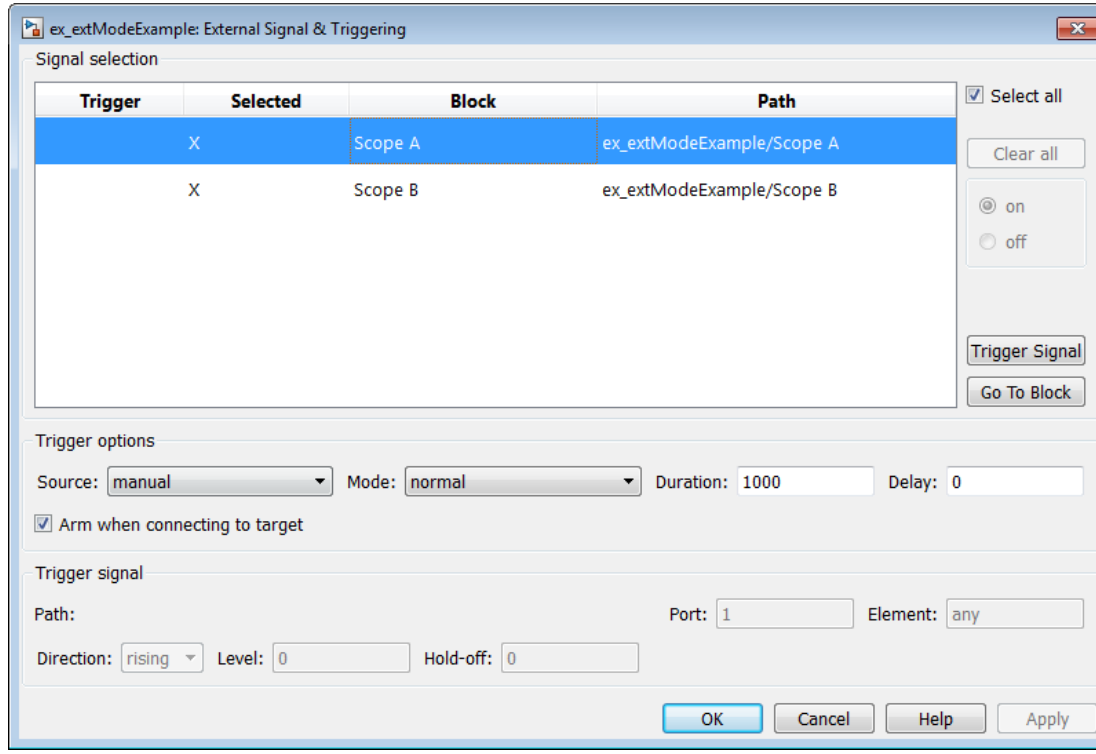
In this example, you observe and use the default settings of the External Signal & Triggering dialog box.

1 From the **Code** menu of the model diagram, select **External Mode Control Panel**. This control panel is where you configure signal monitoring and data archiving. You can also connect to the target program, and start and stop execution of the model code.



- After the target program starts, you use the top row of buttons.
- The **Signal & Triggering** button opens the External Signal & Triggering dialog box. Use this dialog box to select the signals that are collected from the target system and viewed in external mode. You can also select a signal that triggers uploading of data when certain signal conditions are met, and define the triggering conditions.
- The **Data Archiving** button opens the Enable Data Archiving dialog box. Use data archiving to save data sets generated by the target program for future analysis. This example does not use data archiving. See "Configure Host Archiving of Target Program Signal Data" on page 41-31 .

2 Click the **Signal & Triggering** button to open the External Signal & Triggering dialog box. The default configuration selects all signals for monitoring and sets signal monitoring to begin once the host and target programs are connected.



3 Make sure that the External Signal & Triggering dialog box options are set to these defaults:

- **Select all** check box is selected. Signals in the **Signal selection** list are marked with an `X` in the **Selected** column.
- Under **Trigger options:**
  - **Source**: `manual`
  - **Mode**: `normal`
  - **Duration**: `1000`
  - **Delay**: `0`
  - **Arm when connecting to target**: selected

To close the External Signal & Triggering dialog box, click **OK**. Then, close the External Mode Control Panel.

For descriptions of the External Signal & Triggering dialog box parameters, see "Configure Host Monitoring of Target Program Signal Data" on page 41-23.

4 To run the target program, open an operating system command window (on UNIX systems, a terminal emulator window). At the command prompt, use `cd` to navigate to the `ext_mode_example` folder to which you generated the target program executable.

Enter this command:

```
ex_extModeExample -tf inf -w
```

Note Alternatively, you can run the target program from the MATLAB Command Window, using the following syntax.

```
!ex_extModeExample -tf inf -w &
```

The target program begins execution, and enters a wait state.

The `-tf` switch overrides the stop time set for the model in Simulink. The `inf` value directs the model to run indefinitely. The model code runs until the target program receives a stop message from Simulink.

The `-w` switch instructs the target program to enter a wait state until it receives a **Start Real-Time Code** message from the host. If you want to view data from time step 0 of the target program execution, or if you want to modify parameters before the target program begins execution of model code, this switch is required.

5 Open the Scope blocks in the model. Signals are not visible on the scopes. When you connect Simulink to the target program and begin model execution, the signals generated by the target program become visible on the scope displays.

6 Before communication between the model and the target program can begin, the model must be in external mode. To enable external mode, from the **Simulation** > **Mode** menu, select **External**.

7 Reopen the External Mode Control Panel (found in the **Code** menu) and click **Connect**. This action initiates a handshake between Simulink and the target program. When Simulink and the target are connected, the **Start Real-Time**

Code button becomes enabled, and the label of the **Connect** button changes to **Disconnect**.

8 Click **Start Real-Time Code**. The outputs of Gain blocks A and B are displayed on the two scopes in your model.

You have established communication between Simulink and the running target program. You can now tune block parameters in Simulink and observe the effects the parameter changes have on the target program.

Tune Parameters

You can change the gain factor of either Gain block by assigning a new value to the variable `A` or `B` in the MATLAB workspace. When you change block parameter values in the workspace during a simulation, you must explicitly update the block diagram with these changes. When you update the block diagram, the new values are downloaded to the target program.

Under certain conditions, you can also tune the expressions that you use to specify block parameter values. To change an expression during simulation, open the block dialog box.

1 At the command prompt, assign new values to both variables, for example:

```
A = 0.5;
B = 3.5;
```

2 Open the `ex_extModeExample` model window. From the **Simulation** menu, select **Update Diagram**. As soon as Simulink has updated the block parameters, the new gain values are downloaded to the target program, and the scopes are changed because of the gain change.

3 In the Sine Wave block dialog box, set **Amplitude** to `0.5`. Click **Apply** or **OK**.

When you click **Apply** or **OK**, the simulation downloads the new block parameter value to the target program. The Scope block displays the change to reflect the new amplitude value.

4 To simultaneously disconnect host/target communication and end execution of the target program, from the **Simulation** menu, select **Stop**. Alternatively, in the External Mode Control Panel, click **Stop Real-Time Code**.

You cannot change the sample time of the Sine Wave block during simulation. Block sample times are part of the structural definition of the model and are part of the generated code. Therefore, if you want to change a block sample time, you must stop the external mode simulation, reset the sample time of the block, and rebuild the executable.

Block parameter tunability during external mode simulation depends on the way that the generated code represents block parameters.

For example, in the Gain A block dialog box, you cannot change the expression `A` in the **Gain** parameter during simulation. Instead, you must change the value of the variable `A` in the base workspace. You cannot change the expression because the generated code does not allocate storage in memory for the **Gain** parameter. Instead, the code creates a field `A` in a structure:

```
/* Parameters (auto storage) */
struct P_ex_extModeExample_T_ {
  real_T A;                            /* Variable: A
                                        */
  real_T B;                            /* Variable: B
                                        */
  real_T SineWave_Amp;                 /* Expression: 1
                                        */
  real_T SineWave_Bias;                /* Expression: 0
                                        */
  real_T SineWave_Freq;                /* Expression: 1
                                        */
  real_T SineWave_Phase;               /* Expression: 0
                                        */
};
```

The generated code algorithm uses that field in the code that represents the block Gain A. In this case, the global structure variable `ex_extModeExample_P` uses the type `P_ex_extModeExample_T_`:

```
ex_extModeExample_B.GainA = ex_extModeExample_P.A * rtb_SineWave;
```

When you change the value of `A` in the base workspace, the simulation downloads the new value to the field `A` in the target program.

You can change the expressions in the Sine Wave block parameters during simulation because the generated code creates a field in the global structure `ex_extModeExample_P` to represent each parameter in the block. When you change an expression in the block dialog box, the simulation first evaluates the new expression. The simulation then downloads the resulting numeric value to the corresponding structure field in the target program.

See “Block Parameter Representation in the Generated Code” (Simulink Coder).

Configure and Use External Mode

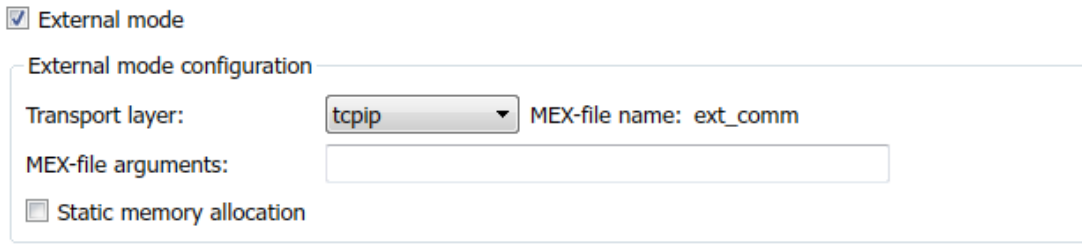
Configure External Mode Options for Code Generation

The list of targets and products that support external mode includes the ERT, GRT, and RSim targets, the Simulink Desktop Real-Time product, and Simulink target hardware platforms. Code generation targets that support external mode provide a set of external mode options in the Configuration Parameters dialog box, on the **Code Generation** > **Interface** pane or their respective target pane.

For targets that support the ability to build target code, connect to the target, and run an application in external mode. Note the following:

- You select external mode from the model window by clicking **Simulation** > **Mode** > **External**.
- External mode parameters continue to appear for the target in the Configuration Parameters dialog box.
- By default, the code generator produces code that is *not* set up for external mode if you build the code by using one of following methods:
  - Press **Ctrl+B**
  - At the MATLAB command line, enter `rtwbuild`

The following figure shows external mode parameters from the GRT and ERT target views of the **Code Generation** > **Interface** pane.



Note The Simulink Real-Time product also uses external mode communication. External mode in the Simulink Real-Time product is always on, and does not have interface options.

The **Data exchange interface** section in the **Code Generation** > **Interface** pane includes the following external mode parameters:

- **External mode** option: Includes the external mode data exchange interface in the generated C code.

  When you select **External mode**, the following parameters appear:

- **Transport layer** menu: Identifies the messaging protocol for host/target communication; typically, the choices are `tcpip` and `serial`.

  The default is `tcpip`. When you select a protocol, the MEX-file name that implements the protocol is shown to the right of the menu.

- **MEX-file arguments** text field: Optionally enter a list of arguments to be passed to the transport layer MEX-file for communicating with executing targets. The arguments vary according to the protocol that you use.

  For more information on the transport options, see “Target Interfacing” on page 41-16 and “Choose Communication Protocol for Client and Server” on page 41-40.

- **Static memory allocation** check box: Controls how memory is allocated for external mode communication buffers in the target. Selecting this option enables the **Static memory buffer size** parameter.

- **Static memory buffer size** text field: Number of bytes to preallocate for external mode communication buffers in the target.

Note Selecting **External mode** does not cause the Simulink model to operate in external mode (see "Control Host and Target Execution" on page 41-18). The **External mode** option instruments the code generated for the target to support external mode.

The **Static memory allocation** check box (for GRT and ERT targets) directs the Simulink Coder software to generate code for external mode that uses only static memory allocation ("malloc-free" code). Selecting **Static memory allocation** enables the **Static memory buffer size** edit field, which you use to specify the size of the static memory buffer used by external mode. The default value is 1,000,000 bytes. If you enter too small a value for your application, external mode issues an out-of-memory error when it tries to allocate more memory than you allowed. In such cases, increase the value in the **Static memory buffer size** field and regenerate the code.

To determine how much memory to allocate, enable verbose mode on the target (by including `OPTS="-DVERBOSE"` on the `make` command line). As it executes, external mode displays the amount of memory it tries to allocate and the amount of memory available to it each time it attempts an allocation. If an allocation fails, you can use this console log to adjust the size in the **Static memory buffer size** field.

Note When you create an ERT target, external mode can generate pure integer code. Select pure integer code by clearing the **Support floating-point numbers** option on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. Clearing this option makes the code, including external mode support code, free of doubles and floats. For more information, see "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

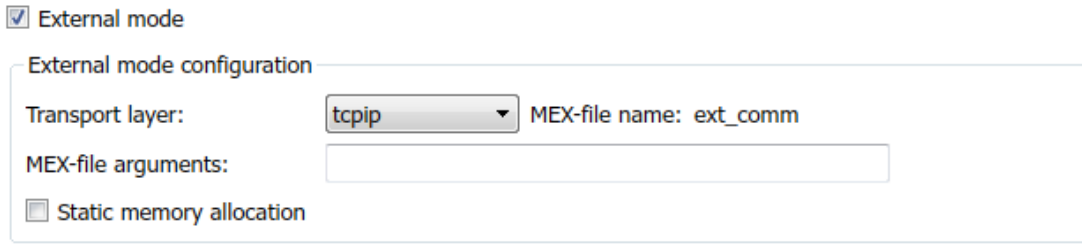
Target Interfacing

The Simulink Coder product lets you implement client and server transport for external mode using either TCP/IP or serial protocols. If your target system supports TCP/IP, you can use the socket-based external mode implementation provided by the Simulink Coder product with the generated code. Otherwise, use or customize the serial transport layer option.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and

code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

You specify the transport mechanism using the **Transport layer** menu in the **External mode configuration** section of the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box.



To the right of the **Transport layer** menu, **MEX-file name** displays the name of an external interface MEX-file. This MEX-file implements host/target communication for the selected external mode transport layer. The default is `ext_comm`, the TCP/IP-based external interface file for use with the GRT, ERT, and RSim targets. If you select the `serial` transport option, the MEX-file name `ext_serial_win32_com` is displayed in this location.

Custom or third-party targets can use a custom transport layer and a different external interface MEX-file. For more information, see "Create a Transport Layer for External Communication" (Simulink Coder). For more information on specifying a TCP/IP or serial transport layer for a custom target, see "Using the TCP/IP Implementation" on page 41-41 or "Using the Serial Implementation" on page 41-44.

In the **MEX-file arguments** edit field, you can optionally specify arguments that are passed to the external mode interface MEX-file for communicating with executing targets. The meaning of the MEX-file arguments depends on the MEX-file implementation.

For TCP/IP interfaces, `ext_comm` allows these optional arguments:

- Network name of your target (for example, `'myPuter'` or `'148.27.151.12'`)
- Verbosity level (`0` for no information or `1` for detailed information)
- TCP/IP server port number (an integer value between `256` and `65535`, with a default of `17725`)

For serial transport, `ext_serial_win32_comm` allows these optional arguments:

- Verbosity level (`0` for no information or `1` for detailed information)
- Serial port ID (for example, `1` for `COM1`, and so on)
- Baud rate (selected from the set `1200`, `2400`, `4800`, `9600`, `14400`, `19200`, `38400`, `57600`, and `115200`, with a default baud rate of `57600`)

For more information on MEX-file transport architecture and arguments, see "Choose Communication Protocol for Client and Server" on page 41-40.

Control Host and Target Execution

Simulink software provides multiple ways to control external mode host and target execution. The following table lists common steps in the external mode workflow and the ways in which they can be initiated.

External Mode Action	Toolbar Control	Menu Control	External Mode Control Panel Button
Set the simulation mode of your model to external mode	From the simulation mode drop-down list, select `External`	**Simulation** > **Mode** > **External**	**Connect** (if the model simulation mode is not already set, sets the simulation mode to external mode)
Connect your model to a waiting or running target program	**Connect to Target** button 	**Simulation** > **Connect to Target**	**Connect**
Start running real-time code in the target environment	**Run** button	**Simulation** > **Run** (keyboard shortcut **Ctrl+T**)	**Start Real-Time Code**
Disconnect your model from the target environment (does not halt running real-time code)	**Disconnect from Target** button 	**Simulation** > **Disconnect from Target**	**Disconnect**
Stop target program execution and disconnect your model from the target environment	**Stop** button	**Simulation** > **Stop** (keyboard shortcut **Ctrl+Shift+T**)	**Stop Real-Time Code**

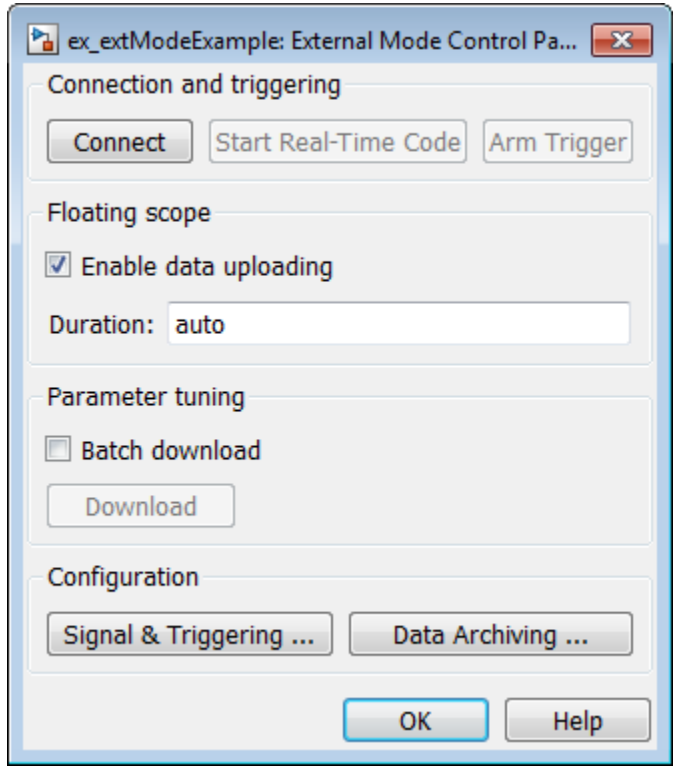
Setting the simulation mode of your model to external mode affects execution only, and does *not* cause the Simulink Coder software to generate code instrumented for external mode. See "Configure External Mode Options for Code Generation" on page 41-14.

Control External Mode Operations

The External Mode Control Panel provides centralized control of external mode operations, including:

- "Connect, Start, and Stop" on page 41-20
- "Upload Target Program Signal Data to Host" on page 41-21
- "Download Parameters to Target Program" on page 41-22
- "Configure Host Monitoring of Target Program Signal Data" on page 41-23
- "Configure Host Archiving of Target Program Signal Data" on page 41-31

To open the External Mode Control Panel dialog box, in the model window, select **Code** > **External Mode Control Panel**.



Connect, Start, and Stop

The External Mode Control Panel performs the same connect/disconnect and start/stop functions found in the **Simulation** menu and the Simulink toolbar (see "Control Host and Target Execution" on page 41-18).

Clicking the **Connect** button connects your model to a waiting or running target program. While you are connected, the button changes to a **Disconnect** button. **Disconnect** disconnects your model from the target environment, but does not halt real-time code running in the target environment.

Connect sets the model simulation mode to external mode.

Clicking the **Start Real-Time Code** button commands the target to start running real-time code. While real-time code is running in the target environment, the button changes

to a **Stop Real-Time Code** button. **Stop Real-Time Code** stops target program execution and disconnects your model from the target environment.

Upload Target Program Signal Data to Host

The External Mode Control Panel allows you to trigger and cancel data uploads to the host. The destination for the uploaded data can be a scope block, Display block, To Workspace block, or another block or subsystem listed in "External Mode Compatible Blocks and Subsystems" on page 41-34.

The **Arm Trigger** and **Cancel Trigger** buttons provide manual control of data uploading to compatible blocks or subsystems, except floating scopes. (For floating scopes, use the **Floating scope** section of the External Mode Control Panel.)

- To trigger data uploading to compatible blocks or subsystems, click the **Arm Trigger** button. The button changes to **Cancel Trigger**.
- To cancel data uploading, click the **Cancel Trigger** button. The button reverts to **Arm Trigger**.

You can trigger data uploads manually or automatically. To configure signals and triggers for data uploads, see "Configure Host Monitoring of Target Program Signal Data" on page 41-23.

A subset of external mode compatible blocks, including Scope, Time Scope, and To Workspace, allow you to log uploaded data to disk. To configure data archiving, see "Configure Host Archiving of Target Program Signal Data" on page 41-31.

The **Floating scope** section of the External Mode Control Panel controls when and for how long data is uploaded to Floating Scope blocks. When used in external mode, floating scopes:

- Do not appear in the External Signal & Triggering dialog box.
- Do not log data to external mode archiving.
- Support manual triggering only.

The **Floating scope** section contains the following parameters:

- **Enable data uploading** option, which functions as an **Arm Trigger** button for floating scopes. When the target is disconnected, the option controls whether to arm the trigger when connecting the floating scopes. When the target is connected, the option acts as a toggle button to arm or cancel the trigger.

  - To trigger data uploading to floating scopes, select **Enable data uploading**.
  - To cancel data uploading to floating scopes, clear **Enable data uploading**.
- **Duration** edit field, which specifies the number of base-rate steps for which external mode logs floating scopes data after a trigger event. By default, it is set to `auto`, which causes the duration value set in the External Signal & Triggering dialog box to be used. The default duration value is 1000 base rate steps.

Download Parameters to Target Program

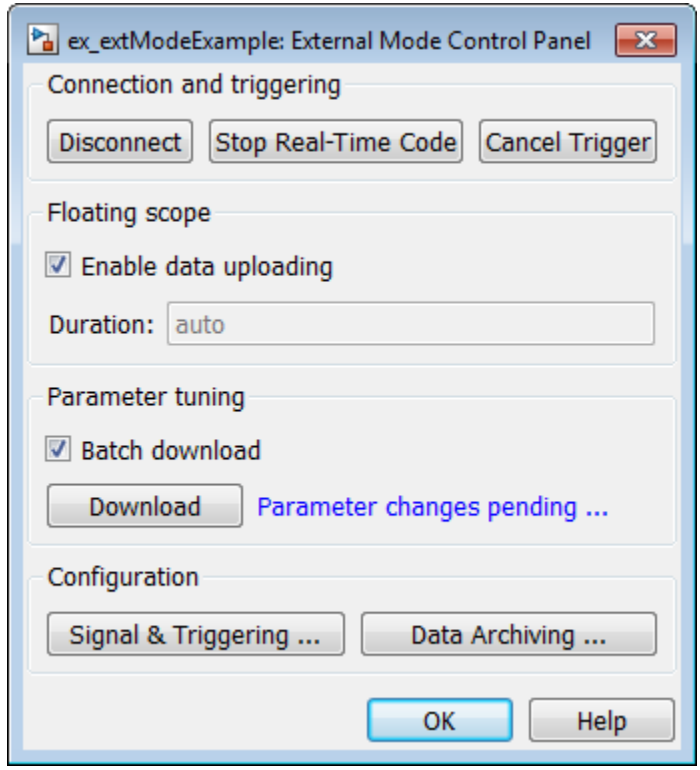
The **Batch download** option on the External Mode Control Panel enables or disables batch parameter changes.

By default, batch download is disabled. If batch download is disabled, when you click **OK** or **Apply**, changes made directly to block parameters by editing block parameter dialog boxes are sent to the target. When you perform an **Update Diagram**, changes to MATLAB workspace variables are sent.

If you select **Batch download**, the **Download** button is enabled. Until you click **Download**, changes made to block parameters are stored locally. When you click **Download**, the changes are sent in a single transmission.

When parameter changes are awaiting batch download, the External Mode Control Panel displays the message `Parameter changes pending...` to the right of the **Download** button. This message remains visible until the Simulink engine receives notification that the new parameters have been installed in the parameter vector of the target system.

The next figure shows the External Mode Control Panel with the **Batch download** option activated and parameter changes pending.



Configure Host Monitoring of Target Program Signal Data

Role of Trigger in Signal Data Uploading

In external mode, uploading target program signal data to the host depends on a *trigger*. The trigger is a set of conditions that must be met for data uploading to begin. The trigger can be armed or not armed.

- When the trigger is armed, the software checks for the trigger conditions that allow data uploading to begin.
- If the trigger is not armed, the software does not check for the trigger conditions and data uploading cannot begin.
- The trigger can be armed automatically, when the host connects to the target, or manually, by clicking the **Arm Trigger** button on the External Mode Control Panel.

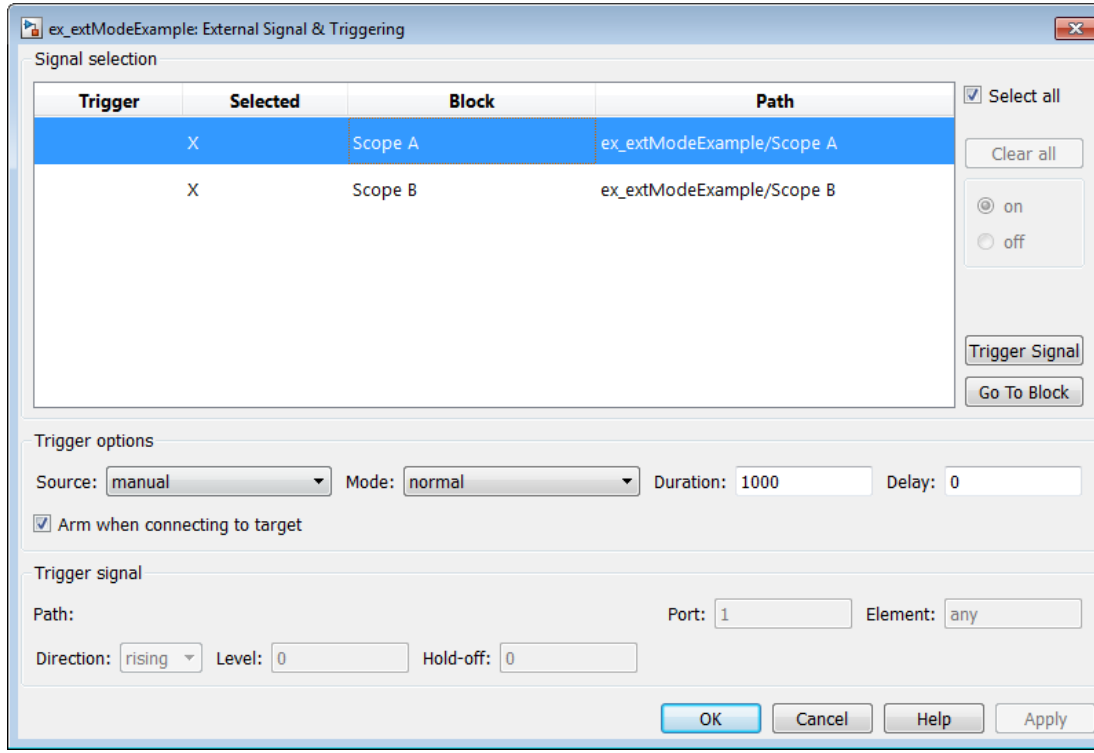
When the trigger is armed and the trigger conditions are met, the trigger fires and data uploading begins.

When data has been collected for a defined duration, the trigger event completes and data uploading stops. The trigger can then rearm, or remain unarmed until you click the **Arm Trigger** button.

To select the target program signals to upload and configure how uploads are triggered, see “Configure Signal Data Uploading” on page 41-24.

Configure Signal Data Uploading

Clicking the **Signal & Triggering** button of the External Mode Control Panel opens the External Signal & Triggering dialog box.



The External Signal & Triggering dialog box displays a list of blocks and subsystems in your model that support external mode signal uploading. For information on which types of blocks are external mode compatible, see “External Mode Compatible Blocks and Subsystems” on page 41-34.

In the External Signal & Triggering dialog box, you can select the signals that are collected from the target system and viewed in external mode. You can also select a trigger signal, which triggers uploading of data based on meeting certain signal conditions, and define the triggering conditions.

Default Trigger Options

The preceding figure shows the default settings of the External Signal & Triggering dialog box. The default operation of the External Signal & Triggering dialog box simplifies monitoring the target program. If you use the default settings, you do not need to preconfigure signals and triggers. You start the target program and connect the

Simulink engine to it. External mode compatible blocks are selected and the trigger is armed. Signal uploading begins immediately upon connection to the target program.

The default configuration of trigger options is:

- `Select all`: on
- `Source`: manual
- `Mode`: normal
- `Duration`: 1000
- `Delay`: 0
- `Arm when connecting to target`: on

Select Signals to Upload

External mode compatible blocks in your model appear in the **Signal selection** list of the External Signal & Triggering dialog box. You use this list to select signals that you want to view. In the **Selected** column, an `X` appears for each selected block.

The **Select all** check box selects all signals. By default, **Select all** is selected.

If **Select all** is cleared, you can select or clear individual signals using the **on** and **off** options. To select a signal, click its list entry and select the **on** option. To clear a signal, click its list entry and select the **off** option.

The **Clear all** button clears all signals.

Configure Trigger Options

As described in "Role of Trigger in Signal Data Uploading" on page 41-24, signal data uploading depends on a trigger. The trigger defines conditions that must be met for uploading to begin. Also, the trigger must be armed for data uploading to begin. When the trigger is armed and trigger conditions are met, the trigger fires and uploading begins. When data has been collected for a defined duration, the trigger event completes and data uploading stops.

To control when and how signal data is collected (uploaded) from the target system, configure the following **Trigger options** in the External Signal & Triggering dialog box.

- **Source**: `manual` or `signal`. Controls whether a button or a signal triggers data uploading.

Selecting `manual` directs external mode to use the **Arm Trigger** button on the External Mode Control Panel as the trigger to start uploading data. When you click **Arm Trigger**, data uploading begins.

Selecting `signal` directs external mode to use a trigger signal as the trigger to start uploading data. When the trigger signal satisfies trigger conditions (that is, the signal crosses the trigger level in the specified direction), a *trigger event* occurs. (Specify trigger conditions in the **Trigger signal** section.) If the trigger is *armed*, external mode monitors for the occurrence of a trigger event. When a trigger event occurs, data uploading begins.

- **Mode**: `normal` or `one-shot`. Controls whether the trigger rearms after a trigger event completes.

  In `normal` mode, external mode automatically rearms the trigger after each trigger event. The next data upload begins when the trigger fires.

  In `one-shot` mode, external mode collects only one buffer of data each time you arm the trigger.

  For more information on the **Mode** setting, see "Configure Host Archiving of Target Program Signal Data" on page 41-31.
- **Duration**: Specifies the number of base rate steps for which external mode uploads data after a trigger event (default is 1000). For example, if **Duration** is set to 1000, and the base (fastest) rate of the model is one second:
  - For a signal sampled at the base rate, one second (1.0 Hz), external mode collects 1000 contiguous samples during a trigger event.
  - For a signal sampled at two seconds (0.5 Hz), external mode collects 500 samples during a trigger event.
- **Delay**: Specifies a delay to be applied to data collection. The delay represents the amount of time that elapses between a trigger event and the start of data collection. The delay is expressed in base rate steps. It can be positive or negative (default is 0). A negative delay corresponds to pretriggering. When the delay is negative, data from the time preceding the trigger event is collected and uploaded.
- **Arm when connecting to target**: Selected or cleared. Whether a button or a signal triggers data uploading (as defined by **Source**), the trigger must be armed to allow data uploading to begin.

  If you select this option, connecting to the target arms the trigger.

- If the trigger **Source** is `manual`, data uploading begins immediately.
- If the trigger **Source** is `signal`, monitoring of the trigger signal begins immediately. Data uploading begins when the trigger signal satisfies trigger conditions (as defined in the **Trigger signal** section).

If you clear **Arm when connecting to target**, manually arm the trigger by clicking the **Arm Trigger** button on the External Mode Control Panel.

When simulating in external mode, each rate in the model creates a buffer on the target. Each entry in the buffer is big enough to hold all of the data required of every signal in that rate for one time step (time plus data plus external mode indices identifying the signal). The number of entries in the circular buffer is determined by the external mode trigger **Duration** parameter (`ExtModeTrigDuration`). The memory allocated on the target for buffering signals is proportional to the **Duration** and the number of signals uploading. The **Duration** also provides an indication of the number of base rate steps with log data after a trigger event in external mode.

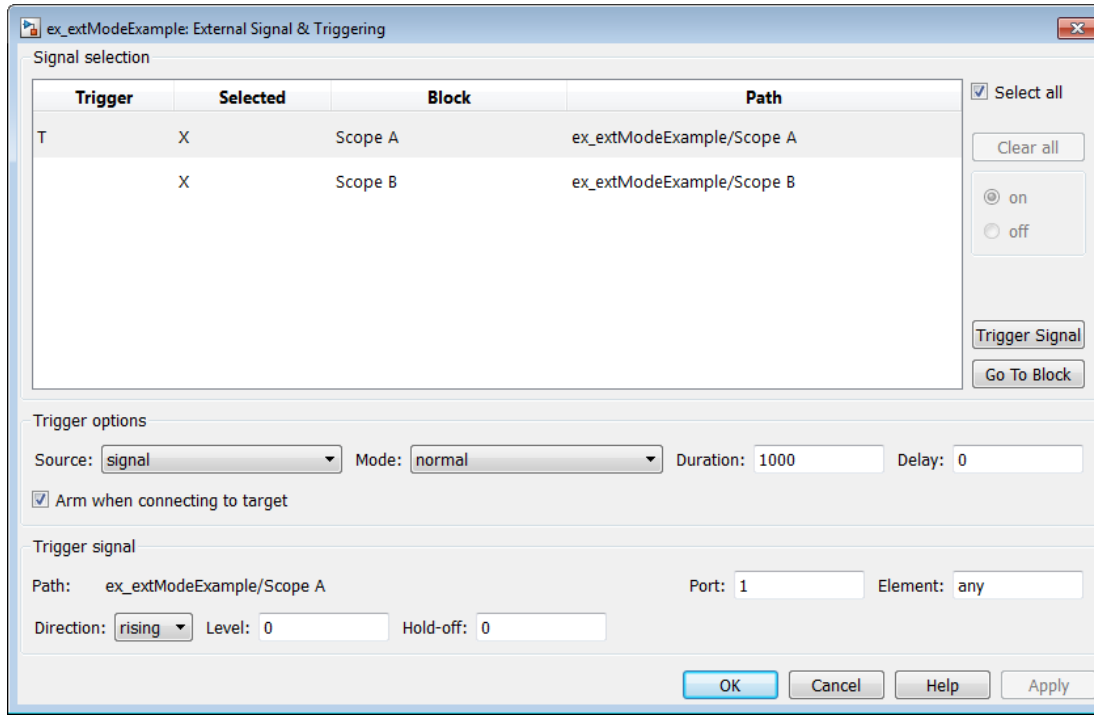
The **Duration** value specifies the number of contiguous points of data to be collected in each buffer of data. You should enter a **Duration** value equal to the number of continuous sample points that you need to collect rather than relying on a series of buffers to be continuous. If you enter a value less than the total number of sample points, you may lose sample points during the time spent transferring values from the data buffer to the MATLAB workspace. The Simulink software maintains point continuity only within one buffer. Between buffers, because of transfer time, some samples may be omitted.

The **Duration** value can affect the **Limit data points to last** value of Scope and To Workspace blocks. The number of sample points that the blocks save to the MATLAB workspace is the smaller of the two values. To set the number of sample points that the blocks save, clear **Limit data points to last**. Then, use **Duration** to specify the number of sample points saved.

Select Trigger Signal

You can designate one signal as a trigger signal. To select a trigger signal, from the **Source** menu in the **Trigger options** section, select `signal`. This action enables the parameters in the **Trigger signal** section. Then, select a signal in the **Signal selection** list, and click the **Trigger Signal** button.

When you select a signal to be a trigger, a `T` appears in the **Trigger** column of the **Signal selection** list. In the next figure, the `Scope A` signal is the trigger. `Scope B` is also selected for viewing, as indicated by the `X` in the **Selected** column.



After selecting the trigger signal, you can use the **Trigger signal** section to define the trigger conditions and set the trigger signal **Port** and **Element** parameters.

Set Trigger Conditions

Use the **Trigger signal** section of the External Signal & Triggering dialog box to set trigger conditions and attributes. **Trigger signal** parameters are enabled only when the trigger parameter **Source** is set to `signal` in the **Trigger options** section.

By default, any element of the first input port of a specified trigger block can cause the trigger to fire (that is, Port 1, any element). You can modify this behavior by adjusting the **Port** and **Element** values in the **Trigger signal** section. The **Port** field accepts a number or the keyword `last`. The **Element** field accepts a number or the keywords `any` or `last`.

In the **Trigger signal** section, you also define the conditions under which a trigger event occurs.

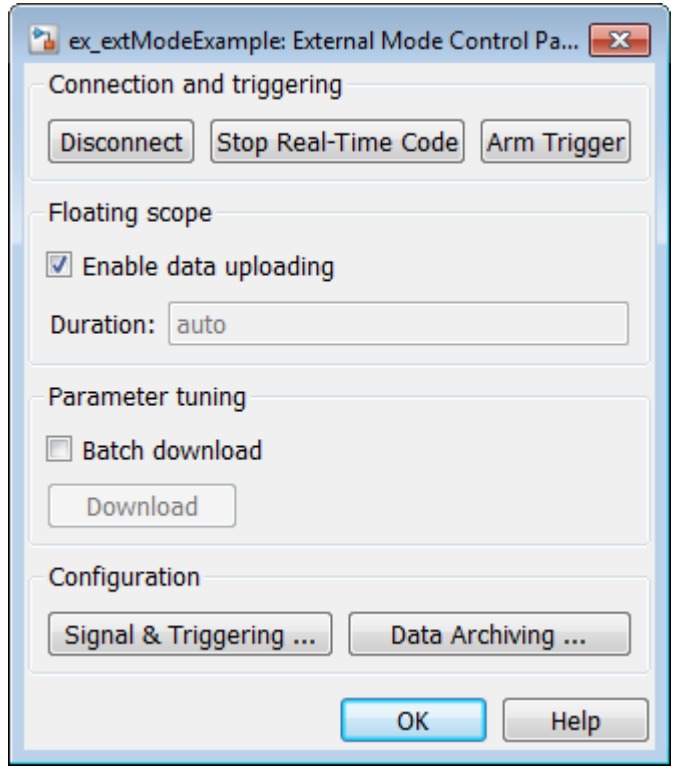
- **Direction**: `rising`, `falling`, or `either`. The direction in which the signal must be traveling when it crosses the threshold value. The default is `rising`.
- **Level**: A value indicating the threshold the signal must cross in a designated direction to fire the trigger. By default, the level is 0.
- **Hold-off**: Applies only to `normal` mode. Expressed in base rate steps, **Hold-off** is the time between the termination of one trigger event and the rearming of the trigger.

Modify Signal and Triggering Options While Connected

After you configure signal data uploading, and connect Simulink to a running target executable, you can modify signal and triggering options without disconnecting from the target.

If the trigger is armed (for example, if the trigger option **Arm when connecting to the target** is selected, which is the default), the External Signal & Triggering dialog box cannot be modified. To modify signal and triggering options:

1. Open the External Mode Control Panel.
2. Click **Cancel Trigger**. Triggering and display of uploaded data stops.
3. Open the External Signal & Triggering dialog box and modify signal and trigger options as required. For example, in the **Signal selection** section, you can enable or disable a scope, and in the **Trigger options** section, change the trigger **Mode**, for example, from `normal` to `one-shot`.
4. Click **Arm Trigger**. Triggering and display of uploaded data resumes, with your modifications.



Configure Host Archiving of Target Program Signal Data

In external mode, you can use the Simulink Scope and To Workspace blocks to archive data to disk.

To understand how the archiving features work, consider the handling of data when archiving is not enabled. There are two cases, one-shot mode and normal mode.

- In one-shot mode, after a trigger event occurs, each selected block writes its data to the workspace, as it would at the end of a simulation. If another one-shot is triggered, the existing workspace data is overwritten.
- In normal mode, external mode automatically rearms the trigger after each trigger event. Consequently, you can think of normal mode as a series of one-shots. Each one-shot in this series, except for the last, is referred to as an *intermediate result*. Because

the trigger can fire at any time, writing intermediate results to the workspace can result in unpredictable overwriting of the workspace variables. For this reason, the default behavior is to write only the results from the final one-shot to the workspace. The intermediate results are discarded. If you know that enough time exists between triggers for inspection of the intermediate results, you can override the default behavior by selecting the **Write intermediate results to workspace** option. This option does not protect the workspace data from being overwritten by subsequent triggers.

If you use a Simulink Scope block to archive data to disk, open the Scope parameters dialog box and select the option **Log data to workspace**. The option is required for these reasons:

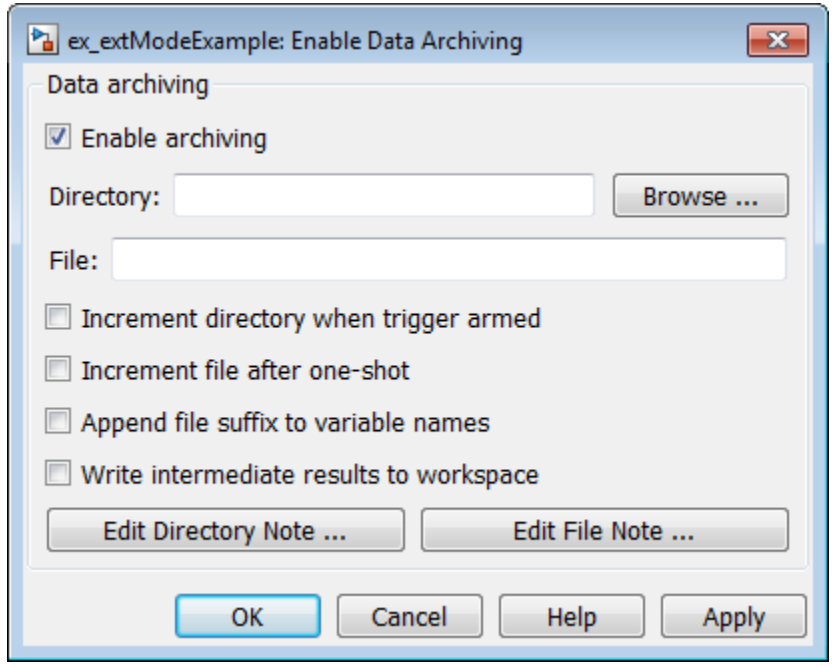
- The data is first transferred from the scope data buffer to the MATLAB workspace, before being written to a MAT-file.
- The **Variable name** entered in the Scope parameters dialog box is the same as the one in the MATLAB workspace and the MAT-file. Enabling the data to be saved enables a variable named with the **Variable name** parameter to be saved to a MAT-file.

Note: If you do not select the Scope block option **Log data to workspace**, the MAT-files for data logging are created, but they are empty.

The Enable Data Archiving dialog box supports:

- Folder notes
- File notes
- Automated data archiving

On the External Mode Control Panel, click the **Data Archiving** button to open the Enable Data Archiving dialog box. If your model is connected to the target environment, disconnect it while you configure data archiving. To enable the other controls in the dialog box, select **Enable archiving**.



These operations are supported by the Enable Data Archiving dialog box.

Folder Notes

To add annotations for a collection of related data files in a folder, in the Enable Data Archiving dialog box, click **Edit Directory Note**. The MATLAB editor opens. Place comments that you want saved to a file in the specified folder in this window. By default, the comments are saved to the folder last written to by data archiving.

File Notes

To add annotations for an individual data file, in the Enable Data Archiving dialog box, click **Edit File Note**. A file finder window opens, which by default is set to the last file to which you have written. Selecting a MAT-file opens an edit window. In this window, add or edit comments that you want saved with your individual MAT-file.

Automated Data Archiving

To configure automatic writing of logging results to disk, optionally including intermediate results, use the **Enable archiving** option and the controls it enables . The dialog box provides the following related controls:

- **Directory**: Specifies the folder in which data is saved. If you select **Increment directory when trigger armed**, external mode appends a suffix.
- **File**: Specifies the name of the file in which data is saved. If you select **Increment file after one-shot**, external mode appends a suffix.
- **Increment directory when trigger armed**: Each time that you click the **Arm Trigger** button, external mode uses a different folder for writing log files. The folders are named incrementally, for example, `dirname1`, `dirname2`, and so on.
- **Increment file after one-shot**: New data buffers are saved in incremental files: `filename1`, `filename2`, and so on. File incrementing happens automatically in normal mode.
- **Append file suffix to variable names**: Whenever external mode increments file names, each file contains variables with identical names. Selecting **Append file suffix to variable name** results in each file containing unique variable names. For example, external mode saves a variable named `xdata` in incremental files (`file_1`, `file_2`, and so on) as `xdata_1`, `xdata_2`, and so on. This approach supports loading the MAT-files into the workspace and comparing variables at the MATLAB command prompt. Without the unique names, each instance of `xdata` would overwrite the previous one in the MATLAB workspace.
- **Write intermediate results to workspace**: If you want the Simulink Coder software to write intermediate results to the workspace, select this option.

External Mode Compatible Blocks and Subsystems

Compatible Blocks

In external mode, you can use the following types of blocks to receive and view signals uploaded from the target program:

- Floating Scope and Scope blocks
- Spectrum Analyzer, Time Scope, and Vector Scope blocks from the DSP System Toolbox product
- Display blocks

- To Workspace blocks
- User-written S-Function blocks

  An external mode method is built into the S-function API. This method allows user-written blocks to support external mode. See *`matlabroot`*`/simulink/include/simstruc.h`.
- XY Graph blocks

You can designate certain subsystems as Signal Viewing Subsystems and use them to receive and view signals uploaded from the target program. See "Signal Viewing Subsystems" on page 41-35 for more information.

You select external mode compatible blocks and subsystems, and arm the trigger, by using the External Signal & Triggering dialog box. By default, such blocks in a model are selected, and a manual trigger is set to be armed when connected to the target program.

Signal Viewing Subsystems

A Signal Viewing Subsystem is an atomic subsystem that encapsulates processing and viewing of signals received from the target system. A Signal Viewing Subsystem runs only on the host, and does not generate code in the target system. Signal Viewing Subsystems run in normal, accelerator, rapid accelerator, and external simulation modes.

Note: Signal Viewing Subsystems are inactive if placed inside a SIL or PIL component, such as a top model in SIL or PIL mode, a Model block in SIL or PIL mode, or a SIL or PIL block. However, a SIL or PIL component can feed a Signal Viewing Subsystem running in a supported mode.

Signal Viewing Subsystems are useful in situations where you want to process or condition signals before viewing or logging them, but you do not want to perform these tasks on the target system. By using a Signal Viewing Subsystem, you can generate smaller and more efficient code on the target system.

Like other external mode compatible blocks, Signal Viewing Subsystems are displayed in the External Signal & Triggering dialog box.

To declare a subsystem to be a Signal Viewing Subsystem:

1 In the Block Parameters dialog box, select the **Treat as atomic unit** option.

For more information on atomic subsystems, see "Code Generation of Subsystems" (Simulink Coder).

2 To turn the SimViewingDevice property on, use the `set_param` command:

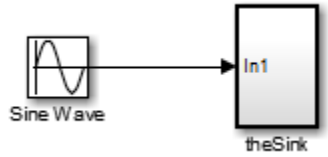
```
set_param('blockname', 'SimViewingDevice','on')
```

`'blockname'` is the name of the subsystem.

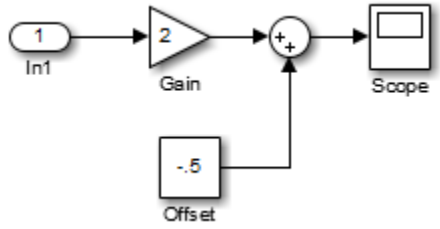
3 Make sure the subsystem meets the following requirements:

- It must be a pure Sink block. That is, it must not contain Outport blocks or Data Store blocks. It can contain Goto blocks only if the corresponding From blocks are contained within the subsystem boundaries.
- It must not have continuous states.

The following model, `sink_examp`, contains an atomic subsystem, `theSink`.



The subsystem `theSink` applies a gain and an offset to its input signal and displays it on a Scope block.



If `theSink` is declared as a Signal Viewing Subsystem, the generated target program includes only the code for the Sine Wave block. If `theSink` is selected and armed in the External Signal & Triggering dialog box, the target program uploads the sine wave

signal to `theSink` during simulation. You can then modify the parameters of the blocks within `theSink` and observe the uploaded signal.

If `theSink` were not declared as a Signal Viewing Subsystem, its Gain, Constant, and Sum blocks would run as subsystem code on the target system. The Sine Wave signal would be uploaded to the Simulink engine after being processed by these blocks, and viewed on `sink_examp/theSink/Scope2`. Processing demands on the target system would be increased by the additional signal processing, and by the downloading of changes in block parameters from the host.

Supported Blocks for Data Archiving

In external mode, you can use the following types of blocks to archive data to disk:

- Scope blocks
- To Workspace blocks

You configure data archiving by using the Enable Data Archiving dialog box, as described in "Configure Host Archiving of Target Program Signal Data" on page 41-31.

External Mode Communication

About External Mode Communication

Depending on the setting of the **Default parameter behavior** option when the target program is generated, there are differences in the way parameter updates are handled. "Download Mechanism" on page 41-37 describes the operation of external mode communication with **Default parameter behavior** set to `Tunable`. "Inlined and Tunable Parameters" on page 41-39 describes the operation of external mode with **Default parameter behavior** set to `Inlined`.

Download Mechanism

In external mode, the Simulink engine does not simulate the system represented by the block diagram. By default, when external mode is enabled, the Simulink engine

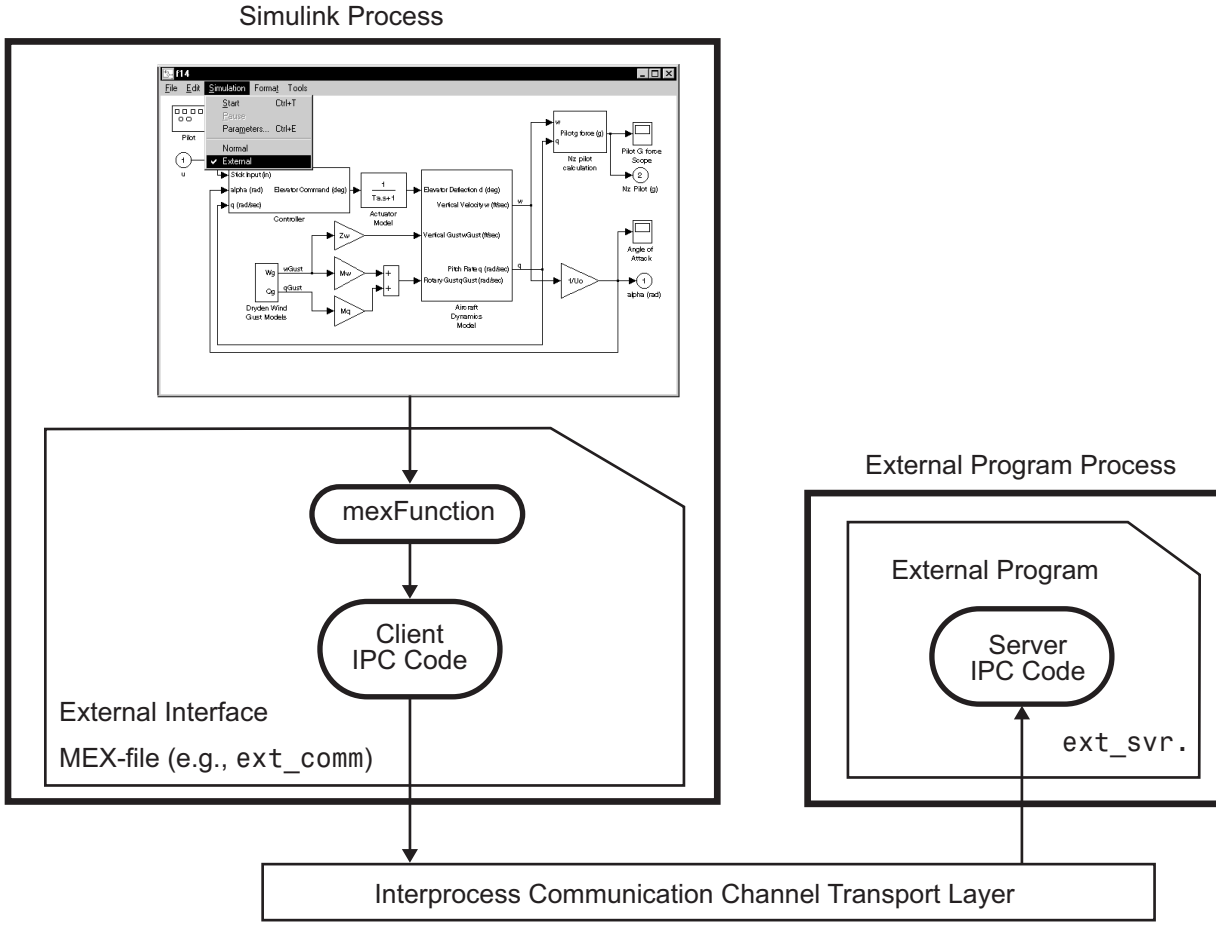
downloads parameters to the target system. After the initial download, the engine remains in a waiting mode until you change parameters in the block diagram or until the engine receives data from the target.

When you change a parameter in the block diagram, the Simulink engine calls the external interface MEX-file, passing new parameter values (along with other information) as arguments. The external interface MEX-file contains code that implements one side of the interprocess communication (IPC) channel. This channel connects the Simulink process (where the MEX-file executes) to the process that is executing the external program. The MEX-file transfers the new parameter values by using this channel to the external program.

The other side of the communication channel is implemented within the external program. This side writes the new parameter values into the target's parameter structure (`model_P`).

The Simulink side initiates the parameter download operation by sending a message containing parameter information to the external program. In the terminology of client/server computing, the Simulink side is the client and the external program is the server. The two processes can be remote, or they can be local. Where the client and server are remote, a protocol such as TCP/IP is used to transfer data. Where the client and server are local, a serial connection or shared memory can be used to transfer data.

The next figure shows this relationship. The Simulink engine calls the external interface MEX-file whenever you change parameters in the block diagram. The MEX-file then downloads the parameters to the external program by using the communication channel.



External Mode Architecture

Inlined and Tunable Parameters

By default, parameters (except those listed in "External Mode Limitations" on page 41-55) in an external mode program are tunable; that is, you can change them by using the download mechanism described in this section.

If you set **Default parameter behavior** to `Inlined` (on the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box), the Simulink Coder code generator embeds the numerical values of model parameters (constants), instead of

symbolic parameter names, in the generated code. Inlining parameters generates smaller and more efficient code. However, inlined parameters, because they effectively become constants, are not tunable.

The Simulink Coder software lets you improve overall efficiency by inlining most parameters, while at the same time retaining the flexibility of run-time tuning for selected parameters that are important to your application. When you inline parameters, you can use `Simulink.Parameter` objects to remove individual parameters from inlining and declare them to be tunable. In addition, you can use these objects to control how parameters are represented in the generated code.

For more information on tunable parameters, see "Block Parameter Representation in the Generated Code" (Simulink Coder).

Automatic Parameter Uploading on Host/Target Connection

Each time the Simulink engine connects to a target program that was generated with **Default parameter behavior** set to `Inlined`, the target program uploads the current value of its tunable parameters to the host. These values are assigned to the corresponding MATLAB workspace variables. This procedure synchronizes the host and target with respect to parameter values.

Workspace variables required by the model must be initialized at the time of host/target connection. Otherwise the uploading cannot proceed and an error results. Once the connection is made, these variables are updated to reflect the current parameter values on the target system.

Automatic parameter uploading takes place only if the target program was generated with **Default parameter behavior** set to `Inlined`. "Download Mechanism" on page 41-37 describes the operation of external mode communication with **Default parameter behavior** set to `Tunable`.

Choose Communication Protocol for Client and Server

Introduction

The Simulink Coder product provides code to implement both the client and server side of external mode communication using either TCP/IP or serial protocols. You can use the socket-based external mode implementation provided by the Simulink Coder product with the generated code, provided that your target system supports TCP/IP. If not, use or customize the serial transport layer option provided.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

For information on selecting a transport layer, see "Target Interfacing" on page 41-16.

Using the TCP/IP Implementation

You can use TCP/IP-based client/server implementation of external mode with real-time programs on The Open Group UNIX or PC systems. For help in customizing external mode transport layers, see "Create a Transport Layer for External Communication" (Simulink Coder).

To use Simulink external mode over TCP/IP:

- Make sure that the external interface MEX-file for your target's TCP/IP transport is specified.

  Targets provided by MathWorks specify the name of the external interface MEX-file in `matlabroot/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The TCP/IP default is `ext_comm`.

  To specify a TCP/IP transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

  - *`stf`*`.tlc` is the name of the system target file for which you are registering the transport (for example, `'mytarget.tlc'`)

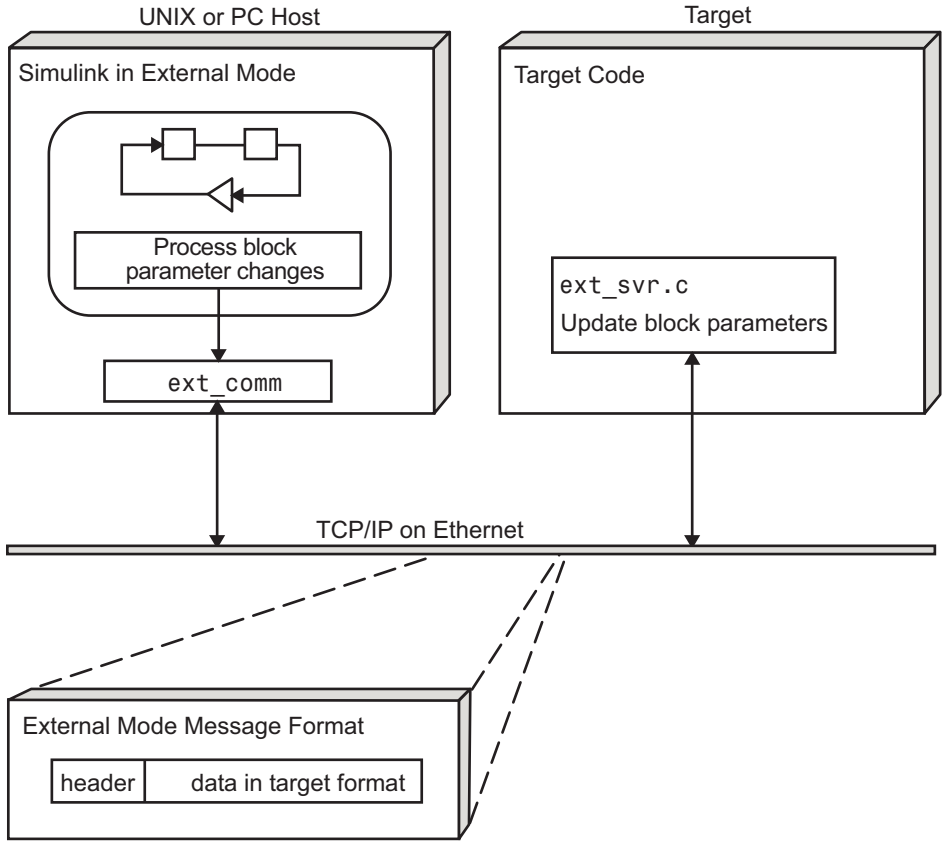
- *`transport`* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, `'tcpip'`)
- *`mexfile`* is the name of the transport's associated external interface MEX-file (for example, `'ext_comm'`)

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
  cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
                           'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the TCP/IP server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

The next figure shows the structure of the TCP/IP-based implementation.



TCP/IP-Based Client/Server Implementation for External Mode

MEX-File Optional Arguments for TCP/IP Transport

In the External Target Interface dialog box, you can specify optional arguments that are passed to the external mode interface MEX-file for communicating with executing targets.

- Target network name: the network name of the computer running the external program. By default, this is the computer on which the Simulink product is running, for example, `'myComputer'`. You can also use the IP address, for example, `'148.27.151.12'`.

- Verbosity level: controls the level of detail of the information displayed during the data transfer. The value is either `0` or `1` and has the following meaning:

  `0` — No information
  `1` — Detailed information
- TCP/IP server port number: The default value is `17725`. You can change the port number to a value between `256` and `65535` to avoid a port conflict.

The arguments are positional and must be specified in the following order:

```
<TargetNetworkName> <VerbosityLevel> <ServerPortNumber>
```

For example, if you want to specify the verbosity level (the second argument), then you must also specify the target network name (the first argument). Arguments can be delimited by white space or commas. For example:

```
'148.27.151.12' 1 30000
```

You can specify command-line options to the external program when you launch it. See "Run the External Program" on page 41-46.

Using the Serial Implementation

Controlling host/target communication on a serial channel is similar to controlling host/target communication on a TCP/IP channel.

To use Simulink external mode over a serial channel, you must:

- Make sure that the external interface MEX-file for your target's serial transport is specified.

  Targets provided by MathWorks specify the name of the external interface MEX-file in *`matlabroot`*`/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The serial default is `serial`.

  To specify a serial transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

  ```
  function sl_customization(cm)
    cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
  %end function
  ```

- *`stf`*`.tlc` is the name of the system target file for which you are registering the transport (for example, `'mytarget.tlc'`)
- *`transport`* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, `'serial'`)
- *`mexfile`* is the name of the transport's associated external interface MEX-file (for example, `'ext_serial_win32_comm'`)

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
  cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
                           'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the serial server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

MEX-File Optional Arguments for Serial Transport

In the **MEX-file arguments** field of the **Interface** pane of the Configuration Parameters dialog box, you can specify arguments that are passed to the external mode interface MEX-file for communicating with the executing targets. For serial transport, the optional arguments to `ext_serial_win32_comm` are as follows:

- Verbosity level: This argument controls the level of detail of the information displayed during data transfer. The value of this argument is:
  - `0` (no information), or
  - `1` (detailed information)
- Serial port ID: The port ID of the host, specified as an integer or character vector. For example, specify the port ID of a USB to serial converter as `'/dev/ttyusb0'`.Simulink Coder prefixes integer port IDs with `\\.\COM` on Windows and by `/dev/ttyS` on Unix.

When you start the target program using a serial connection, you must specify the port ID to use to connect it to the host. Do this by including the `-port` command-line option. For example:

```
mytarget.exe -port 2 -w
```

- Baud rate: Specify an integer value. The default value is `57600`.

The MEX-file options arguments are positional and must be specified in the following order:

```
<VerbosityLevel> <SerialPortID> <BaudRate>
```

For example, if you want to specify the serial port ID (the second argument), then you must also specify the verbosity level (the first argument). Arguments can be delimited by white space or commas. For example:

```
1 '/dev/ttyusb0' 57600
```

When you launch the external program, you can specify command-line options.

Run the External Program

Before you can use the Simulink product in external mode, the external program must be running.

If the target program is executing on the same machine as the host and communication is through a loopback serial cable, the target's port ID must differ from that of the host (as specified in the **MEX-file arguments** edit field).

To run the external program, you type a command of the form:

```
model -opt1 ... -optN
```

`model` is the name of the external program and *`-opt1 ... -optN`* are options. (See "Command-Line Options for the External Program" on page 41-47.) In the examples in this section, the name of the external program is `ext_example`.

Running the External Program in the Windows Environment

In the Windows environment, you can run the external programs in either of the following ways:

- Open a Command Prompt window. At the command prompt, type the name of the target executable, followed by possible options, such as:

```
ext_example -tf inf -w
```

- Alternatively, you can launch the target executable from the MATLAB Command Window. The command must be preceded by an exclamation point (`!`) and followed by an ampersand (`&`), as in the following example:

  ```
  !ext_example -tf inf -w &
  ```

  The ampersand (`&`) causes the operating system to spawn another process to run the target executable. If you do not include the ampersand, the program still runs, but you cannot enter commands at the MATLAB command prompt or manually terminate the executable.

Running the External Program in the UNIX Environment

In the UNIX environment, you can run the external programs in either of the following ways:

- Open an `Xterm` window. At the command prompt, type the name of the target executable, followed by possible options, such as:

  ```
  ./ext_example -tf inf -w
  ```

- Alternatively, you can launch the target executable from the MATLAB Command Window. You must run it in the background so that you can still access the Simulink environment. The command must be preceded by an exclamation point (`!`), dot slash (./ indicating the current directory), and followed by an ampersand (`&`), as in the following example:

  ```
  !./ext_example -tf inf -w &
  ```

  The ampersand (`&`) causes the operating system to spawn another process to run the target executable.

Command-Line Options for the External Program

External mode target executables generated by the Simulink Coder code generator support the following command-line options:

- `-tf n`

  The `-tf` option overrides the stop time set in the Simulink model. The argument `n` specifies the number of seconds the program will run. The value `inf` directs the model

to run indefinitely. In this case, the model code runs until the target program receives a stop message from the Simulink engine.

The following example sets the stop time to 10 seconds.

```
ext_example -tf 10
```

When integer-only ERT targets are built and executed in external mode, the stop time parameter (`-tf`) is interpreted by the target as the number of base rate ticks rather than the number of seconds to execute.

- `-w`

  Instructs the target program to enter a wait state until it receives a message from the host. At this point, the target is running, but not executing the model code. The start message is sent when you select **Start Real-Time Code** from the **Simulation** menu or click the **Start Real-Time Code** button in the External Mode Control Panel.

  Use the `-w` option if you want to view data from time step 0 of the target program execution, or if you want to modify parameters before the target program begins execution of model code.

- `-port n`

  Specifies the TCP/IP port number or the serial port ID, `n`, for the target program. The port number of the target program must match that of the host for TCP/IP transport. The port number depends on the type of transport.

  - For TCP/IP transport: Port number is an integer between `256` and `65535`, with the default value being `17725`.
  - For serial transport: Port ID is an integer or a character vector. For example, specify the port ID of a USB to serial converter as `'/dev/ttyusb0'`

- `-baud r`

  Specified as an integer, this option is only available for serial transport.

Implement an External Mode Protocol Layer

If you want to implement your own transport layer for external mode communication, you must modify certain code modules provided by the Simulink Coder product and create a new external interface MEX-file. See “Create a Transport Layer for External Communication” (Simulink Coder).

Use External Mode Programmatically

You can run external-mode applications from the MATLAB command line or programmatically in scripts. Use the `get_param` and `set_param` commands to retrieve and set the values of model simulation command-line parameters, such as `SimulationMode` and `SimulationCommand`, and external mode command-line parameters, such as `ExtModeCommand` and `ExtModeTrigType`.

The following model simulation commands assume that a Simulink model is open and that you have loaded a target program to which the model will connect using external mode.

1. Change the Simulink model to external mode:

   ```
   set_param(gcs,'SimulationMode','external')
   ```

2. Connect the open model to the loaded target program:

   ```
   set_param(gcs,'SimulationCommand','connect')
   ```

3. Start running the target program:

   ```
   set_param(gcs,'SimulationCommand','start')
   ```

4. Stop running the target program:

   ```
   set_param(gcs,'SimulationCommand','stop')
   ```

5. Disconnect the target program from the model:

   ```
   set_param(gcs,'SimulationCommand','disconnect')
   ```

To tune a workspace parameter, change its value at the command prompt. If the workspace parameter is a `Simulink.Parameter` object, assign the new value to the `Value` property.

```
myVariable = 5.23;
myParamObj.Value = 5.23;
```

To download the workspace parameter in external mode, you update the model diagram. The following model simulation command initiates a model update:

```
set_param(gcs,'SimulationCommand','update')
```

To trigger or cancel data uploading to scopes, use the `ExtModeCommand` values `armFloating` and `cancelFloating`, or `armWired` and `cancelWired`. For example, to trigger and then cancel data uploading to wired (nonfloating) scopes:

```
set_param(gcs,'ExtModeCommand','armWired')
set_param(gcs,'ExtModeCommand','cancelWired')
```

The next table lists external mode command-line parameters that you can use in `get_param` and `set_param` commands. The table provides brief descriptions, valid values (bold type highlights defaults), and a mapping to External Mode dialog box equivalents. For external mode parameters that are equivalent to **Interface** pane options in the Configuration Parameters dialog box, see "Model Configuration Parameters: Code Generation Interface" (Simulink Coder).

External Mode Command-Line Parameters

Parameter and Values	Dialog Box Equivalent	Description
`ExtModeAddSuffixToVar` **`off`**, on	Enable Data Archiving: **Append file suffix to variable names** check box	Increment variable names for each incremented filename.
`ExtModeArchiveDirName` *`character vector`*	Enable Data Archiving: **Directory** text field	Save data in specified folder.
`ExtModeArchiveFileName` *`character vector`*	Enable Data Archiving: **File** text field	Save data in specified file.
`ExtModeArchiveMode` *`character vector`* - **`off`**, on	Enable Data Archiving: **Enable archiving** check box	Activate automated data archiving features.
`ExtModeArmWhenConnect` `off`, **`on`**	External Signal & Triggering: **Arm when connecting to target** check box	Arm the trigger as soon as the Simulink Coder software connects to the target.
`ExtModeAutoIncOneShot` **`off`**, on	Enable Data Archiving: **Increment file after one-shot** check box	Save new data buffers in incremental files.
`ExtModeAutoUpdateStatusClock` (Microsoft Windows platforms only) `off`, **`on`**	Not available	Continuously upload and display target time on the model window status bar.
`ExtModeBatchMode` **`off`**, on	External Mode Control Panel: **Batch download** check box	Enable or disable downloading of parameters in batch mode.
`ExtModeChangesPending` **`off`**, on	Not available	When `ExtModeBatchMode` is enabled, indicates whether parameters remain in the queue of parameters

Parameter and Values	Dialog Box Equivalent	Description
		to be downloaded to the target.
`ExtModeCommand` *`character vector`* - `armFloating`, `armWired`, `cancelFloating`, `cancelWired`	• `armFloating` and `cancelFloating` are equivalent to selecting and clearing External Mode Control Panel check box **Floating scope** > **Enable data uploading** • `armWired` and `cancelWired` are equivalent to External Mode Control Panel buttons **Arm Trigger** and **Cancel Trigger**	Issue an external mode command to the target program.
`ExtModeConnected` **`off`**, `on`	External Mode Control Panel: **Connect/Disconnect** button	Indicate the state of the connection with the target program.
`ExtModeEnableFloating` `off`, **`on`**	External Mode Control Panel: **Enable data uploading** check box	Enable or disable the arming and canceling of triggers when a connection is established with floating scopes.
`ExtModeIncDirWhenArm` **`off`**, `on`	Enable Data Archiving: **Increment directory when trigger armed** check box	Write log files to incremental folders each time the trigger is armed.
`ExtModeLogAll` `off`, **`on`**	External Signal & Triggering: **Select all** check box	Upload available signals from the target to the host.
`ExtModeParamChangesPending` **`off`**, `on`	Not available	When the Simulink Coder software is connected to the target and `ExtModeBatchMode` is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the

Parameter and Values	Dialog Box Equivalent	Description
		target. More efficient than `ExtModeChangesPending`, because it checks for a connection to the target.
`ExtModeSkipDownloadWhenConnect` **`off`**, `on`	Not available	Connect to the target program without downloading parameters.
`ExtModeTrigDelay` *`integer`* (**0**)	External Signal & Triggering: **Delay** text field	Specify the amount of time (expressed in base rate steps) that elapses between a trigger occurrence and the start of data collection.
`ExtModeTrigDirection` *`character vector`* - **`rising`**, `falling`, `either`	External Signal & Triggering: **Direction** menu	Specify the direction in which the signal must be traveling when it crosses the threshold value.
`ExtModeTrigDuration` *`integer`* (**1000**)	External Signal & Triggering: **Duration** text field	Specify the number of base rate steps for which external mode is to log data after a trigger event.
`ExtModeTrigDurationFloating` *`character vector`* - *`integer`* (**`auto`**)	External Mode Control Panel: **Duration** text field	Specify the duration for floating scopes. If `auto` is specified, the value of `ExtModeTrigDuration` is used.
`ExtModeTrigElement` *`character vector`* - *`integer`*, **`any`**, `last`	External Signal & Triggering: **Element** text field	Specify the elements of the input port of the specified trigger block that can cause the trigger to fire.
`ExtModeTrigHoldOff` *`integer`* (**0**)	External Signal & Triggering: **Hold-off** text field	Specify the base rate steps between when a trigger event terminates and the trigger is rearmed.

Parameter and Values	Dialog Box Equivalent	Description
`ExtModeTrigLevel` *integer* (**0**)	External Signal & Triggering: **Level** text field	Specify the threshold value the trigger signal must cross to fire the trigger.
`ExtModeTrigMode` *character vector* - **`normal`**, `oneshot`	External Signal & Triggering: **Mode** menu	Specify whether the trigger is to rearm automatically after each trigger event or whether only one buffer of data is to be collected each time the trigger is armed.
`ExtModeTrigPort` *character vector* - *integer* (**1**), `last`	External Signal & Triggering: **Port** text field	Specify the input port of the specified trigger block for which elements can cause the trigger to fire.
`ExtModeTrigType` *character vector* - **`manual`**, `signal`	External Signal & Triggering: **Source** menu	Specify whether to start logging data when the trigger is armed or when a specified trigger signal satisfies trigger conditions.
`ExtModeUploadStatus` *character vector* - `inactive`, `armed`, `uploading`	Not available	Return the status of the external mode upload mechanism — inactive, armed, or uploading.
`ExtModeWriteAllDataToWs` **`off`**, `on`	Enable Data Archiving: **Write intermediate results to workspace** check box	Write intermediate results to the workspace.

Animate Stateflow Charts in External Mode

If you have Stateflow, you can animate a chart in external mode. In external mode, you can animate states in a chart, and view test point signals in a floating scope or signal viewer.

- "Animate States During Simulation in External Mode" on page 41-54
- "View Test Point Data in Floating Scopes and Signal Viewers" on page 41-54

Animate States During Simulation in External Mode

To animate states in a chart in external mode:

1. Load the chart you want to animate to the target machine.
2. Open the Model Configuration Parameters dialog box.
3. In the left Select pane, select **Code Generation > Interface**.
4. In the **Data exchange interface** section, select **External mode** and click **OK**.
5. In the Simulink Editor, select **Code > External Mode Control Panel**.
6. In the External Mode Control Panel dialog box, click **Signal & Triggering**.
7. In the External Signal & Triggering dialog box, set these parameters.

In:	Select:
Signal selection pane	Chart you want to animate
Trigger pane	**Arm when connecting to target** check box
Trigger pane	`normal` from drop-down menu in **Mode** field

8. Build the model to generate an executable file.
9. Start the target in the background. At the MATLAB prompt, type:

   ```
   !model_name.exe -w &
   ```

   For example, if the name of your model is `my_control_sys`, enter this command:

   ```
   !my_control_sys.exe -w &
   ```

   `-w` allows the target code to wait for the Simulink model connection.
10. In the Model Editor, select **Simulation > Mode > External**, and then select **Simulation > Connect to Target**.
11. Start simulation. The chart highlights states as they execute.

View Test Point Data in Floating Scopes and Signal Viewers

When you simulate a chart in external mode, you can designate chart data of local scope to be test points and view the test point data in floating scopes and signal viewers.

To view test point data during simulation in external mode:

1. Open the Model Explorer and for each data you want to view, follow these steps:

   a. In the middle **Contents** pane, select the state or local data of interest.
   b. In the right **Dialog** pane, select the **Logging** tab and select **Test point** check box.
2. From a floating scope or signal viewer, click the signal selection button:

   The Signal Selector dialog box opens.
3. In the Signal Selector **Model hierarchy** pane, select the chart.
4. In the Signal Selector **List contents** menu, select **Testpointed/Logged signals only** and then select the signals you want to view.
5. Simulate the model in external mode as described in "Animate States During Simulation in External Mode" on page 41-54.

   The scope or viewer displays the values of the test point signals as the simulation runs.

For more information, see "Behavior of Scopes and Viewers with Rapid Accelerator Mode" (Simulink).

External Mode Limitations

Changing Parameters

In general, you cannot change a parameter if doing so results in a change in the structure of the model. For example, you cannot change

- The number of states, inputs, or outputs of a block
- The sample time or the number of sample times
- The integration algorithm for continuous systems
- The name of the model or of a block
- The parameters to the Fcn block

If you make these changes to the block diagram, then you must rebuild the program with newly generated code.

You can change parameters in transfer function and state space representation blocks in specific ways:

- The parameters (numerator and denominator polynomials) for the Transfer Fcn (continuous and discrete) and Discrete Filter blocks can be changed (as long as the number of states does not change).
- Zero entries in the State-Space and Zero Pole (both continuous and discrete) blocks in the user-specified or computed parameters (that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation) cannot be changed once external simulation is started.
- In the State-Space block, if you specify the matrices in the controllable canonical realization, then all changes to the A, B, C, D matrices that preserve this realization and the dimensions of the matrices are allowed.

If the Simulink block diagram does not match the external program, the Simulink engine displays an error informing you that the checksums do not match (that is, the model has changed since you generated code). This means that you must rebuild the program from the new block diagram (or reload another one) to use external mode.

If the external program is not running, the Simulink engine displays an error informing you that it cannot connect to the external program.

Mixing 32-Bit and 64-Bit Architectures

When you use external mode, the machine running the Simulink product and the machine running the target executable must have matching bit architectures, either 32-

bit or 64-bit. The Simulink Coder software varies a model's checksum based on whether it is configured for a 32-bit or 64-bit platform.

If you attempt to connect from a 32-bit machine to a 64-bit machine or vice versa, the external mode connection fails.

Uploading Data

External mode does not support uploading data values for fixed-point or enumerated types into workspace parameters.

Uploading Variable-Size Signals

External mode does not support uploading variable-size signals for the following targets:

- Simulink Real-Time
- Texas Instruments™ C2000™

Signal Value Display in Simulation

External mode does not support graphical display of signal values in models (described in "Displaying Signal Values in Model Diagrams" (Simulink)). For example, you cannot use the **Data Display in Simulation** menu selections **Show Value Labels When Hovering**, **Toggle Value Labels When Clicked**, and **Show Value Label of Selected Port**.

Tunable Structure Parameters

External mode does not support uploading or downloading tunable structure parameters.

Archiving Data

External mode supports the Scope and To Workspace blocks for archiving data to disk. However, external mode does not support scopes other than the Scope block for archiving data. For example, you cannot use Floating Scope blocks or Signal and Scope Manager viewer objects to archive data in external mode.

Scopes in Referenced Models

In a model hierarchy, if the top model simulates in external mode and a referenced model simulates in normal or accelerator mode, scopes in the referenced model are not displayed.

However, if the top model is changed to simulate in normal mode, the behavior of scopes in the referenced models differs between normal and accelerator mode. Scopes in a referenced model simulating in normal mode are displayed, while scopes in a referenced model simulating in accelerator mode are not displayed.

Simulation Start Time

External mode does not support nonzero simulation start times. In the Configuration Parameters dialog box, **Solver** pane, leave **Start time** set to the default value of `0.0`.

File-Scoped Data

External mode does not support file-scoped data, for example, data items to which you apply the built-in custom storage class `FileScope`. File-scoped data are not externally accessible.

Use of `printf` Statements

External mode simulations support the use of `printf` calls to display error and information messages from the target program. For some target hardware, the use of `printf` statements can increase the external mode binary file size. To disable `printf` calls, specify the preprocessor macro definition `EXTMODE_DISABLEPRINTF` for your target program compiler.

Command-Line Arguments

External mode simulations support the use of command-line arguments for running target programs. These limitations apply:

- Parsing of the command-line arguments requires the `sscanf` function, which increases the program size for some target hardware.
- Some target programs do not accept command-line arguments.

To disable the processing of command-line arguments, specify the preprocessor macro definition `EXTMODE_DISABLE_ARGS_PROCESSING=1` for your target program compiler.

Logging in Simulink Coder

Log Program Execution Results

Multiple techniques are available by which a program generated by the Simulink Coder software can save data to a MAT-file for analysis. A generated executable can save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) *model*`.mat`, where *model* is the name of your model. See "Log Data for Analysis" on page 42-2 for a data logging tutorial.

Note: Data logging is available only for system target files that have access to a file system. In addition, only the RSim target executables are capable of accessing MATLAB workspace data.

For MAT-file logging limitations, see the configuration parameter "MAT-file logging" (Simulink Coder).

In this section...
"Log Data for Analysis" on page 42-2
"Configure State, Time, and Output Logging" on page 42-9

"Log Data with To File Blocks" on page 42-11
"Data Logging Differences Between Single- and Multitasking" on page 42-12

Log Data for Analysis

- "Set Up and Configure Model" on page 42-2
- "Data Logging During Simulation" on page 42-4
- "Data Logging from Generated Code" on page 42-7

Set Up and Configure Model

This example shows how data generated by a copy of the model `slexAircraftExample` is logged to the file `myAircraftExample.mat`. Refer to "Build Process Workflow for a Real-Time STF" on page 40-30 for instructions on setting up a copy of `slexAircraftExample` as`myAircraftExample` in a working folder if you have not done so already.

Note: When you configure the code generator to produce code that includes support for data logging during execution, the code generator can include text for block names in the block paths included in the log file. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ｱ with the escape sequence `&#x30A2;`. For more information, see "Internationalization and Code Generation" (Simulink Coder).

To configure data logging, open the Configuration Parameters dialog box and select the **Data Import/Export** pane. The process is the same as configuring a Simulink model to save output to the MATLAB workspace. For each workspace return variable you define and enable, the Simulink Coder software defines a parallel MAT-file variable. For example, if you save simulation time to the variable `tout`, your generated program logs the same data to a variable named `rt_tout`. You can change the prefix `rt_` to a suffix (`_rt`), or eliminate it entirely. You do this by setting **Configuration Parameters** > **All Parameters** > **MAT-file variable name modifier**.

Simulink lets you log signal data from anywhere in a model. In the Simulink Editor, select the signals that you want to log and then in the **Simulation Data Inspector** button drop-down, select **Log Selected Signals**. However, the Simulink Coder software does not use this method of signal logging in generated code. To log signals in generated code, you must either use the **Data Import/Export** options described below or include To File or To Workspace blocks in your model.

Note: If you enable MAT-file and signal logging (through the **Data Import/Export** pane) and select signals for logging (through the Simulink Editor), you see the following warning when you build the model:

```
Warning: MAT-file logging does not support signal logging.
When your model code executes, the signal logging variable 'rt_logsout' will
not be saved to the MAT-file.
```

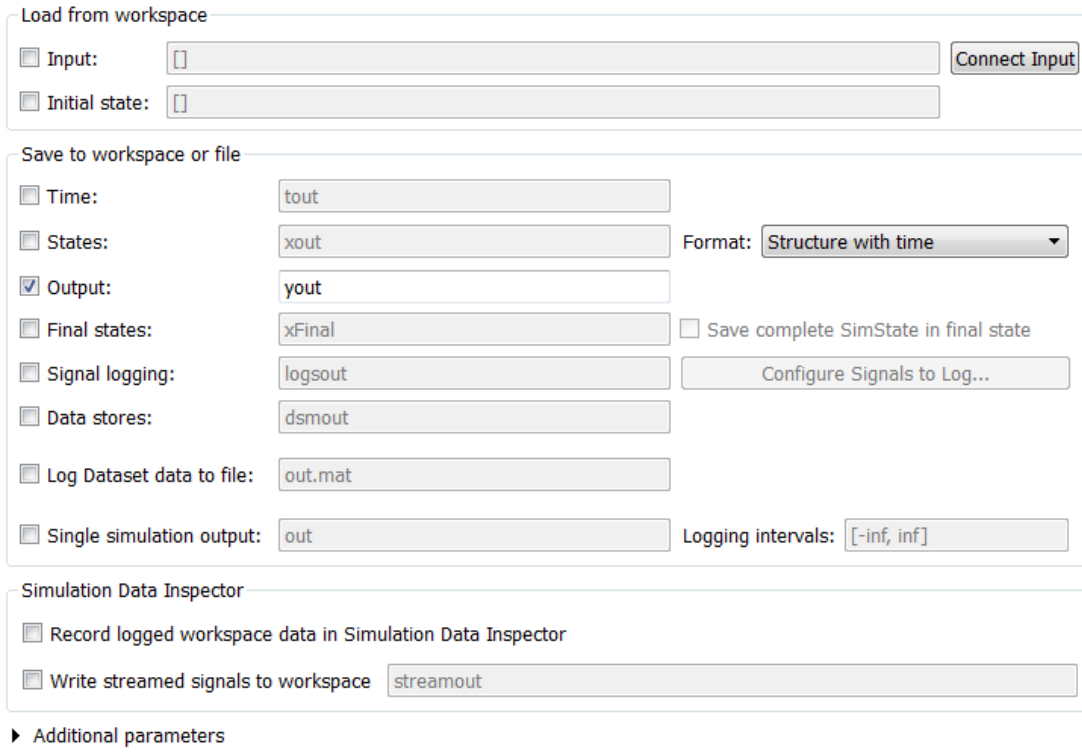
To avoid this warning, clear the **Data Import/Export** > **Signal logging** check box.

In this example, you modify the `myAircraftExample` model so that the generated program saves the simulation time and system outputs to the file `myAircraftExample.mat`. Then you load the data into the base workspace and plot simulation time against one of the outputs. The `myAircraftExample` model should be configured as described in "Build Process Workflow for a Real-Time STF" on page 40-30.

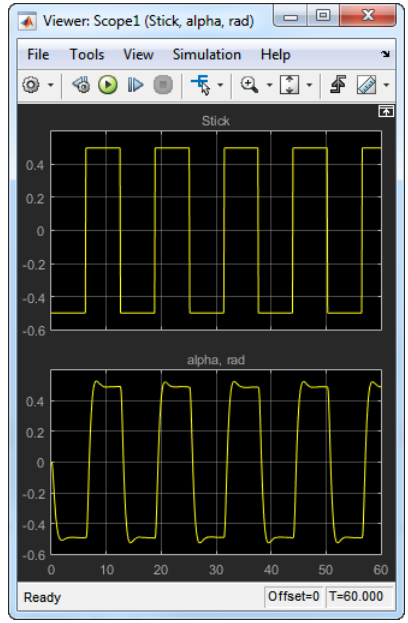
Data Logging During Simulation

To use the data logging feature:

1. Open the `myAircraftExample` model if it is not already open.
2. Open the Configuration Parameters dialog box by selecting **Simulation** > **Model Configuration Parameters** from the model window.
3. Select the **Data Import/Export** pane. The **Data Import/Export** pane lets you specify which outport data is to be saved to the workspace and what variable names to use for it.
4. Set **Format** to `Structure with time`. When you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Save to workspace or file** area. By default, the structures are `xout` for states and `yout` for output. The structure used to save output has two top-level fields: `time` and `signals`. The `time` field contains a vector of simulation times and `signals` contains an array of substructures, each of which corresponds to a model output port.
5. Select the **Output** option. This tells Simulink to save output signal data during simulation as a variable named `yout`. Selecting **Output** enables the code generator to create code that logs the root Output block (`alpha, rad`) to a MAT-file.
6. Set **Decimation** to `1`.
7. If other options are enabled, clear them. The figure below shows how the dialog box should appear.



8. Click **Apply** and **OK** to register your changes and close the dialog box.
9. Save the model.
10. In the model window, double-click the scope symbol next to the Aircraft Dynamics Model block, then run the model by choosing **Simulation** > **Run** in the model window. The resulting scope display is shown below.



11 Verify that the simulation time and outputs have been saved to the base workspace in MAT-files. At the MATLAB prompt, type:

```
whos yout
```

Simulink displays:

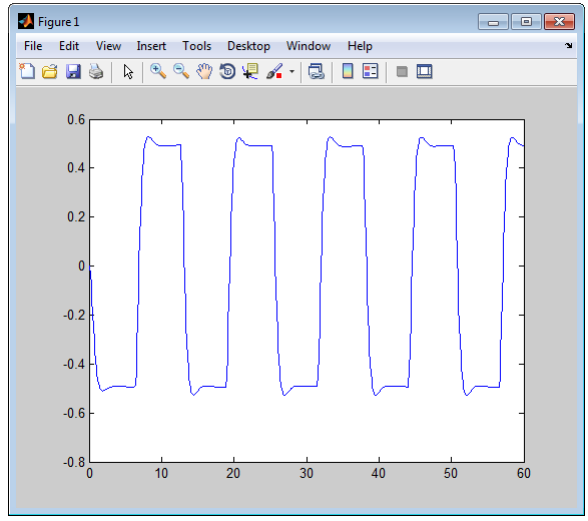
```
  Name        Size            Bytes  Class     Attributes

  yout        1x1             10756  struct
```

12 Verify that `alpha, rad` was logged by plotting simulation time versus that variable. In the Command Window, type:

```
plot(yout.time,yout.signals.values)
```

The resulting plot is shown below.



Data Logging from Generated Code

In the second part of this example, you build and run a Simulink Coder executable of the `myAircraftExample` model that outputs a MAT-file containing the simulation time and output you previously examined. Even though you have already generated code for the `myAircraftExample` model, you must now regenerate that code because you have changed the model by enabling data logging. The steps below explain this procedure.

To avoid overwriting workspace data with data from simulation runs, the code generator modifies identifiers for variables logged by Simulink. You can control these modifications.

1. Set **Configuration Parameters > All Parameters > MAT-file variable name modifier** to `_rt`. This adds the suffix `_rt` to each variable that you selected to be logged in the first part of this example.
2. Click **Apply** and **OK** to register your changes and close the dialog box.
3. Save the model.
4. Build an executable.
5. When the build concludes, run the executable with the command:

   ```
   !myAircraftExample
   ```
6. The program now produces two message lines, indicating that the MAT-file has been written.

```
** starting the model **
** created myAircraftExample.mat **
```

7 Load the MAT-file data created by the executable and look at the workspace variables from simulation and the generated program by typing:

```
load myAircraftExample.mat
whos yout*
```

Simulink displays:

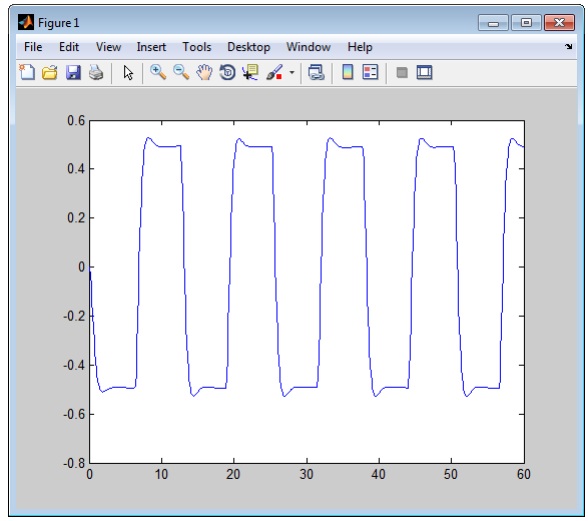
```
  Name           Size            Bytes  Class     Attributes

  yout           1x1             10756  struct
  yout_rt        1x1             10756  struct
```

Note the size and bytes of the structures resulting from the simulation run and generated code are the same.

8 Plot the generated code output by entering the following command in the Command Window:

```
plot(yout_rt.time,yout_rt.signals.values)
```



The plot should be identical to the plot that you produced in the previous part of this example.

Tip: For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Configure State, Time, and Output Logging

The **Data Import/Export** pane enables a generated program to save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) `model.mat`.

Before using this data logging feature, you should learn how to configure a Simulink model to return output to the MATLAB workspace. This is discussed in "Export Simulation Data" (Simulink).

For each workspace return variable that you define and enable, the code generator defines a MAT-file variable. For example, if your model saves simulation time to the workspace variable `tout`, your generated program logs the same data to a variable named (by default) `rt_tout`.

The code generated by the code generator logs the following data:

- Root Outport blocks

  The default MAT-file variable name for system outputs is `rt_yout`.

  The sort order of the `rt_yout` array is based on the port number of the Outport block, starting with 1.
- Continuous and discrete states in the model

  The default MAT-file variable name for system states is `rt_xout`.
- Simulation time

  The default MAT-file variable name for simulation time is `rt_tout`.

- "Override Default MAT-File Variable Names" on page 42-10

- “Override Default MAT-File Name or Buffer Size” on page 42-10

Override Default MAT-File Variable Names

By default, the code generation software prefixes the text `rt_` to the variable names for system outputs, states, and simulation time to form MAT-file variable names. To change this prefix for a model, select a prefix (`rt_`), a suffix (`_rt`), or no modifier (`none`) for **Configuration Parameters > All Parameters > MAT-file variable name modifier**. Other system target files might not support this parameter.

Override Default MAT-File Name or Buffer Size

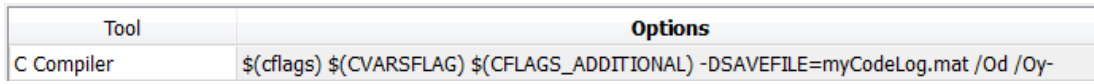
You can specify compiler options to override the following MAT-file attributes in generated code:

MAT-File Attribute	Default	Compiler Option
Name	*`model`*`.mat`	`-DSAVEFILE=`*`filename`*
Size of data logging buffer	1024 bytes	`-DDEFAULT_BUFFER_SIZE=`*`n`*

Note: Valid option syntax can vary among compilers. For example, Microsoft Visual C++ compilers typically accept `/DSAVEFILE=`*`filename`* as well as `-DSAVEFILE=`*`filename`*.

For a template makefile (TMF) based target, append the compiler option to the **Make command** field on the **Code Generation** pane of the Configuration Parameters dialog box. For example:

For a toolchain-based target such as GRT or ERT, add the compiler option to the **Build configuration** settings on the **Code Generation** pane of the Configuration Parameters dialog box. Set **Build configuration** to `Specify`, and add the compiler option to the **C Compiler** row of the **Tool/Options** table. For example:



To add the compiler option to a custom toolchain, you can modify and reregister the custom toolchain using the procedures shown in the example “Adding a Custom

Toolchain" (MATLAB Coder). For example, to add the compiler option to the MATLAB source file for the custom toolchain, you could define `myCompilerOpts` as follows:

```
optimsOffOpts    = {'/c /Od'};
optimsOnOpts     = {'/c /O2'};
cCompilerOpts    = '$(cflags) $(CVARSFLAG) $(CFLAGS_ADDITIONAL)';
cppCompilerOpts  = '$(cflags) $(CVARSFLAG) $(CPPFLAGS_ADDITIONAL)';
myCompilerOpts   = {' -DSAVEFILE=myCodeLog.mat '};
...
```

Then you can add `myCompilerOpts` to the flags for each configuration and compiler to which it applies, for example:

```
cfg = tc.getBuildConfiguration('Faster Builds');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, myCompilerOpts, optimsOffOpts));
```

As shown in "Adding a Custom Toolchain" (MATLAB Coder), after modifying the custom toolchain, you save the configuration to a MAT-file and refresh the target registry.

Log Data with Scope and To Workspace Blocks

The code generated by the code generator also logs data from these sources:

- Scope blocks that have the **Log data to workspace** parameter enabled

  You must specify the variable name and data format in each Scope block's dialog box.
- To Workspace blocks in the model

  You must specify the variable name and data format in each To Workspace block's dialog box.

The variables are written to `model.mat`, along with variables logged from the **Workspace I/O** pane.

Log Data with To File Blocks

You can also log data to a To File block. The generated program creates a separate MAT-file (distinct from `model.mat`) for each To File block in the model. The file contains the block time and input variable(s). You must specify the filename, variable names, decimation, and sample time in the To File block dialog box.

Note: Models referenced by Model blocks do not perform data logging in that context except for states, which you can include in the state logged for top models. Code

generated by the Simulink Coder software for referenced models does not perform data logging to MAT-files.

Data Logging Differences Between Single- and Multitasking

When logging data in single-tasking and multitasking systems, you will notice differences in the logging of

- Noncontinuous root Outport blocks
- Discrete states

In multitasking mode, the logging of states and outputs is done after the first task execution (and not at the end of the first time step). In single-tasking mode, the code generated by the build procedure logs states and outputs after the first time step.

See Data Logging in Single-Tasking and Multitasking Model Execution (Simulink Coder) for more details on the differences between single-tasking and multitasking data logging.

Note: The rapid simulation target (RSim) provides enhanced logging options. See "Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File" (Simulink Coder) for more information.

Data Interchange Using the C API in Simulink Coder

Exchange Data Between Generated and External Code Using C API

Some Simulink Coder applications must interact with signals, states, root-level inputs/outputs, or parameters in the generated code for a model. For example, calibration applications monitor and modify parameters. Signal monitoring or data logging applications interface with signal, state, and root-level input/output data. Using the Simulink Coder C API, you can build target applications that log signals, states, and root-level inputs/outputs, monitor signals, states, and root-level inputs/outputs, and tune parameters, while the generated code executes.

The C API minimizes its memory footprint by sharing information common to signals, states, root-level inputs/outputs, and parameters in smaller structures. Signal, state, root-level input/output, and parameter structures include an index into the structure map, allowing multiple signals, states, root-level inputs/outputs, or parameters to share data.

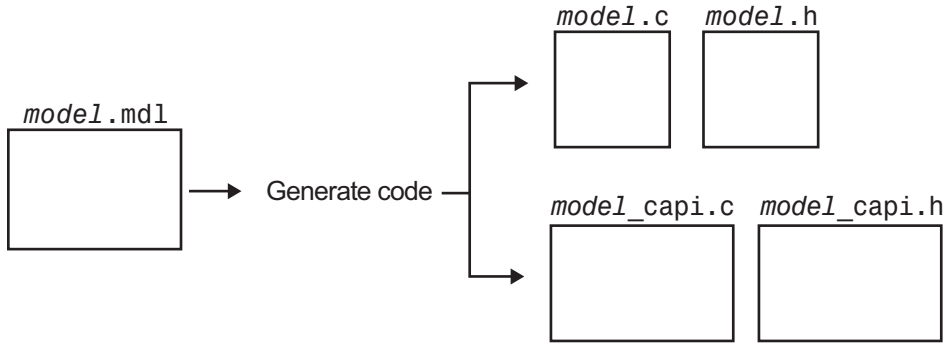
To get started with an example, see "Use C API to Access Model Signals and States" on page 43-24 or "Use C API to Access Model Parameters" on page 43-30.

In this section...

Generated C API Files

When you configure a model to use the C API, the Simulink Coder code generator generates two additional files, *`model`*`_capi.c` (or `.cpp`) and *`model`*`_capi.h`, where *`model`* is the name of the model. The code generator places the two C API files in the build folder, based on settings in the Configuration Parameters dialog box. The C API source code file contains information about global block output signals, states, root-level inputs/outputs, and global parameters defined in the generated code model source code. The C API header file is an interface header file between the model source code and

the generated C API. You can use the information in these C API files to create your application. Among the files generated are those shown in the next figure.



Generated Files with C API Selected

Note: When you configure the code generator to produce code that includes support for the C API interface and data logging, the code generator can include text for block names in the block paths logged to C API files *model*`_capi.c` (or `.cpp`) and *model*`_capi.h`. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ア with the escape sequence `&#x30A2;`. For more information, see "Internationalization and Code Generation" (Simulink Coder).

Generate C API Files

To generate C API files for your model:

1. Select the C API interface for your model. There are two ways to select the C API interface for your model, as described in the following sections.
   - "Select C API with Configuration Parameters Dialog" on page 43-4
   - "Select C API from the Command Line" on page 43-4
2. Generate code for your model.

After generating code, you can examine the files *model*`_capi.c` (or `.cpp`) and *model*`_capi.h` in the model build folder.

Select C API with Configuration Parameters Dialog

1. Open your model, and open the Configuration Parameters dialog box.
2. Go to the **Code Generation** > **Interface** pane and, in the **Data exchange interface** subgroup, select one or more `C API` options. Based on the options you select, support for accessing signals, parameters, states, and root-level I/O will appear in the C API generated code.

   - If you want to generate C API code for global block output signals, select **Generate C API for: signals**.
   - If you want to generate C API code for global block parameters, select **Generate C API for: parameters**.
   - If you want to generate C API code for discrete and continuous states, select **Generate C API for: states**.
   - If you want to generate C API code for root-level inputs and outputs, select **Generate C API for: root-level I/O**.

Select C API from the Command Line

From the MATLAB command line, you can use the `set_param` function to select or clear the C API check boxes on the **Interface** pane of the Configuration Parameters dialog box. At the MATLAB command line, enter one or more of the following commands, where `modelname` is the name of your model.

To select **Generate C API for: signals**, enter:

```
set_param('modelname','RTWCAPISignals','on')
```

To clear **Generate C API for: signals**, enter:

```
set_param('modelname','RTWCAPISignals','off')
```

To select **Generate C API for: parameters**, enter:

```
set_param('modelname','RTWCAPIParams','on')
```

To clear **Generate C API for: parameters**, enter:

```
set_param('modelname','RTWCAPIParams','off')
```

To select **Generate C API for: states**, enter:

```
set_param('modelname','RTWCAPIStates','on')
```

To clear **Generate C API for: states**, enter:

```
set_param('modelname','RTWCAPIStates','off')
```

To select **Generate C API for: root-level I/O**, enter:

```
set_param('modelname','RTWCAPIRootIO','on')
```

To clear **Generate C API for: root-level I/O**, enter:

```
set_param('modelname','RTWCAPIRootIO','off')
```

Description of C API Files

About C API Files

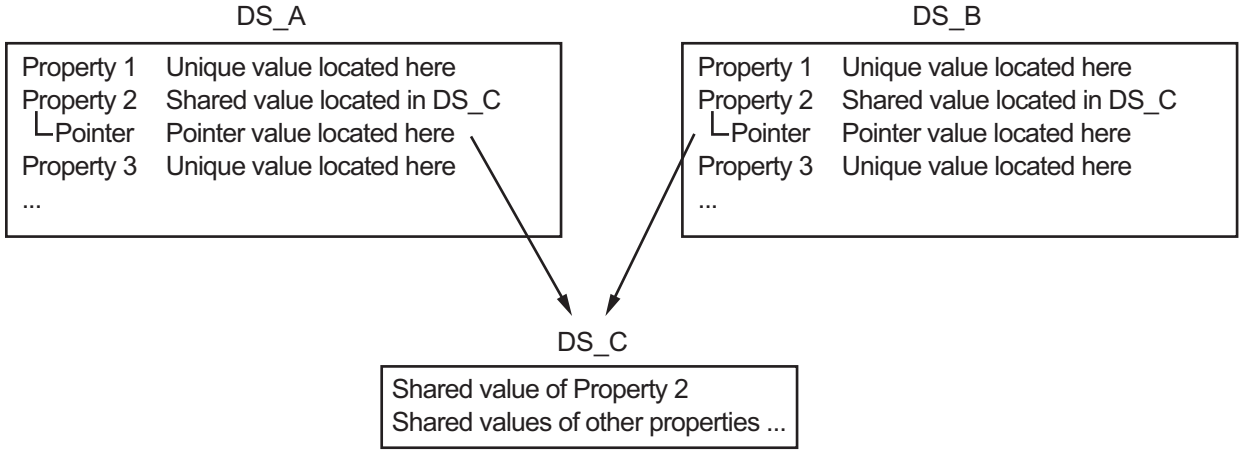
The *`model`*`_capi.c` (or `.cpp`) file provides external applications with a consistent interface to model data. Depending on your configuration settings, the data could be a signal, state, root-level input or output, or parameter. In this document, the term *data item* refers to either a signal, a state, a root-level input or output, or a parameter. The C API uses structures that provide an interface to the data item properties. The interface packages the properties of each data item in a data structure. If the model contains multiple data items, the interface generates an array of data structures. The members of a data structure map to data properties.

To interface with data items, an application requires the following properties for each data item:

- Name

- Block path
- Port number (for signals and root-level inputs/outputs only)
- Address
- Data type information: native data type, data size, complexity, and other attributes
- Dimensions information: number of rows, number of columns, and data orientation (scalar, vector, matrix, or *n*-dimensional)
- Fixed-point information: slope, bias, scale type, word length, exponent, and other attributes
- Sample-time information (for signals, states, and root-level inputs/outputs only): sample time, task identifier, frames

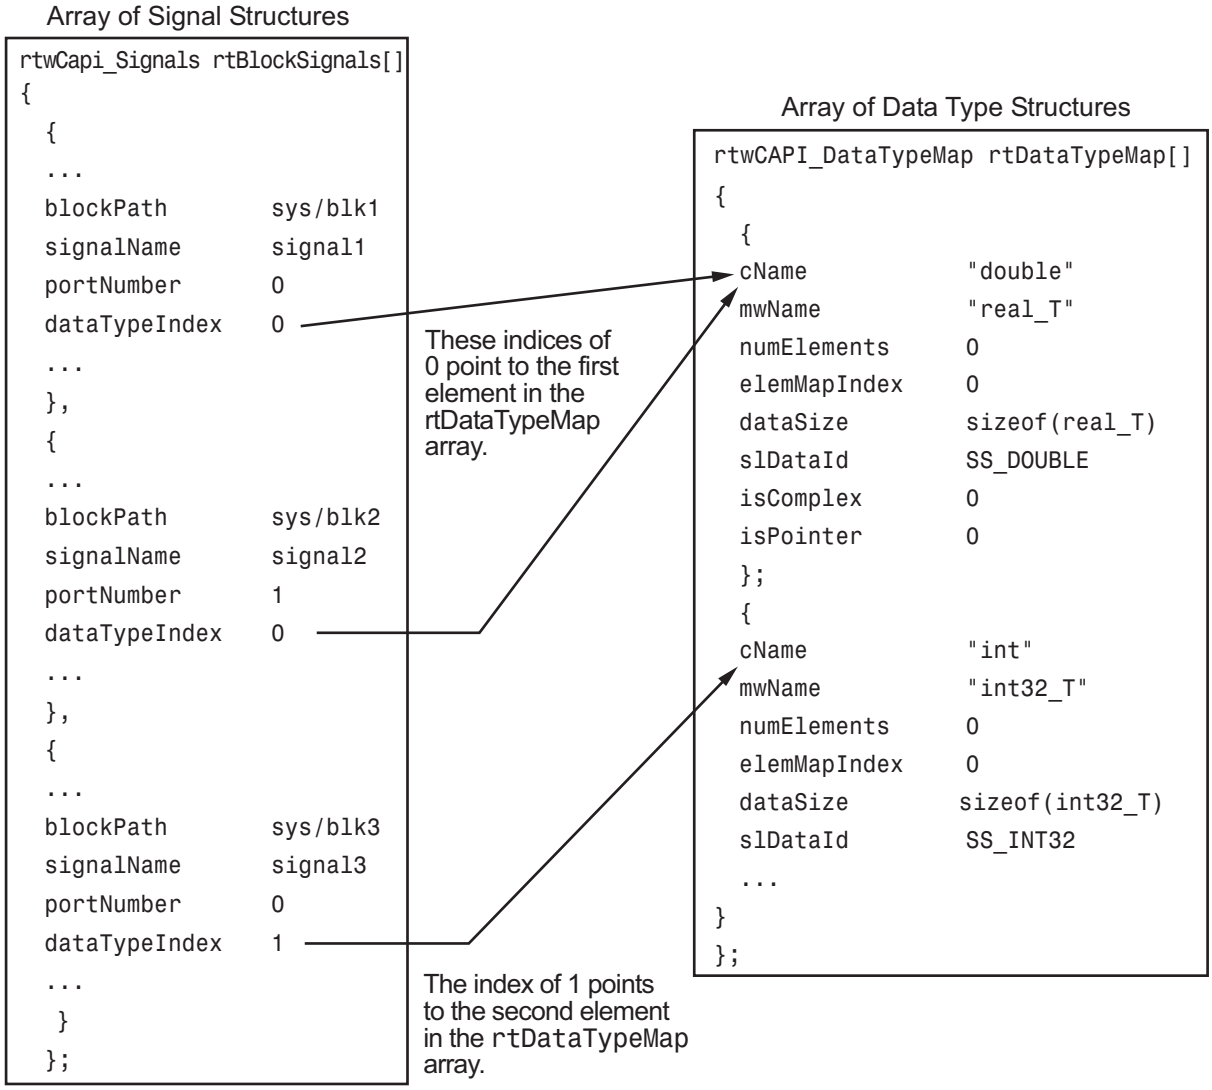
As illustrated in the next figure, the properties of data item A, for example, are located in data structure DS_A. The properties of data item B are located in data structure DS_B.



Some property *values* can be unique to each data item, and there are some property values that several data items can share in common. Name, for example, has a unique value for each data item. The interface places the unique property values directly in the structure for the data item. The name value of data item A is in DS_A, and the name value of data item B is in DS_B.

But data type could be a property whose value several data items have in common. The ability of some data items to share a property allows the C API to have a reuse feature. In this case, the interface places only an index value in DS_A and an index value in

DS_B. These indices point to a different data structure, DS_C, that contains the actual data type value. The next figure shows this scheme with more detail.



The figure shows three signals. `signal1` and `signal2` share the same data type, `double`. Instead of specifying this data type value in each signal data structure, the

interface provides only an index value, 0, in the structure. `"double"` is described by entry 0 in the `rtDataTypeMap` array, which is referenced by both signals. Additionally, property values can be shared between signals, states, root-level inputs/outputs, and parameters, so states, root-level inputs/outputs, and parameters also might reference the `double` entry in the `rtDataTypeMap` array. This reuse of information reduces the memory size of the generated interface.

Structure Arrays Generated in C API Files

As with data type, the interface maps other common properties (such as address, dimension, fixed-point scaling, and sample time) into separate structures and provides an index in the structure for the data item. For a complete list of structure definitions, refer to the file *`matlabroot`*`/rtw/c/src/rtw_capi.h`. This file also describes each member in a structure. The structure arrays generated in the *`model`*`_capi.c` (or `.cpp`) file are of structure types defined in the `rtw_capi.h` file. Here is a brief description of the structure arrays generated in *`model`*`_capi.c` (or `.cpp`):

- **`rtBlockSignals`** is an array of structures that contains information about global block output signals in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the signal name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **`rtBlockParameters`** is an array of structures that contains information about the tunable block parameters in the model by block name and parameter name. Each element in the array is of type `struct rtwCAPI_BlockParameters`. The members of this structure provide the parameter name, block path, address, and indices to data type, dimension, and fixed-point structure arrays.
- **`rtBlockStates`** is an array of structures that contains information about discrete and continuous states in the model. Each element in the array is of type `struct rtwCAPI_States`. The members of this structure provide the state name, block path, type (continuous or discrete), and indices to the address, data type, dimension, fixed-point, and sample-time structure arrays.
- **`rtRootInputs`** is an array of structures that contains information about root-level inputs in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the root-level input name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **`rtRootOutputs`** is an array of structures that contains information about root-level outputs in the model. Each element in the array is of type `struct`

`rtwCAPI_Signals`. The members of this structure provide the root-level output name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.

- **`rtModelParameters`** is an array of structures that contains information about workplace variables that one or more blocks or Stateflow charts in the model reference as block parameters. Each element in the array is of data type `rtwCAPI_ModelParameters`. The members of this structure provide the variable name, address, and indices to data type, dimension, and fixed-point structure arrays.
- **`rtDataAddrMap`** is an array of base addresses of signals, states, root-level inputs/outputs, and parameters that appear in the `rtBlockSignals`, `rtBlockParameters`, `rtBlockStates`, and `rtModelParameters` arrays. Each element of the `rtDataAddrMap` array is a pointer to `void (void*)`.
- **`rtDataTypeMap`** is an array of structures that contains information about the various data types in the model. Each element of this array is of type `struct rtwCAPI_DataTypeMap`. The members of this structure provide the data type name, size of the data type, and information on whether or not the data is complex.
- **`rtDimensionMap`** is an array of structures that contains information about the various data dimensions in the model. Each element of this array is of type `struct rtwCAPI_DimensionMap`. The members of this structure provide information on the number of dimensions in the data, the orientation of the data (whether it is scalar, vector, or a matrix), and the actual dimensions of the data.
- **`rtFixPtMap`** is an array of structures that contains fixed-point information about the signals, states, root-level inputs/outputs, and parameters. Each element of this array is of type `struct rtwCAPI_FixPtMap`. The members of this structure provide information about the data scaling, bias, exponent, and whether or not the fixed-point data is signed. If the model does not have fixed-point data (signal, state, root-level input/output, or parameter), the Simulink Coder software assigns `NULL` or zero values to the elements of the `rtFixPtMap` array.
- **`rtSampleTimeMap`** is an array of structures that contains sampling information about the global signals, states, and root-level inputs/outputs in the model. (This array does not contain information about parameters.) Each element of this array is of type `struct rtwCAPI_SampleTimeMap`. The members of this structure provide information about the sample period, offset, and whether or not the data is frame-based or sample-based.

Generate Example C API Files

Subtopics “C API Signals” on page 43-11, “C API States” on page 43-14, “C API Root-Level Inputs and Outputs” on page 43-15, and “C API Parameters” on page

43-16 discuss generated C API structures using the example model `rtwdemo_capi`. To generate code from the example model, do the following:

1. Open the model by clicking the `rtwdemo_capi` link above or by typing `rtwdemo_capi` on the MATLAB command line.
2. If you want to generate C API structures for root-level inputs/outputs in `rtwdemo_capi`, open the Configuration Parameters dialog box, go to the **Code Generation** > **Interface** pane, and select **Generate C API for: root-level I/O**.

   Note: The setting of **Generate C API for: root-level I/O** must match between the top model and the referenced model. If you modify the option, save the top model and the referenced model to the same writable work folder.
3. Generate code for the model by double-clicking **Generate Code Using Simulink Coder**.

Note: The C API code examples in the next subtopics are generated with C as the target language.

This model has three global block output signals that will appear in C API generated code:

- `top_sig1`, which is a test point at the output of the Gain1 block in the top model
- `sig2_eg`, which appears in the top model and is defined in the base workspace as a `Simulink.Signal` object having storage class `ExportedGlobal`
- `bot_sig1`, which appears in the referenced model `rtwdemo_capi_bot` and is defined as a `Simulink.Signal` object having storage class `SimulinkGlobal`

The model also has two discrete states that will appear in the C API generated code:

- `top_state`, which is defined for the Delay1 block in the top model
- `bot_state`, which is defined for the Discrete Filter block in the referenced model

The model has root-level inputs/outputs that will appear in the C API generated code if you select the option **Generate C API for: root-level I/O**:

- Four root-level inputs, `In1` through `In4`
- Six root-level outputs, `Out1` through `Out6`

Additionally, the model has five global block parameters that will appear in C API generated code:

- `Kp` (top model `Gain1` block and referenced model `Gain2` block share)
- `Ki` (referenced model `Gain3` block)
- `p1` (lookup table `lu1d`)
- `p2` (lookup table `lu2d`)
- `p3` (lookup table `lu3d`)

C API Signals

The `rtwCAPI_Signals` structure captures signal information including the signal name, address, block path, output port number, data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API signals for the top model in `rtwdemo_capi`:

```
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 0, 0, "rtwdemo_capi/Gain1",
    "top_sig1", 0, 0, 0, 0, 0 },

  { 1, 0, "rtwdemo_capi/lu2d",
    "sig2_eg", 0, 0, 1, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

Note To better understand the code, read the comments in the file. For example, notice the comment that begins on the third line in the preceding code. This comment lists the members of the `rtwCAPI_Signals` structure, in order. This tells you the order in which the assigned values for each member appear for a signal. In this example, the comment tells you that `signalName` is the fourth member of the structure. The following lines describe the first signal:

```
{ 0, 0, "rtwdemo_capi/Gain1",
  "top_sig1", 0, 0, 0, 0, 0 },
```

From these lines you infer that the name of the first signal is `top_sig1`.

Each array element, except the last, describes one output port for a block signal. The final array element is a sentinel, with all elements set to null values. For example, examine the second signal, described by the following code:

```
  { 1, 0, "rtwdemo_capi/lu2d",
    "sig2_eg", 0, 0, 1, 0, 0 },
```

This signal, named `sig2_eg`, is the output signal of the first port of the block `rtwdemo_capi/lu2d`. (This port is the first port because the zero-based index for `portNumber` displayed on the second line is assigned the value `0`.)

The address of this signal is given by `addrMapIndex`, which, in this example, is displayed on the first line as `1`. This provides an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`:

```
/* Declare Data Addresses statically */
static void* rtDataAddrMap[] = {
  &rtwdemo_capi_B.top_sig1,            /* 0: Signal */
  &sig2_eg[0],                         /* 1: Signal */
  &rtwdemo_capi_DWork.top_state,       /* 2: Discrete State */
  &rtP_Ki,                             /* 3: Model Parameter */
  &rtP_Kp,                             /* 4: Model Parameter */
  &rtP_p1[0],                          /* 5: Model Parameter */
  &rtP_p2[0],                          /* 6: Model Parameter */
  &rtP_p3[0],                          /* 7: Model Parameter */
};
```

The index of `1` points to the second element in the `rtDataAddrMap` array. From the `rtDataAddrMap` array, you can infer that the address of this signal is `&sig2_eg[0]`.

This level of indirection supports multiple code instances of the same model. For multiple instances, the signal information remains constant, except for the address. In this case, the model is a single instance. Therefore, the `rtDataAddrMap` is declared statically. If you choose to generate reusable code, an initialize function is generated that initializes the addresses dynamically per instance. For details on generating reusable code, see "Entry-Point Functions and Scheduling" (Simulink Coder) and see "Configure Code Reuse Support" on page 30-15.

The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the signal:

```
/* Data Type Map - use dataTypeMapIndex to access this structure */
static const rtwCAPI_DataTypeMap rtDataTypeMap[] = {
  /* cName, mwName, numElements, elemMapIndex, dataSize, slDataId, *
   * isComplex, isPointer */
  { "double", "real_T", 0, 0, sizeof(real_T), SS_DOUBLE, 0, 0 }
};
```

Because the index is `0` for `sig2_eg`, the index points to the first structure element in the array. You can infer that the data type of the signal is `double`. The value of `isComplex` is `0`, indicating that the signal is not complex. Rather than providing the data type information directly in the `rtwCAPI_Signals` structure, a level of indirection is introduced. The indirection allows multiple signals that share the same data type to point to one map structure, saving memory for each signal.

The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`, indicating the dimensions of the signal. Because this index is `1` for `sig2_eg`, the index points to the second element in the `rtDimensionMap` array:

```
/* Dimension Map - use dimensionMapIndex to access elements of ths structure*/
static const rtwCAPI_DimensionMap rtDimensionMap[] = {
  /* dataOrientation, dimArrayIndex, numDims, vardimsIndex */
  { rtwCAPI_SCALAR, 0, 2, 0 },

  { rtwCAPI_VECTOR, 2, 2, 0 },
...
};
```

From this structure, you can infer that this is a nonscalar signal having a dimension of `2`. The `dimArrayIndex` value, 2, provides an index into `rtDimensionArray`, found later in `rtwdemo_capi_capi.c`:

```
/* Dimension Array- use dimArrayIndex to access elements of this array */
static const uint_T rtDimensionArray[] = {
  1,                                   /* 0 */
  1,                                   /* 1 */
  2,                                   /* 2 */
...
};
```

The `fxpIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the signal. Your code can use the scaling information to compute the real-world value of the signal, using the equation `V=SQ+B`, where V is "real-world" (that is, base-10) value, S is user-specified slope, Q is "quantized fixed-point value" or "stored integer," and B is user-specified bias. For details, see "Scaling" (Fixed-Point Designer).

Because this index is `0` for `sig2_eg`, the signal does not have fixed-point information. A fixed-point map index of zero means that the signal does not have fixed-point information.

The `sTimeIndex` (sample-time index) provides the index to the `rtSampleTimeMap` array, found later in `rtwdemo_capi_capi.c`, indicating task information about the

signal. If you log multirate signals or conditionally executed signals, the sampling information can be useful.

Note: *model*_capi.c (or .cpp) includes rtw_capi.h. A source file that references the rtBlockSignals array also must include rtw_capi.h.

C API States

The rtwCAPI_States structure captures state information including the state name, address, block path, type (continuous or discrete), data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in rtwdemo_capi_capi.c that provides information on C API states for the top model in rtwdemo_capi:

```
/* Block states information */
static const rtwCAPI_States rtBlockStates[] = {
  /* addrMapIndex, contStateStartIndex, blockPath,
   * stateName, pathAlias, dWorkIndex, dataTypeIndex, dimIndex,
   * fixPtIdx, sTimeIndex, isContinuous
   */
  { 2, -1, "rtwdemo_capi/Delay1",
    "top_state", "", 0, 0, 0, 0, 0, 0 },

  {
    0, -1, (NULL), (NULL), (NULL), 0, 0, 0, 0, 0, 0
  }
};
```

Each array element, except the last, describes a state in the model. The final array element is a sentinel, with all elements set to null values. In this example, the C API code for the top model displays one state:

```
{ 2, -1, "rtwdemo_capi/Delay1",
  "top_state", "", 0, 0, 0, 0, 0, 0 },
```

This state, named top_state, is defined for the block rtwdemo_capi/Delay1. The value of isContinuous is zero, indicating that the state is discrete rather than continuous. The other fields correspond to the like-named signal equivalents described in "C API Signals" on page 43-11, as follows:

- The address of the signal is given by addrMapIndex, which, in this example, is 2. This is an index into the rtDataAddrMap array, found later in

`rtwdemo_capi_capi.c`. Because the index is zero based, `2` corresponds to the third element in `rtDataAddrMap`, which is `&rtwdemo_capi_DWork.top_state`.

- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 0 corresponds to the first entry, which is `{ rtwCAPI_SCALAR, 0, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

C API Root-Level Inputs and Outputs

The `rtwCAPI_Signals` structure captures root-level input/output information including the input/output name, address, block path, port number, data type information, dimensions information, fixed-point information, and sample-time information. (This structure also is used for block output signals, as previously described in "C API Signals" on page 43-11.)

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API root-level inputs/outputs for the top model in `rtwdemo_capi`:

```
/* Root Inputs information */
static const rtwCAPI_Signals rtRootInputs[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 3, 0, "rtwdemo_capi/In1",
    "", 1, 0, 0, 0, 0 },

  { 4, 0, "rtwdemo_capi/In2",
    "", 2, 0, 0, 0, 0 },

  { 5, 0, "rtwdemo_capi/In3",
    "", 3, 0, 0, 0, 0 },

  { 6, 0, "rtwdemo_capi/In4",
    "", 4, 0, 0, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

```
/* Root Outputs information */
static const rtwCAPI_Signals rtRootOutputs[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 7, 0, "rtwdemo_capi/Out1",
    "", 1, 0, 0, 0, 0 },

  { 8, 0, "rtwdemo_capi/Out2",
    "", 2, 0, 0, 0, 0 },

  { 9, 0, "rtwdemo_capi/Out3",
    "", 3, 0, 0, 0, 0 },

  { 10, 0, "rtwdemo_capi/Out4",
    "", 4, 0, 0, 0, 0 },

  { 11, 0, "rtwdemo_capi/Out5",
    "sig2_eg", 5, 0, 1, 0, 0 },

  { 12, 0, "rtwdemo_capi/Out6",
    "", 6, 0, 1, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

For information about interpreting the values in the `rtwCAPI_Signals` structure, see the previous section "C API Signals" on page 43-11.

C API Parameters

The `rtwCAPI_BlockParameters` and `rtwCAPI_ModelParameters` structures capture parameter information including the parameter name, block path (for block parameters), address, data type information, dimensions information, and fixed-point information.

The `rtModelParameters` array contains entries for workspace variables that are referenced as tunable Simulink block parameters or Stateflow data of machine scope. For example, tunable parameters include `Simulink.Parameter` objects that use a storage class other than `Auto`. The Simulink Coder software assigns its elements only `NULL` or zero values in the absence of such data.

The setting that you choose for **Configuration Parameters** > **Optimization** > **Signals and Parameters** > **Default parameter behavior** determines how information is generated into the `rtBlockParameters` array in *`model`*`_capi.c` (or `.cpp`).

- If you set **Default parameter behavior** to `Tunable`, the `rtBlockParameters` array contains an entry for every modifiable parameter of every block in the model.

However, if you use a MATLAB variable or a tunable parameter to specify a block parameter, the block parameter does not appear in `rtBlockParameters`. Instead, the variable or tunable parameter appears in `rtModelParameters`.

- If you set **Default parameter behavior** to `Inlined`, the `rtBlockParameters` array is empty. The Simulink Coder software assigns its elements only `NULL` or zero values.

The last member of each array is a sentinel, with all elements set to null values.

Here is the `rtBlockParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Individual block tuning is not valid when inline parameters is *
 * selected. An empty map is produced to provide a consistent     *
 * interface independent  of inlining parameters.                 *
 */
static const rtwCAPI_BlockParameters rtBlockParameters[] = {
  /* addrMapIndex, blockPath,
   * paramName, dataTypeIndex, dimIndex, fixPtIdx
   */
  {
    0, (NULL), (NULL), 0, 0, 0
  }
};
```

In this example, only the final, sentinel array element is generated, with all members of the structure `rtwCAPI_BlockParameters` set to `NULL` and zero values. This is because **Default parameter behavior** is set to `Inlined` by default for the `rtwdemo_capi` example model. If you set **Default parameter behavior** to `Tunable`, the block parameters are generated in the `rtwCAPI_BlockParameters` structure. However, MATLAB variables and tunable parameters appear in the `rtwCAPI_ModelParameters` structure.

Here is the `rtModelParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Tunable variable parameters */
static const rtwCAPI_ModelParameters rtModelParameters[] = {
  /* addrMapIndex, varName, dataTypeIndex, dimIndex, fixPtIndex */
  { 2, TARGET_STRING("Ki"), 0, 0, 0 },

  { 3, TARGET_STRING("Kp"), 0, 0, 0 },

  { 4, TARGET_STRING("p1"), 0, 2, 0 },

  { 5, TARGET_STRING("p2"), 0, 3, 0 },
```

```
  { 6, TARGET_STRING("p3"), 0, 4, 0 },

  { 0, (NULL), 0, 0, 0 }
};
```

In this example, the `rtModelParameters` array contains entries for each variable that is referenced as a tunable Simulink block parameter.

For example, the `varName` (variable name) of the fourth parameter is `p2`. The other fields correspond to the like-named signal equivalents described in "C API Signals" on page 43-11, as follows:

- The address of the fourth parameter is given by `addrMapIndex`, which, in this example, is `5`. This is an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`. Because the index is zero based, `5` corresponds to the sixth element in `rtDataAddrMap`, which is `rtP_p2`.
- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 3 corresponds to the fourth entry, which is `{ rtwCAPI_MATRIX_COL_MAJOR, 6, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

For more information about tunable parameter storage in the generated code, see "Block Parameter Representation in the Generated Code" (Simulink Coder).

Map C API Data Structures to rtModel

The real-time model data structure encapsulates model data and associated information that describes the model fully. When you select the C API feature and generate code, the Simulink Coder code generator adds another member to the real-time model data structure generated in *`model`*`.h`:

```
/*
 * DataMapInfo:
 * The following substructure contains information regarding
 * structures generated in the model's C API.
```

```
 */
struct {
  rtwCAPI_ModelMappingInfo mmi;
} DataMapInfo;
```

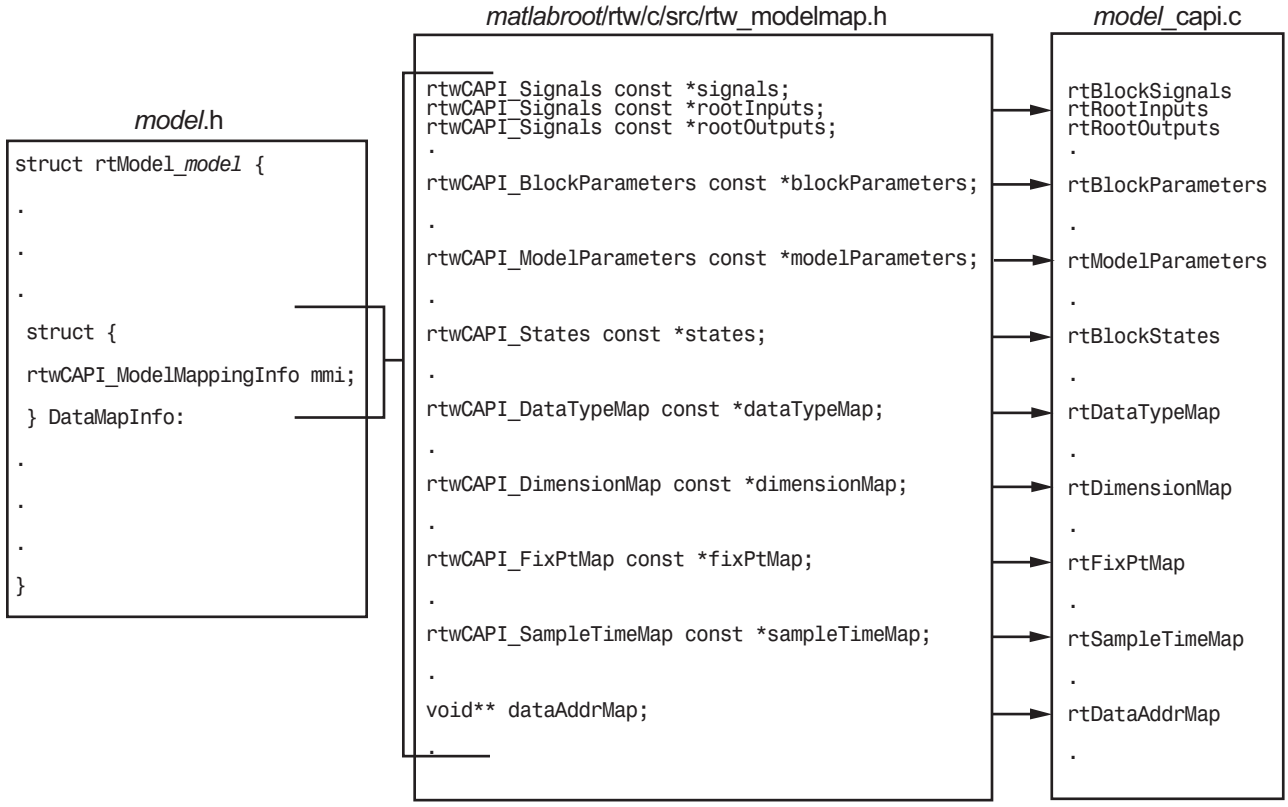
This member defines `mmi` (for model mapping information) of type `struct rtwCAPI_ModelMappingInfo`. The structure is located in *`matlabroot`*`/rtw/c/src/rtw_modelmap.h`. The `mmi` substructure defines the interface between the model and the C API files. More specifically, members of `mmi` map the real-time model data structure to the structures in *`model`*`_capi.c` (or `.cpp`).

Initializing values of `mmi` members to the arrays accomplishes the mapping, as shown in Map Model to C API Arrays of Structures. Each member points to one of the arrays of structures in the generated C API file. For example, the address of the `rtBlockSignals` array of structures is allocated to the first member of the `mmi` substructure in *`model`*`.c` (or `.cpp`), using the following code in the `rtw_modelmap.h` file:

```
/* signals */
struct {
    rtwCAPI_Signals const *signals;     /* Signals Array */
    uint_T                numSignals;   /* Num Signals   */
    rtwCAPI_Signals const *rootInputs;  /* Root Inputs array */
    uint_T               numRootInputs; /* Num Root Inputs  */
    rtwCAPI_Signals const *rootOutputs; /* Root Outputs array */
    uint_T               numRootOutputs;/* Num Root Outputs  */
} Signals;
```

The model initialize function in *`model`*`.c` (or `.cpp`) performs the initializing by calling the C API initialize function. For example, the following code is generated in the model initialize function for example model `rtwdemo_capi`:

```
/* Initialize DataMapInfo substructure containing ModelMap for C API */
rtwdemo_capi_InitializeDataMapInfo(rtwdemo_capi_M);
```



Map Model to C API Arrays of Structures

Note: This figure lists the arrays in the order that their structures appear in `rtw_modelmap.h`, which differs slightly from their generated order in *`model`*`_capi.c`.

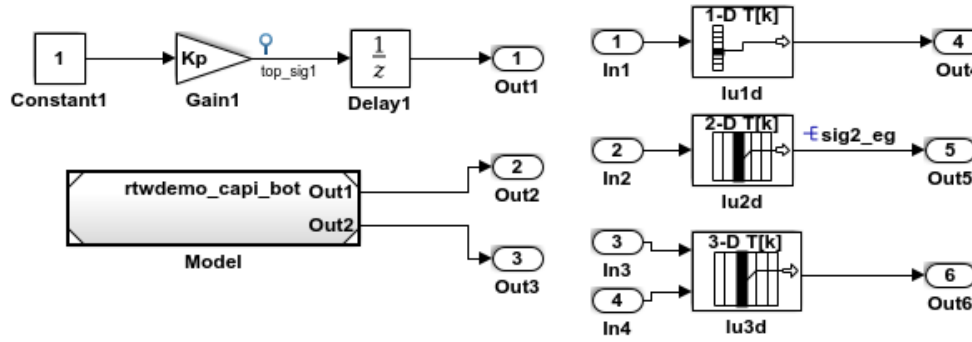
Generate C API Data Definition File for Exchanging Data with a Target System

This model illustrates the target-based C API for interfacing signals, parameters, and states in the generated code.

Open Example Model

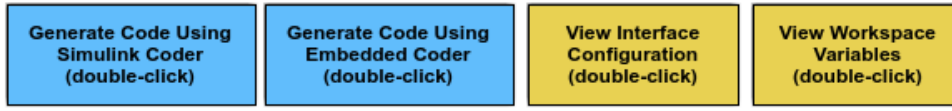
Open the example model `rtwdemo_capi`.

```
open_system('rtwdemo_capi');
```



This model illustrates the target-based C API for interfacing signals, parameters and states in the generated code. The C API is useful for real-time interaction with the data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The purpose of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You can enable the C API by selecting one or more C API options on the "Code Generation > Interface" pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in <model>_capi.c. Note that signals, states and parameters in the referenced model can be accessed using C-API. So make sure that C-API is enabled for the referenced model.



The C API is useful for real-time interaction with application data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The

purpose of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You enable the C API by selecting one or more C API options on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in *`model`*`_capi.c`. Note that signals, states, and parameters in the referenced model can be accessed using C API. So make sure that C API is enabled for the referenced model.

C API Limitations

The C API feature has the following limitations.

- The C API does not support the following values for the `CodeFormat` TLC variable:
  - `S-Function`
  - `Accelerator_S-Function` (for accelerated simulation)
- For ERT-based targets, the C API requires that support for floating-point code be enabled.
- Local block output signals are not supported.
- Local Stateflow parameters are not supported.
- The following custom storage class objects are not supported:
  - Objects without the package `csc_registration` file
  - Grouped custom storage classes
  - Objects defined by using macros
  - `BitField` objects
  - `FileScope` objects
- Customized data placement is disabled when you are using the C API. The interface looks for global data declaration in *`model`*`.h` and *`model`*`_private.h`. Declarations placed in any other file by customized data placement result in code that does not compile.

Note Custom Storage Class objects work in code generation, only if you use the ERT target and clear the **Ignore custom storage classes** check box in the Configuration Parameters dialog box.

Use C API to Access Model Signals and States

This example helps you get started writing application code to interact with model signals and states. To get started writing application code to interact with model parameters, see "Use C API to Access Model Parameters" on page 43-30.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in *model*_capi.c (or .cpp). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files rtw_modelmap.h and rtw_capi.h, located in *matlabroot*/rtw/c/src (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that logs global signals and states in a model to a text file. This code is intended as a starting point for accessing signal and state addresses. You can extend the code to perform signal logging and monitoring, state logging and monitoring, or both.

This example uses the following macro and function interfaces:

- rtmGetDataMapInfo macro

  Accesses the model mapping information (MMI) substructure of the real-time model structure. In the following macro call, rtM is the pointer to the real-time model structure in *model*.c (or .cpp):

  ```
  rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
  ```

- rtmGetTPtr macro

  Accesses the absolute time information for the base rate from the timing substructure of the real-time model structure. In the following macro call, rtM is the pointer to the real-time model structure in *model*.c (or .cpp):

  ```
  rtmGetTPtr(rtM)
  ```

- Custom functions capi_StartLogging, capi_UpdateLogging, and capi_TerminateLogging, provided via the files rtwdemo_capi_datalog.h and rtwdemo_capi_datalog.c. These files are located in *matlabroot*/toolbox/rtw/rtwdemos (open).

- `capi_StartLogging` initializes signal and state logging.
- `capi_UpdateLogging` logs a signal and state value at each time step.
- `capi_TerminateLogging` terminates signal and state logging and writes the logged values to a text file.

You can integrate these custom functions into generated model code using one or more of the following methods:

- **Code Generation** > **Custom Code** pane of the Configuration Parameters dialog box
- Custom Code library blocks
- TLC custom code functions

This tutorial uses the **Code Generation** > **Custom Code** pane and the System Outputs block from the Custom Code library to insert calls to the custom functions into *`model`*`.c` (or `.cpp`), as follows:

- `capi_StartLogging` is called in the *`model`*`_initialize` function.
- `capi_UpdateLogging` is called in the *`model`*`_step` function.
- `capi_TerminateLogging` is called in the *`model`*`_terminate` function.

The following excerpts of generated code from *`model`*`.c` (rearranged to reflect their order of execution) show how the function interfaces are used.

```
void rtwdemo_capi_initialize(void)
{
...
  /* user code (Initialize function Body) */

  /* C API Custom Logging Function: Start Signal and State logging via C API.
   * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
   */
  {
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
    printf("** Started state/signal logging via C API **\n");
    capi_StartLogging(MMI, MAX_DATA_POINTS);
  }
...
}
...
/* Model step function */
void rtwdemo_capi_step(void)
{
...
  /* user code (Output function Trailer) */

  /* System '<Root>' */
```

```
  /* C API Custom Logging Function: Update Signal and State logging buffers.
   * capi_UpdateLogging: Function prototype in rtwdemo_capi_datalog.h
   */
  {
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
    capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
  }
...
}
...
/* Model terminate function */
void rtwdemo_capi_terminate(void)
{
  /* user code (Terminate function Body) */

  /* C API Custom Logging Function: Dump Signal and State buffers into a text file.
   * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
   */
  {
    capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
    printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
  }
}
```

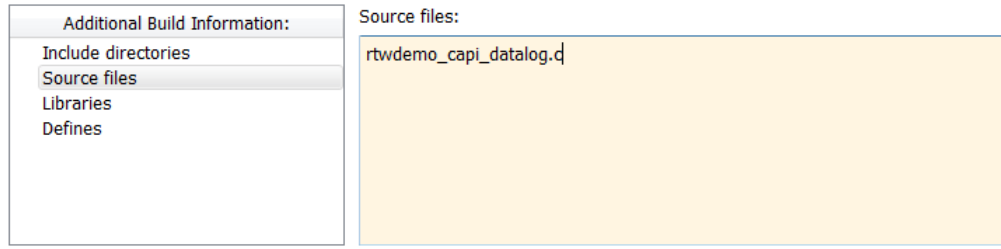
The following procedure illustrates how you can use the C API macro and function interfaces to log global signals and states in a model to a text file.

1. At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
2. Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
3. Open the Configuration Parameters dialog box.
4. If you are licensed for Embedded Coder software and you want to use the `ert.tlc` target instead of the default `grt.tlc`, go to the **Code Generation** pane and use the **System target file** field to select an `ert.tlc` target. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
5. In the top model, go to the **Code Generation** > **Interface** pane.
   a. In the **Data exchange interface** subgroup, verify that the model options **Generate C API for: signals** and **Generate C API for: states** are selected. This example also leaves **Generate C API for: parameters** selected.
   b. If you are using the `ert.tlc` system target file, verify that the option **Support: complex numbers** is selected.
   c. Click the **All Parameters** tab, and select the **MAT-file logging** option.
   d. Click **Apply**.
   e. Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.

6 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Include directories**. The **Include directories** input field is displayed.

7 In the **Include directories** field, type *`matlabroot`*`/toolbox/rtw/rtwdemos`, where *`matlabroot`* represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)

8 In the **Additional Build Information** subpane, click **Source files**, and type `rtwdemo_capi_datalog.c`.



9 In the **Include custom C code in generated** subpane, click **Source file**, and type or copy and paste the following include statement:

```
#include "rtwdemo_capi_datalog.h"
```

10 In the **Initialize function** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
  rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
  printf("** Started state/signal logging via C API **\n");
  capi_StartLogging(MMI, MAX_DATA_POINTS);
}
```

Note: If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

11 In the **Terminate function** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
```

```
  {
capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
  }
```

Click **Apply**.

12 In the MATLAB Command Window, enter `custcode` to open the Simulink Coder Custom Code library. At the top level of the `rtwdemo_capi` model, add a System Outputs block.

13 Double-click the System Outputs block to open the System Outputs Function Custom Code dialog box. In the **System Outputs Function Exit Code** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
  rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
  capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}
```

Note: If you renamed the top model `rtwdemo_capi`, update two instances of the name `rtwdemo_capi_M` in the application code to reflect the new model name.

Click **OK**.

14 On the **Code Generation** pane, verify that the **Generate code only** check box is *cleared*.

Press **Ctrl+B** to build the model and generate an executable file. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

15 In the MATLAB Command Window, enter the command `!rtwdemo_capi` to run the executable file. During execution, signals and states are logged using the C API and then written to the text file `rtwdemo_capi_ModelLog.txt` in your current working folder.

```
>> !rtwdemo_capi

** starting the model **
** Started state/signal logging via C API **
** Logging 2 signal(s) and 1 state(s). In this demo, only scalar named
 signals/states are logged **
** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **
```

16 Examine the text file in the MATLAB editor or other text editor. Here is an excerpt of the signal and state logging output.

```
******** Signal Log File ********

Use C API to Access Model Parameters

This example helps you get started writing application code to interact with model parameters. To get started writing application code to interact with model signals and states, see "Use C API to Access Model Signals and States" on page 43-24.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in *`model`*`_capi.c` (or `.cpp`). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files `rtw_modelmap.h` and `rtw_capi.h`, located in *`matlabroot`*`/rtw/c/src` (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that prints the parameter values of tunable parameters in a model to the standard output. This code is intended as a starting point for accessing parameter addresses. You can extend the code to perform parameter tuning. The application:

- Uses the `rtmGetDataMapInfo` macro to access the mapping information in the `mmi` substructure of the real-time model structure

  ```
  rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
  ```

  where `rtM` is the pointer to the real-time model structure in *`model`*`.c` (or `.cpp`).
- Uses `rtwCAPI_GetNumModelParameters` to get the number of model parameters in mapped C API:

  ```
  uint_T nModelParams = rtwCAPI_GetNumModelParameters(mmi);
  ```
- Uses `rtwCAPI_GetModelParameters` to access the array of model parameter structures mapped in C API:

  ```
  rtwCAPI_ModelParameters* capiModelParams = \
   rtwCAPI_GetModelParameters(mmi);
  ```
- Loops over the `capiModelParams` array to access individual parameter structures. A call to the function `capi_PrintModelParameter` displays the value of the parameter.

The example application code is provided below:

```
{
/* Get CAPI Mapping structure from Real-Time Model structure */
rtwCAPI_ModelMappingInfo* capiMap = \
&(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);

/* Get number of Model Parameters from capiMap */
uint_T nModelParams = rtwCAPI_GetNumModelParameters(capiMap);
printf("Number of Model Parameters: %d\n", nModelParams);

/* If the model has Model Parameters, print them using the
application capi_PrintModelParameter */
if (nModelParams == 0) {
   printf("No Tunable Model Parameters in the model \n");
}
else {
   unsigned int idx;

   for (idx=0; idx < nModelParams; idx++) {
      /* call print utility function */
      capi_PrintModelParameter(capiMap, idx);
   }
}
}
```

The print utility function is located in *`matlabroot`*`/rtw/c/src/rtw_capi_examples.c`. This file contains utility functions for accessing the C API structures.

To become familiar with the example code, try building a model that displays the tunable block parameters and MATLAB variables. You can use `rtwdemo_capi`, the C API example model. The following steps apply to both `grt.tlc` and `ert.tlc` targets, unless otherwise indicated.

1. At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
2. Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
3. If you are licensed for Embedded Coder software and you want to use the `ert.tlc` target instead of the default `grt.tlc`, go to the **Code Generation** pane of the Configuration Parameters dialog box and use the **System target file** field to select an `ert.tlc` target. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
4. Go to the **Code Generation** > **Interface** pane.

a In the **Data exchange interface** subgroup, verify that the model option **Generate C API for: parameters** is selected.

b If you are using the `ert.tlc` system target file, verify that the option **Support: complex numbers** is selected.

c Click the **All Parameters** tab, and select the **MAT-file logging** option.

d Click **Apply**.

e Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.

5 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Initialize function**. The **Initialize function** input field is displayed.

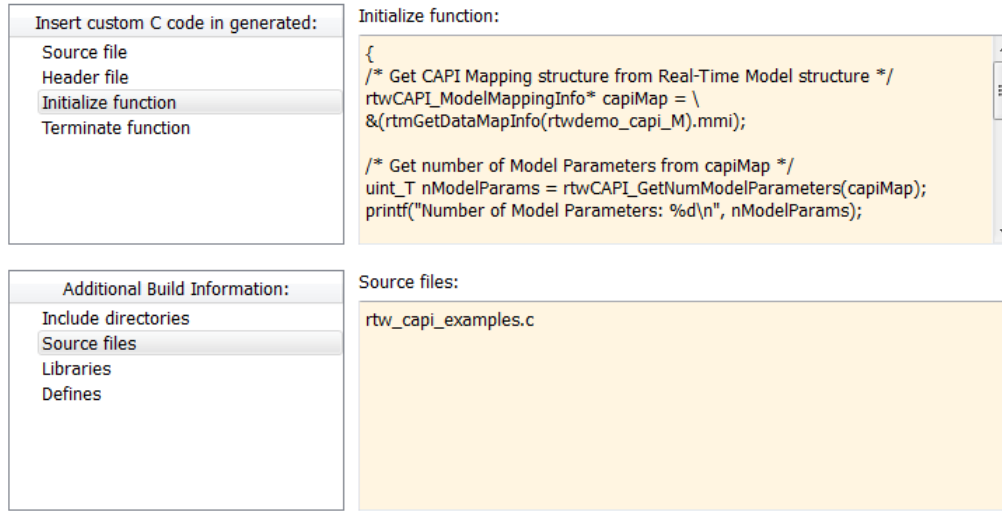
6 In the **Initialize function** input field, type or copy and paste the example application code shown above step 1. This embeds the application code in the *`model`*`_initialize` function.

Note: If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

7 Click **Include directories**, and type *`matlabroot`*`/rtw/c/src`, where *`matlabroot`* represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)

8 In the **Additional Build Information** subpane, click **Source files**, and type `rtw_capi_examples.c`.



Click **Apply**.

9 On the **Code Generation** pane, verify that the **Generate code only** check box is *cleared*.

Press **Ctrl+B** to build the model and generate an executable file. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

10 In the MATLAB Command Window, enter `!rtwdemo_capi` to run the executable file. Running the program displays parameter information in the Command Window.

```
>> !rtwdemo_capi

** starting the model **
Number of Model Parameters: 5
Ki =
     7
Kp =
     4
p1 =
    0.15
    0.36
    0.81
```

```
p2 =
    0.09    0.75    0.57
    0.13    0.96    0.059
p3 =
ans(:,:,1) =
    0.23    0.82    0.04    0.64
    0.35    0.01    0.16    0.73

ans(:,:,2) =
    0.64    0.54    0.74    0.68
    0.45    0.29    0.18    0.18
```

ASAP2 Data Measurement and Calibration in Simulink Coder

Export ASAP2 File for Data Measurement and Calibration

The ASAM MCD-2 MC standard, also known as ASAP2, is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostic systems. For more information on ASAM and the ASAM MCD-2 MC (ASAP2) standard, see the ASAM Web site at `http://www.asam.net`.

The Simulink Coder product lets you export an ASAP2 file containing information about your model during the code generation process.

You can run an interactive example of ASAP2 file generation. To open the example at the MATLAB command prompt, enter the following command:

```
rtwdemo_asap2
```

Note: Simulink Coder support for ASAP2 file generation is version-neutral. By default, the software generates ASAP2 version 1.31 format, but the generated model information is generally compatible with all ASAP2 versions. ASAP2 file generation also is neutral with respect to the specific needs of ASAP2 measurement and calibration tools. The software provides customization APIs that you can use to customize ASAP2 file generation to generate any ASAP2 version and to meet the specific needs of your ASAP2 tools.

In this section...

What You Should Know

To make use of ASAP2 file generation, you should become familiar with the following topics:

- ASAM and the ASAP2 standard and terminology. See the ASAM Web site at http://www.asam.net.
- Simulink data objects. Data objects are used to supply information not contained in the model. For an overview, see "Data Objects" (Simulink).
- Storage and representation of signals and parameters in generated code. See "Data Representation" (Simulink Coder).
- If you are licensed for Embedded Coder, see also the Embedded Coder topic "Data Representation".

Targets Supporting ASAP2

ASAP2 file generation is available to all Simulink Coder target configurations. You can select these target configurations from the System Target File Browser. For example,

- The `Generic Real-Time Target` (`grt.tlc`) lets you generate an ASAP2 file as part of the code generation and build process.
- The `Embedded Coder` (`ert.tlc`) target selections also lets you generate an ASAP2 file as part of the code generation and build process.
- The `ASAM-ASAP2 Data Definition Target` (`asap2.tlc`) lets you generate only an ASAP2 file, without building an executable.

Procedures for generating ASAP2 files by using these target configurations are given in "Generate an ASAP2 File" on page 44-9.

Define ASAP2 Information

Define ASAP2 Information for Parameters and Signals

The ASAP2 file generation process requires information about parameters and signals in your model. Some of this information is contained in the model itself. You must supply the rest by using Simulink data objects and corresponding properties.

You can use built-in Simulink data objects to provide the information. For example, you can use `Simulink.Signal` objects to provide MEASUREMENT information and `Simulink.Parameter` objects to provide CHARACTERISTIC information. Also, you can use data objects from data classes that are derived from `Simulink.Signal` and `Simulink.Parameter` to provide the information. For details, see "Data Objects" (Simulink).

The following table contains the minimum set of data attributes required for ASAP2 file generation. Some data attributes are defined in the model; others are supplied in the properties of objects. For attributes that are defined in `Simulink.Signal` or `Simulink.Parameter` objects, the table gives the associated property name.

Data Attribute	Defined In	Property Name
Name (symbol)	Data object	Inherited from the handle of the data object to which parameter or signal name resolves
Description	Data object	`Description`
Data type	Model	Not applicable
Scaling (if fixed-point data type)	Model	Data type (for signals) Inherited from value (for parameters)
Minimum allowable value	Data object	`Min`
Maximum allowable value	Data object	`Max`
Unit	Data object	`Unit`
Memory address (optional)	Data object	`MemoryAddress_ASAP2` (optional; see "Memory Address Attribute" on page 44-4.)

Memory Address Attribute

If the memory address attribute is unknown before code generation, the code generator inserts `ECU Address` placeholder text in the generated ASAP2 file. You can substitute an actual address for the placeholder by postprocessing the generated file. See the file *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/asap2post.m` for an example.

`asap2post.m` parses through the linker map file that you provide and replaces the `ECU Address` placeholders in the ASAP2 file with the actual memory addresses. Since linker map files vary from compiler to compiler, you might need to modify the regular expression code in `asap2post.m` to match the format of the linker map you use.

Note: If Embedded Coder is licensed and installed on your system, and if you are generating ELF (Executable and Linkable Format) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate ECU address replacement. For more information, see "Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)" on page 44-6.

If the memory address attribute is known before code generation, it can be defined in the data object. By default, the `MemoryAddress_ASAP2` property does not exist in the `Simulink.Signal` or `Simulink.Parameter` data object classes. If you want to add the attribute, add a property called `MemoryAddress_ASAP2` to a custom class that is a subclass of the `Simulink` or `ASAP2` class. For information on subclassing Simulink data classes, see "Define Data Classes" (Simulink).

Note In previous releases, for ASAP2 file generation, you had to define objects explicitly as `ASAP2.Signal` and `ASAP2.Parameter`. This is no longer a limitation. As explained above, you can use built-in Simulink objects for generating an ASAP2 file. If you have been using an earlier release, you can continue to use the ASAP2 objects. If one of these ASAP2 objects was created in the previous release, and you use it in this release, the MATLAB Command Window displays a warning the first time the objects are loaded.

The following table indicates the Simulink object properties that have replaced the ASAP2 object properties of the previous release:

Differences Between ASAP2 and Simulink Parameter and Signal Object Properties

ASAP2 Object Properties (Previous)	Simulink Object Properties (Current)
LONGIG_ASAP2	Description
PhysicalMin_ASAP2	Min
PhysicalMax_ASAP2	Max
Units_ASAP2	Unit

Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)

If Embedded Coder is licensed and installed on your system, and if you are generating ELF (Executable and Linkable Format) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate the replacement of `ECU Address` placeholder memory address values with actual addresses in the generated ASAP2 file.

If the memory address attribute is unknown before code generation, the code generator inserts `ECU Address` placeholder text in the generated ASAP2 file, as shown in the example below.

```
/begin CHARACTERISTIC
  /* Name            */ Ki
  /* Long Identifier */ ""
  /* Type            */ VALUE
  /* ECU Address     */ 0x0
                       /*ECU_Address@Ki@ */
```

To substitute actual addresses for the `ECU Address` placeholders, process the generated ASAP2 file using the `rtw.asap2SetAddress` function. The general syntax is as follows:

```
rtw.asap2SetAddress(ASAP2File, InfoFile)
```

where the arguments are character vectors specifying the name of the generated ASAP2 file and the name of the generated executable ELF file or DWARF debug information file for the model. When called, `rtw.asap2SetAddress` extracts the actual ECU address from the specified ELF or DWARF file and replaces the placeholder in the ASAP2 file with the actual address, for example:

```
/begin CHARACTERISTIC
  /* Name            */ Ki
  /* Long Identifier */ ""
  /* Type            */ VALUE
  /* ECU Address     */ 0x40009E60
```

Define ASAP2 Information for Lookup Tables

Simulink Coder software generates ASAP2 descriptions for lookup table data and its breakpoints. The software represents 1-D table data as `CURVE` information, 2-D table data as `MAP` information, and breakpoints as `AXIS_DESCR` and `AXIS_PTS` information. You can model lookup tables using one of the following Simulink Lookup Table blocks:

- Direct Lookup Table (n-D) — 1 and 2 dimensions
- Interpolation Using Prelookup — 1 and 2 dimensions
- 1–D Lookup Table
- 2–D Lookup Table
- n-D Lookup Table — 1 and 2 dimensions

The software supports the following types of lookup table breakpoints (axis points):

Breakpoint Type	Generates
Tunable and shared among multiple table axes (common axis)	`COM_AXIS`
Fixed and nontunable (fixed axis)	One of these variants of `FIX_AXIS`: • `FIX_AXIS_PAR` if breakpoints are integers with equidistant spacing and the equidistant spacing is a power of two • `FIX_AXIS_PAR_DIST` if breakpoints are integers with equidistant spacing • `FIX_AXIS_PAR_LIST` if breakpoints are integers with non-equidistant spacing
Tunable but not shared among multiple tables (standard axis)	`STD_AXIS`

When you configure the blocks for ASAP2 code generation:

- For table data, use a `Simulink.Parameter` data object with a non-`Auto` storage class.
- For tunable breakpoint data that is shared among multiple table axes (`COM_AXIS`), use a `Simulink.Parameter` data object with a non-`Auto` storage class.
- For fixed, nontunable breakpoint data (`FIX_AXIS`), use workspace variables or arrays specified in the block parameters dialog box. The breakpoints should be stored as integers in the code, so the data type should be a built-in integer type (`int8`, `int16`, `int32`, `uint8`, `uint16`, or `uint32`), a fixed-point data type, or an equivalent alias type.
- For tunable breakpoint data that is not shared among multiple tables (STD_AXIS):

  1. Create a `Simulink.Bus` object to define the `struct` packaging (names and order of the fields). The fields of the parameter structure must correspond to the lookup table data and each axis of the lookup table block. For example, in an n-D Lookup Table block with 2 dimensions, the structure must contain only three fields. This bus object describes the record layout for the lookup characteristic.
  2. Create a `Simulink.Parameter` object to represent a tunable parameter.
  3. Create table and axis values.
  4. Optionally, specify the **Units**, **Minimum**, and **Maximum** properties for the parameter object. The properties will be applied to table data only.

Here is an example of an n-D Lookup Table record generated into an ASAP2 file in Standard Axis format:

```
/begin CHARACTERISTIC
  /* Name */  STDAxisParam
  ...
  /* Record Layout */   Lookup1D_X_WORD_Y_FLOAT32_IEEE
  ...
  begin AXIS_DESCR
    /* Description of X-Axis Points */
    /* Axis Type */      STD_AXIS
    ...
  /end AXIS_DESCR
/end CHARACTERISTIC

/begin RECORD_LAYOUT Lookup1D_X_WORD_Y_FLOAT32_IEEE
  AXIS_PTS_X 1 WORD INDEX_INCR DIRECT
```

```
  FNC_VALUES 2 FLOAT32_IEEE COLUMN_DIR DIRECT
/end   RECORD_LAYOUT
```

Note: The example model `rtwdemo_asap2` illustrates ASAP2 file generation for Lookup Table blocks, including both tunable (COM_AXIS) and fixed (FIX_AXIS) lookup table breakpoints.

Generate an ASAP2 File

About Generating ASAP2 Files

You can generate an ASAP2 file from your model in one of the following ways:

- Use the Generic Real-Time Target or a Embedded Coder target to generate an ASAP2 file as part of the code generation and build process.
- Use the ASAM-ASAP2 Data Definition Target to generate only an ASAP2 file, without building an executable.

This section discusses how to generate an ASAP2 file by using the targets that have built-in ASAP2 support. For an example, see the ASAP2 example model `rtwdemo_asap2`.

Use GRT or ERT Target

The procedure for generating the ASAP2 data definition for a model using the Generic Real-Time Target or an Embedded Coder target is as follows:

1. Create the desired model. Use parameter names and signal labels to refer to corresponding CHARACTERISTIC records and MEASUREMENT records, respectively.
2. Create `Simulink.Parameter` and `Simulink.Signal` objects in the MATLAB workspace and reference them from parameters and signals in the model. A convenient way of creating multiple signal and parameter data objects is to use the

Data Object Wizard. Alternatively, you can create data objects one at a time from the MATLAB command line. For details on how to use the Data Object Wizard, see "Create Data Objects for a Model Using Data Object Wizard" (Simulink).

3 For each data object, configure the **Storage class** property to a setting other than `Auto`, `FileScope`, or `SimulinkGlobal`. This setting declares the data object as global in the generated code. For example, a storage class setting of `ExportedGlobal` configures the data object as unstructured global in the generated code.

Note: The data object is not represented in the ASAP2 file if any of the following conditions exist:

- You set the storage class to `Auto`, `FileScope`, or `SimulinkGlobal`.
- You set the storage class to `Custom` and custom storage class settings cause the code generator to generate a macro or non-addressable variable.

---

4 Configure the remaining properties as desired for each data object.

5 On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `grt.tlc` or an ERT based target file and click **OK**.

6 On the **Code Generation** > **Interface** pane, in the **Data exchange interface** subgroup, select **ASAP2 interface**.

7 Select the **Generate code only** check box on the **Code Generation** pane.

8 Click **Apply**.

9 Press **Ctrl+B** to build the model.

The Simulink Coder code generator writes the ASAP2 file to the build folder. By default, the file is named *`model`*`.a2l`, where *`model`* is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see "Customize Generated ASAP2 File" on page 69-2.

Use the ASAM-ASAP2 Data Definition Target

The procedure for generating the ASAP2 data definition for a model using the ASAM-ASAP2 Data Definition Target is as follows:

1 Create the desired model. Use parameter names and signal labels to refer to corresponding CHARACTERISTIC records and MEASUREMENT records, respectively.

2. Create `Simulink.Parameter` and `Simulink.Signal` objects in the MATLAB workspace and reference them from parameters and signals in the model. A convenient way of creating multiple signal and parameter data objects is to use the Data Object Wizard. Alternatively, you can create data objects one at a time from the MATLAB command line. For details on how to use the Data Object Wizard, see "Create Data Objects for a Model Using Data Object Wizard" (Simulink).
3. For each data object, configure the **Storage class** property to a setting other than `Auto`, `FileScope`, or `SimulinkGlobal`. This setting declares the data object as global in the generated code. For example, a storage class setting of `ExportedGlobal` configures the data object as unstructured global in the generated code.

   Note: The data object is not represented in the ASAP2 file if any of the following conditions exist:

   - You set the storage class to `Auto`, `FileScope`, or `SimulinkGlobal`.
   - You set the storage class to `Custom` and custom storage class settings cause the code generator to generate a macro or non-addressable variable.

   ---

4. Configure the remaining properties as desired for each data object.
5. On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `asap2.tlc` and click **OK**.
6. Select the **Generate code only** check box on the **Code Generation** pane.
7. Click **Apply**.
8. Press **Ctrl+B**.

   The Simulink Coder code generator writes the ASAP2 file to the build folder. By default, the file is named *`model`*`.a2l`, where *`model`* is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see "Customize Generated ASAP2 File" on page 69-2.

Generate ASAP2 Files for Referenced Models

The build process can generate an ASAP2 file for each referenced model in a model reference hierarchy. In the generated ASAP2 file, MEASUREMENT records represent signals and states inside the referenced model.

To generate ASAP2 files for referenced models, select ASAP2 file generation for the top model and for each referenced model in the reference hierarchy. For example, if you are

using the Generic Real-Time Target or an Embedded Coder target, follow the procedure described in "Use GRT or ERT Target" on page 44-9 for the top model and each referenced model.

Merge ASAP2 Files for Top and Referenced Models

Use function `rtw.asap2MergeMdlRefs` to merge the ASAP2 files generated for top and referenced models. The function has the following syntax:

```
[status,info]=rtw.asap2MergeMdlRefs(topModelName,asap2FileName)
```

- `topModelName` is the name of the model containing one or more referenced models.
- `asap2FileName` is the name you specify for the merged ASAP2 file.
- *Optional:*: `status` returns false (logical 0) if the merge completes and true (logical 1) otherwise.
- *Optional:*: `info` returns additional information about merge failure if `status` is true. Otherwise, it returns an empty character vector.

Consider the following example.

```
[status,info]=rtw.asap2MergeMdlRefs('myTopMdl','merged.a2l')
```

This command merges the ASAP2 files generated for the top model `myTopMdl` and its referenced models in the file `merged.a2l`.

The example model `rtwdemo_asap2` includes an example of merging ASAP2 files.

Structure of the ASAP2 File

The following table outlines the basic structure of the ASAP2 file and describes the Target Language Compiler (TLC) functions and files used to create each part of the file:

- Static parts of the ASAP2 file are shown in **bold**.
- Function calls are indicated by `%<FunctionName()>`.

File Section	Contents of asap2main.tlc	TLC File Containing Function Definition
File header	`%<ASAP2UserFcnWriteFileHead()>`	`asap2userlib.tlc`
`/begin PROJECT ""`	**`/begin PROJECT`** `"%<ASAP2ProjectName>"`	`asap2setup.tlc`

File Section	Contents of asap2main.tlc	TLC File Containing Function Definition
/begin HEADER "" HEADER contents	**/begin HEADER**"%<ASAP2HeaderName>" %<ASAP2UserFcnWriteHeader()>	asap2setup.tlc asap2userlib.tlc
/end HEADER	**/end HEADER**	
/begin MODULE "" MODULE contents:	**/begin MODULE** "%<ASAP2ModuleName>"}	asap2setup.tlc asap2userlib.tlc
- A2ML - MOD_PAR - MOD_COMMON ...	%<ASAP2UserFcnWriteHardwareInterface()>	
Model-dependent MODULE contents:	%<SLibASAP2WriteDynamicContents()> Calls user-defined functions:	asap2lib.tlc
- RECORD_LAYOUT - CHARACTERISTIC - ParameterGroups - ModelParameters	...WriteRecordLayout_TemplateName() ...WriteCharacteristic_TemplateName() ...WriteCharacteristic_Scalar()	user/templates/...
- MEASUREMENT - ExternalInputs - BlockOutputs	...WriteMeasurement()	asap2userlib.tlc
- COMPU_METHOD	...WriteCompuMethod()	asap2userlib.tlc
/end MODULE	**/end MODULE**	
File footer/tail	%<ASAP2UserFcnWriteFileTail()>	asap2userlib.tlc

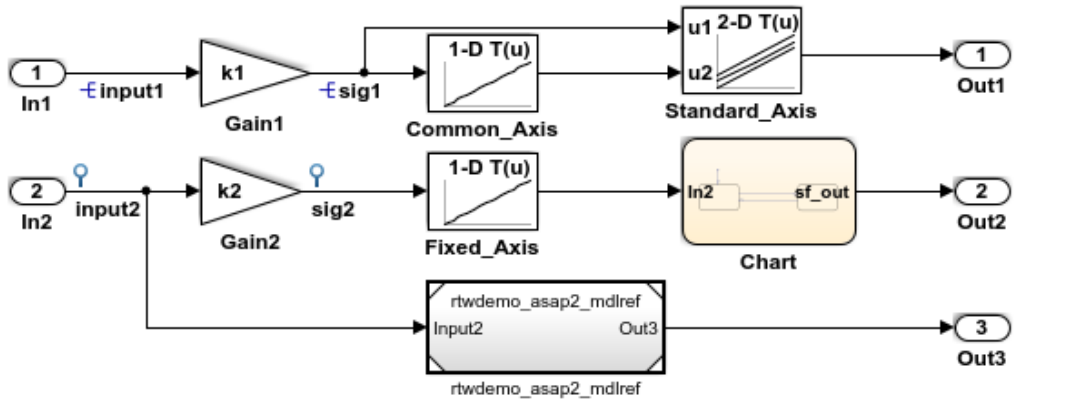
Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration

This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM).

Open Example Model

Open the example model `rtwdemo_asap2`.

```
open_system('rtwdemo_asap2');
```



This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: http://www.asam.de.

ASAP2 data definition is achieved with Simulink data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions for your application. See the Simulink Coder documentation for details on ASAP2 file generation.

You can configure ASAP2 file generation from "Code Generation > Interface > ASAP2 interface" in the Configuration Parameters dialog box.

Generate Code Using Simulink Coder (double-click) | **Generate Code Using Embedded Coder (double-click)** | **View Interface Configuration (double-click)** | **View Workspace Variables (double-click)**

ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: http://www.asam.de.

ASAP2 data definition is achieved with Simulink® data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions

for your application. See the Simulink Coder® documentation for details on ASAP2 file generation.

You can configure ASAP2 file generation by selecting **ASAP2 interface** on the **Code Generation > Interface** pane of the Configuration Parameters dialog box.

Direct Memory Access to Generated Code for Simulink Coder

Access Memory in Generated Code Using Global Data Map

Simulink Coder provides a Target Language Compiler (TLC) function library that lets you create a *global data map record*. The global data map record, when generated, is added to the `CompiledModel` structure in the `model.rtw` file. The global data map record is a database containing information required for accessing memory in the generated code, including

- Signals (Block I/O)
- Parameters
- Data type work vectors (DWork)
- External inputs
- External outputs

Use of the global data map requires knowledge of the Target Language Compiler and of the structure of the `model.rtw` file. See "Target Language Compiler Overview" (Simulink Coder) for information on these topics.

The TLC functions that are required to generate and access the global data map record are contained in *`matlabroot`*`/rtw/c/tlc/mw/globalmaplib.tlc`. The comments in the source code fully document the global data map structures and the library functions.

The global data map structures and functions might be modified or enhanced in future releases.

Desktops in Simulink Coder

Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File

After you create a model, you can use the rapid simulation (RSim) system target file to characterize model behavior. The executable program that results from the build process is for non-real-time execution on your development computer. The executable program is highly optimized for simulating models of hybrid dynamic systems, including models that use variable-step solvers and zero-crossing detection. The speed of the generated code makes the RSim system target file ideal for building programs for batch or Monte Carlo simulations.

About Rapid Simulation

Use the RSim target to generate an executable that runs fast, standalone simulations. You can repeat simulations with varying data sets, interactively or programmatically with scripts, without rebuilding the model. This can accelerate the characterization and tuning of model behavior and code generation testing.

Using command-line options:

- Define parameter values and input signals in one or more MAT-files that you can load and reload at the start of simulations without rebuilding your model.
- Redirect logging data to one or more MAT-files that you can then analyze and compare.
- Control simulation time.
- Specify external mode options.

Note: To run an RSim executable, configure your computer to run MATLAB and have the MATLAB and Simulink installation folders accessible. To deploy a standalone host executable (i.e., without MATLAB and Simulink installed), consider using the Host-Based Shared Library target (ert_shrlib)."

Rapid Simulation Advantage

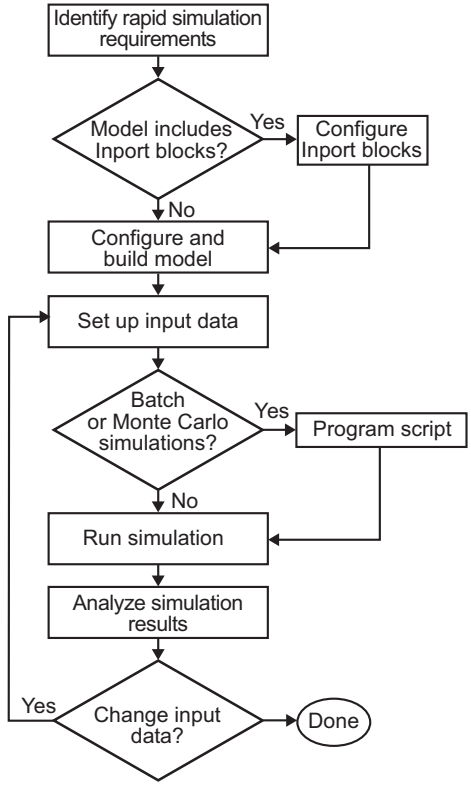
The advantage that you gain from rapid simulation varies. Larger simulations achieve speed improvements of up to 10 times faster than standard Simulink simulations. Some

models might not show noticeable improvement in simulation speed. To determine the speed difference for your model, time your standard Simulink simulation and compare the results with a rapid simulation. In addition, test the model simulation in Rapid Accelerator simulation mode.

General Rapid Simulation Workflow

Like other stages of Model-Based Design, characterization and tuning of model behavior is an iterative process, as shown in the general workflow diagram in the figure. Tasks in the workflow are:

1. Identify your rapid simulation requirements.
2. Configure Inport blocks that provide input source data for rapid simulations.
3. Configure the model for rapid simulation.
4. Set up simulation input data.
5. Run the rapid simulations.



Identify Rapid Simulation Requirements

The first step to setting up a rapid simulation is to identify your simulation requirements.

Question...	For More Information, See...
How long do you want simulations to run?	“Configure and Build Model for Rapid Simulation” on page 46-6
Are there solver requirements? Do you expect to use the same solver for which the model is configured for your rapid simulations?	“Configure and Build Model for Rapid Simulation” on page 46-6

Question...	For More Information, See...
Do your rapid simulations need to accommodate flexible custom code interfacing? Or, do your simulations need to retain storage class settings?	"Configure and Build Model for Rapid Simulation" on page 46-6
Will you be running simulations with multiple data sets?	"Set Up Rapid Simulation Input Data" on page 46-8
Will the input data consist of global parameters, signals, or both?	"Set Up Rapid Simulation Input Data" on page 46-8
What type of source blocks provide input data to the model — From File, Inport, From Workspace?	"Set Up Rapid Simulation Input Data" on page 46-8
Will the model's parameter vector (`model_P`) be used as input data?	"Create a MAT-File That Includes a Model Parameter Structure" on page 46-9
What is the data type of the input parameters and signals?	"Set Up Rapid Simulation Input Data" on page 46-8
Will the source data consist of one variable or multiple variables?	"Set Up Rapid Simulation Input Data" on page 46-8
Does the input data include tunable parameters?	"Create a MAT-File That Includes a Model Parameter Structure" on page 46-9
Do you need to gain access to tunable parameter information — model checksum and parameter data types, identifiers, and complexity?	"Create a MAT-File That Includes a Model Parameter Structure" on page 46-9
Will you have a need to vary the simulation stop time for simulation runs?	"Configure and Build Model for Rapid Simulation" on page 46-6 and"Override a Model Simulation Stop Time" on page 46-21
Do you want to set a time limit for the simulation? Consider setting a time limit if your model experiences frequent zero crossings and has a small minor step size.	"Set a Clock Time Limit for a Rapid Simulation" on page 46-21
Do you need to preserve the output of each simulation run?	"Specify a New Output File Name for a Simulation" on page 46-30 and "Specify New Output File Names for To File Blocks" on page 46-30

Question...	For More Information, See...
Do you expect to run the simulations interactively or in batch mode?	"Scripts for Batch and Monte Carlo Simulations" on page 46-18

Configure Inports to Provide Simulation Source Data

You can use Inport blocks as a source of input data for rapid simulations. To do so, configure the blocks so that they can import data from external MAT-files. By default, the Inport block inherits parameter settings from downstream blocks. In most cases, to import data from an external MAT-file, you must explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you do not have control over the model content, you might need to modify the data in the MAT-file to conform to what the model expects for input. Input data characteristics and specifications of the Inport block that receives the data must match.

For details on adjusting these parameters and on creating a MAT-file for use with an Inport block, see "Create a MAT-File for an Inport Block" on page 46-14. For descriptions of the preceding block parameters, see the block description of Inport.

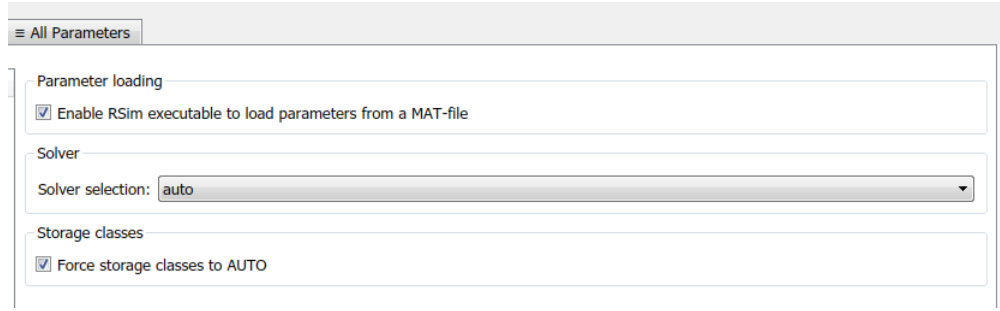
Configure and Build Model for Rapid Simulation

After you identify your rapid simulation requirements, configure the model for rapid simulation.

1. Open the Configuration Parameters dialog box.
2. Go to the **Code Generation** pane.
3. On the **Code Generation** pane, click **Browse**. The System Target File Browser opens.
4. Select `rsim.tlc` (Rapid Simulation Target) and click **OK**.

   On the **Code Generation** pane, the code generator populates the **Make command** and "Template makefile" (Simulink Coder) fields with default settings and adds the **RSim Target** pane under **Code Generation**.

5 Click **RSim Target** to view the **RSim Target** pane.



6 Set the RSim target configuration parameters to your rapid simulation requirements.

If You Want to...	Then...
Generate code that allows the RSim executable to load parameters from a MAT-file	Select **Enable RSim executable to load parameters from a MAT-file** (default).
Let the target choose a solver based on the solver already configured for the model	Set **Solver selection** to `auto` (default). The code generator uses a built-in solver if a fixed-step solver is specified on the **Solver** pane or calls the Simulink solver module (a shared library) if a variable-step solver is specified.
Explicitly instruct the target to use a fixed-step solver	Set **Solver selection** to `Use fixed-step solvers`. In the Configuration Parameters dialog box, on the **Solver** pane, specify a fixed-step solver.
Explicitly instruct the target to use a variable-step solver	Set **Solver selection** to `Use Simulink solver module`. In the Configuration Parameters dialog box, on the **Solver** pane, specify a variable-step solver.
Force storage classes to `Auto` for flexible custom code interfacing	Select **Force storage classes to AUTO** (default).
Retain storage class settings, such as `ExportedGlobal` or `ImportedExtern`, due to application requirements	Clear **Force storage classes to AUTO**.

7 Set up data import and export options. On the **Data Import/Export** pane, in the **Save to Workspace** section, select the **Time**, **States**, **Outputs**, and **Final States** options, as they apply. By default, the code generator saves simulation logging results to a file named *`model`*`.mat`. For more information, see "Export Simulation Data" (Simulink).

8 If you are using external mode communication, set up the interface, using the **Code Generation > Interface** pane. See "What You Can Do with a Host/Target Communication Channel" on page 41-2 for details.

9 Press **Ctrl+B**. The code generator builds a highly optimized executable program that you can run on your development computer with varying data, without rebuilding.

For more information on compilers that are compatible with the Simulink Coder product, see "Select and Configure C or C++ Compiler or IDE" on page 40-3 and "Template Makefiles and Make Options" on page 40-24 .

Set Up Rapid Simulation Input Data

About Rapid Simulation Data Setup

The format and setup of input data for a rapid simulation depends on your requirements.

If the Input Data Source Is...	Then...
The model's global parameter vector (*`model`*`_P`)	Use the `rsimgetrtp` function to get the vector content and then save it to a MAT-file.
The model's global parameter vector and you want a mapping between the vector and tunable parameters	Call the `rsimgetrtp` function to get the global parameter structure and then save it to a MAT-file.
Provided by a From File block	Create a MAT-file that a From File block can read.
Provided by an Inport block	Create a MAT-file that adheres to one of the three data file formats that the Inport block can read.

If the Input Data Source Is...	Then...
Provided by a From Workspace block	Create structure variables in the MATLAB workspace.

The RSim target requires that MAT-files used as input for From File and Inport blocks contain data. The `grt` target inserts MAT-file data directly into the generated code, which is then compiled and linked as an executable. In contrast, RSim allows you to replace data sets for each successive simulation. A MAT-file containing From File or Inport block data must be present if a From File block or Inport block exists in your model.

Create a MAT-File That Includes a Model Parameter Structure

To create a MAT-file that includes a model global parameter structure (*`model`*`_P`),

1. Get the structure by calling the function `rsimgetrtp`.
2. Save the parameter structure to a MAT-file.

If you want to run simulations over varying data sets, consider converting the parameter structure to a cell array and saving the parameter variations to a single MAT-file.

Get the Parameter Structure for a Model

Get the global parameter structure (*`model`*`_P`) for a model by calling the function `rsimgetrtp`.

```
param_struct = rsimgetrtp('model')
```

Argument	Description
`model`	The model for which you are running the rapid simulations.

The `rsimgetrtp` function forces an update diagram action for the specified model and returns a structure that contains the following fields.

Field	Description
`modelChecksum`	A four-element vector that encodes the structure of the model. The code generator uses the checksum to check whether the structure of the model has changed since the RSim executable was generated. If you delete or add a block, and then generate a new *`model`*`_P` vector, the new checksum does not match the

Field	Description
	original checksum anymore. The RSim executable detects this incompatibility in parameter vectors and exits to avoid returning incorrect simulation results. If the model structure changes, you must regenerate the code for the model.
`parameters`	A structure that contains the model's global parameters.

The parameter structure contains the following information.

Field	Description
`dataTypeName`	The name of the parameter data type, for example, `double`
`dataTypeID`	Internal data type identifier used by the code generator
`complex`	The value 0 if real; 1 if complex
dtTransIdx	Internal data index used by the code generator
values	A vector of the parameter values associated with this structure
map	This field contains the mapping information that correlates the 'values' to the tunable parameters of the model. This mapping information, in conjunction with `rsimsetrtpparam`, is useful for creating subsequent rtP structures without compiling the block diagram.

The code generator reports a tunable fixed-point parameter according to its stored value. For example, an `sfix(16)` parameter value of `1.4` with a scaling of `2^-8` has a value of `358` as an `int16`.

In the following example, `rsimgetrtp` returns the parameter structure for the example model rtwdemo_rsimtf to `param_struct`.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf')
```

```
param_struct =

    modelChecksum: [1.7165e+009 3.0726e+009 2.6061e+009 2.3064e+009]
       parameters: [1x1 struct]
```

Save the Parameter Structure to a MAT-File

After you issue a call to `rsimgetrtp`, save the return value of the function call to a MAT-file. Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

The following example saves the parameter structure returned for `rtwdemo_rsimtf` to the MAT-file `myrsimdemo.mat`.

```
save myrsimdemo.mat param_struct;
```

For information on using command-line options to specify required files, see "Run Rapid Simulations" on page 46-18.

Convert the Parameter Structure for Running Simulations on Varying Data Sets

To use rapid simulations to test changes to specific parameters, you can convert the model parameter structure to a cell array. You can then access a specific parameter set by using the @ operator to specify the index for a specific parameter set in the file.

To convert the structure to a cell array:

1. Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

   ```
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   ```

   The `parameters` field of the structure is a substructure that contains parameter information. The `values` field of the `parameters` substructure contains the numeric values of the parameters that you can tune during execution of the simulation code.

2. Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

   ```
   param_struct = rsimsetrtpparam(param_struct,3);
   ```

   The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

3. Specify new values for the parameters in the second and third parameter sets.

   ```
   param_struct.parameters{2}.values = [-150 -5000 0 4950];
   param_struct.parameters{3}.values = [-170 -5500 0 5100];
   ```

4. Save the structure containing the parameter set information to a MAT-file.

   ```
   save rtwdemo_rsimtf.mat param_struct;
   ```

Alternatively, you can modify the block parameters in the model, and use `rsimgetrtp` to create multiple parameter sets:

1. Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

   ```
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   ```

2. Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

   ```
   param_struct = rsimsetrtpparam(param_struct,3);
   ```

   The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

3. Change the values of block parameters or workspace variables. For example, change the value of the variable `w` from `70` to `72`.

   ```
   w = 72;
   ```

4. Use `rimsgetrtp` to get another structure containing parameter information. Store the structure in a temporary variable `rtp_temp`.

   ```
   rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
   ```

5. Assign the value of the `parameters` field of `rtp_temp` to the structure `param_struct` as a second parameter set.

   ```
   param_struct.parameters{2} = rtp_temp.parameters;
   ```

6. Change the value of the variable `w` from `72` to `75`.

   ```
   w = 75;
   ```

7. Use `rimsgetrtp` to get another structure containing parameter information. Then, assign the value of the `parameters` field to `param_struct` as a third parameter set.

   ```
   rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
   param_struct.parameters{3} = rtp_temp.parameters;
   ```

8. Save the structure containing the parameter set information to a MAT-file.

```
save rtwdemo_rsimtf.mat param_struct;
```

For more information on how to specify each parameter set when you run the simulations, see "Change Block Parameters for an RSim Simulation" on page 46-28.

Create a MAT-File for a From File Block

You can use a MAT-file as the input data source for a From File block. The format of the data in the MAT-file must match the data format expected by that block. For example, if you are using a matrix as an input for the MAT file, this cannot be different from the matrix size for the executable.

To create a MAT-file for a From File block:

1. For array format data, in the workspace create a matrix that consists of two or more rows. The first row must contain monotonically increasing time points. Other rows contain data points that correspond to the time point in that column. The time and data points must be data of type `double`.

   For example:

   ```
   t=[0:0.1:2*pi]';
   Ina1=[2*sin(t) 2*cos(t)];
   Ina2=sin(2*t);
   Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
   var_matrix=[t Ina1 Ina2 Ina3]';
   ```

   For other supported data types, such as `int16` or fixed-point, the time data points must be of type `double`, just as for array format data. However, the sample data can be of any dimension.

   For more information on setting up the input data, see the block description of From File.

2. Save the matrix to a MAT-file.

   The following example saves the matrix `var_matrix` to the MAT-file `myrsimdemo.mat` in Version 7.3 format.

   ```
   save '-v7.3' myrsimdemo.mat var_matrix;
   ```

   Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

Create a MAT-File for an Inport Block

You can use a MAT-file as the input data source for an Inport block.

The format of the data in the MAT-file must adhere to one of the three column-based formats listed in the following table. The table lists the formats in order from least flexible to most flexible.

Format	Description
Single time/data matrix	• Least flexible. • One variable. • Two or more *columns*. Number of columns must equal the sum of the dimensions of all root Inport blocks plus 1. First column must contain monotonically increasing time points. Other columns contain data points that correspond to the time point in a given row. • Data of type `double`. For an example, see Single time/data matrix in the following procedure, step 4. For more information, see "Create Data Arrays for Root-Level Inports" (Simulink).
Signal-and-time structure	• More flexible than the single time/data matrix format. • One variable. • Must contain two top-level fields: `time` and `signals`. The `time` field contains a *column* vector of the simulation times. The `signals` field contains an array of substructures, each of which corresponds to an Inport block. The substructure index corresponds to the Inport block number. Each `signals` substructure must contain a field named `values`. The `values` field must contain an array of inputs for the corresponding Inport block, where each input corresponds to a time point specified by the `time` field. • If the `time` field is set to an empty value, clear the check box for the Inport block **Interpolate data** parameter. • Data type must match Inport block settings. For an example, see Signal-and-time structure in the following procedure, step 4. For more information on this format, see "Create Data Structures for Root Inports" (Simulink).

Format	Description
Per-port structure	• Most flexible • Multiple variables. Number of variables must equal the number of Inport blocks. • Consists of a separate structure-with-time or structure-without-time for each Inport block. Each Inport block data structure has only one `signals` field. To use this format, in the **Input** text field, enter the names of the structures as a comma-separated list, `in1`, `in2`,..., `inN`, where `in1` is the data for your model's first port, `in2` for the second port, and so on. • Each variable can have a different time vector. • If the `time` field is set to an empty value, clear the check box for the Inport block **Interpolate data** parameter. • Data type must match Inport block settings. • To save multiple variables to the same data file, you must save them in the order expected by the model, using the `-append` option. For an example, see Per-port structure in the following procedure, step 4. For more information, see "Create Data Structures for Root Inports" (Simulink).

The supported formats and the following procedure are illustrated in rtwdemo_rsim_i.

To create a MAT-file for an Inport block:

1. Choose one of the preceding data file formats.
2. Update Inport block parameter settings and specifications to match specifications of the data to be supplied by the MAT-file.

   By default, the Inport block inherits parameter settings from downstream blocks. To import data from an external MAT-file, explicitly set the following parameters to match the source data in the MAT-file.

   - **Main** > **Interpolate data**
   - **Signal Attributes** > **Port dimensions**
   - **Signal Attributes** > **Data type**
   - **Signal Attributes** > **Signal type**

If you choose to use a structure format for workspace variables and the `time` field is empty, you must clear **Interpolate data** or modify the field so that it is set to a nonempty value. Interpolation requires time data.

For descriptions of the preceding block parameters, see the block description of Inport.

3. Build an RSim executable program for the model. The build process creates and calculates a structural checksum for the model and embeds it in the generated executable. The RSim target uses the checksum to verify that data being passed into the model is consistent with what the model executable expects.
4. Create the MAT-file that provides the source data for the rapid simulations. You can create the MAT-file from a workspace variable. Using the specifications in the preceding format comparison table, create the workspace variables for your simulations.

   An example of each format follows:

   Single time/data matrix

```
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3];
```

   Signal-and-time structure

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

   Per-port structure

```
t=[0:0.1:2*pi]';
Inb1.time=t;
```

```
Inb1.signals.values(:,1)=2*sin(t);
Inb1.signals.values(:,2)=2*cos(t);
t=[0:0.2:2*pi]';
Inb2.time=t;
Inb2.signals.values(:,1)=sin(2*t);
t=[0:0.1:2*pi]';
Inb3.time=t;
Inb3.signals.values(:,1)=0.5*sin(3*t);
Inb3.signals.values(:,2)=0.5*cos(3*t);
```

5 Save the workspace variables to a MAT-file.

Single time/data matrix

The following example saves the workspace variable `var_matrix` to the MAT-file `rsim_i_matrix.mat`.

```
save rsim_i_matrix.mat var_matrix;
```

Signal-and-time structure

The following example saves the workspace structure variable `var_single_struct` to the MAT-file `rsim_i_single_struct.mat`.

```
save rsim_i_single_struct.mat var_single_struct;
```

Per-port structure

To order data when saving per-port structure variables to a single MAT-file, use the `save` command's `-append` option. Be sure to append the data in the order that the model expects it.

The following example saves the workspace variables `Inb1`, `Inb2`, and `Inb3` to MAT-file `rsim_i_multi_struct.mat`.

```
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
```

The `save` command does not preserve the order in which you specify your workspace variables in the command line when saving data to a MAT-file. For example, if you specify the variables `v1`, `v2`, and `v3`, in that order, the order of the variables in the MAT-file could be `v2 v1 v3`.

Using a command-line option, you can then specify the MAT-files as input for rapid simulations.

Scripts for Batch and Monte Carlo Simulations

The RSim target is for batch simulations in which parameters and input signals vary for multiple simulations. New output file names allow you to run new simulations without overwriting prior simulation results. You can set up a series of simulations to run by creating a `.bat` file for use on a Microsoft Windows platform.

Create a file for the Windows platform with a text editor and execute it by typing the file name, for example, `mybatch`, where the name of the text file is `mybatch.bat`.

```
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run1.mat -o results1.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run2.mat -o results2.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run3.mat -o results3.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run4.mat -o results4.mat -tf 10.0
```

In this case, batch simulations run using four sets of input data in files `run1.mat`, `run2.mat`, and so on. The RSim executable saves the data to the files specified with the `-o` option.

The variable names containing simulation results in each of the files are identical. Therefore, loading consecutive sets of data without renaming the data once it is in the MATLAB workspace results in overwriting the prior workspace variable with new data. To avoid overwriting, you can copy the result to a new MATLAB variable before loading the next set of data.

You can also write MATLAB scripts to create new signals and new parameter structures, as well as to save data and perform batch runs using the bang command (`!`).

For details on running simulations and available command-line options, see “Run Rapid Simulations” on page 46-18. For an example of a rapid simulation batch script, see the example “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

Run Rapid Simulations

Rapid Simulations

Using the RSim target, you can build a model once and run multiple simulations to study effects of varying parameter settings and input signals. You can run a simulation directly from your operating system command line, redirect the command from the MATLAB command line by using the bang (!) character, or execute commands from a script.

From the operating system command line, use

```
rtwdemo_rsimtf
```

From the MATLAB command line, use

```
!rtwdemo_rsimtf
```

The following table lists ways you can use RSim target command-line options to control a simulation.

To...	Use...
Read input data for a From File block from a MAT-file other than the MAT-file used for the previous simulation	*model* `-f` *oldfilename*`.mat=`*newfilename*`.mat`
Print a summary of the options for RSim executable targets	*executable filename* `-h`
Read input data for an Inport block from a MAT-file	*model* `-i` *filename*`.mat`
Time out after *n* clock time seconds, where *n* is a positive integer value	*model* `-L` *n*

To...	Use...
Write MAT-file logging data to file *filename*.mat	*model* -o *filename*.mat
Read a parameter vector from file *filename*.mat	*model* -p *filename*.mat
Override the default TCP port (17725) for external mode	*model* -port *TCPport*
Write MAT-file logging data to a MAT-file other than the MAT-file used for the previous simulation	*model* -t *oldfilename*.mat=*newfilename*.mat
Run the simulation until the time value *stoptime* is reached	*model* -tf *stoptime*
Run in verbose mode	*model* -v
Wait for the Simulink engine to start the model in external mode	*model* -w

The following sections use the rtwdemo_rsimtf example model in examples to illustrate some of these command-line options. In each case, the example assumes you have already done the following:

- Created or changed to a working folder.
- Opened the example model.
- Copied the data file *matlabroot*/toolbox/rtw/rtwdemos/rsimdemos/rsim_tfdata.mat to your working folder. You can perform this operation using the command:

  ```
  copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos',...
  'rsimdemos','rsim_tfdata.mat'),pwd);
  ```

Requirements for Running Rapid Simulations

The following requirements apply to both fixed and variable step executables.

- You must run the RSim executable on a computer configured to run MATLAB. Also, the RSim.exe file must be able to access the MATLAB and Simulink installation folders on this machine. To obtain that access, your PATH environment variable must include /bin and /bin/($ARCH), where ($ARCH) represents your operating system

architecture. For example, for a personal computer running on a Windows platform, ($ARCH) is “win64”, whereas for a Linux machine, ($ARCH) is “glnxa64”.

- On GNU Linux platforms, to run an RSim executable, define the LD_LIBRARY_PATH environment variable to provide the path to the MATLAB installation folder, as follows:

  ```
  % setenv LD_LIBRARY_PATH /matlab/sys/os/glnx64:$LD_LIBRARY_PATH
  ```

- On the Apple Macintosh OS X platform, to run RSim target executables, you must define the environment variable `DYLD_LIBRARY_PATH` to include the folders `bin/mac` and `sys/os/mac` under the MATLAB installation folder. For example, if your MATLAB installation is under `/MATLAB`, add `/MATLAB/bin/mac` and `/MATLAB/sys/os/mac` to the definition for `DYLD_LIBRARY_PATH`.

Set a Clock Time Limit for a Rapid Simulation

If a model experiences frequent zero crossings and the model's minor step size is small, consider setting a time limit for a rapid simulation. To set a time limit, specify the `-L` option with a positive integer value. The simulation aborts after running for the specified amount of clock time (not simulation time). For example,

```
!rtwdemo_rsimtf -L 20
```

Based on your clock, after the executable runs for 20 seconds, the program terminates. You see a message similar to one of the following:

- On a Microsoft Windows platform,

  ```
  Exiting program, time limit exceeded
  Logging available data ...
  ```

- On The Open Group UNIX platform,

  ```
  ** Received SIGALRM (Alarm) signal @ Fri Jul 25 15:43:23 2003
  ** Exiting model  'vdp' @ Fri Jul 25 15:43:23 2003
  ```

You do not need to do anything to your model or to its configuration to use this option.

Override a Model Simulation Stop Time

By default, a rapid simulation runs until the simulation time reaches the time specified the Configuration Parameters dialog box, on the **Solver** pane. You can override the model simulation stop time by using the `-tf` option. For example, the following simulation runs until the time reaches 6.0 seconds.

```
!rtwdemo_rsimtf -tf 6.0
```

The RSim target stops and logs output data using MAT-file data logging rules.

If the model includes a From File block, the end of the simulation is regulated by the stop time setting specified in the Configuration Parameters dialog box, on the **Solver** pane, or with the RSim target option `-tf`. The values in the block's time vector are ignored. However, if the simulation time exceeds the endpoints of the time and signal matrix (if the final time is greater than the final time value of the data matrix), the signal data is extrapolated to the final time value.

Read the Parameter Vector into a Rapid Simulation

To read the model parameter vector into a rapid simulation, you must first create a MAT-file that includes the parameter structure as described in “Create a MAT-File That Includes a Model Parameter Structure” on page 46-9. You can then specify the MAT-file in the command line with the `-p` option.

For example:

1. Build an RSim executable for the example model `rtwdemo_rsimtf`.
2. Modify parameters in your model and save the parameter structure.

   ```
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   save myrsimdata.mat param_struct
   ```
3. Run the executable with the new parameter set.

   ```
   !rtwdemo_rsimtf -p myrsimdata.mat

   ** Starting model 'rtwdemo_rsimtf' @ Tue Dec 27 12:30:16 2005
   ** created rtwdemo_rsimtf.mat **
   ```
4. Load workspace variables and plot the simulation results by entering the following commands:

   ```
   load myrsimdata.mat
   plot(rt_yout)
   ```

Specify New Signal Data File for a From File Block

If your model's input data source is a From File block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one

simulation to the next. Each MAT-file must adhere to the format described in “Create a MAT-File for a From File Block” on page 46-13.

To change the MAT-file after an initial simulation, you specify the executable with the `-f` option and an *`oldfile`*`.mat=`*`newfile`*`.mat` parameter, as shown in the following example.

1. Set some parameters in the MATLAB workspace. For example:

   ```
   w = 100;
   theta = 0.5;
   ```

2. Build an RSim executable for the example model `rtwdemo_rsimtf`.

3. Run the executable.

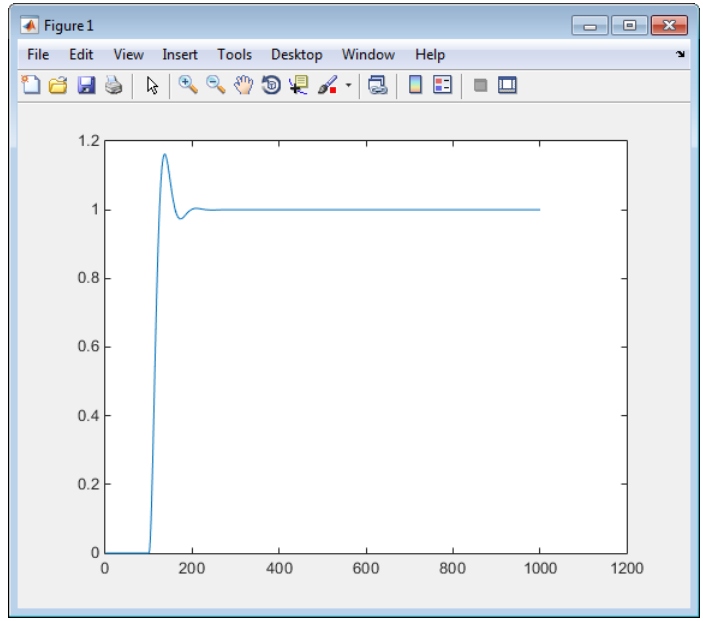
   ```
   !rtwdemo_rsimtf
   ```

   The RSim executable runs a set of simulations and creates output MAT-files containing the specific simulation result.

4. Load the workspace variables and plot the simulation results by entering the following commands:

   ```
   load rtwdemo_rsimtf.mat
   plot(rt_yout)
   ```

   The resulting plot shows simulation results based on default input data.



5 Create a new data file, `newfrom.mat`, that includes the following data:

```
t=[0:.001:1];
u=sin(100*t.*t);
tu=[t;u];
save newfrom.mat tu;
```

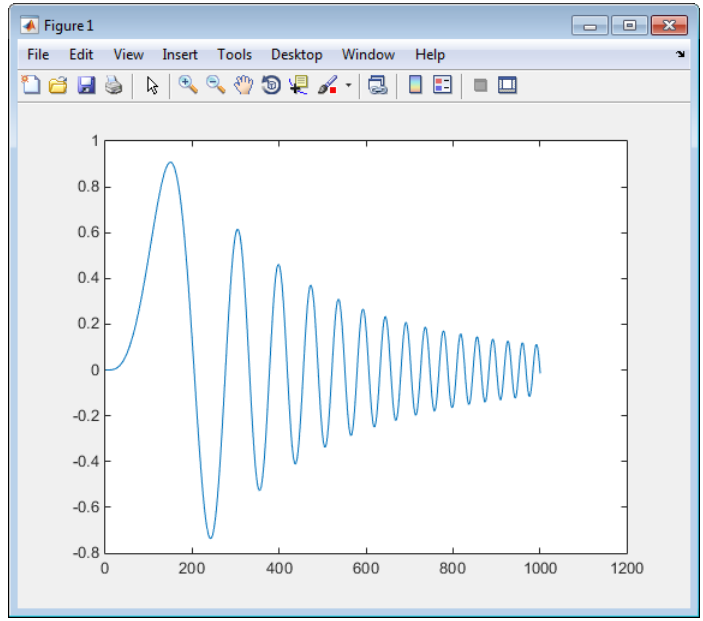
6 Run a rapid simulation with the new data by using the `-f` option to replace the original file, `rsim_tfdata.mat`, with `newfrom.mat`.

```
!rtwdemo_rsimtf -f rsim_tfdata.mat=newfrom.mat
```

7 Load the data and plot the new results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The next figure shows the resulting plot.



From File blocks require input data of type `double`. If you need to import signal data of a data type other than `double`, use an Inport block (see "Create a MAT-File for an Inport Block" on page 46-14) or a From Workspace block with the data specified as a structure.

Workspace data must be in the format:

```
variable.time
variable.signals.values
```

If you have more than one signal, use the following format:

```
variable.time
variable.signals(1).values
variable.signals(2).values
```

Specify Signal Data File for an Inport Block

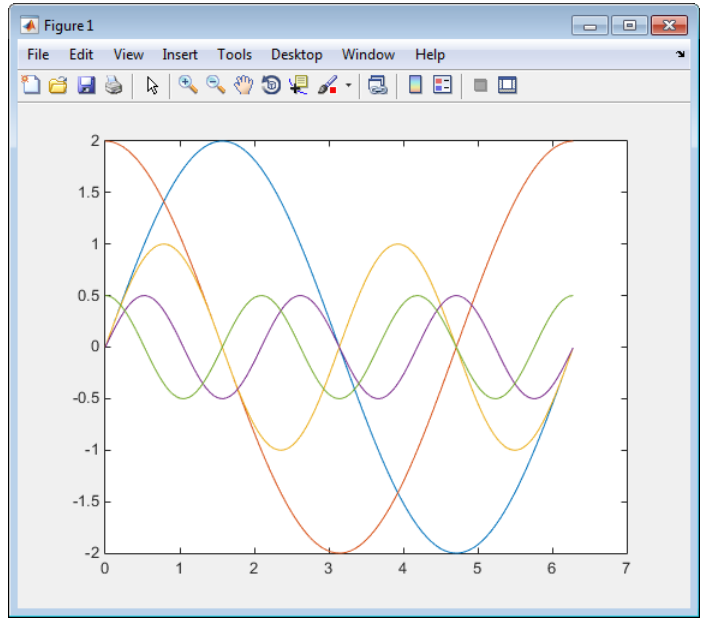
If your model's input data source is an Inport block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one

simulation to the next. Each MAT-file must adhere to one of the three formats described in “Create a MAT-File for an Inport Block” on page 46-14.

To specify the MAT-file after a simulation, you specify the executable with the `-i` option and the name of the MAT-file that contains the input data. For example:

1. Open the model rtwdemo_rsim_i.
2. Check the Inport block parameter settings. The following Inport block data parameter settings and specifications that you specify for the workspace variables must match settings in the MAT-file, as indicated in “Configure Inports to Provide Simulation Source Data” on page 46-6:
   - **Main > Interpolate data**
   - **Signal Attributes > Port dimensions**
   - **Signal Attributes > Data type**
   - **Signal Attributes > Signal type**
3. Build the model.
4. Set up the input signals. For example:

```
t=[0:0.01:2*pi]';
s1=[2*sin(t) 2*cos(t)];
s2=sin(2*t);
s3=[0.5*sin(3*t) 0.5*cos(3*t)];
plot(t, [s1 s2 s3])
```



5 Prepare the MAT-file by using one of the three available file formats described in "Create a MAT-File for an Inport Block" on page 46-14. The following example defines a signal-and-time structure in the workspace and names it `var_single_struct`.

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

6 Save the workspace variable `var_single_struct` to MAT-file `rsim_i_single_struct`.

```
save rsim_i_single_struct.mat var_single_struct;
```

7 Run a rapid simulation with the input data by using the `-i` option. Load and plot the results.

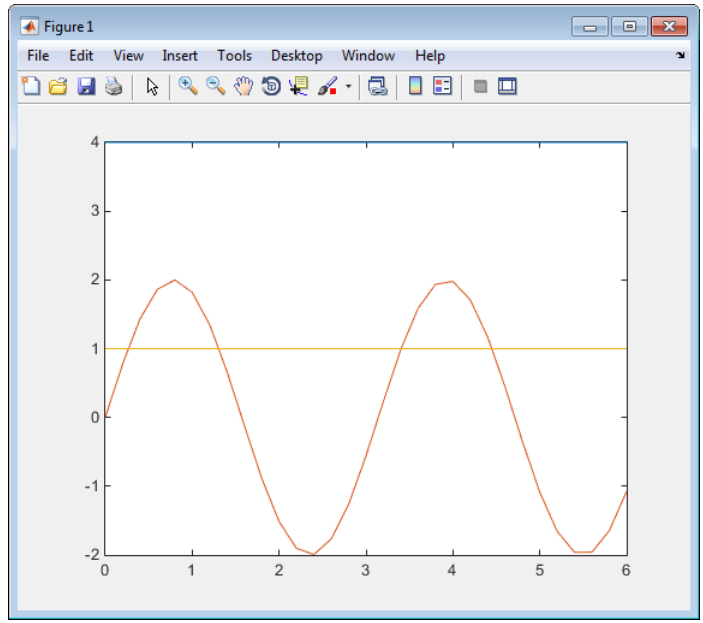
```
!rtwdemo_rsim_i -i rsim_i_single_struct.mat

** Starting model 'rtwdemo_rsim_i' @ Tue Aug 19 10:26:53 2014
 *** rsim_i_single_struct.mat is successfully loaded! ***
** created rtwdemo_rsim_i.mat **

** Execution time = 0.02024185130718954s
```

8 Load and plot the results.

```
load rtwdemo_rsim_i.mat
plot(rt_tout, rt_yout);
```



Change Block Parameters for an RSim Simulation

As described in "Create a MAT-File That Includes a Model Parameter Structure" on page 46-9, after you alter one or more parameters in a Simulink block diagram, you can extract the parameter vector, *`model`*`_P`, for the entire model. You can then save the parameter vector, along with a model checksum, to a MAT-file. This MAT-file can be read directly by the standalone RSim executable, allowing you to replace the entire parameter

vector or individual parameter values, for running studies of variations of parameter values representing coefficients, new data for input signals, and so on.

RSim can read the MAT-file and replace the entire *model*_P structure whenever you change one or more parameters, without recompiling the entire model.

For example, assume that you changed one or more parameters in your model, generated the new *model*_P vector, and saved *model*_P to a new MAT-file called `mymatfile.mat`. To run the same `rtwdemo_rsimtf` model and use these new parameter values, use the `-p` option, as shown in the following example:

```
!rtwdemo_rsimtf -p mymatfile.mat
load rtwdemo_rsimtf
plot(rt_yout)
```

If you have converted the parameter structure to a cell array for running simulations on varying data sets, as described in "Convert the Parameter Structure for Running Simulations on Varying Data Sets" on page 46-11, you must add an `@`*n* suffix to the MAT-file specification. *n* is the element of the cell array that contains the specific input that you want to use for the simulation.

The following example converts `param_struct` to a cell array, changes parameter values, saves the changes to MAT-file `mymatfile.mat`, and then runs the executable using the parameter values in the second element of the cell array as input.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
param_struct = rsimsetrtpparam(param_struct,2);
param_struct.parameters{1}

ans =

       dataTypeName: 'double'
         dataTypeId: 0
            complex: 0
         dtTransIdx: 0
             values: [-140 -4900 0 4900]
                map: []
    structParamInfo: []

param_struct.parameters{2}.values=[-150 -5000 0 4950];
save mymatfile.mat param_struct;
!rtwdemo_rsimtf -p mymatfile.mat@2 -o rsim2.mat
```

Specify a New Output File Name for a Simulation

If you have specified one or more of the **Save to Workspace** options — **Time**, **States**, **Outputs**, or **Final States** — in the Configuration Parameters dialog box, on the **Data Import/Export** pane, the default is to save simulation logging results to the file *`model`*`.mat`. For example, the example model `rtwdemo_rsimtf` normally saves data to `rtwdemo_rsimtf.mat`, as follows:

```
!rtwdemo_rsimtf
created rtwdemo_rsimtf.mat
```

You can specify a new output file name for data logging by using the `-o` option when you run an executable.

```
!rtwdemo_rsimtf -o rsim1.mat
```

In this case, the set of parameters provided at the time of code generation, including From File block data parameters, is run.

Specify New Output File Names for To File Blocks

In much the same way as you can specify a new system output file name, you can also provide new output file names for data saved from one or more To File blocks. To do this, specify the original file name at the time of code generation with a new name, as shown in the following example:

```
!rtwdemo_rsimtf -t rtwdemo_rsimtf_data.mat=mynewrsimdata.mat
```

In this case, assume that the original model wrote data to the output file `rtwdemo_rsimtf_data.mat`. Specifying a new file name forces RSim to write to the file `mynewrsimdata.mat`. With this technique, you can avoid overwriting an existing simulation run.

Tune Parameters Interactively During Rapid Simulation

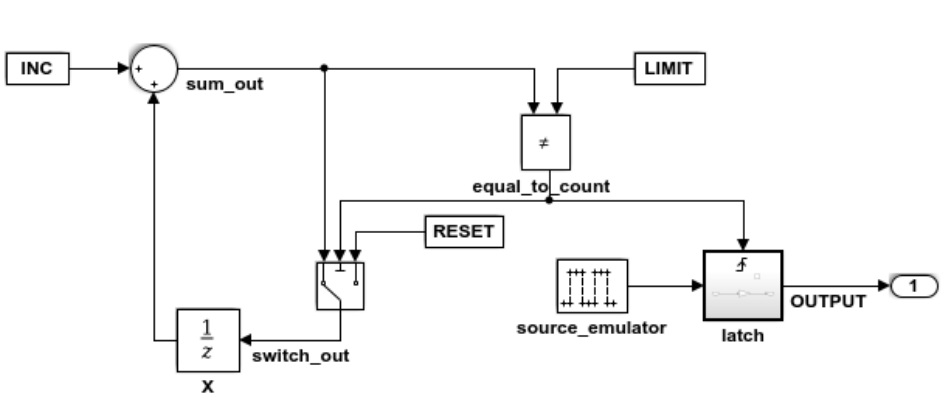
The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, whether you set **Default parameter behavior** to `Tunable` or to `Inlined`, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the file name to use for results.

For this example, **Default parameter behavior** is set to `Inlined`. The model declares workspace variables as tunable parameters. To use RSim with **Default parameter behavior** set to `Tunable`, and without explicitly declaring tunable parameters, see "Run Batch Simulations Without Recompiling Generated Code" (Simulink Coder).

Open Example Model

Open the example model `rtwdemo_rsim_param_tuning`.

```
open_system('rtwdemo_rsim_param_tuning');
```



The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the filename to use for results.

This model uses the RSim target to allow a non-real-time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to easily get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

View MATLAB programs

Double-click the buttons at the upper right sequentially to run the example. To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.

This model uses the RSim target and the `rsimgetrtp` function to allow a non real time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

Double-click the buttons at the upper right sequentially to run the example.

To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.

Rapid Simulation Target Limitations

The RSim target has the following limitations:

- Does not support algebraic loops.
- Does not support Interpreted MATLAB Function blocks.
- Does not support noninlined MATLAB language or Fortran S-functions.
- If an RSim build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In such cases, you must regenerate the code for the model.

More About

- “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” (Simulink Coder)

Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target

S-functions are an important class of system target file for which the code generator can produce code. The ability to encapsulate a subsystem into an S-function allows you to increase its execution efficiency and facilitate code reuse.

The following sections describe the properties of S-function targets and illustrate how to generate them. For more details on the structure of S-functions, see "Host-Specific Code" (Simulink).

In this section...

About the S-Function Target

Using the S-function target, you can build an S-function component and use it as an S-Function block in another model. The following sections describe deployment considerations for the S-function target.

- "Required Files for S-Function Deployment" on page 46-35
- "Sample Time Propagation in Generated S-Functions" on page 46-36
- "Choose a Solver Type" on page 46-36
- "Solver Type Overrides" on page 46-37

The `'S-Function'` value for `CodeFormat` TLC variable used by the S-function target generates code that conforms to the Simulink C MEX S-function application programming interface (API). Applications of this format include

- Conversion of a model to a component. You can generate an S-Function block for a model, `m1`. Then, you can place the generated S-Function block in another model, `m2`. Regenerating code for `m2` does not require regenerating code for `m1`.
- Conversion of a subsystem to a component. By extracting a subsystem to a separate model and generating an S-Function block from that model, you can create a reusable component from the subsystem. See "Create S-Function Blocks from a Subsystem" on page 46-37 for an example of this procedure.
- Speeding up simulation. Often, an S-function generated from a model performs more efficiently than the original model.
- Code reuse. You can incorporate multiple instances of one model inside another without replicating the code for each instance. Each instance continues to maintain its own unique data.

You can place a generated S-function block into another model from which you can generate another S-function. This approach allows any level of nested S-functions. For limitations related to nesting, see "Limitations on Nesting S-Functions" on page 46-49.

Note: While the S-function target provides a means to deploy an application component for reuse while shielding its internal logic from inspection and modification, the preferred solutions for protecting intellectual property in distributed components are:

- The protected model, a referenced model that hides all block and line information. For more information, see "Protected Model" (Simulink).
- The shared library system target file, used to generate a shared library for a model or subsystem for use in a system simulation external to Simulink. For more information, see "Package Generated Code as Shared Libraries" on page 47-2.

Required Files for S-Function Deployment

There are different files required to deploy a generated S-Function block for simulation versus code generation.

To deploy your generated S-Function block for inclusion in other models *for simulation*, you need only provide the binary MEX-file object that was generated in the current working folder when the S-Function block was created. The required file is:

- *subsys*`_sf.`*mexext*

where *subsys* is the subsystem name and *mexext* is a platform-dependent MEX-file extension (see mexext (MATLAB)). For example, `SourceSubsys_sf.mexw64`.

To deploy your generated S-Function block for inclusion in other models *for code generation*, you must provide all of the files that were generated in the current working folder when the S-Function block was created. The required files are:

- *subsys*`_sf.c` or `.cpp`, where *subsys* is the subsystem name (for example, `SourceSubsys_sf.c`)
- *subsys*`_sf.h`
- *subsys*`_sf.`*mexext*, where *mexext* is a platform-dependent MEX-file extension (see mexext (MATLAB))
- Subfolder *subsys*`_sfcn_rtw` and its contents

Note: The generated S-function code uses **Configuration Parameters > Hardware Implementation** parameter values that match the host system on which the function was built. When you use the S-function in a model for code generation, make sure that these parameter values for the model match the parameter values of the S-function.

Sample Time Propagation in Generated S-Functions

A generated S-Function block can inherit its sample time from the model in which it is placed if certain criteria are met. Conditions that govern sample time propagation for both Model blocks and generated S-Function blocks are described in "Sample Times for Model Referencing" (Simulink) and "Inherited Sample Time for Referenced Models" on page 5-23.

To generate an S-Function block that meets the criteria for inheriting sample time, you must constrain the solver for the model from which the S-Function block is generated. On the **Solver** configuration parameters dialog box pane, set **Type** to `Fixed-step` and **Periodic sample time constraint** to `Ensure sample time independent`. If the model is unable to inherit sample times, this setting causes the Simulink software to display an error message when building the model. For more information about this option, see "Periodic sample time constraint" (Simulink).

Choose a Solver Type

The table shows the possible combinations of top-level model solver types as these types relate to subsystem build types and solver types for generated S-functions.

Top-level Model Solver Options and Subsystem Build Types

	Model Configuration Parameters: top-level model configuration	
Subsystem Build Type	**Solver options, Type: Variable-step**	**Solver options, Type: Fixed-step**
Build This Subsystem	Generated S-function does NOT require variable-step solver	Generated S-function does NOT require variable-step solver
Generate S-Function	Generated S-function requires variable-step solver	Generated S-function does NOT require variable-step solver

Note: S-functions generated from a subsystem have parameters that are hard coded into the block. Simulink calculates parameters such as sample time when it generates the block, not during simulation run time. Hence, it is important to verify whether the generated S-Function block works as expected in the destination model.

Solver Type Overrides

There are instances when the subsystem build type selection produces an override of the subsystem solver type. The table summarizes the relationships between subsystem build types and the applied subsystem solver types.

Top-level Model Solver Type Overrides of Subsystem Solver Types by Build Type

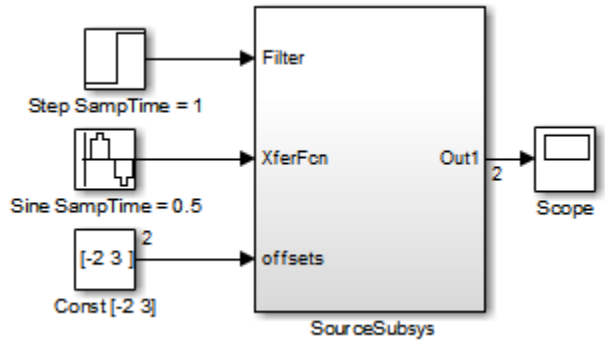
	Model Configuration Parameters: top-level model configuration	
Subsystem Build Type	**Solver options, Type: Variable-step**	**Solver options, Type: Fixed-step**
Build This Subsystem	Subsystem uses fixed-step solver type	Subsystem uses fixed-step solver type
Generate S-Function	Subsystem uses variable-step solver type	Subsystem uses fixed-step solver type

Create S-Function Blocks from a Subsystem

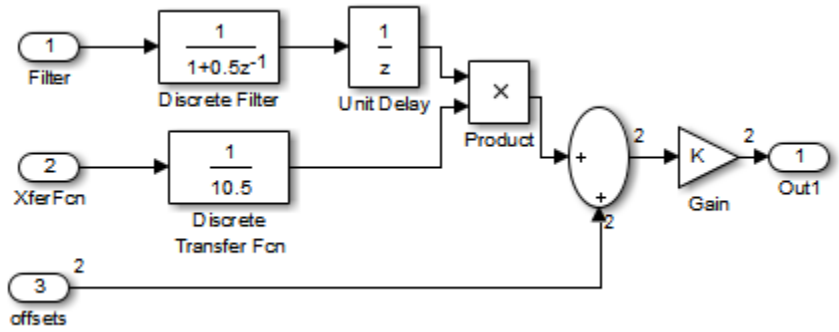
This section illustrates how to extract a subsystem from a model and generate a reusable S-function component from it.

The next figure shows `SourceModel`, a simple model that inputs signals to a subsystem. The subsequent figure shows the subsystem, `SourceSubsys`. The signals, which have different widths and sample times, are:

- A Step block with sample time 1
- A Sine Wave block with sample time 0.5
- A Constant block whose value is the vector [-2 3]



SourceModel



SourceSubsys

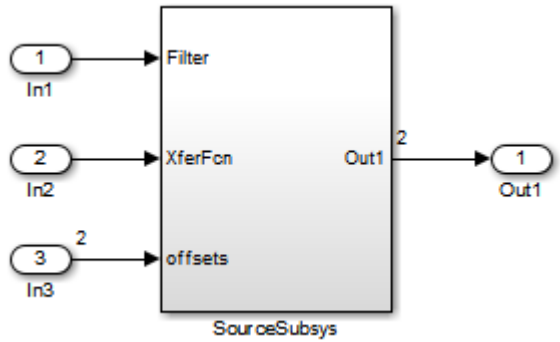
The objective is to extract `SourceSubsys` from the model and build an S-Function block from it, using the S-function target. The S-Function block must perform identically to the subsystem from which it was generated.

In this model, `SourceSubsys` inherits sample times and signal widths from its input signals. However, S-Function blocks created from a model using the S-function target has all signal attributes (such as signal widths or sample times) hard-wired. (The sole exception to this rule concerns sample times, as described in "Sample Time Propagation in Generated S-Functions" on page 46-36.)

In this example, you want the S-Function block to retain the properties of `SourceSubsys` as it exists in `SourceModel`. Therefore, before you build the subsystem as a separate S-function component, you must set the inport sample times and widths explicitly. In addition, the solver parameters of the S-function component must be the same as those parameters of the original model. The generated S-function component operates identically to the original subsystem (see "Choose a Solver Type" on page 46-36 for more information).

To build `SourceSubsys` as an S-function component,

1. Create a new model and copy/paste the `SourceSubsys` block into the empty window.
2. Set the signal widths and sample times of inports inside `SourceSubsys` such that they match those of the signals in the original model. Inport 1, `Filter`, has a width of 1 and a sample time of 1. Inport 2, `Xferfcn`, has a width of 1 and a sample time of 0.5. Inport 3, `offsets`, has a width of 2 and a sample time of 0.5.
3. The generated S-Function block should have three inports and one outport. Connect inports and an outport to `SourceSubsys`, as shown in the next figure.



The signal widths and sample times are propagated to these ports.

4 Set the solver type, mode, and other solver parameters such that they are identical to those of the source model. This is easiest to do if you use Model Explorer.

5 In the Configuration Parameters dialog box, go to the **Code Generation** pane.

6 Click **Browse** to open the System Target File Browser.

7 In the System Target File Browser, select the S-function target, `rtwsfcn.tlc`, and click **OK**.

8 Select the **S-Function Target** pane. Make sure that **Create new model** is selected, as shown in the next figure:

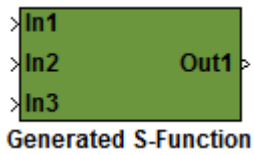
When this option is selected, the build process creates a new model after it builds the S-function component. The new model contains an S-Function block, linked to the S-function component.

Click **Apply**.

9 Save the new model containing your subsystem, for example as `SourceSubsys`.

10 Build the model.

11 The build process produces the S-function component in the working folder. After the build, a new model window is displayed.

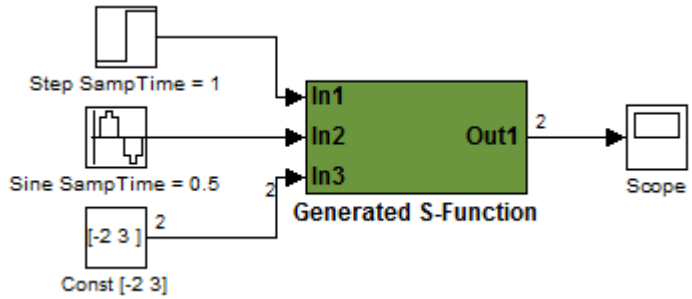


Optionally you can save the generated model, for example as `SourceSubsys_Sfunction`.

12 You can now copy the S-Function block generated from the new model and use it in other models or in a library.

Note: For a list of files required to deploy your S-Function block for simulation or code generation, see "Required Files for S-Function Deployment" on page 46-35.

The next figure shows the S-Function block plugged into the original model. Given identical input signals, the S-Function block performs identically to the original subsystem.



Generated S-Function Configured Like SourceModel

The speed at which the S-Function block executes is typically faster than the original model. This difference in speed is more pronounced for larger and more complicated models. By using generated S-functions, you can increase the efficiency of your modeling process.

Tunable Parameters in Generated S-Functions

You can use tunable parameters in generated S-functions in two ways:

- Use the **Generate S-function** feature (see "Automate S-Function Generation with S-Function Builder" on page 11-61).

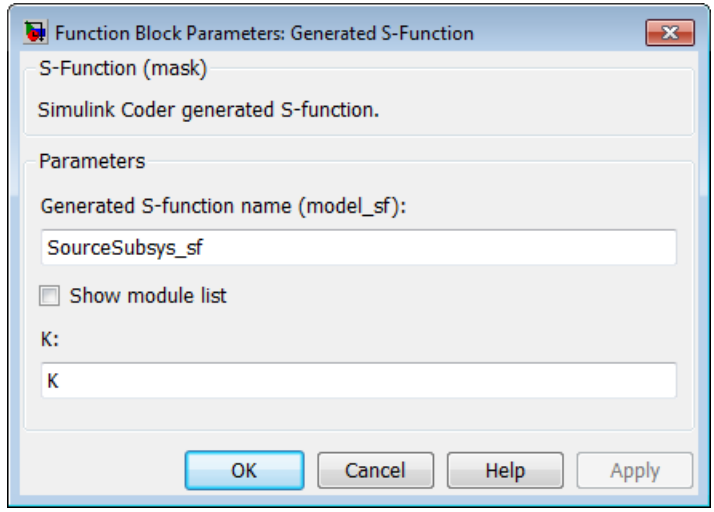
  or

- Use the Model Parameter Configuration dialog box (see "Block Parameter Representation in the Generated Code" on page 19-47) to declare desired block parameters tunable.

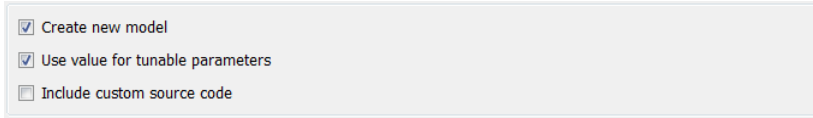
Block parameters that are declared tunable with the `auto` storage class in the source model become tunable parameters of the generated S-function. These parameters do not become part of a generated *`model`*`_P` (formerly `rtP`) parameter data structure, as they would in code generated from other targets. Instead, the generated code accesses these parameters by using MEX API calls such as `mxGetPr` or `mxGetData`. Your code should access these parameters in the same way.

For more information on MEX API calls, see "About C S-Functions" (Simulink) and "MATLAB API for Other Languages" (MATLAB).

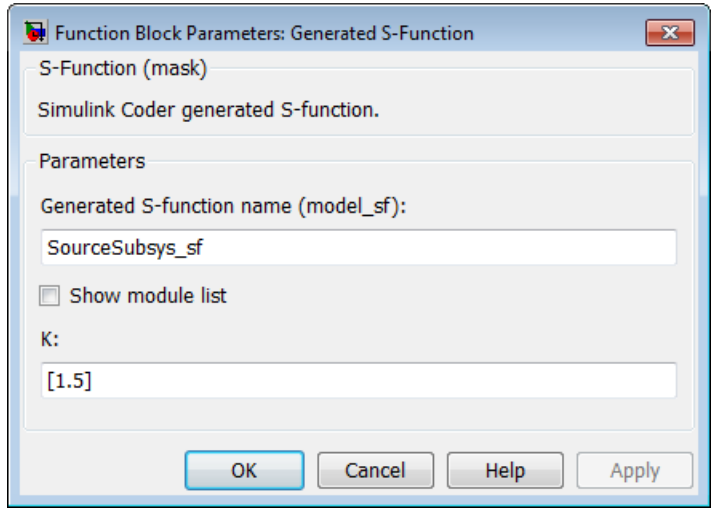
S-Function blocks created by using the S-function target are automatically masked. The mask displays each tunable parameter in an edit field. By default, the edit field displays the parameter by variable name, as in the following example.



You can choose to display the value of the parameter rather than its variable name by selecting **Use value for tunable parameters** on the **Code Generation > S-Function Target** pane of the Configuration Parameters dialog box.



When this option is chosen, the value of the variable (at code generation time) is displayed in the edit field, as in the following example.



System Target File

The `rtwsfcn.tlc` system target file is provided for use with the S-function target.

Checksums and the S-Function Target

The code generator creates a checksum for a model and uses the checksum during the build process for code reuse, model reference, and external mode features.

The code generator calculates a model checksum by

1. Calculating a checksum for each subsystem in the model. A subsystem's checksum is the combination of properties (data type, complexity, sample time, port dimensions, and so forth) of the subsystem's blocks.
2. Combining the subsystem checksums and other model-level information.

An S-function can add additional information, not captured during the block property analysis, to a checksum by calling the function `ssSetChecksumVal`. For the S-Function target, the value that gets added to the checksum is the checksum of the model or subsystem from which the S-function is generated.

The code generator applies the subsystem and model checksums as follows:

- Code reuse — If two subsystems in a model have the same checksum, the code generator produces code for one function only.
- Model reference — If the current model checksum matches the checksum when the model was built, the build process does not rebuild referenced models.
- External mode — If the current model checksum does not match the checksum of the code that is running on the target hardware, the build process generates an error.

Generated S-Function Compatibility

When you build a MEX S-function from your model, the code generator builds a level 2 noninlined S-function. Cross-release usage limitations on the generated code and binary MEX file (for example, `*.mexw64`) include:

- S-function target generated code from previous MATLAB release software is not compatible with newer releases. Do not recompile the generated code from a previous release with newer MATLAB release software. Use the same MATLAB release software to generate code for the S-function target and compile the code into a MEX file.
- You can use binary S-function MEX files generated from previous MATLAB release software with the same or newer releases with the same compatibility considerations as handwritten S-functions. For more information, see "S-Function Compatibility" (Simulink).
- The code generator can generate code and build an executable from a model that contains generated S-functions. This support requires that the S-functions are built with the same MATLAB release software that builds the model. It is not possible to incorporate a generated S-function MEX file from previous MATLAB release software into a model and build the model with newer releases.

S-Function Target Limitations

Limitations on Using Tunable Variables in Expressions

Certain limitations apply to the use of tunable variables in expressions. When the code generator encounters an unsupported expression while producing code, a warning appears and the equivalent numeric value is generated in the code. For a list of the limitations, see "Tunable Expression Limitations" on page 19-53.

Parameter Tuning

The S-Function block does not support tuning of tunable parameters with:

- Complex values.
- Values or data types that are transformed to a constant (by setting the model configuration parameter **Optimization > Signals and Parameters > Default parameter behavior** to `Inlined`).
- Data types that are not built-in.

If you select these tunable parameters (through the Generate S-Function for Subsystem dialog box):

- The software produces warnings during the build process.
- The generated S-Function block mask does not display these parameters.

Run-Time Parameters and S-Function Compatibility Diagnostics

If you set the **S-function upgrades needed** option on the **Diagnostics > Compatibility** pane of the Configuration Parameters dialog box to `warning` or `error`, the code generator instructs you to upgrade S-functions that you create with the **Generate S-function** feature. This is because the S-function system target file does

not register run-time parameters. Run-time parameters are only supported for inlined S-Functions and the generated S-Function supports features that prevent it from being inlined (for example, it can call or contain other noninlined S-functions).

You can work around this limitation by setting the **S-function upgrades needed** option to `none`.

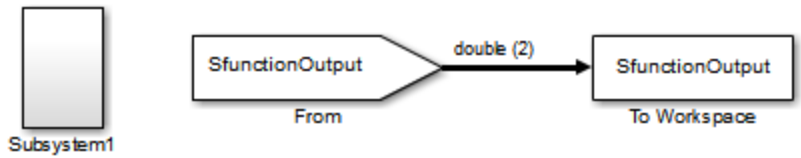
Limitations on Using Goto and From Block

When using the S-function system target file, the code generator restricts I/O to correspond to the root model Inport and Outport blocks (or the Inport and Outport blocks of the Subsystem block from which the S-function target was generated). No code is generated for Goto or From blocks.

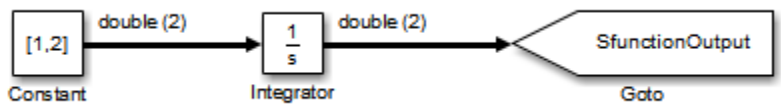
To work around this restriction, create your model and subsystem with the required Inport and Outport blocks, instead of using Goto and From blocks to pass data between the root model and subsystem. In the model that incorporates the generated S-function, you would then add Goto and From blocks.

Example Before Work Around

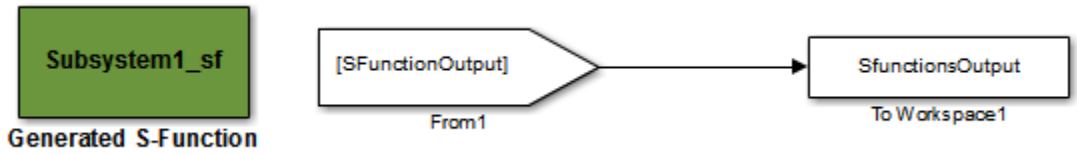
- Root model with a From block and subsystem, `Subsystem1`



- `Subsystem1` with a Goto block, which has global visibility and passes its input to the From block in the root model

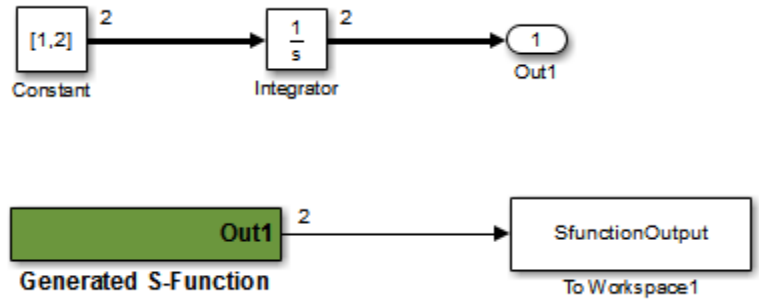


- `Subsystem1` replaced with an S-function generated with the S-Function target — a warning results when you run the model because the generated S-function does not implement the Goto block



Example After Work Around

An Outport block replaces the GoTo block in `Subsystem1`. When you plug the generated S-function into the root model, its output connects directly to the To Workspace block.



Limitations on Building and Updating S-Functions

The following limitations apply to building and updating S-functions using the S-function system target file:

- You cannot build models that contain Model blocks using the S-function system target file. This also means that you cannot build a subsystem module by right-clicking (or by using **Code > C/C++ Code > Build Selected Subsystem**) if the subsystem contains Model blocks. This restriction applies only to S-functions generated using the S-function target, not to ERT S-functions.
- If you modify the model that generated an S-Function block, the build process does not automatically rebuild models containing the generated S-Function block. This is in contrast to the practice of automatically rebuilding models referenced by Model blocks when they are modified (depending on the Model Reference **Rebuild** configuration setting).

- Handwritten S-functions without corresponding TLC files must contain exception-free code. For more information on exception-free code, see "Exception Free Code" (Simulink).

Unsupported Blocks

The S-function format does not support the following built-in blocks:

- Interpreted MATLAB Function block
- S-Function blocks containing any of the following:
  - MATLAB language S-functions (unless you supply a TLC file for C code generation)
  - Fortran S-functions (unless you supply a TLC file for C code generation)
  - C/C++ MEX S-functions that call into the MATLAB environment
- Scope block
- To Workspace block

The S-function format does not support blocks from the `embeddedtargetslib` block library.

`SimState` Not Supported for Code Generation

You can use `SimState` within C-MEX and Level-2 MATLAB language S-functions to save and restore the simulation state. See "S-Function Compliance with the SimState" (Simulink). However, `SimState` is not supported for code generation, including with the S-function system target file.

Profiling Code Performance with TLC Hook Function Not Supported

Profiling the performance of generated code using the Target Language Compiler (TLC) hook function interface described in "Profile Code Performance" (Simulink Coder) is not supported for the S-function target.

Note: If you have an Embedded Coder license, see "Code Execution Profiling" for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

Limitations on Nesting S-Functions

The following limitations apply to nesting a generated S-Function block in a model or subsystem from which you generate another S-function:

- The software does not support nonvirtual bus input and output signals for a nested S-function.
- You should avoid nesting an S-function in a model or subsystem having the same name as the S-function (possibly several levels apart). In such situations, the S-function can be called recursively. The software currently does not detect such loops in S-function dependency, which can result in aborting or hanging your MATLAB session. To prevent this from happening, be sure to name the subsystem or model to be generated as an S-function target uniquely, to avoid duplicating existing MEX filenames on the MATLAB path.

Limitations on User-Defined Data Types

The S-function system target file does not support the `HeaderFile` property that can be specified on user-defined data types, including those based on `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType` objects. If a user-defined data type in your model uses the `HeaderFile` property to specify an associated header file, code generation with the S-function system target file disregards the value and does not generate a corresponding include statement.

Limitation on Right-Click Generation of an S-Function Target

If you generate an S-function target by right-clicking a Function-Call Subsystem block, the original subsystem and the generated S-function might not be consistent. An inconsistency occurs when the **States when enabling** parameter of the Trigger Port block inside the Function-Call Subsystem block is set to **inherit**. You must set the **States when enabling** parameter to **reset** or **held**, otherwise Simulink reports an error.

Limitation on S-Functions with Bus I/O Signals

If an S-function generated using the S-function target has bus input or output signals, the generated bus data structures might include padding to align fields of the bus elements with the Simulink representation used during simulation. However, if you insert the S-function in a model and generate code using a model target such as `grt.tlc`, the bus structure alignment generated for the model build might be incompatible with the padding generated for the S-function and might affect the

numerical results of code execution. To make the structure alignment consistent between model simulation and execution of the model code, for each `Simulink.Bus` object, you can modify the `HeaderFile` property to remove the unpadded bus structure header file. This will cause the bus typedefs generated for the S-function to be reused in the model code.

Limitation on Subsystems with Function-Call I/O Signals

The S-function target does not support creating an S-Function block from a subsystem that has a function-call trigger input or a function-call output.

Data Store Access

When an S-Function in your model accesses a data store during simulation, Simulink disables data store diagnostics.

- If you created the S-Function from a model, the diagnostic is disabled for global data stores as well.
- If you created the S-Function from a subsystem, the diagnostic is disabled for the following data stores:
  - Global data stores
  - Data stores placed outside the subsystem, but accessed by Data Store Read or Data Store Write blocks.

Cannot Specify Outport Dimensions Through Subsystem Mask

You cannot specify **Port dimensions** for an Outport block through a subsystem mask if you want to generate an S-Function block from the subsystem. The software produces an error when you try to run a simulation that uses the S-Function block, for example:

```
Invalid setting in 'testSystem/Subsystem/__OutputSSForSFun__/Out2'
for parameter 'PortDimensions'
...
```

Desktops in Embedded Coder

Package Generated Code as Shared Libraries

If you have an Embedded Coder license, you can package generated source code from a model component for easy distribution and shared use by building the code as a shared library—Windows dynamic link library (`.dll`), UNIX shared object (`.so`), or Macintosh OS X dynamic library (`.dylib`). You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. The generated `.dll`, `.so`, or `.dylib` file is shareable among different applications and upgradeable without having to recompile the applications that use it.

About Generated Shared Libraries

You build a shared library by configuring the code generator to use the system target file `ert_shrlib.tlc`. Code generation for that system target file exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (*`model`*`_M`) as data
- Functions essential to executing your model code

To view a list of symbols contained in a generated shared library:

- On Windows, use the Dependency Walker utility, downloadable from http://www.dependencywalker.com
- On UNIX, use `nm -D` *`model`*`.so`
- On Macintosh OS X , use `nm -g` *`model`*`.dylib`

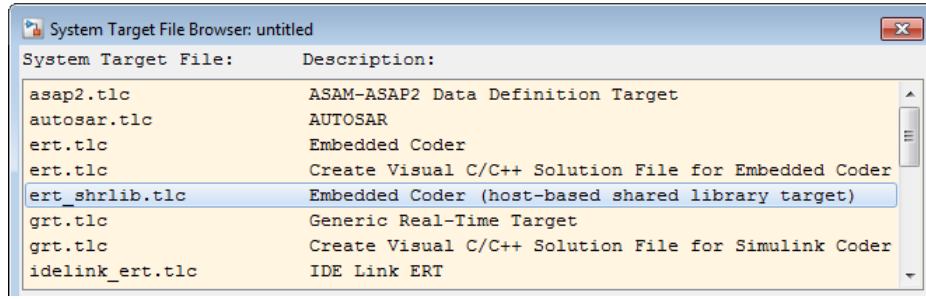
To generate and use a shared library:

1. Generate a shared library version of your model code
2. Create application code to load and use your shared library file

Generate Shared Library Version of Model Code

To generate a shared library version of your model code:

1. Open your model and configure it to use the `ert_shrlib.tlc` system target file.



Selecting the `ert_shrlib.tlc` system target file causes the build process to generate a shared library version of your model code into your current working folder. The selection does not change the code that the code generator produces for your model.

2. Build the model.
3. After the build completes, examine the generated code in the model subfolder and examine the `.dll`, `.so`, or `.dylib` file in your current folder.

Create Application Code to Use Shared Library

To illustrate how application code can load a shared library file and access its functions and data, MathWorks provides the model `rtwdemo_shrlib`.

Note: Change directory to a writable working folder before running the `rtwdemo_shrlib` script.

In the model, click the blue button to run a script. The script:

1. Builds a shared library file from the model (for example, `rtwdemo_shrlib_win64.dll` on 64-bit Windows).
2. Compiles and links an example application, `rtwdemo_shrlib_app`, that loads and uses the shared library file.
3. Executes the example application.

Tip: Explicit linking is preferred for portability. But, on Windows systems, the `ert_shrlib` system target file generates and retains the `.lib` file to support implicit linking.

To use implicit linking, the generated *`model`*`.h` file needs a small modification for you to use it with t with the generated `ert_main.c`. For example, if you are using Visual C++, declare `__declspec(dllimport)` in front of data to be imported implicitly from the shared library file.

The model uses the following example application files, which are located in the folder *`matlabroot`*`/toolbox/rtw/rtwdemos/shrlib_demo` (open).

File	Description
`rtwdemo_shrlib_app.h`	Example application header file
`rtwdemo_shrlib_app.c`	Example application that loads and uses the shared library file generated for the model
`run_rtwdemo_shrlib_app.m`	Script to compile, link, and execute the example application

You can view each of these files by clicking white buttons in the model window. Additionally, running the script places the relevant source and generated code files in your current folder. The files can be used as templates for writing application code for your own ERT shared library files.

The following sections present key excerpts of the example application files.

Example Application Header File

The example application header file `rtwdemo_shrlib_app.h` contains type declarations for the model's external input and output.

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

#endif /*_APP_MAIN_HEADER_*/
```

Example Application C Code

The example application `rtwdemo_shrlib_app.c` includes the following code for dynamically loading the shared library file. Notice that, depending on platform, the code invokes Windows or UNIX library commands.

```
#if (defined(_WIN32)||defined(_WIN64)) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

#endif

int main()
{
    void* handleLib;
...
#if defined(_WIN64)
    handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
#else
#if defined(_WIN32)
    handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
#else /* UNIX */
    handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
#endif
#endif
...
    return(CLOSELIB(handleLib));
}
```

The following code excerpt shows how the C application accesses the model's exported data and functions. Notice the hooks for adding user-defined initialization, step, and termination code.

```
    int32_T i;
 ...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);

    uint8_T (*sum_outptr);
...
#if (defined(LCCDLL)||defined(BORLANDCDLL))
```

```
    /* Exported symbols contain leading underscores when DLL is linked with
       LCC or BORLANDC */
    mdl_initialize =(void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_initialize");
    mdl_step       =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_step");
    mdl_terminate  =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_terminate");
    mdl_Uptr       =(ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_U");
    mdl_Yptr       =(ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_Y");
    sum_outptr     =(uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
    mdl_initialize =(void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_initialize");
    mdl_step       =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_step");
    mdl_terminate  =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_terminate");
    mdl_Uptr       =(ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_U");
    mdl_Yptr       =(ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_Y");
    sum_outptr     =(uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

    if ((mdl_initialize && mdl_step && mdl_terminate && mdl_Uptr && mdl_Yptr &&
         sum_outptr)) {
        /* === user application initialization function === */
        mdl_initialize(1);
        /* insert other user defined application initialization code here */

        /* === user application step function === */
        for(i=0;i<=12;i++){
            mdl_Uptr->Input = i;
            mdl_step();
            printf("Counter out(sum_out): %d\tAmplifier in(Input): %d\tout(Output): %d\n",
                   *sum_outptr, i, mdl_Yptr->Output);
            /* insert other user defined application step function code here */
        }

        /* === user application terminate function === */
        mdl_terminate();
        /* insert other user defined application termination code here */
    }
    else {
        printf("Cannot locate the specified reference(s) in the shared library.\n");
        return(-1);
    }
```

Example Application Script

The application script `run_rtwdemo_shrlib_app` loads and rebuilds the model, and then compiles, links, and executes the model's shared library target file. You can view the script source file by opening `rtwdemo_shrlib` and clicking a white button to view source code. The script constructs platform-dependent command character vectors for compilation, linking, and execution that may apply to your development environment. To run the script, click the blue button.

Note: To run the `run_rtwdemo_shrlib_app` script without first opening the `rtwdemo_shrlib` model, change directory to a writable working folder and issue the following MATLAB command:

```
addpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','shrlib_demo'))
```

Shared Library Limitations

The following limitations apply to building shared libraries:

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (*`model`*`_M`)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is greyed out on the **Code Generation** pane of the Configuration Parameters dialog box.
- To reconstruct a model simulation using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing needs to be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables parameters **Support: continuous time** and **Single output/update function**. For more information, see "Single output/update function" (Simulink Coder) dependencies.

Real-Time Systems in Simulink Coder

Deploy Algorithm Model for Real-Time Rapid Prototyping

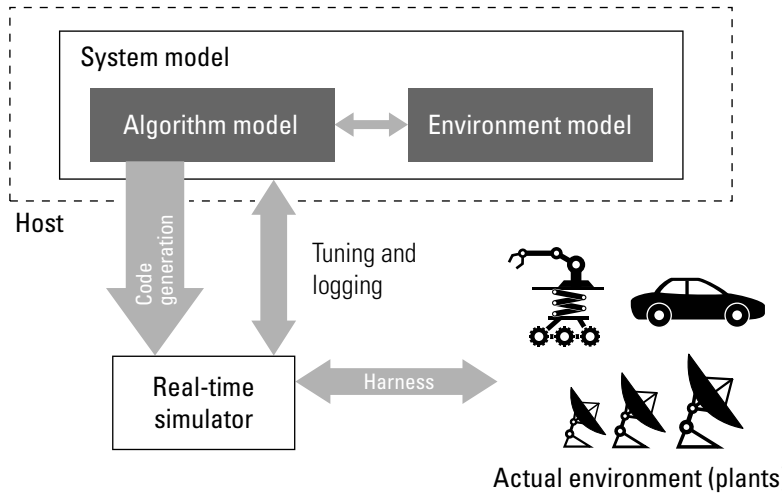
Use the code generator to deploy algorithm models for real-time rapid prototyping.

In this section...

About Real-Time Rapid Prototyping

Real-time rapid prototyping requires the use of a real-time simulator, potentially connected to system hardware (for example, physical plant or vehicle) being controlled. You generate, deploy, and tune code as it runs on the real-time simulator or embedded microprocessor. This design step is crucial for verifying whether a component can adequately control the system, and allows you to assess, interact with, and optimize code.

The following figure shows a typical approach for real-time rapid prototyping.



Goals of Real-Time Rapid Prototyping

Assuming that you have documented functional requirements, refined concept models, system hardware for the physical plant or vehicle being controlled, and access to target

products you intend to use (for example, for example, the Simulink Real-Time or Simulink Desktop Real-Time product), you can use real-time prototyping to:

- Refine component and environment model designs by rapidly iterating between algorithm design and prototyping
- Validate whether a component can adequately control the physical system in real time
- Evaluate system performance before laying out hardware, coding production software, or committing to a fixed design
- Test hardware

Refine Code With Real-Time Rapid Prototyping

To perform real-time rapid prototyping:

1. Create or acquire a real-time system that runs in real time on rapid prototyping hardware. The Simulink Real-Time product facilitates real-time rapid prototyping. This product provides a real-time operating system that makes PCs run in real time. It also provides device driver blocks for numerous hardware I/O cards. You can then create a rapid prototyping system using inexpensive commercial-off-the-shelf (COTS) hardware. In addition, third-party vendors offer products based on the Simulink Real-Time product or other code generation technology that you can integrate into a development environment.
2. Use provided system target files to generate code that you can deploy onto a real-time simulator. See the following information.

Engineering Tasks	Related Product Information	Examples
Generate code for real-time rapid prototyping	"Compare System Target File Support" (Simulink Coder) "Event-Based Scheduling" (Simulink Coder) Embedded Coder "Support for Standards and Guidelines" on page 12-2	`rtwdemo_counter` `rtwdemo_counter_msvc`

Engineering Tasks	Related Product Information	Examples
Generate code for rapid prototyping in hard real time, using PCs	Simulink Real-Time "Simulink Real-Time Options Pane" (Simulink Real-Time)	`help xpcdemos`
Generate code for rapid prototyping in soft real time, using PCs	Simulink Desktop Real-Time "Simulink Desktop Real-Time Pane" (Simulink Desktop Real-Time)	`sldrtex_vdp` (and others)

3 Monitor signals, tune parameters, and log data.

Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation

In this section...

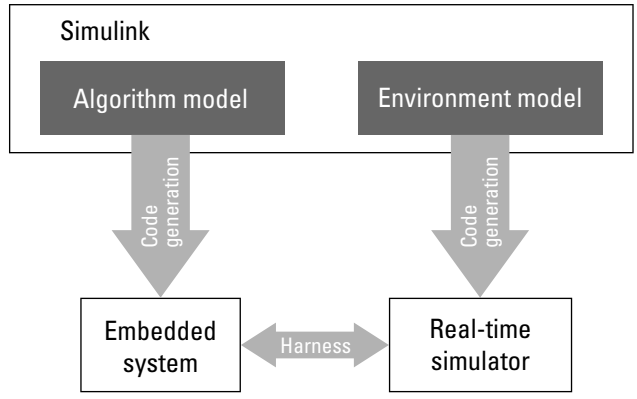
About Hardware-In-the-Loop Simulation

Hardware-in-the-loop (HIL) simulation tests and verifies an embedded system or control unit in the context of a software test platform. Examples of test platforms include real-time target systems and instruction set simulators (IISs). You use Simulink software to develop and verify a model that represents the test environment. Using the code generator, you produce, build, and download an executable program for the model to the HIL simulation platform. After you set up the environment, you can run the executable to validate the embedded system or control unit in real time.

During HIL simulation, you gradually replace parts of a system environment with hardware components as you refine and fabricate the components. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

The code that you build for the system simulator provides real-time system capabilities. For example, the code can include VxWorks from Wind River or another real-time operating system (RTOS).

The following figure shows a typical HIL setup.



The HIL platform available from MathWorks is the Simulink Real-Time product. Several third-party products are also available for use as HIL platforms. The Simulink Real-Time product offers hard real-time performance for PCs with Intel or AMD® 32-bit processors functioning as your real-time target. The Simulink Real-Time product enables you to add I/O interface blocks to your models and automatically generate code with code generation technology. The Simulink Real-Time product can download the code to a second PC running the Simulink Real-Time real-time kernel. System integrator solutions that are based on Simulink Real-Time are also available.

Set Up and Run HIL Simulations

To set up and run HIL simulations iterate through the following steps:

1. Develop a model that represents the environment or system under development.

   For more information, see "Compare System Target File Support" (Simulink Coder).
2. Generate an executable for the environment model.
3. Download the executable for the environment model to the HIL simulation platform.
4. Replace software representing a system component with corresponding hardware.
5. Test the hardware in the context of the HIL system.
6. Repeat steps 4 and 5 until you can simulate the system after including components that require testing.

Real-Time and Embedded Systems in Embedded Coder

Deploy Generated Standalone Executable Programs To Target Hardware

By default, the Embedded Coder software generates *standalone* executable programs that do not require an external real-time executive or operating system. A standalone program requires minimal modification to be adapted to the target hardware. The standalone program architecture supports execution of models with either single or multiple sample rates.

In this section...

Generate a Standalone Program

To generate a standalone program:

1. In the **Custom templates** section of the **Code Generation > Templates** pane of the Configuration Parameters dialog box, select the **Generate an example main program** option (which is on by default). This enables the **Target operating system** menu.
2. From the **Target operating system** menu, select `BareBoardExample` (the default selection).
3. Generate the code.

Different code is generated for multirate models depending on the following factors:

- Whether the model executes in single-tasking or multitasking mode.
- Whether or not reusable code is being generated.

These factors affect the scheduling algorithms used in generated code, and in some cases affect the API for the model entry point functions. The following sections discuss these variants.

Standalone Program Components

The core of a standalone program is the main loop. On each iteration, the main loop executes a background or null task and checks for a termination condition.

The main loop is periodically interrupted by a timer. The function `rt_OneStep` is either installed as a timer interrupt service routine (ISR), or called from a timer ISR at each clock step.

The execution driver, `rt_OneStep`, sequences calls to the *`model`*`_step` functions. The operation of `rt_OneStep` differs depending on whether the generating model is single-rate or multirate. In a single-rate model, `rt_OneStep` simply calls the *`model`*`_step` function. In a multirate model, `rt_OneStep` prioritizes and schedules execution of blocks according to the rates at which they run.

Main Program

Overview of Operation

The following pseudocode shows the execution of a main program.

```
main()
{
  Initialization (including installation of rt_OneStep as an
    interrupt service routine for a real-time clock)
  Initialize and start timer hardware
  Enable interupts
  While(not Error) and (time < final time)
    Background task
  EndWhile
  Disable interrupts (Disable rt_OneStep from executing)
  Complete any background tasks
  Shutdown
}
```

The pseudocode is a design for a harness program to drive your model. The main program only partially implements this design. You must modify it according to your specifications.

Guidelines for Modifying the Main Program

This section describes the minimal modifications you should make in your production version of the main program module to implement your harness program.

1. Call *`model`*`_initialize`.
2. Initialize target-specific data structures and hardware, such as ADCs or DACs.
3. Install `rt_OneStep` as a timer ISR.
4. Initialize timer hardware.
5. Enable timer interrupts and start the timer.

   Note `rtModel` is not in a valid state until *`model`*`_initialize` has been called. Servicing of timer interrupts should not begin until *`model`*`_initialize` has been called.
6. Optionally, insert background task calls in the main loop.
7. On termination of the main loop (if applicable):

   - Disable timer interrupts.
   - Perform target-specific cleanup such as zeroing DACs.
   - Detect and handle errors. Note that even if your program is designed to run indefinitely, you may need to handle severe error conditions, such as timer interrupt overruns.

     You can use the macros `rtmGetErrorStatus` and `rtmSetErrorStatus` to detect and signal errors.

rt_OneStep and Scheduling Considerations

Overview of Operation

The operation of `rt_OneStep` depends upon

- Whether your model is single-rate or multirate. In a single-rate model, the sample times of all blocks in the model, and the model's fixed step size, are the same. A model in which the sample times and step size do not meet these conditions is termed multirate.
- Your model's solver mode (`SingleTasking` versus `MultiTasking`)

Permitted Solver Modes for Embedded Real-Time System Target Files summarizes the permitted solver modes for single-rate and multirate models. Note that for a single-rate model, only `SingleTasking` solver mode is allowed.

Permitted Solver Modes for Embedded Real-Time System Target Files

Mode	Single-Rate	Multirate
`SingleTasking`	Allowed	Allowed
`MultiTasking`	Disallowed	Allowed
`Auto`	Allowed (defaults to `SingleTasking`)	Allowed (defaults to `MultiTasking`)

The generated code for `rt_OneStep` (and associated timing data structures and support functions) is tailored to the number of rates in the model and to the solver mode. The following sections discuss each possible case.

Single-Rate Single-Tasking Operation

The only valid solver mode for a single-rate model is `SingleTasking`. Such models run in “single-rate” operation.

The following pseudocode shows the design of `rt_OneStep` in a single-rate program.

```
rt_OneStep()
{
  Check for interrupt overflow or other error
  Enable "rt_OneStep" (timer) interrupt
  Model_Step()  -- Time step combines output,logging,update
}
```

For the single-rate case, the generated *`model`*`_step` function is

```
void model_step(void)
```

Single-rate `rt_OneStep` is designed to execute *`model`*`_step` within a single clock period. To enforce this timing constraint, `rt_OneStep` maintains and checks a timer overrun flag. On entry, timer interrupts are disabled until the overrun flag and other error conditions have been checked. If the overrun flag is clear, `rt_OneStep` sets the flag, and proceeds with timer interrupts enabled.

The overrun flag is cleared only upon successful return from *`model`*`_step`. Therefore, if `rt_OneStep` is reinterrupted before completing *`model`*`_step`, the reinterruption is detected through the overrun flag.

Reinterruption of `rt_OneStep` by the timer is an error condition. If this condition is detected `rt_OneStep` signals an error and returns immediately. (Note that you can change this behavior if you want to handle the condition differently.)

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the interrupt overflow flag has been checked.

Multirate Multitasking Operation

In a multirate multitasking system, code generation uses a prioritized, preemptive multitasking scheme to execute the different sample rates in your model.

The following pseudocode shows the design of `rt_OneStep` in a multirate multitasking program.

```
rt_OneStep()
{
  Check for base-rate interrupt overrun
  Enable "rt_OneStep" interrupt
  Determine which rates need to run this time step

  Model_Step0()        -- run base-rate time step code

  For N=1:NumTasks-1   -- iterate over sub-rate tasks
    If (sub-rate task N is scheduled)
    Check for sub-rate interrupt overrun
      Model_StepN()    -- run sub-rate time step code
    EndIf
  EndFor
}
```

Task Identifiers

The execution of blocks having different sample rates is broken into tasks. Each block that executes at a given sample rate is assigned a *task identifier* (`tid`), which associates it with a task that executes at that rate. Where there are `NumTasks` tasks in the system, the range of task identifiers is 0..`NumTasks`-1.

Prioritization of Base-Rate and Subrate Tasks

Tasks are prioritized, in descending order, by rate. The *base-rate* task is the task that runs at the fastest rate in the system (the hardware clock rate). The base-rate task has highest priority (`tid` 0). The next fastest task (`tid` 1) has the next highest priority, and so on down to the slowest, lowest priority task (`tid NumTasks`-1).

The slower tasks, running at multiples of the base rate, are called *subrate* tasks.

Rate Grouping and Rate-Specific model_step Functions

In a single-rate model, the block output computations are performed within a single function, *`model`*`_step`. For multirate, multitasking models, the code generator tries to use a different strategy. This strategy is called *rate grouping*. Rate grouping generates separate *`model`*`_step` functions for the base rate task and each subrate task in the model. The function naming convention for these functions is

`model``_step`*`N`*

where *`N`* is a task identifier. For example, for a model named `my_model` that has three rates, the following functions are generated:

```
void my_model_step0 (void);
void my_model_step1 (void);
void my_model_step2 (void);
```

Each *`model`*`_step`*`N`* function executes the blocks sharing `tid` *`N`*; in other words, the block code that executes within task *`N`* is grouped into the associated *`model`*`_step`*`N`* function.

Scheduling model_stepN Execution

On each clock tick, `rt_OneStep` maintains scheduling counters and *event flags* for each subrate task. The counters are implemented as `taskCounter` arrays indexed on `tid`. The event flags are implemented as arrays indexed on `tid`.

The scheduling counters and task flags for sub-rates are maintained by `rt_OneStep`. The scheduling counters are basically clock rate dividers that count up the sample period

associated with each sub-rate task. A pair of tasks that exchanges data maintains an interaction flag at the faster rate. Task interaction flags indicate that both fast and slow tasks are scheduled to run.

The event flags indicate whether or not a given task is scheduled for execution. `rt_OneStep` maintains the event flags based on a task counter that is maintained by code in the main program module for the model. When a counter indicates that a task's sample period has elapsed, the main code sets the event flag for that task.

On each invocation, `rt_OneStep` updates its scheduling data structures and steps the base-rate task (`rt_OneStep` calls *`model`*`_step0` because the base-rate task must execute on every clock step). Then, `rt_OneStep` iterates over the scheduling flags in `tid` order, unconditionally calling *`model`*`_step`*`N`* for any task whose flag is set. The tasks are executed in order of priority.

Preemption

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the base-rate interrupt overflow flag has been checked (see pseudocode above).

The event flag array and loop variables used by `rt_OneStep` are stored as local (stack) variables. Therefore, `rt_OneStep` is reentrant. If `rt_OneStep` is reinterrupted, higher priority tasks preempt lower priority tasks. Upon return from interrupt, lower priority tasks resume in the previously scheduled order.

Overrun Detection

Multirate `rt_OneStep` also maintains an array of timer overrun flags. `rt_OneStep` detects timer overrun, per task, by the same logic as single-rate `rt_OneStep`.

Note If you have developed multirate S-functions, or if you use a customized static main program module, see “Rate Grouping Compliance and Compatibility Issues” on page 49-17 for information about how to adapt your code for rate grouping compatibility. This adaptation lets your multirate, multitasking models generate more efficient code.

Multirate Single-Tasking Operation

In a multirate single-tasking program, by definition, sample times in the model must be an integer multiple of the model's fixed-step size.

In a multirate single-tasking program, blocks execute at different rates, but under the same task identifier. The operation of `rt_OneStep`, in this case, is a simplified version of multirate multitasking operation. Rate grouping is not used. The only task is the base-rate task. Therefore, only one *`model`*`_step` function is generated:

```
void model_step(void)
```

On each clock tick, `rt_OneStep` checks the overrun flag and calls *`model`*`_step`. The scheduling function for a multirate single-tasking program is `rate_scheduler` (rather than `rate_monotonic_scheduler`). The scheduler maintains scheduling counters on each clock tick. There is one counter for each sample rate in the model. The counters are implemented in an array (indexed on tid) within the `Timing` structure within `rtModel`.

The counters are clock rate dividers that count up the sample period associated with each subrate task. When a counter indicates that a sample period for a given rate has elapsed, `rate_scheduler` clears the counter. This condition indicates that blocks running at that rate should execute on the next call to *`model`*`_step`, which is responsible for checking the counters.

Guidelines for Modifying rt_OneStep

`rt_OneStep` does not require extensive modification. The only required modification is to reenable interrupts after the overrun flags and error conditions have been checked. If applicable, you should also

- Save and restore your FPU context on entry and exit to `rt_OneStep`.
- Set model inputs associated with the base rate before calling *`model`*`_step0`.
- Get model outputs associated with the base rate after calling *`model`*`_step0`.

Note: If you modify `rt_OneStep` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline below.

- In a multirate, multitasking model, set model inputs associated with subrates before calling *`model`*`_step`*`N`* in the subrate loop.
- In a multirate, multitasking model, get model outputs associated with subrates after calling *`model`*`_step`*`N`* in the subrate loop.

Comments in `rt_OneStep` indicate the place to add your code.

In multirate `rt_OneStep`, you can improve performance by unrolling `for` and `while` loops.

In addition, you may choose to modify the overrun behavior to continue execution after error recovery is complete.

Also observe the following cautionary guidelines:

- You should not modify the way in which the counters, event flags, or other timing data structures are set in `rt_OneStep`, or in functions called from `rt_OneStep`. The `rt_OneStep` timing data structures (including `rtModel`) and logic are critical to the operation of the generated program.
- If you have customized the main program module to read model outputs after each base-rate model step, be aware that selecting model options **Support: continuous time** and **Single output/update function** together may cause output values read from `main` for a continuous output port to differ slightly from the corresponding output values in the model's logged data. This is because, while logged data is a snapshot of output at major time steps, output read from `main` after the base-rate model step potentially reflects intervening minor time steps. To eliminate the discrepancy, either separate the generated output and update functions (clear the **Single output/update function** option) or place a Zero-Order Hold block before the continuous output port.
- It is possible to observe a mismatch between results from simulation and logged MAT file results from generated code if you do not set model inputs before each time you call the model step function. In the generated example main program, the following comments show the locations for setting the inputs and stepping the model with your code:

  ```
  /* Set model inputs here */
  /* Step the model */
  ```

  If your model applies signal reuse and you are using `MatFileLogging` for comparing results from simulation against generated code, modify `rt_OneStep` to write model inputs in every time step as directed by these comments. Alternatively, you could “Choose a SIL or PIL Approach” on page 64-11 for verification.

Static Main Program Module

Overview

In most cases, the easiest strategy for deploying generated code is to use the **Generate an example main program option** to generate the `ert_main.c` or `.cpp` module (see "Generate a Standalone Program" on page 49-2).

However, if you turn the **Generate an example main program** option off, you can use a static main module as an example or template for developing your embedded applications. Static main modules provided by MathWorks include:

- *matlabroot*`/rtw/c/src/common/rt_main.c` — Supports `Nonreusable function` code interface packaging.
- *matlabroot*`/rtw/c/src/common/rt_malloc_main.c` — Supports `Reusable function` code interface packaging. The model option **Use dynamic memory allocation for model initialization** must be on and model parameter **Pass root-level I/O as** must be set to `Part of model data structure`.
- *matlabroot*`/rtw/c/src/common/rt_cppclass_main.cpp` — Supports `C++ class` code interface packaging.

The static main module is not part of the generated code; it is provided as a basis for your custom modifications, and for use in simulation. If your existing applications depend upon a static `ert_main.c` (developed in releases before R2012b), `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`, you may need to continue using a static main program module.

When developing applications using a static main module, you should copy the module to your working folder and rename it before making modifications. For example, you could rename `rt_main.c` to *`model`*`_rt_main.c`. Also, you must modify the template makefile or toolchain settings such that the build process creates a corresponding object file, such as *`model`*`_rt_main.obj` (on UNIX, *`model`*`_rt_main.o`), in the build folder.

The static main module contains

- `rt_OneStep`, a timer interrupt service routine (ISR). `rt_OneStep` calls *`model`*`_step` to execute processing for one clock period of the model.
- A skeletal `main` function. As provided, `main` is useful in simulation only. You must modify `main` for real-time interrupt-driven execution.

For single-rate models, the operation of `rt_OneStep` and the main function are essentially the same in the static main module as they are in the automatically generated version described in "Deploy Generated Standalone Executable Programs To

Target Hardware" on page 49-2. For multirate, multitasking models, however, the static and generated code are slightly different. The next section describes this case.

Rate Grouping and the Static Main Program

Targets based on the ERT target sometimes use a static main module and disallow use of the **Generate an example main program** option. This is done because target-specific modifications have been added to the static main module, and these modifications would not be preserved if the main program were regenerated.

Your static main module may or may not use rate grouping compatible *model*_step*N* functions. If your main module is based on the static `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` module, it does not use rate-specific *model*_step*N* function calls. It uses the old-style *model*_step function, passing in a task identifier:

```
void model_step(int_T tid);
```

By default, when the **Generate an example main program** option is off, the ERT target generates a *model*_step "wrapper" for multirate, multitasking models. The purpose of the wrapper is to interface the rate-specific *model*_step*N* functions to the old-style call. The wrapper code dispatches to the *model*_step*N* call with a `switch` statement, as in the following example:

```
void mymodel_step(int_T tid) /* Sample time:  */
{

  switch(tid) {
   case 0 :
    mymodel_step0();
    break;
   case 1 :
    mymodel_step1();
    break;
   case 2 :
    mymodel_step2();
    break;
   default :
    break;
  }
}
```

The following pseudocode shows how `rt_OneStep` calls *model*_step from the static main program in a multirate, multitasking model.

```
rt_OneStep()
{
  Check for base-rate interrupt overflow
  Enable "rt_OneStep" interrupt
  Determine which rates need to run this time step

  ModelStep(tid=0)     --base-rate time step

  For N=1:NumTasks-1  -- iterate over sub-rate tasks
    Check for sub-rate interrupt overflow
    If (sub-rate task N is scheduled)
      ModelStep(tid=N)    --sub-rate time step
    EndIf
  EndFor
}
```

You can use the TLC variable `RateBasedStepFcn` to specify that only the rate-based step functions are generated, without the wrapper function. If your target calls the rate grouping compatible *`model`*`_step`*`N`* function directly, set `RateBasedStepFcn` to `1`. In this case, the wrapper function is not generated.

You should set `RateBasedStepFcn` prior to the `%include "codegenentry.tlc"` statement in your system target file. Alternatively, you can set `RateBasedStepFcn` in your `target_settings.tlc` file.

Modify the Static Main Program

As with the generated `ert_main.c` or `.cpp`, you should make a few modifications to the main loop and `rt_OneStep`. See "Guidelines for Modifying the Main Program" on page 49-4 and "Guidelines for Modifying rt_OneStep" on page 49-9.

Also, you should replace the `rt_OneStep` call in the main loop with a background task call or null statement.

Other modifications you may need to make are

- If applicable, follow comments in the code regarding where to add code for reading/writing model I/O and saving/restoring FPU context.

Note: If you modify `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline in "Guidelines for Modifying rt_OneStep" on page 49-9.

- When the **Generate an example main program** option is off, `rtmodel.h` is generated to provide an interface between the main module and generated model code. If you create your own static main program module, you would normally include `rtmodel.h`.

  Alternatively, you can suppress generation of `rtmodel.h`, and include *`model`*`.h` directly in your main module. To suppress generation of `rtmodel.h`, use the following statement in your system target file:

  ```
  %assign AutoBuildProcedure = 0
  ```

- If you have cleared the **Terminate function required** option, remove or comment out the following in your production version of `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`:

  - The `#if TERMFCN...` compile-time error check
  - The call to `MODEL_TERMINATE`

- For `rt_main.c` (not applicable to `rt_cppclass_main.cpp`): If you do *not* want to combine output and update functions, clear the **Single output/update function** option and make the following changes in your production version of `rt_main.c`:

  - Replace calls to `MODEL_STEP` with calls to `MODEL_OUTPUT` and `MODEL_UPDATE`.
  - Remove the `#if ONESTEPFCN...` error check.

- The static `rt_main.c` module does not support `Reusable function` code interface packaging. The following error check raises a compile-time error if `Reusable function` code interface packaging is used illegally.

  ```
  #if MULTI_INSTANCE_CODE==1
  ```

Modify Static Main to Allocate and Access Model Instance Data

If you are using a static main program module, and your model is configured for `Reusable function` code interface packaging, but the model option **Use dynamic memory allocation for model initialization** is not selected, model instance data must be allocated either statically or dynamically by the calling main code. Pointers to the individual model data structures (such as Block IO, DWork, and Parameters) must be set up in the top-level real-time model data structure.

To support main modifications, the build process generates a subset of the following real-time model (RTM) macros, based on the data requirements of your model, into *`model`*`.h`.

RTM Macro Syntax	Description
`rtmGetBlockIO(rtm)`	Get the block I/O data structure
`rtmSetBlockIO(rtm,val)`	Set the block I/O data structure
`rtmGetContStates(rtm)`	Get the continuous states data structure
`rtmSetContStates(rtm,val)`	Set the continuous states data structure
`rtmGetDefaultParam(rtm)`	Get the default parameters data structure
`rtmSetDefaultParam(rtm,val)`	Set the default parameters data structure
`rtmGetPrevZCSigState(rtm)`	Get the previous zero-crossing signal state data structure
`rtmSetPrevZCSigState(rtm,val)`	Set the previous zero-crossing signal state data structure
`rtmGetRootDWork(rtm)`	Get the DWork data structure
`rtmSetRootDWork(rtm,val)`	Set the DWork data structure
`rtmGetU(rtm)`	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmSetU(rtm,val)`	Set the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmGetY(rtm)`	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
`rtmSetY(rtm,val)`	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

Use these macros in your static main program to access individual model data structures within the RTM data structure. For example, suppose that the example model `rtwdemo_reusable` is configured with `Reusable function` code interface packaging, **Use dynamic memory allocation for model initialization** cleared, **Pass root-level I/O as** set to `Individual arguments`, and **Optimization** pane option **Remove root level I/O zero initialization** cleared. Building the model generates the following model data structures and model entry-points into `rtwdemo_reusable.h`:

```
/* Block states (auto storage) for system '<Root>' */
typedef struct {
  real_T Delay_DSTATE;                 /* '<Root>/Delay' */
} D_Work;
```

```
/* Parameters (auto storage) */
struct Parameters_ {
  real_T k1;                           /* Variable: k1
                                        * Referenced by: '<Root>/Gain'
                                        */
};

/* Model entry point functions */
extern void rtwdemo_reusable_initialize(RT_MODEL *const rtM, real_T *rtU_In1,
  real_T *rtU_In2, real_T *rtY_Out1);
extern void rtwdemo_reusable_step(RT_MODEL *const rtM, real_T rtU_In1, real_T
  rtU_In2, real_T *rtY_Out1);
```

Additionally, if **Generate an example main program** is not selected for the model, `rtwdemo_reusable.h` contains definitions for the RTM macros `rtmGetDefaultParam`, `rtmsetDefaultParam`, `rtmGetRootDWork`, and `rtmSetRootDWork`.

Also, for reference, the generated `rtmodel.h` file contains an example parameter definition with initial values (non-executing code):

```
#if 0

/* Example parameter data definition with initial values */
static Parameters rtP = {
  2.0                                  /* Variable: k1
                                        * Referenced by: '<Root>/Gain'
                                        */
};                                     /* Modifiable parameters */

#endif
```

In the definitions section of your static main file, you could use the following code to statically allocate the real-time model data structures and arguments for the `rtwdemo_reusable` model:

```
static RT_MODEL rtM_;
static RT_MODEL *const rtM = &rtM_;    /* Real-time model */
static Parameters rtP = {
  2.0                                  /* Variable: k1
                                        * Referenced by: '<Root>/Gain'
                                        */
};                                     /* Modifiable parameters */

static D_Work rtDWork;                 /* Observable states */

/* '<Root>/In1' */
static real_T rtU_In1;

/* '<Root>/In2' */
static real_T rtU_In2;

/* '<Root>/Out1' */
```

```
static real_T rtY_Out1;
```

In the body of your main function, you could use the following RTM macro calls to set up the model parameters and DWork data in the real-time model data structure:

```
int_T main(int_T argc, const char *argv[])
{
...
/* Pack model data into RTM */

rtmSetDefaultParam(rtM, &rtP);
rtmSetRootDWork(rtM, &rtDWork);

/* Initialize model */
rtwdemo_reusable_initialize(rtM, &rtU_In1, &rtU_In2, &rtY_Out1);
...
}
```

Follow a similar approach to set up multiple instances of model data, where the real-time model data structure for each instance has its own data. In particular, the parameter structure (`rtP`) should be initialized, for each instance, to the desired values, either statically as part of the `rtP` data definition or at run time.

Rate Grouping Compliance and Compatibility Issues

Main Program Compatibility

When the **Generate an example main program** option is off, code generation produces slightly different rate grouping code, for compatibility with the older static `ert_main.c` module. See "Rate Grouping and the Static Main Program" on page 49-12 for details.

Make Your S-Functions Rate Grouping Compliant

Built-in Simulink blocks, as well as DSP System Toolbox blocks, are compliant with the requirements for generating rate grouping code. However, user-written multirate inlined S-functions may not be rate grouping compliant. Noncompliant blocks generate less efficient code, but are otherwise compatible with rate grouping. To take full advantage of the efficiency of rate grouping, your multirate inlined S-functions must be upgraded to be fully rate grouping compliant. You should upgrade your TLC S-function implementations, as described in this section.

Use of noncompliant multirate blocks to generate rate-grouping code generates dead code. This can cause two problems:

- Reduced code efficiency.
- Warning messages issued at compile time. Such warnings are caused when dead code references temporary variables before initialization. Since the dead code does not run, this problem does not affect the run-time behavior of the generated code.

To make your S-functions rate grouping compliant, you can use the following TLC functions to generate `ModelOutputs` and `ModelUpdate` code, respectively:

```
OutputsForTID(block, system, tid)
UpdateForTID(block, system, tid)
```

The code listings below illustrate generation of output computations without rate grouping (Listing 1) and with rate grouping (Listing 2). Note the following:

- The `tid` argument is a task identifier (`0..NumTasks-1`).
- Only code guarded by the `tid` passed in to `OutputsForTID` is generated. The `if (%<LibIsSFcnSampleHit(portName)>)` test is not used in `OutputsForTID`.
- When generating rate grouping code, `OutputsForTID` and/or `UpdateForTID` is called during code generation. When generating non-rate-grouping code, `Outputs` and/or `Update` is called.
- In rate grouping compliant code, the top-level `Outputs` and/or `Update` functions call `OutputsForTID` and/or `UpdateForTID` functions for each rate (`tid`) involved in the block. The code returned by `OutputsForTID` and/or `UpdateForTID` must be guarded by the corresponding `tid` guard:

  ```
  if (%<LibIsSFcnSampleHit(portName)>)
  ```

  as in Listing 2.

Deploy Generated Component Software to Application Target Platforms

The code generator supports integration of generated code with operating systems and processors. For details, see “Embedded Coder Supported Hardware” on page 68-2.

Interface to an Example Real-Time Operating System (VxWorks®)

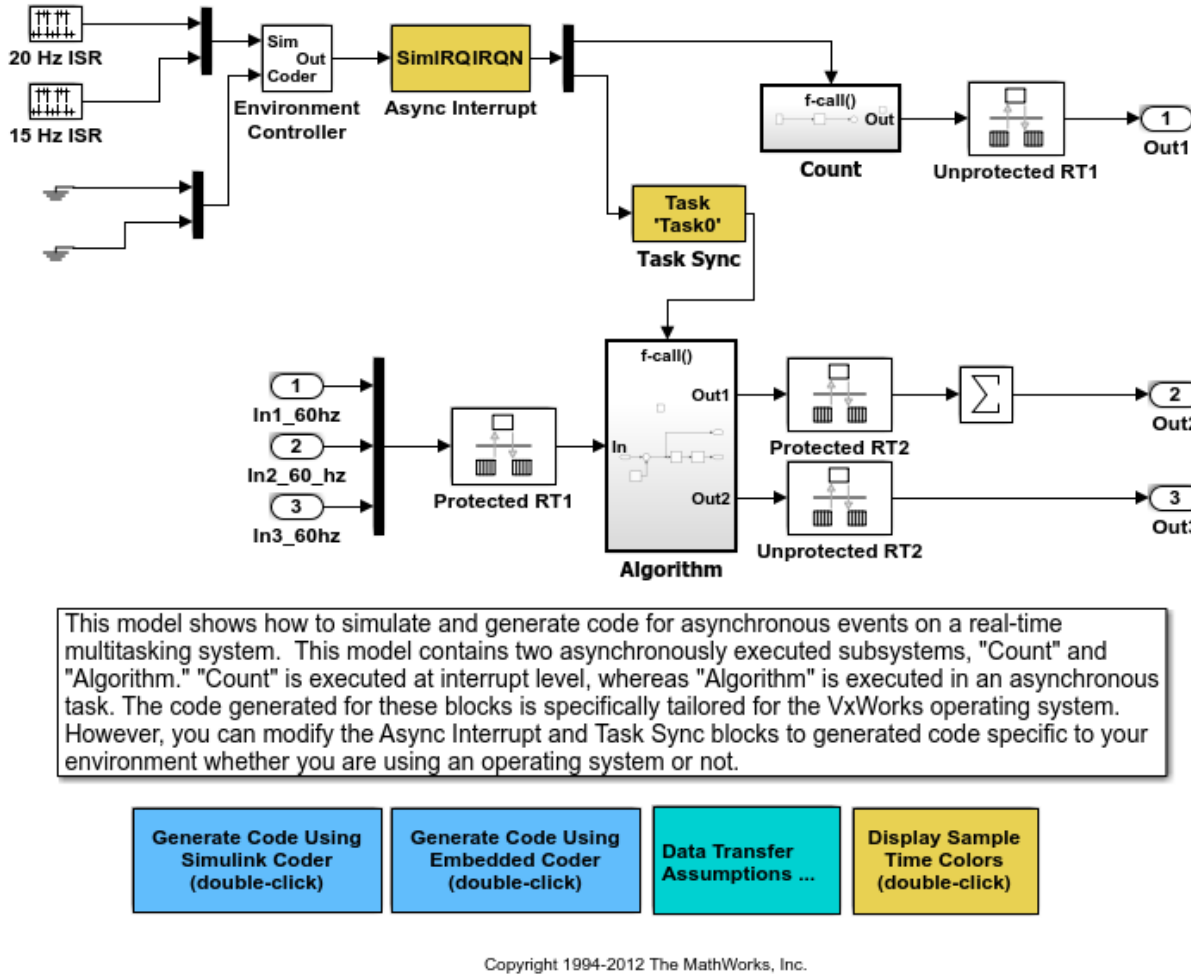
This example shows how to simulate and generate code for asynchronous events on an example RTOS (VxWorks).

The operating system integration techniques that are demonstrated in this example use one or more blocks the blocks in the `vxlib1` library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

Example Model

Open the `rtwdemo_vxworks` model.

```
model = 'rtwdemo_vxworks';
open_system(model);
%
```



Model Description

The example model contains two asynchronously executed subsystems, `Count` and `Algorithm`. `Count` executes at interrupt level. `Algorithm` executes in an asynchronous task. The generated code for these blocks is tailored for the VxWorks® operating system. However, you can modify the `Async Interrupt` and `Task Sync` blocks to generate code for your run-time environment whether you are using an operating system or not.

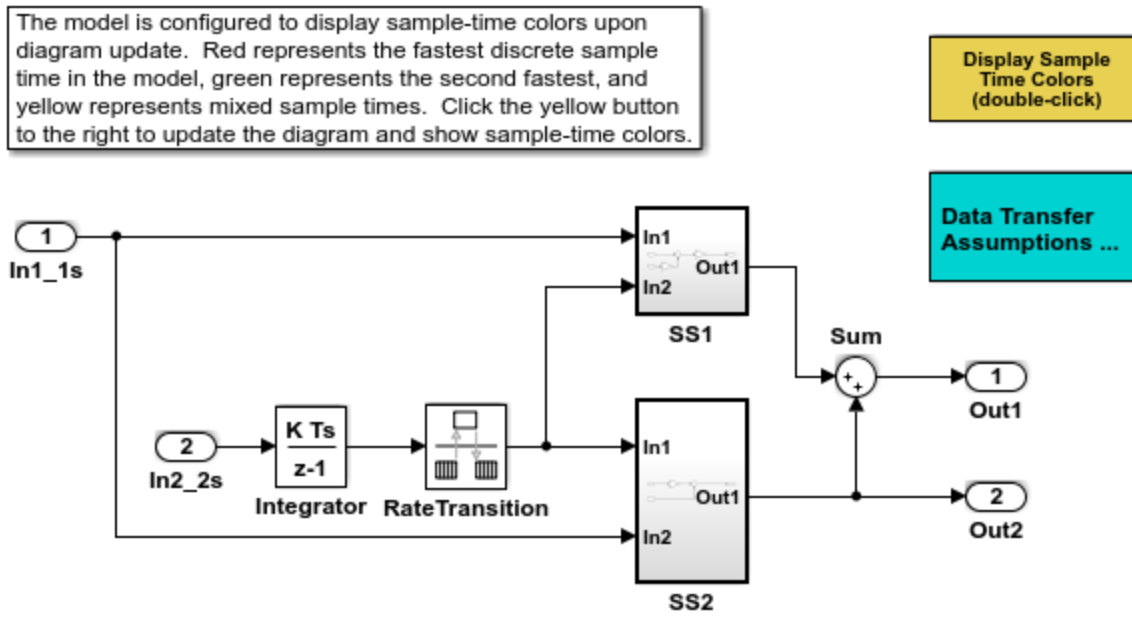
Multirate Modeling in Multitasking Mode (VxWorks® OS)

This example generates code for a multirate discrete-time model configured for a multitasking operating system target (VxWorks®). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the **Periodic sample time constraint** solver configuration parameter setting. The solver is set for multitasking operation, which means a Rate Transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Simulink® and the code generator enforce proper rate transitions. This model specifies an explicit Rate Transition block. Alternatively, you can instruct Simulink® to insert this block for you by setting the **Automatically handle data transfers between tasks** solver configuration parameter.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the **Display Sample Time Colors** button to update the diagram and show sample-time colors.

Example Model

```
model = 'rtwdemo_mrmtos';
open_system(model);
```



This model shows the code generated for a multirate discrete-time model configured for a multitasking operating system target (VxWorks). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the "Automatically handle data transfers between tasks" option on the Solver configuration page.

This example uses a Embedded Coder feature to generate an example VxWorks main (i.e., "Target operating system" on the Template configuration page.) Simulink Coder also supports VxWorks via the Tornado target.

Generate Code Using Embedded Coder (double-click)

Export Code Generated from Model to External Application in Embedded Coder

Control Generation of Function Prototypes

The Embedded Coder software provides a **Configure Model Functions** button, located on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, that allows you to control the model function prototypes that are generated for ERT-based models.

By default, the function prototype of an ERT-based model's generated *`model`*`_step` function resembles the following:

```
void model_step(void);
```

The function prototype of an ERT-based model's generated *`model`*`_initialize` function resembles the following:

```
void model_initialize(void);
```

(For more detailed information about the default calling interface for the *`model`*`_step` function, see the `model_step` reference page.)

The **Configure Model Functions** button on the **Interface** pane provides you flexible control over the model function prototypes that are generated for your model. Clicking **Configure Model Functions** launches a Model Interface dialog box. Based on the **Function specification** value you specify for your model function (supported values include `Default model initialize and step functions` and `Model specific C prototypes`), you can preview and modify the function prototypes. Once you validate and apply your changes, you can generate code based on your function prototype modifications.

For more information about using the **Configure Model Functions** button and the Model Interface dialog box, see “Sample Procedure for Configuring Function Prototypes” on page 26-11 and the example model `rtwdemo_fcnprotoctrl`, which is preconfigured to demonstrate function prototype control.

Alternatively, you can use function prototype control functions to programmatically control model function prototypes. For more information, see “Configure Function Prototypes Programmatically” on page 26-16“Configure Function Prototypes Programmatically” on page 26-16.

You can also control model function prototypes for nonvirtual subsystems, if you generate subsystem code using right-click build. To launch the **Model Interface for subsystem** dialog box, use the `RTW.configSubsystemBuild` function.

Right-click building the subsystem generates the step and initialization functions according to the customizations you make. For more information, see “Configure Function Prototypes for Nonvirtual Subsystems” on page 26-9.

For limitations that apply, see “Function Prototype Control Limitations” on page 26-21.

Control Generation of C++ Class Interfaces

Using the **Code interface packaging** (Simulink Coder) option `C++ class`, on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see "Configure C++ Class Interfaces for Nonvirtual Subsystems" on page 26-44.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an `ert.tlc` system target file provided by MathWorks.
2. Select the `C++` language for your model.
3. Select `C++ class` code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see "Simple Use of C++ Class Control" on page 26-24. For more details about configuring C++ class interfaces for your model code, see "Customize C++ Class Interfaces Using Graphical Interfaces" on page 26-31 and "Customize C++ Class Interfaces Programmatically" on page 26-45. For limitations that apply, see "C++ Class Interface Control Limitations" on page 26-50.

Note: For an example of C++ class code generation, see the example model `rtwdemo_cppclass`.

Code Replacement Customization for Simulink Models in Embedded Coder

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator's match and replacement process for functions

To get started, "Quick Start Library Development" on page 51-28.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority
3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
4. Uses the C or C++ replacement function prototype in the code replacement object to generate code.

Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See "Verify Code Replacements" on page 51-76.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See "Specify Build Information for Replacement Code" on page 51-59.
- Addition and subtraction operation replacements—See"Addition and Subtraction Operator Code Replacement" on page 51-170 for relevant limitations.
- Data alignment—
  - Not supported for
    - Arguments associated with a built-in custom storage class with `DataScope` set to `Exported` or the imported built-in custom storage class `GetSet`
    - Software-in-the-loop (SIL)
    - Processor-in-the-loop (PIL)
    - Model reference parameters
    - Exported functions in Stateflow charts
    - Replaced functions that are generated with C function prototype control or C++ class I/O arguments step method and that use root-level I/O variables
    - Replaced functions that are generated with the AUTOSAR system target file and that use root-level I/O or AUTOSAR inter-runnable access functions
  - If the following conditions exist, the code generator includes data alignment directives for root-level I/O variables in the `ert_main.c` or `ert_main.cpp` file it produces:
    - Compiler supports global variable alignment
    - Generate an example main program (select **Configuration Parameters** > **All Parameters** > **Generate an example main program**)
    - Generate a reusable function interface for the model (set **Configuration Parameters** > **Code Generation** > **Interface** > **Code interface packaging** to `Reusable function`)

  - Function uses root-level I/O variables that are passed in as individual arguments (set **Configuration Parameters** > **Code Generation** > **Interface** > **Pass root-level I/O as**to `Individual arguments`)
  - Replaced function uses a root-level I/O variable
  - Replaced function imposes alignment requirements

  If you discard the generated example main program, align used root-level I/O variables correctly.

  If you choose not to generate an example main program in this case, the code generator does not replace the function.
- If a replacement imposes alignment requirements on the shared utility interface arguments, the code generator does not honor data alignment. Under these conditions, replacement does not occur. Replacement is allowed if the registered data alignment type specification supports alignment of local variables, and the replacement involves only local variables.
- For `Simulink.Bus`:
  - If user registered alignment specifications do not support structure field alignment, aligning `Simulink.Bus` objects is not supported unless the `Simulink.Bus` is imported.
  - When aligning a `Simulink.Bus` data object, the elements in the bus object are aligned on the same boundary. The boundary is the lowest common multiple of the alignment requirements for each individual bus element.
- When you specify alignment for functions that occur in a model reference hierarchy, and multiple models in the hierarchy operate on the same function data, the bottommost model dictates alignment for the rest of the hierarchy. If the alignment requirement for a function in a model higher in the hierarchy cannot be honored due to the alignment set by a model lower in the hierarchy, the replacement in the higher model does not occur. In some cases, an error message is generated. To work around this issue, if the shared data is represented by a bus or signal object, manually set the alignment property on the shared data by setting the alignment property of the `Simulink.Bus` or `Simulink.Signal` object.
- It is your responsibility to honor the `Alignment` property setting for custom storage classes that you create.

See “Data Alignment for Code Replacement” on page 51-133.

- `coder.replace` function — See `coder.replace` for relevant limitations.

Code You Can Replace From Simulink Models

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

For information on how to explore functions and operators that a code replacement library supports, see "Choose a Code Replacement Library" on page 38-9 license and want to develop a custom code replacement library, see Code Replacement Customization.

In this section...

Math Functions – Simulink Support

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`abs`[1]	Integer Floating point Fixed point	Scalar Vector Matrix	Real
`acos`	Floating point	Scalar	Real Complex input/complex output Real input/complex output
`acosd`[2]	Floating point	Scalar Vector	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Matrix	
`acosh`	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output
`acot`[2]	Floating point	Scalar Vector Matrix	Real Complex
`acotd`[2]	Floating point	Scalar Vector Matrix	Real Complex
`acoth`[2]	Floating point	Scalar Vector Matrix	Real Complex
`acsc`[2]	Floating point	Scalar Vector Matrix	Real Complex
`acscd`[2]	Floating point	Scalar Vector Matrix	Real Complex
`acsch`[2]	Floating point	Scalar Vector Matrix	Real Complex
`asec`[2]	Floating point	Scalar Vector Matrix	Real Complex
`asecd`[2]	Floating point	Scalar Vector Matrix	Real Complex
`asech`[2]	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`asin`	Floating point	Scalar	Real Complex input/complex output Real input/complex output
`asind`[2]	Floating point	Scalar Vector Matrix	Real Complex
`asinh`	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output

`sqrt`	Integer Floating point Fixed point	Scalar Vector Matrix	Real
`tan`	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output
`tand`[2]	Floating point	Scalar Vector Matrix	Real Complex
`tanh`	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output

[1] Wrap on integer overflow only. Clear block parameter **Saturate on integer overflow**.

[2] Only when used with the MATLAB Function block.

[3] Supports the CORDIC approximation method.

[4] Stateflow support only.

Math Functions – Stateflow Support

When generating C/C++ code from Stateflow charts, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`abs`[1]	Integer Floating point	Scalar	Real
`acos`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
			Real input/complex output
`acosd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acot`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acotd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acoth`[3,5]	Floating point	Scalar Vector Matrix	Real Complex
`acsc`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acscd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acsch`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asec`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asecd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asech`[3]	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`asin`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`asind`[3]	Floating point	Scalar Vector Matrix	Real Complex
`atan`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`atan2`[2]	Floating point	Scalar Vector Matrix	Real
`atan2d`[3]	Floating point	Scalar Vector Matrix	Real
`atand`[3]	Floating point	Scalar Vector Matrix	Real Complex
`ceil`	• Floating-point • Scalar	• Floating-point • Scalar	• Floating-point • Scalar

`sind`[3]	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`sinh`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`sqrt`	Floating point	Scalar	Real
`tan`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`tand`[3]	Floating point	Scalar Vector Matrix	Real Complex
`tanh`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output

[1] Wrap on integer overflow only.

[2] For models involving vectors or matrices, the code generator replaces only functions coded in the MATLAB action language.

[3] The code generator replaces only functions coded in the MATLAB action language.

Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`memcmp`	Void pointer (`void*`)	Scalar	Real

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Vector Matrix	Complex
`memcpy`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset2zero`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

Nonfinite Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following nonfinite functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`getInf`	Floating point	Scalar	Real
`getMinusInf`	Floating point	Scalar	Real
`getNaN`	Floating point	Scalar	Real
`rtIsInf`	Floating point	Scalar	Real Complex
`rtIsNaN`	Floating point	Scalar	Real Complex

Mutex and Semaphore Functions

Mutex and semaphore functions control access to resources shared by multiple processes in multicore target environments. MathWorks provides code replacement libraries that support mutex and semaphore replacement for Rate Transition and Task Transition blocks on Windows, Linux, Mac, and VxWorks platforms.

Generated mutex and semaphore code typically consists of:

- In model initialization code, an initialization function call to create a mutex or semaphore to control entry to a critical section of code.
- In model step code:
  - Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls to reserve a critical section of code.
  - After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls to release the critical section of code.
- In model termination code, an optional destroy function call to explicitly delete the mutex or semaphore.

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following mutex and semaphore functions with application-specific implementations.

Function	Key
Mutex Destroy	`RTW_MUTEX_DESTROY`
Mutex Init	`RTW_MUTEX_INIT`
Mutex Lock	`RTW_MUTEX_LOCK`
Mutex Unlock	`RTW_MUTEX_UNLOCK`
Semaphore Destroy	`RTW_SEM_DESTROY`
Semaphore Init	`RTW_SEM_INIT`
Semaphore Post	`RTW_SEM_POST`
Semaphore Wait	`RTW_SEM_WAIT`

Operators

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates that you can specify different data types for different inputs.

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Addition (+)[1]	`RTW_OP_ADD`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Subtraction (-)[1]	`RTW_OP_MINUS`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*)[2]	`RTW_OP_MUL`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Division (/)	`RTW_OP_DIV`	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	`RTW_OP_CAST`	Integer Floating point[3] Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	`RTW_OP_SL`	Integer Fixed-point Mixed	Scalar Vector Matrix[4]	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Shift right arithmetic (>>)[5]	RTW_OP_SRA	Integer Fixed-point Mixed	Scalar Vector Matrix[4]	Real
Shift right logical (>>)	RTW_OP_SRL	Integer Fixed-point Mixed	Scalar Vector Matrix[4]	Real
Element-wise matrix multiplication (.*)[6]	RTW_OP_ELEM_MUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix right division (/)	RTW_OP_RDIV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix left division (\)	RTW_OP_LDIV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix inversion (inv)	RTW_OP_INV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Complex conjugation	RTW_OP_CONJUGATE	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Transposition (.')	RTW_OP_TRANS	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Hermitian (complex conjugate) transposition (')	RTW_OP_HERMITIAN	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with transposition[2]	RTW_OP_TRMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with Hermitian transposition[2]	RTW_OP_HMMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication followed by shift right arithmetic (u1*u2>>u3)[7]	RTW_OP_MUL_SRA	Integer Fixed-point	Scalar	Real
Multiplication followed by division (u1*u2/u3)[8]	RTW_OP_MULDIV	Integer Fixed-point	Scalar	Real
Greater than (>)	RTW_OP_GREATER_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Greater than or equal (>=)	RTW_OP_GREATER_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than (<)	RTW_OP_LESS_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Less than or equal (<=)	RTW_OP_LESS_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Equal (==)	RTW_OP_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Not equal (!=)	RTW_OP_NOT_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support

[1] See "Addition and Subtraction Operator Code Replacement" on page 51-170 for details to consider when defining mappings for addition and subtraction code replacements.

[2] Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

[3] Scaled floating point is not supported.

[4] Shift operator replacement with matrix data is supported for shift values that you specify with an input port. Replacement is not supported for shift values that you specify in a block parameter dialog.

[5] The code generator converts some arithmetic shift rights to logical shift rights. To avoid unexpected results, when creating a code replacement library that includes a table entry for an arithmetic shift right implementation, also include an entry for a logical shift right implementation.

[6] Use the multiplication (`*`) operator (`RTW_OP_MUL`) for scalar multiplication.

[7] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope` and `Mul_output_slope == output_slope_of_shift_operation`).

[8] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope`).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. "Identify Code Replacement Requirements" on page 51-38
2. "Prepare for Code Replacement Library Development" on page 51-41
3. "Define Code Replacement Mappings" on page 51-42
4. "Specify Build Information for Replacement Code" on page 51-59
5. "Register Code Replacement Mappings" on page 51-68
6. "Verify Code Replacements" on page 51-76
7. "Deploy Code Replacement Library" on page 51-93

To get started, see "Identify Code Replacement Requirements" on page 51-38.

To experiment with the process and tools, see "Quick Start Library Development" on page 51-28.

More About

- "Code You Can Replace From Simulink Models" on page 51-7
- "Identify Code Replacement Requirements" on page 51-38
- "Quick Start Library Development" on page 51-28
- "What Is Code Replacement Customization?" on page 51-3

Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the Code Replacement Tool.

Prerequisites

To complete this example, install the following software:

- MATLAB
- Simulink
- Simulink Coder
- Embedded Coder

For instructions on installing MathWorks products, see the "Installation and Activation" (Installation, Licensing, and Activation). If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

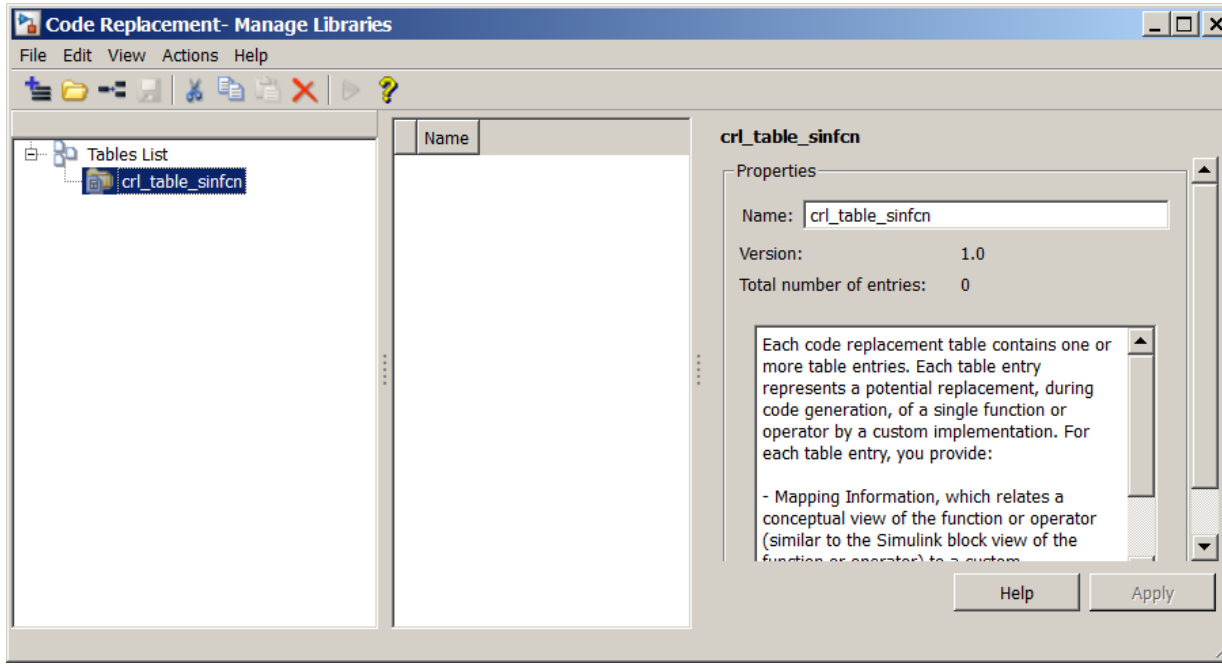
For a list of supported compilers, see http://www.mathworks.com/support/compilers/current_release/.

Open the Code Replacement Tool

1. Start a new MATLAB session.
2. Create or navigate (`cd`) to an empty folder.
3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

Create Code Replacement Table

1. In the Code Replacement Tool window, select **File > New table**.
2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.



Create Table Entry

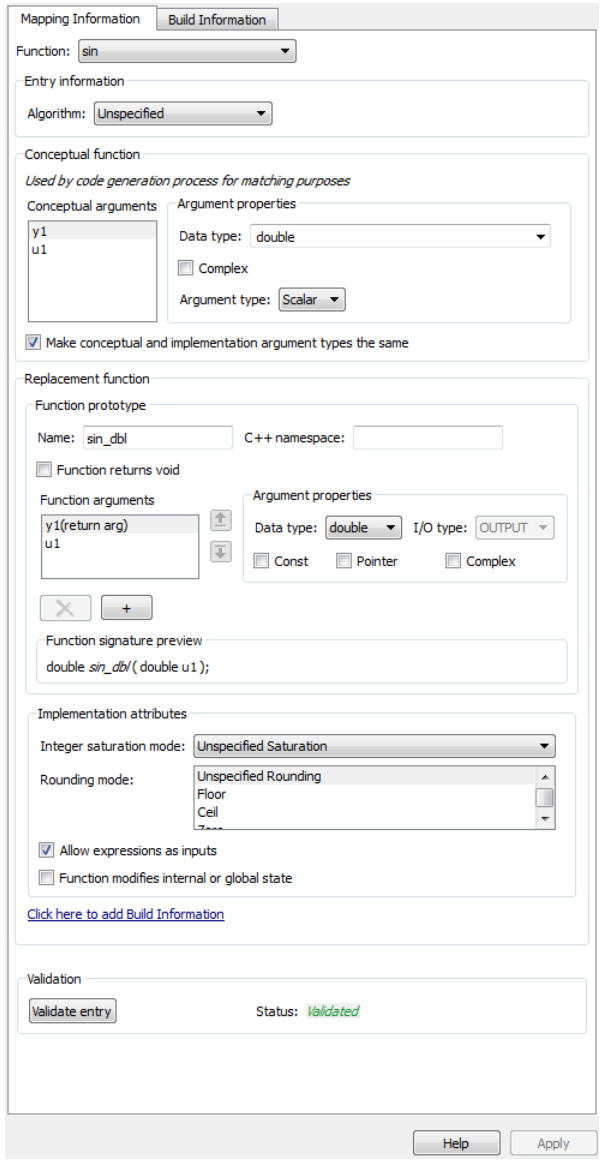
Create a table entry that maps a `sin` function with `double` input and `double` output to a custom implementation function.

1. In the left pane, select table `crl_table_sinfcn`. Then, select **File** > **New entry** > **Function**. The new entry appears in the middle pane, initially without a name.
2. In the middle pane, select the new entry.
3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
4. Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.
5. In the **Replacement function** group, name the replacement function `sin_dbl`.
6. Leave the remaining parameters in the **Replacement function** group set to default values.

7 Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.

8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.



Mapping Information
Build Information
Function: sin
Entry information
Algorithm: Unspecified
Conceptual function
Used by code generation process for matching purposes
Conceptual arguments
y1
u1
Argument properties
Data type: double
Complex
Argument type: Scalar
Make conceptual and implementation argument types the same
Replacement function

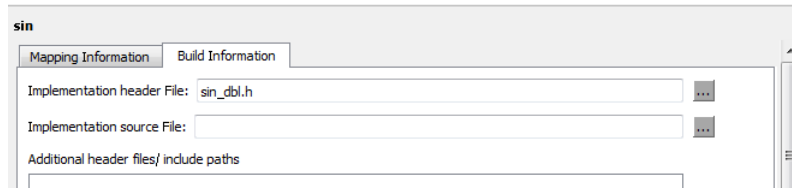
Help
Apply

Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
2. Leave the remaining parameters set to default values.
3. Click **Apply**.



4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.
2. Select **Edit** > **Copy**
3. Select **Edit** > **Paste**
4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

Validate the Code Replacement Table

1. Select **Actions** > **Validate table**.

2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

	Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
✓	sin	sin_dbl	1	double		double		100
✓	sin	sin_sgl	1	single		double		100

Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File** > **Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

Review the Code Replacement Table Definition

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

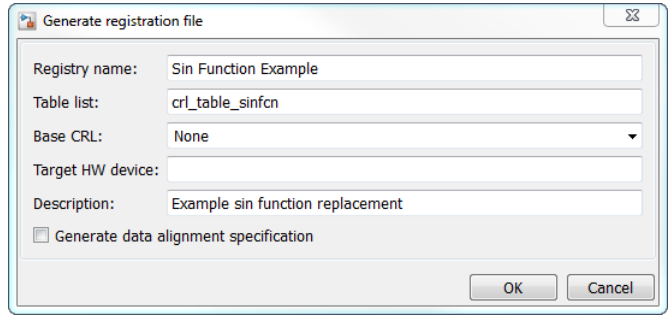
To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1 In the Code Replacement Tool, select **File** > **Generate registration file**.

2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.



3 In the **Select location** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

Register the Code Replacement Table

At the command prompt, enter:

```
sl_refresh_customizations
```

Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1 Check for errors. At the command line, invoke the table definition file. For example:

```
tbl = crl_table_sinfcn

tbl =

  TflTable with properties:

               Version: '1.0'
       ReservedSymbols: []
    StringResolutionMap: []
             AllEntries: [2x1 RTW.TflCFunctionEntry]
           EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message. Fix the error and try again.

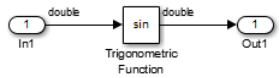
2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

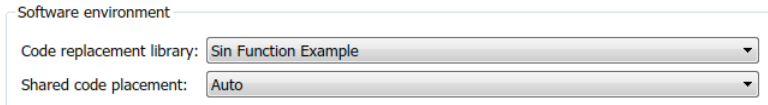
- Incorrect argument order.
- Conceptual argument names that do not match what the code generator expects.
- Incorrect priority settings.

3 Identify an existing model or create a new model that includes a Trigonometric Function block that is set to the `sin` function. For example:



4 Open the model and configure it for code generation with an Embedded Coder (ERT-based) target.

5 See whether your library is listed as an available option for the **Code Generation > Interface > Code replacement library** model configuration parameter. If it is, select it.



If it is not listed, open the registration file, `rtwTargetInfo.m`. See whether you entered the correct code replacement table name when you created the file. If you hover the cursor over the selected library, a tool tip appears. This tip contains information derived from your code replacement library registration file, such as the library description and the list of tables it contains.

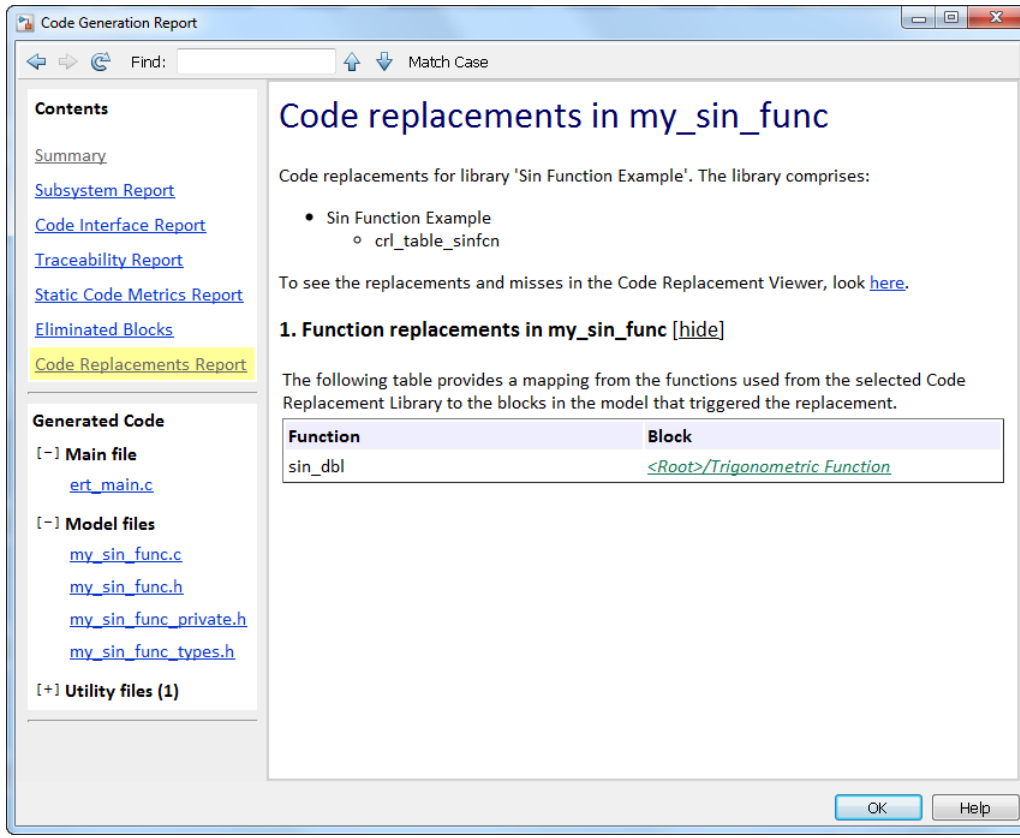
6 Configure the code generation report for code replacement analysis by setting the following parameters:

- On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
- On the **Code Generation > Comments** pane, select **Include comments**, **Simulink block / Stateflow object comments**, and **Simulink block descriptions**.
- On the **All Parameters** tab, select **Code-to-model**, **Model-to-code**, and **Summarize which blocks triggered code replacements**.

7 Configure the model to generate code only. Before you build an executable, confirm that the code generator is replacing code as expected.

8 Generate code for the model.

9 Review code replacement results in the Code Replacement Report section of the code generation report.



The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

10 Review the code replacements. In the model window, right-click the Trigonometric Function block. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report opens and highlights the code replacement in `my_sin_func.c`. In this case, the code generator replaced `sin` with `sin_dbl`.

- "What Is Code Replacement Customization?" on page 51-3

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for the library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?

Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.

- Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

- "Develop a Code Replacement Library" on page 51-27
- "Prepare for Code Replacement Library Development" on page 51-41
- "What Is Code Replacement Customization?" on page 51-3

Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

Situation	Approach
Defining mappings for the first time.	Code Replacement Tool.
Rapid prototyping mappings.	Code Replacement Tool to quickly generate, register, and test mappings.
Developing a mapping as a template or starting point for defining similar mappings.	Code Replacement Tool to generate definition code that you can copy and modify.
Modifying a registration file, including copying and pasting content.	MATLAB Editor to update the programming interface directly.
Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).	Programming interface.
Reusing existing code for new mappings by copying, pasting, and editing existing mappings.	Programming interface.

Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to **All Parameters** > **Code Generation** > **Code replacement library** and click **Custom**.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select **View** > **Show dialog pane** to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select **Hide** to remove the column from the display. (You cannot hide the **Name** column.)

Create a Code Replacement Table

1. In the Code Replacement Tool window, select **File** > **New table**.
2. In the right pane, name the table and click **Apply**. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.

Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select **File** > **New entry** > **entry-type**, where **entry-type** is one of:

   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.
3. In the middle pane, select the new entry.
4. In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.
5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (`Cast before operation` or `Cast after operation`).
6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

   If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that

specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`. In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select `Custom` for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click **Apply**.

Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can address them and retry the validation. Repeat the process until the tool does not report errors.

To	Do
Validate table entries	Select an entry, scroll to the bottom of the **Mapping Information** tab, and click **Validate entry**. Alternatively, select one or more entries, right-click, and select **Validate entries**.
Validate a table	Select the table. Then, select **Actions** > **Validate table**.

Save a Table

When you save a table, the tool validates unvalidated content.

1. Select **File** > **Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
3. Click **Save**.

Open and Modify Tables

After saving a code replacement table, to make changes in the table:

1. Select **File** > **Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

Define Mappings Programmatically

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for

- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

Create Code Replacement Table

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_sinfcn()
   ```
2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1 Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

Entry Type	Function
Math operation	`RTW.TflCOperationEntry`
Function	`RTW.TflCFunctionEntry`
BLAS operation	`RTW.TflBlasEntryGenerator`
CBLAS operation	`RTW.TflCBlasEntryGenerator`
Fixed-point addition and subtraction operations (support for `SlopesMustBeTheSame` and `ZeroNetBias` parameters)	`RTW.TflCOperationEntryGenerator`
Net slope fixed-point operation	`RTW.TflCOperationEntryGenerator_NetSlope`
Semaphore or mutex entry	`RTW.TflCSemaphoreEntry`
Custom function entry	*`MyCustomFunctionEntry`* (where *`MyCustomFunctionEntry`* is a class derived from `RTW.TflCFunctionEntryML`)
Custom operation entry	*`MyCustomOperationEntry`* (where *`MyCustomOperationEntry`* is a class derived from `RTW.TflCOperationEntryML`)

For example:

```
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a

single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator's default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:

```
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
   'sin_dbl', 'double', 'sin_dbl.h','','');
```

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector specifications.

For example:

```
hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

Entry Type	Function
Math operation	`setTflCOperationEntryParameters`
Function	`setTflCFunctionEntryParameters`
BLAS operation	`setTflCOperationEntryParameters`
CBLAS operation	`setTflCOperationEntryParameters`
Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for `SlopesMustBeTheSame` and `ZeroNetBias` parameters)	`setTflCOperationEntryParameters`
Net slope fixed-point operation	`setTflCOperationEntryParameters`
Semaphore or mutex entry	`setTflCSemaphoreEntryParameters`
Custom function entry	`setTflCFunctionEntryParameters`
Custom operation entry	`setTflCOperationEntryParameters`

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```
hEnt = RTW.TflCFunctionEntry
```

```
hEnt =

  TflCFunctionEntry with properties:

             Implementation: [1x1 RTW.CImplementation]
        SlopesMustBeTheSame: 0
          BiasMustBeTheSame: 0
            AlgorithmParams: []
                   ImplType: 'FCN_IMPL_FUNCT'
      AdditionalHeaderFiles: {0x1 cell}
      AdditionalSourceFiles: {0x1 cell}
```

```
      AdditionalIncludePaths: {0x1 cell}
       AdditionalSourcePaths: {0x1 cell}
          AdditionalLinkObjs: {0x1 cell}
      AdditionalLinkObjsPaths: {0x1 cell}
          AdditionalLinkFlags: {0x1 cell}
       AdditionalCompileFlags: {0x1 cell}
                  SearchPaths: {0x1 cell}
                          Key: ''
                     Priority: 100
               ConceptualArgs: [0x1 handle]
                    EntryInfo: []
                   GenCallback: ''
                   GenFileName: ''
               SaturationMode: 'RTW_SATURATE_UNSPECIFIED'
                RoundingModes: {'RTW_ROUND_UNSPECIFIED'}
           TypeConversionMode: 'RTW_EXPLICIT_CONVERSION'
              AcceptExprInput: 1
                  SideEffects: 0
                   UsageCount: 0
           RecordedUsageCount: 0
                  Description: ''
    StoreFcnReturnInLocalVar: 0
                TraceManager: [1x1 RTW.TflTraceManager]
```

To see the implementation parameters, enter:

```
hEnt.Implemenation
```

```
ans =

  CImplementation with properties:

              HeaderFile: ''
              SourceFile: ''
              HeaderPath: ''
              SourcePath: ''
                  Return: []
          StructFieldMap: []
                    Name: ''
               Arguments: [0x1 handle]
    ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```
setTflCFunctionEntryParameters(hEnt, ...
          'Key', 'sin', ...
          'ImplementationName', 'sin_dbl');
```

Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.
- Specify argument names that comply with code generator argument naming conventions:
  - `y1` for a return argument
  - `u1`, `u2`, ..., `un` for input arguments
- Specify data types that are familiar to the code generator.
- The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
- The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1. Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the `sin` function, open the tool, create a table, create a function entry, and in the **Function** menu select `sin`.
2. Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

If	Then

You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).	Call the function `createAndAddConceptualArg`. For example:
	`createAndAddConceptualArg(hEnt, ...`
	`  'RTW.TflArgNumeric', ...`
	`  'Name', 'y1',...`
	`  'IOType', 'RTW_IO_OUTPUT',...`
	`  'DataTypeMode', 'double');`

If	Then
	The second argument specifies whether the argument is scalar (`RTW.TflArgNumeric` or`RTW.TflArgMatrix`) .

You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).	Call `getTflArgFromString` to create the argument. Then, call `addConceptualArg` to add the argument to the entry.
	`arg = getTflArgFromString(hEnt, 'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`addConceptualArg(hEnt, arg);`

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	`hEnt = createCRLEntry(hTable, ...`
	`'double y1 = sin(double u1)', ...`
	`'mySin');`

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```
% Conceptual Args

arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.

- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
- For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, `y1=u1+u2`, the conceptual arguments are `y1`, `u1`, and `u2`, in that order. If the signature of your implementation function is `t myAdd(t u2, t u1)`, where `t` is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, `u1`, to the second implementation argument of `myAdd`. The code generator passes the value of the second conceptual argument, `u2`, to the first implementation argument of `myAdd`.
- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.
2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want to populate implementation arguments as copies of previously created matching conceptual arguments	Call the function `copyConceptualArgsToImplementation`. For example: `copyConceptualArgsToImplementation(hEnt);`

You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order	Call functions `createAndSetCImplementationReturn` and`createAndAddImplementationArg` . For example:
	`createAndSetCImplementationReturn(hEnt,`
	`'RTW.TflArgNumeric', ...`
	`'Name', 'y1', ...`
	`'IOType', 'RTW_IO_OUTPUT', ...`
	`'IsSigned', true, ...`
	`'WordLength', 32, ...`
	`'FractionLength', 0);`
	
	`createAndAddImplementationArg(op_entry,`
	`'RTW.TflArgNumeric',...`
	`'Name', 'u1', ...`

If	Then

	`'IOType', 'RTW_IO_INPUT',...`
	`'IsSigned', true,...`
	`'WordLength', 32, ...`
	`'FractionLength', 0 );`

If	Then

You want to minimize the amount of code, or specify constant arguments to pass to the implementation function	Create the argument with a call to the function `getTflArgFromString`. Then, use the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument and to add the argument to the entry's array of implementation arguments. For example:
	
	`arg = getTflArgFromString(hEnt, 'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setReturn(arg);`
	
	`arg = getTflArgFromString(hEnt, 'u1','double');`
	`hEnt.Implementation.addArgument(arg);`
	
	The following call to `getTflArgFromString` passes the constant `0` to argument `u2`:
	
	`arg = getTflArgFromString(hEnt, 'u2', 'int16', 0)`
	`hEnt.Implementation.addArgument(arg);`
	
	For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example:
	
	`arg = getTflDWorkFromString('d1', 'void*')`
	`hEnt.addDWorkArg(arg);`
	
	`arg = hEnt.getTflArgFromString('y1', 'void');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setRetrurn(arg);`
	
	`arg = hEnt.getTflArgFromString('u1', 'integer');`
	`hEnt.Implementation.addArgument(arg);`
	
	`arg = hEnt.getTflArgFromString('d1', 'void**');`
	`hEnt.Implementation.addArgument(arg);`

If	Then

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	`hEnt = createCRLEntry(hTable, ...`
	`'double y1 = sin(double u1)', ...`
	`'mySin');`

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```
% Implementation Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```
addEntry(hTable, hEnt);
```

Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```
hTbl = crl_table_sinfcn

hTbl =

RTW.TflTable
    Version: '1.0'
    AllEntries: [2x1 RTW.TflCFunctionEntry]
    ReservedSymbols: []
```

```
    StringResolutionMap: []
```

If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```
hTbl = crl_table_sinfcn

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(1OO, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Save Table

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Build Information

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

Situation	Approach
Creating code replacement entries for the first time.	Code Replacement Tool.
You used the Code Replacement Tool to create the entries for which the build information applies.	Code Replacement Tool to specify the build information quickly .
Rapid prototyping entries.	Code Replacement Tool to generate, register, and test entries quickly.

Situation	Approach
Developing an entry to use as a template or starting point for defining similar entries.	Code Replacement Tool to generate entry code that you can copy and modify.
Modifying existing mappings.	MATLAB Editor to update the programming interface directly.

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGo` function to relocate static and generated code files to another development environment:
  - In the call to `packNGo`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGo` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector or cell array of character vectors in the MATLAB workspace that you enclose with dollar signs (`$`*`variable`*`$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$\folder1`, where `myfolder` is a character vector variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

1 Determine the information that you must specify.

2. Open the Code Replacement Tool.
3. Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4. In the right pane, select the **Build Information** tab.
5. On the **Build Information** tab, specify your build information.

Parameter	Specify
Implementation header file	File name and extension for the header file the code generator needs to generate the replacement code. For example, `sin_dbl.h`.
Implementation source file	File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, `sin_dbl.c`.
Additional header files/include paths	Paths and file names for additional header files the code generator needs to generate the replacement code. For example, `C:\libs\headerFiles` and `C:\libs\headerFiles\common.h`. This parameter adds `-I` to the compile line in the generated makefile.
Additional source files/ paths	Paths and file names for additional source files the code generator needs to generate the replacement code. For example, `C:\libs\srcFiles` and `C:\libs\srcFiles\common.c`. This parameter adds `-I` to the compile line in the generated makefile.
Additional object files/ paths	Paths and file names for additional object files the linker needs to build the replacement code. For example, `C:\libs\objFiles` and `C:\libs\objFiles\common.obj`.
Additional link flags	Flags the linker needs to generate an executable file for the replacement code.
Additional compile flags	Flags the compiler needs to generate object code for the replacement code.
Copy files to build directory	Whether to copy header, source, or object files, which are required to generate replacement

Parameter	Specify
	code, to the build folder before code generation. If you specify files with **Additional header files/include paths** or **Additional source files/ paths** and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

6 Click **Apply**.

7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.

8 Save the table that includes the entry that you just modified.

Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1 Identify or create the code replacement entry that you want to specify the build information.

2 Determine what information to specify.

3 Specify your build information.

Specify	Action

Implementation header file	Use one of the following:
	• Set properties `ImplementationHeaderFile` and `ImplementationHeaderPath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`

Specify	Action

	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`
	• Set argument `headerFile` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry`

Implementation source file	Set properties `ImplementationSourceFile` and `ImplementationSourcePath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.c', ...`
	`'ImplementationHeaderPath', 'D:/lib/sourceFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`

Additional header files/include paths	For each file, specify the file name and path in calls to the functions `addAdditionalHeaderFile` and `addAdditionalIncludePath`. For example:
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	`hEnt = RTW.TflCFunctionEntry;`
	`addAdditionalHeaderFile(hEnt, 'common.h');`
	`addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));`
	These functions add `-I` to the compile line in the generated makefile.

Specify	Action

Additional source files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalSourceFile` and `addAdditionalSourcePath`. For example:
	
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`addAdditionalSourceFile(hEnt, 'common.c');`
	`addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));`
	
	These functions add `-I` to the compile line in the generated makefile.

Additional object files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalLinkObj` and `addAdditionalLinkObjPath`. For example:
	
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`addAdditionalLinkObj(hEnt, 'sin.o');`
	`addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));`

Compile flags	Set the entry property `AdditionalCompileFlags` to a cell array of character vectors representing the required compile flags. For example:
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-O3'};`

Link flags	Set the entry property `AdditionalLinkFlags` to a cell array of character vectors representing the required link flags. For example:
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};`

Specify	Action

Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation	Use one of the following:
	• Set property `GenCallback` to `'RTW.copyFileToBuildDir'` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`
	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl'`
	`'GenCallback', 'RTW.copyFileToBuildDir');`
	• Set argument `genCallback` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` to `'RTW.copyFileToBuildDir'`.
	If a match occurs for a table entry, a call to the function `RTW.copyFileToBuildDir` copies required files to the build folder.
	If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the `genCallback` property to `'RTW.copyFileToBuildDir'` in the call to the `setTflCOperationEntryParameters` function. In this example, the header file `s32_mul.h` contains an inlined function that invokes assembly functions contained in `s32_mul.s`. If a match occurs for the table

entry, the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```
function hTable = make_my_crl_table

hTable = RTW.TflTable;

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_MUL', ...
                'Priority',                 100, ...
                'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_mul_s32_s32_sat', ...
                'ImplementationHeaderFile', 's32_mul.h', ...
                'ImplementationSourceFile', 's32_mul.s', ...
                'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'GenCallback',              'RTW.copyFileToBuildDir');
.
.
.
addEntry(hTable, op_entry);
```

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_ADD', ...
                'Priority',                 90, ...
                'SaturationMode',           'RTW_SATURATE_UNSPECIFIED', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_add_s32_s32', ...
                'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
                'ImplementationSourceFile', 's32_add_s32_s32.c'...
                'GenCallback',              'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
.
```

```
.
.
addEntry(hTable, op_entry);
```

Next, include your code replacement table in a code replacement library and register the library with the code generator.

More About

- “Code You Can Replace From Simulink Models” on page 51-7
- “Define Code Replacement Mappings” on page 51-42
- “Register Code Replacement Mappings” on page 51-68
- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

Register Code Replacement Mappings

After you define code replacement entries and specify build information in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

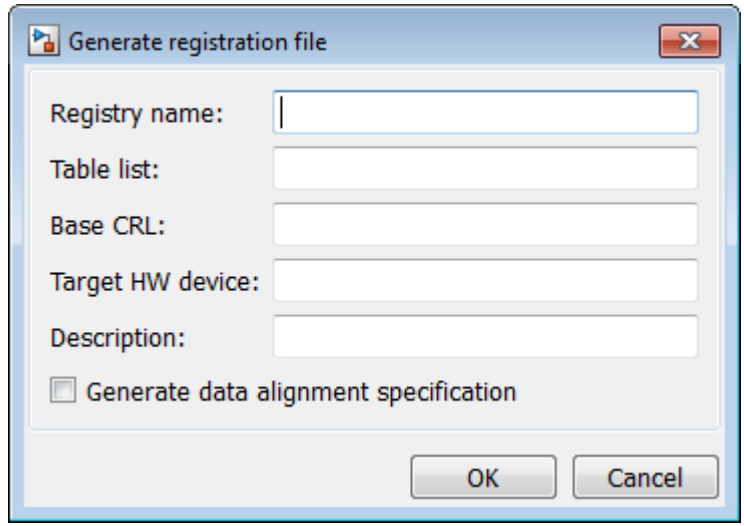
The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

If...	Then...
Registering a code replacement table for the first time	Use the Code Replacement Tool.
You used the Code Replacement Tool to create the table	Use the Code Replacement Tool to quickly register the table.
Rapid prototyping code replacement	Use the Code Replacement Tool to quickly generate, register, and test entries.
Creating registration file to use as a template or starting point for defining similar registration files	Use the Code Replacement Tool to generate code that you can copy and modify.
Modifying existing registration files	Use the MATLAB Editor to update the registration file.
Defining multiple code replacement libraries in one registration file	Use the MATLAB Editor to create a new or extend an existing registration file.
Defining code replacement library hierarchy in a registration file	Use the MATLAB Editor to create a new or extend an existing registration file.

Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1 After you validate and save a code replacement table, select **File > Generate registration file** to open the **Generate registration file** dialog box.



2 Enter the registration information. Minimally, specify:

For...	Specify...
Registry name	Text naming the code replacement library. For example, `Sin Function Example`.
Table list	Text naming one or more code replacement tables to include in the library. Specify each table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)`

For...	Specify...
	You can specify multiple tables. If you do, separate the table specifications with a comma. For example: `crl_table_sinfcn, c:/work_crl/crl_table_muldiv` See "Registration Files That Define Multiple Code Replacement Libraries" on page 52-61 for examples of each type of table specification.

Optionally, you can specify:

For...	Specify...
Description	Text that describes the purpose and content of the library.
Target HW device	Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, `TI C28x, TI C62x`.
Base CRL	Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.
Generate data alignment specification	Flag that enables data alignment specification.

Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1. Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'crl-name';
this(1).TableList = {'table',...};
```

For...	Replace...
`this(1).Name = 'crl-name';`	*`crl-name`* with text naming the code replacement library. For example, `Sin Function Example`.
`this(1).TableList = {'table',...};`	*`table`* with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)` You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

For...	Replace...
`this(1).Description = '`*`text`*`'`	*`text`* with text that describes the purpose and content of the library.
`this(1).TargetHWDeviceType = {'`*`device-type`*`',...}`	*`device-type`* with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, `TI C28x, TI C62x`. To support all device types, enter an asterisk (*).
`this(1).BaseTfl = '`*`base-lib`*`'`	*`base-lib`* with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device` library as the base library for a `TI C28x device` library. See "Registration Files That Define Code Replacement Library Hierarchies" on page 52-61 for an example.

For example:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'Sin Function Example';
this(1).TableList = {'crl_table_sinfcn'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example - sin function replacement';
```

2 Save the file with the name `rtwTargetInfo.m`.

3 Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```
sl_refresh_customizations
```

Register a Library that Includes Multiple Code Replacement Tables

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The `TableList` fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library for use with model: rtwdemo_crladdsub
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Addition & Subtraction Examples';
  thisCrl(1).Description = 'Example of addition/subtraction op replacement';
  thisCrl(1).TableList = {'crl_table_addsub'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlmuldiv
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'Multiplication & Division Examples';
  thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
  thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
  thisCrl(2).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlfixpt
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'Fixed-Point Examples';
  thisCrl(3).Description = 'Example of fixed-point operator replacement';
  thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)', ...
     'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
  thisCrl(3).TargetHWDeviceType = {'*'};
```

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code

replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library that includes common entries
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Common Replacements';
  thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
  thisCrl(1).TableList = {'crl_table_general'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for TI devices
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'TI Device Replacements';
  thisCrl(2).Description = 'Code replacement entries shared across TI devices';
  thisCrl(2).TableList = {'crl_table_TI_devices'};
  thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
  thisCrl(1).BaseTfl = 'Common Replacements'

  % Register a code replacement library for TI c6xx devices
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'TI c6xx Device Replacements';
  thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
  thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
  thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

  % Register a code replacement library for the TI c67x device
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'TI c67x Device Replacements';
  thisCrl(3).Description = 'Code replacement entries for the TI C67x device';
  thisCrl(3).TableList = {'crl_table_TIC67x_device'};
  thisCrl(3).TargetHWDeviceType = {'TI 67x'};
```

After registering your code replacement mappings, verify that code replacements occur.

- “Verify Code Replacements” on page 51-76
- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (`RTW.TargetRegistry.getInstance('reset');` or for the Simulink environment,`sl_refresh_customizations`).
- See whether the registration file, `rtwTargetInfo.m`, contains an error.

More About

- "Register Code Replacement Mappings" on page 51-68

Verify Code Replacements

After you create or modify and register a code replacement table, use the following techniques to examine and verify the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.

Validate Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```
isvalid(crl_table_sinfcn)

ans =

      1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```
isvalid(crl_table_sinfcn)

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Review Library Content

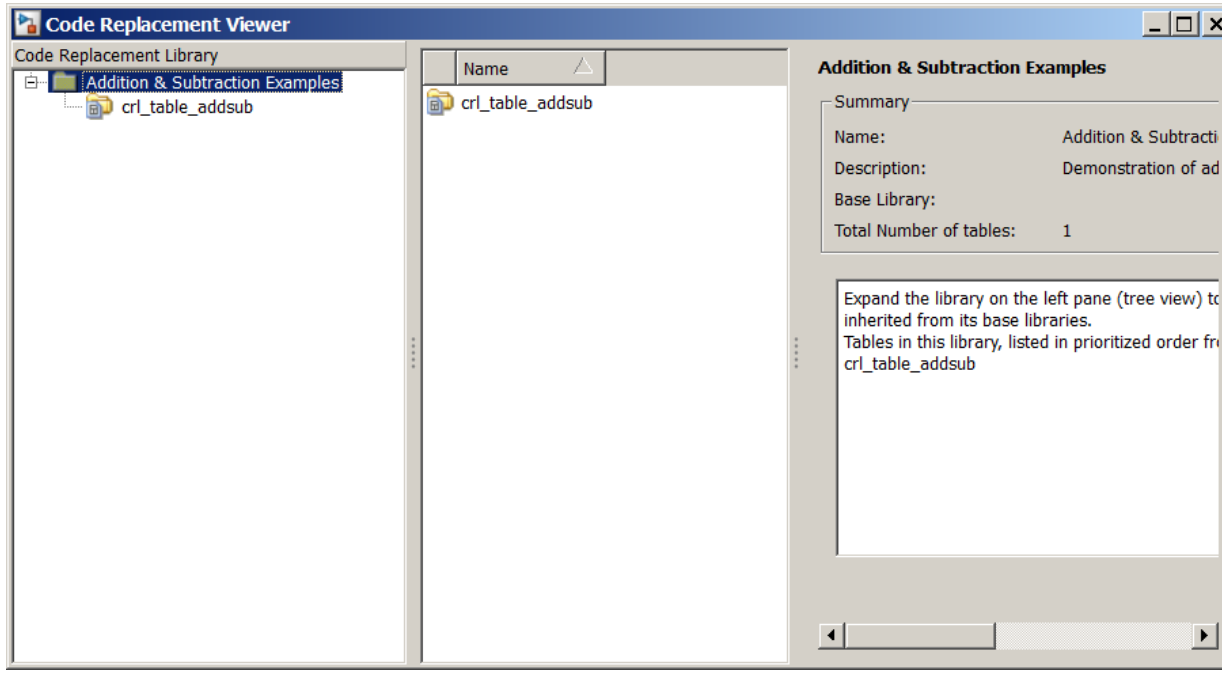
After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

1 Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```
crviewer('library')
```

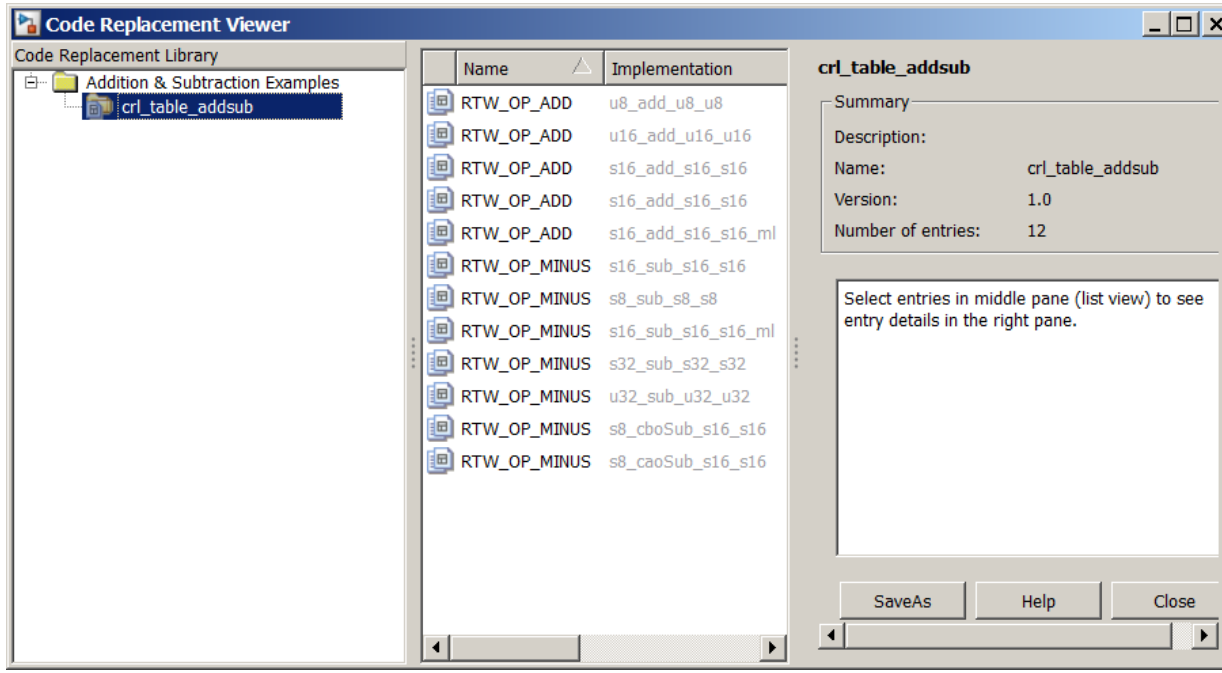
For example:

```
crviewer('Addition & Subtraction Examples')
```



2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.

3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?



Review Table Content

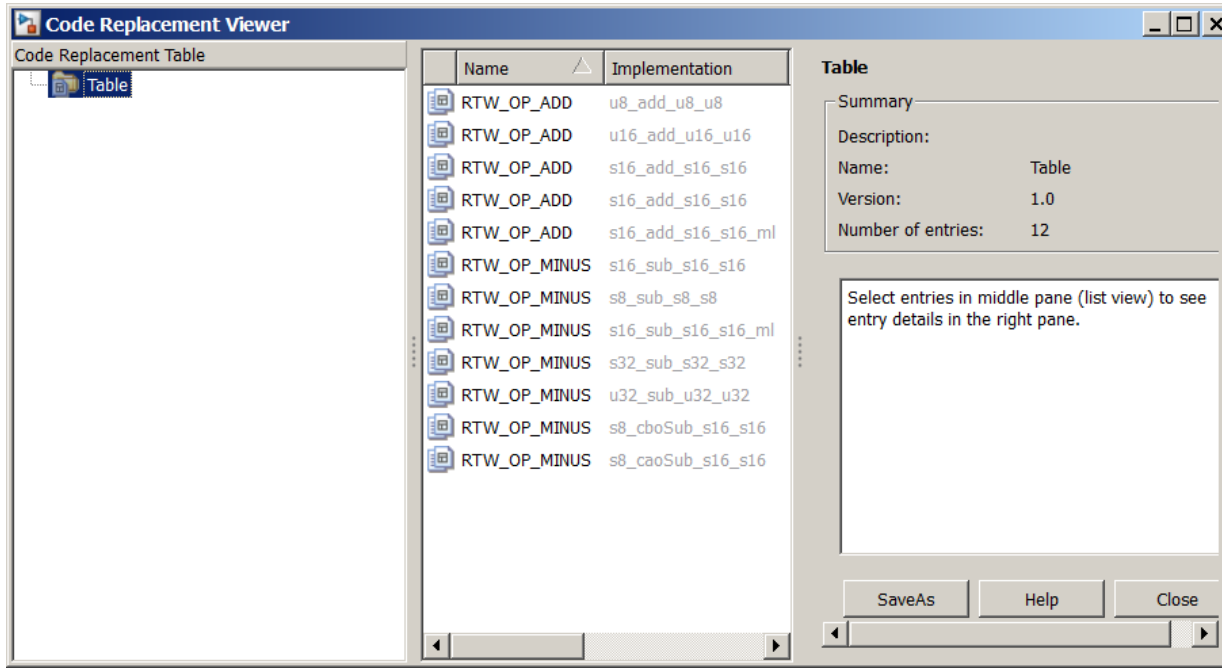
After you create or modify a code replacement table, use the Code Replacement Viewer to review and verify table entries.

1 Open the viewer to display the contents of your table. At the command prompt, enter the following command. *`table`* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

```
crviewer(table)
```

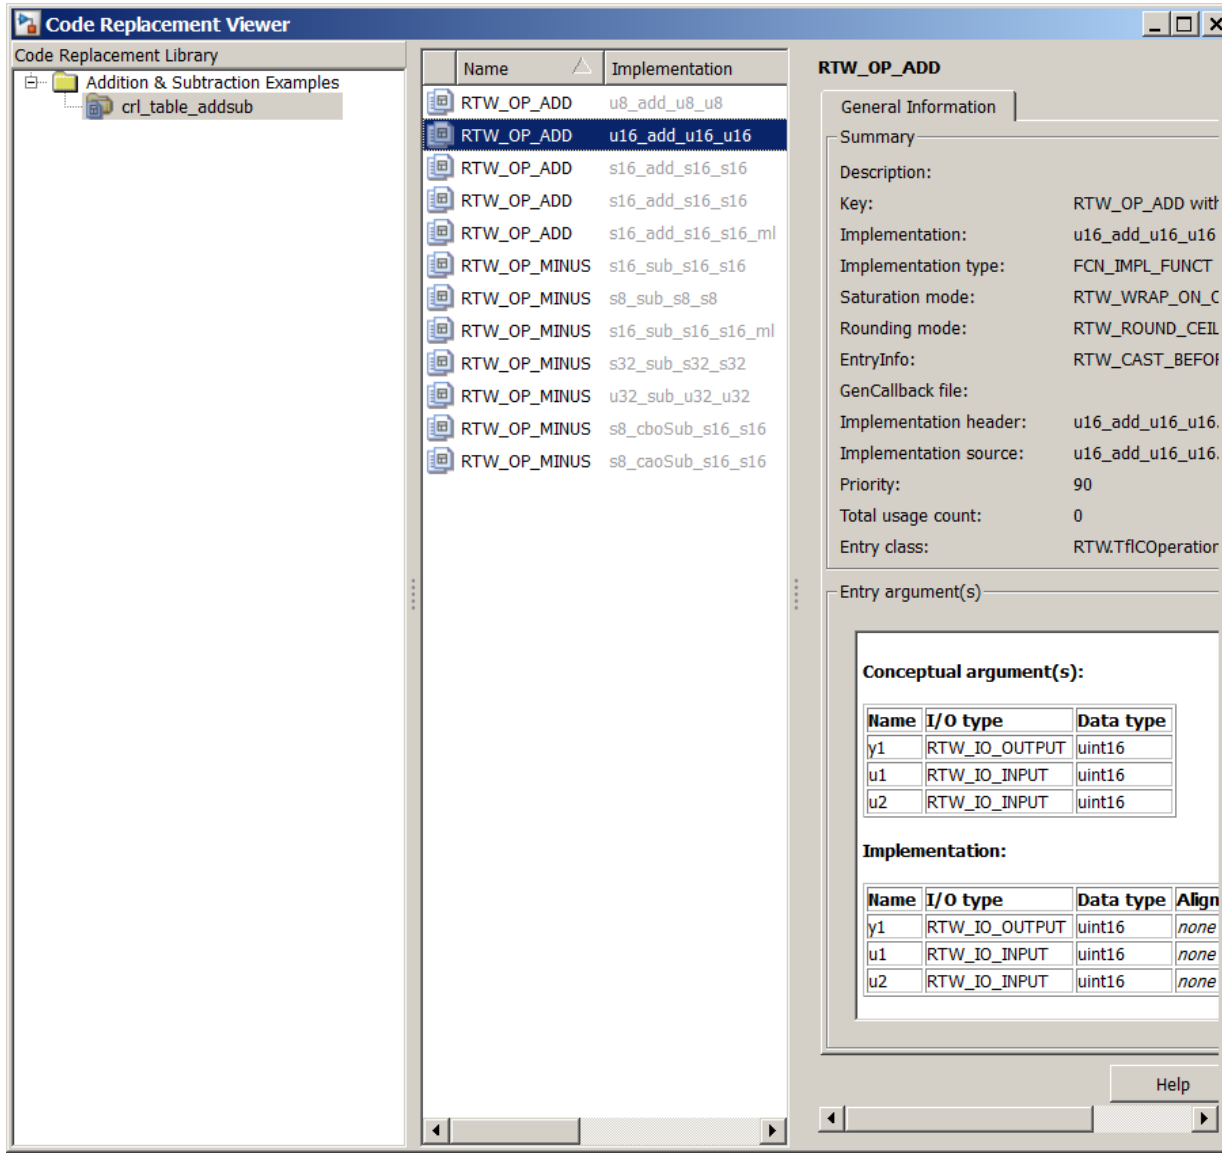
For example:

```
crviewer(crl_table_addsub)
```



2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.

3 In the center pane, click each entry and verify the entry information in the right pane.



- Argument order is correct.

- Conceptual argument names match code generator naming conventions.
- Implementation argument names are correct.
- Algorithm properties (for example, saturation and rounding mode) are set correctly.
- Header or source file specification is not missing.
- I/O types are correct.
- Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the model element that triggered the replacement.

The following example illustrates two complementary approaches to reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
- Trace code replacements.

For models that consist of model hierarchies, repeat the following procedure for each model in the hierarchy. Generate code for and review the trace information of each referenced model separately. Logged cache hit and miss information captured in the Code Replacement Viewer is valid for the last model for which code was generated. As you generate code for each model in the hierarchy, the code generator overwrites logged information.

1. Open the model where you anticipate that a function or operator replacement occurs. This example uses the model `rtwdemo_crladdsub`.
2. Configure the code generator to use your code replacement library. For this example, set the library to `Addition & Subtraction Examples`.
3. Configure the code generation report to include the Code Replacements Report. On the **Code Generation** > **Report** pane, select **Create code generation report** and

Open report automatically. On the **All Parameters** tab, select **Model-to-code** and **Summarize which blocks triggered code replacements**.

4 Configure comments for the generated code. On the **Code Generation** > **Comments** pane, select:

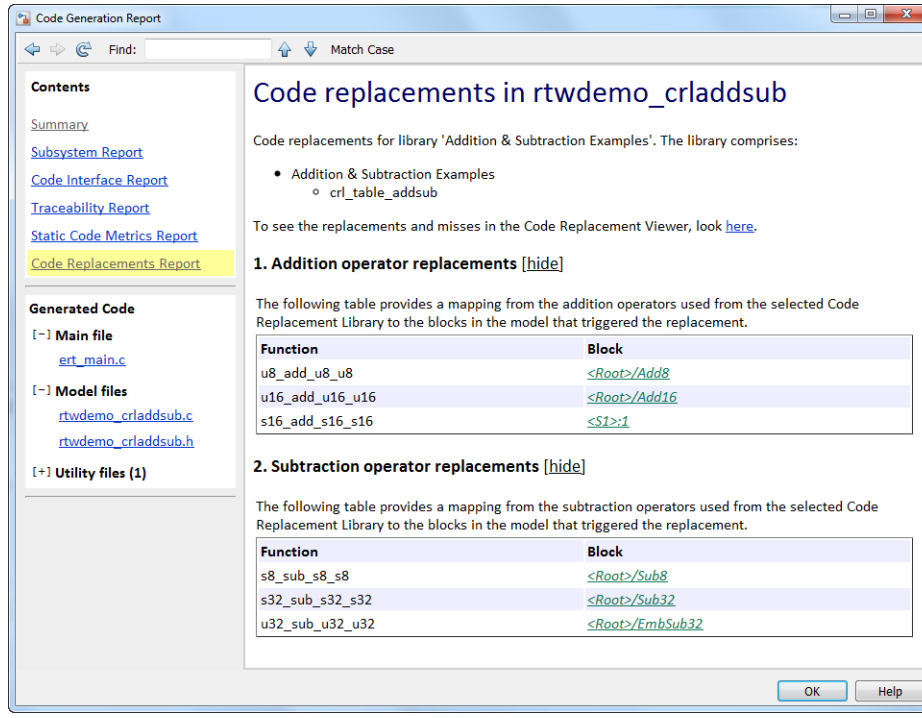
- **Include comments**
- Either or both of **Simulink block / Stateflow object comments** and **Simulink block descriptions**

In the **Code Replacements Report**, these options include Simulink block information.

5 Configure the code generator to generate only code. Before you build an executable file, review your code replacements in the generated code.

6 Generate code and a report.

7 Open the **Code Replacements Report** section of the code generation report.



The report lists the replacement functions that the code generator used. It provides a mapping between each replacement instance and the Simulink block that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each block link to see the source that triggered the reported code replacement.

8 In the Simulink model window, use model-to-code highlighting to trace code replacements. Identify and right-click a block where you expected code replacement to occur. Select **C/C++ Code** > **Navigate to C/C++ Code**. The code generation report appears with the corresponding replacement code highlighted. In the example model rtwdemo_crladdsub, right-click the Add8 block and select **C/C++ Code** > **Navigate to C/C++ Code**.

```
24 /* Real-time model */
25 RT_MODEL rtM_;
26 RT_MODEL *const rtM = &rtM_;
27
28 /* Model step function */
29 void rtwdemo_crladdsub_step(void)
30 {
31   /* Outport: '<Root>/Out1' incorporates:
32    *  Inport: '<Root>/In1'
33    *  Inport: '<Root>/In2'
34    *  Sum: '<Root>/Add8'
35    */
36   rtY.Out1 = u8_add_u8_u8(rtU.In1, rtU.In2);
37
38   /* Outport: '<Root>/Out2' incorporates:
39    *  Inport: '<Root>/In3'
40    *  Inport: '<Root>/In4'
41    *  Sum: '<Root>/Add16'
42    */
43   rtY.Out2 = u16_add_u16_u16(rtU.In3, rtU.In4);
```

Inspect the generated code to see if the function or operator replacement occurred as you expected.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 51-86.

Next, deploy your code replacement library for others to use.

More About

- “Troubleshoot Code Replacement Misses” on page 51-86

- “Deploy Code Replacement Library” on page 51-93
- “What Is Code Replacement Customization?” on page 51-3

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

```
1. Mismatched data types (argument name, CSO value, table entry value)
```

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

```
1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32
```

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
- Information missing from the code replacement table entry or a source parameter setting.

- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.
  - Input casts resulting in loss of bits.

Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your model.

1 Review the code generated for a model element, looking for expected code replacements. For this example, examine the code generated for block Sub32 in model `rtwdemo_crladdsub`. Right-click the block and select **C/C++ Code** > **Navigate to C/C++ Code**.

The Code Generation Report opens to the location of the generated code for that block.

```
63   /* Outport: '<Root>/Out5' incorporates:
64    *  Inport: '<Root>/In10'
65    *  Inport: '<Root>/In9'
66    *  Sum: '<Root>/Sub32'
67    */
68   rtY.Out5 = s32_sub_s32_s32(rtU.In9, rtU.In10);
```

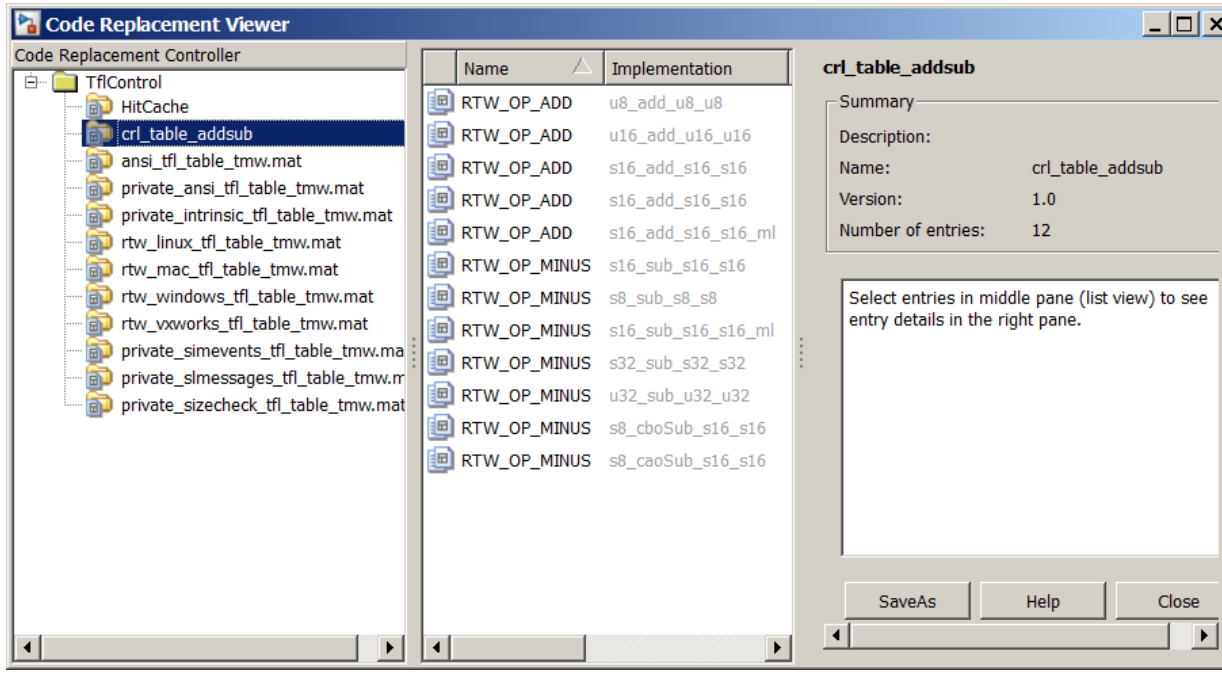
The code generator replaced code, but the replacement was for the signed version of the 32-bit subtraction operation. You expected an unsigned operation.

2 Regenerate or reopen the Code Replacements Report for your model. If you already generated the code generation report that includes the Code Replacements Report

for model rtwdemo_crladdsub, open the file `rtwdemo_crladdsub_ert_rtw/html/rtwdemo_crladdsub_codegen_rpt.html`. For information on how to regenerate the report, see "Review Code Replacements" on page 51-82.

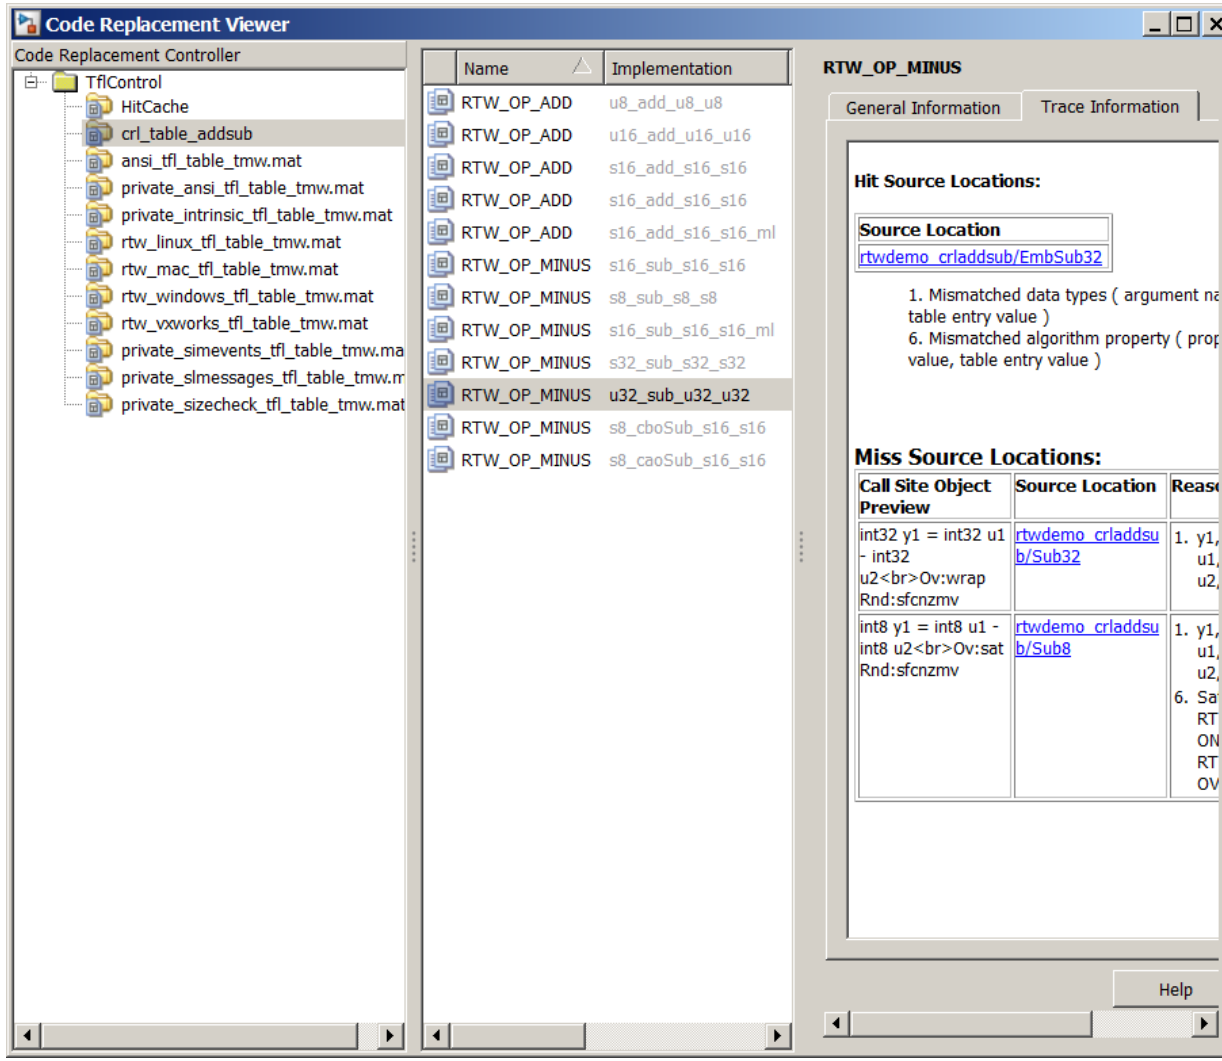
3 Click the link to open the Code Replacement Viewer.

4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `crl_table_addsub`.



5 In the middle pane, select table entry `RTW_OP_MINUS` with implementation function `u32_sub_u32_u32`.

6 In the right pane, select the **Trace Information** tab.



The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of a subtraction operator. The code generator uses this object to query the code replacement library for a match.

- A link to the source location in the model for which the code generator considered replacing code.
- The reasons that the miss occurred. For the list of reasons that misses occur, see "Miss Reason Messages" on page 51-86.

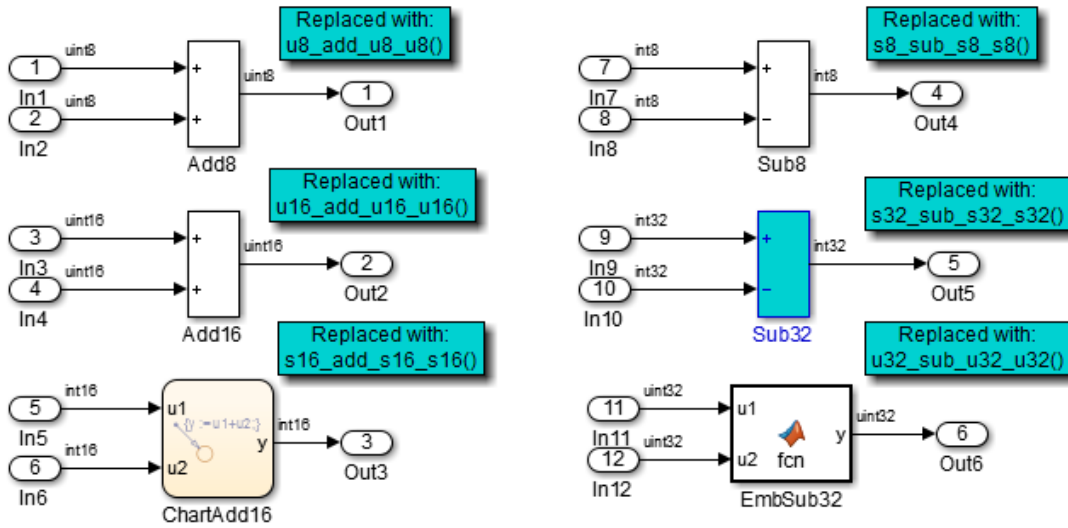
For this example, the report shows misses for two blocks: Sub32 and Sub8.

7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or in a source parameter setting. "Miss Reason Messages" on page 51-86 lists conditions to consider.

For this example, determine why code for the Sub32 block was not replaced with code for an unsigned 32-bit subtraction operation. The miss reason for the Sub32 block indicates a data type mismatch. The data type in the call site object for the three arguments is a signed 32-bit integer. The code replacement entry specifies an unsigned 32-bit integer.

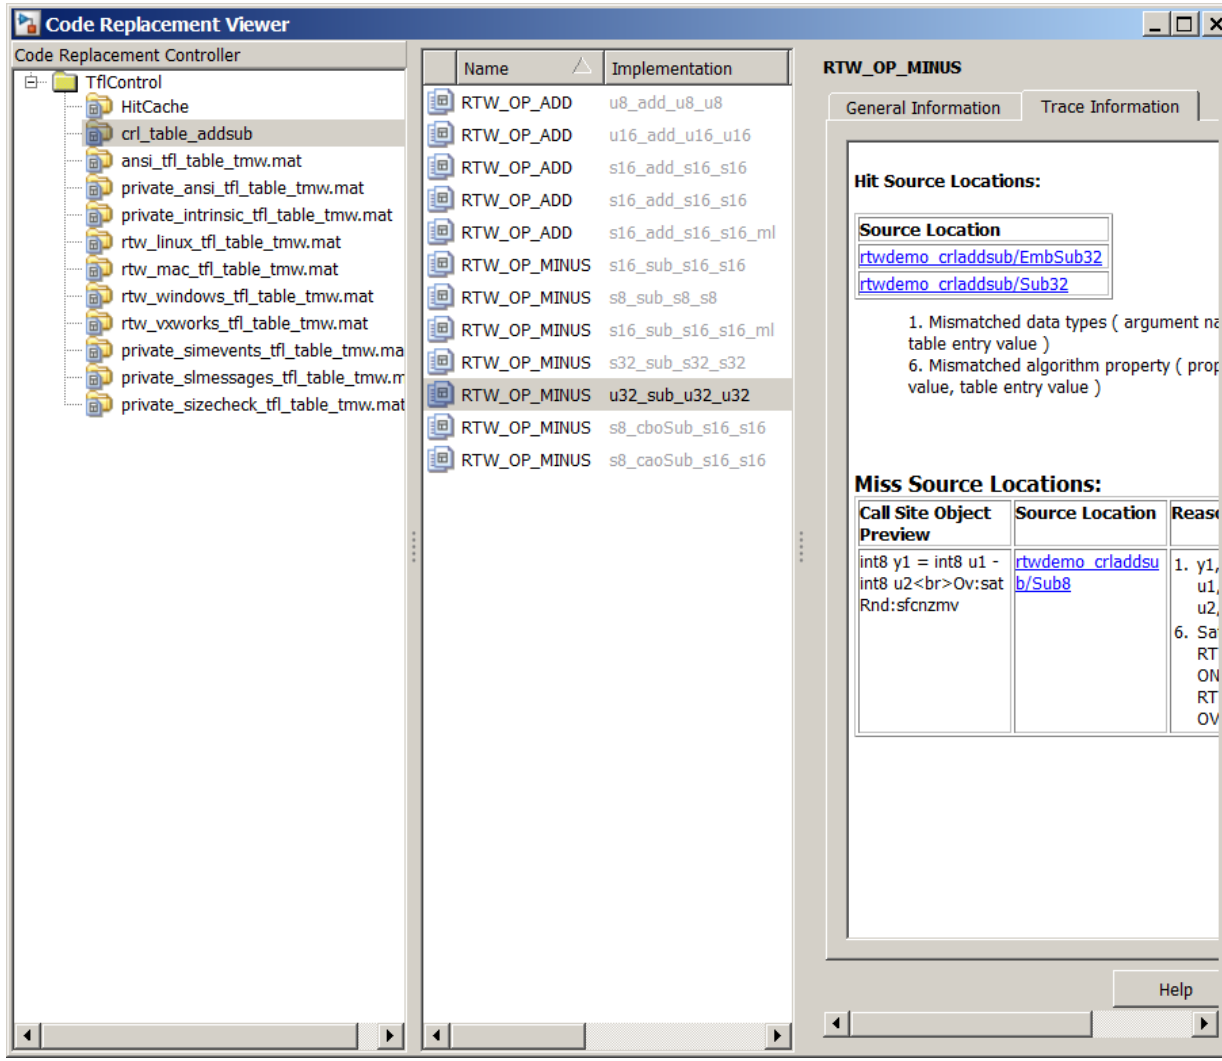
8 Correct the model or code replacement table entry. If the issue is in the model, use the source location link in the trace information to find the model element to correct. For this example, you expected an unsigned subtraction operation for the Sub32 block. Click the link in the trace report for the Sub32 block.

The model opens with the Sub32 block highlighted.



Change the data type setting for the two input signals and the output signal for the Sub32 block to `uint32`.

9 Regenerate code. Use the Code Replacement Viewer trace information to verify that your model or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for block Sub32.



More About

- “Verify Code Replacements” on page 51-76

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
3. Register the library customizations or restart MATLAB.
4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
5. Inform users that the libraries are available and provide direction on when and how to apply them.

More About

- "Verify Code Replacements" on page 51-76

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
% Create entry for sin function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(fcn_entry, ...
                               'Key',                    'sin', ...
                               'Priority',               30, ...
                               'ImplementationName',     'mySin', ...
                               'ImplementationHeaderFile', 'basicMath.h',...
                               'ImplementationSourceFile', 'basicMath.c');
```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'y1',...
                          'IOType',       'RTW_IO_OUTPUT',...
                          'DataTypeMode', 'double');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'u1', ...
                          'IOType',       'RTW_IO_INPUT',...
                          'DataTypeMode', 'double');
```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

- "Customize Match and Replacement Process" on page 51-153
- "Develop a Code Replacement Library" on page 51-27

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_memcpy()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   % Set SideEffects to 'true' for function returning void to prevent it from
   % being optimized away.
   setTflCFunctionEntryParameters(fcn_entry, ...
                                  'Key',                    'memcpy', ...
                                  'Priority',               90, ...
                                  'ImplementationName',     'memcpy_int', ...
                                  'ImplementationHeaderFile', 'memcpy_int.h',...
                                  'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

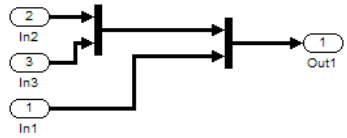
8 Save the table definition file. Use the name of the table definition function to name the file.

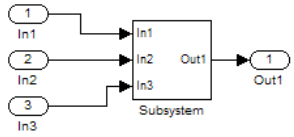
To test this example:

1 Register the code replacement mapping.

2 Create a model that uses the `memcpy` function for vector assignments. For example, use In, Out, and Mux blocks to create the following model. (Alternatively, open the example model rtwdemo_crlmath and copy the contents of Subsystem1 to a new model.)



3 Select the diagram and use **Edit > Subsystem** to make it a subsystem.



4 Configure the subsystem with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Optimization > Signals and Parameters** pane, select **Use memcpy for vector assignment** and set **Memcpy threshold (bytes)** to 64.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your memory function entry.

5 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For each, set **Port dimensions** to `[1,100]`, and set **Data type** to `int32`. Apply the changes. Save the model.

6 Generate code and a code generation report.

7 Review the code replacements.

- "Customize Match and Replacement Process" on page 51-153
- "Develop a Code Replacement Library" on page 51-27

Nonfinite Function Code Replacement

This example shows how to define a code replacement mapping for nonfinite utility functions.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_nonfinite()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create entries for the function mappings. To minimize the size of this function, the example uses a local function, `locAddFcnEnt`, to group lines of code repeated for each entry. A call to the `RTW.TflCFunctionEntry` function creates an entry for the collection of local function entry definitions.

   ```
   %% Create entries for nonfinite utility functions
   % locAddFcnEnt(hTable, key, implName, out, in1, hdr)

   locAddFcnEnt(hTable, 'getNaN', 'getNaN', 'double', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getNaN', 'getNaNF', 'single', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getInf', 'getInf',  'double', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getInf', 'getInfF', 'single', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInf', 'double', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInfF', 'single', 'void', 'nonfin.h');

   %% Local Function
   function locAddFcnEnt(hTable, key, implName, out, in1, hdr)
     if isempty(hTable)
       return;
     end

    fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
    setTflCFunctionEntryParameters(fcn_entry, ...
                                   'Key', key, ...
                                   'Priority', 90, ...
                                   'ImplementationName', implName, ...
                                   'ImplementationHeaderFile', hdr);
   ```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
     arg = getTflArgFromString(hTable, 'y1', out);
     arg.IOType = 'RTW_IO_OUTPUT';
     addConceptualArg(fcn_entry, arg);
   ```

```
arg = getTflArgFromString(hTable, 'u1', in1);
addConceptualArg(fcn_entry, arg);
```

6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

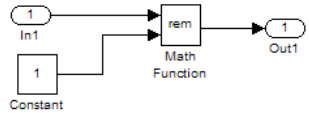
```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that uses a nonfinite function. For example, create a model that includes a Math Function block that is set to the `rem` function. For example:



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your memory function entry and select **Support: non-finite numbers**.

4 In the Model Explorer, configure the **Signal Attributes** for the `In1` and `Constant` source blocks. For each source block, set **Data type** to `double`. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements.

Semaphore and Mutex Function Replacement

You can create a code replacement table for a custom target that supports concurrent execution. Create table entries that specify custom implementations of semaphore or mutex operations. The table must have four semaphore entries, four mutex entries, or both, and include the table in a custom code replacement library. (The semaphore or mutex entries are mutually dependent. Provide them in complete sets of four.)

Note: A custom target that supports concurrent multitasking must set the target configuration parameter `ConcurrentExecutionCompliant`. For more information, see "Support Concurrent Execution of Multiple Tasks" (Simulink Coder).

If the build process generates semaphore or mutex function calls for data transfer between tasks during code generation for a multicore target environment, use a custom library. The library can specify code replacements for custom semaphore or mutex implementations that are optimal for your target environment. Using the Code Replacement Tool (`crtool`) or equivalent code replacement functions, you can:

- Configure code replacement table entries for custom semaphore or mutex functions. During system startup, execution of the code for data transfer between tasks, and system shutdown the generated code calls these functions.
- Configure DWork arguments that represent global data, which the semaphore or mutex functions access. A DWork pointer is passed to the model entry functions.

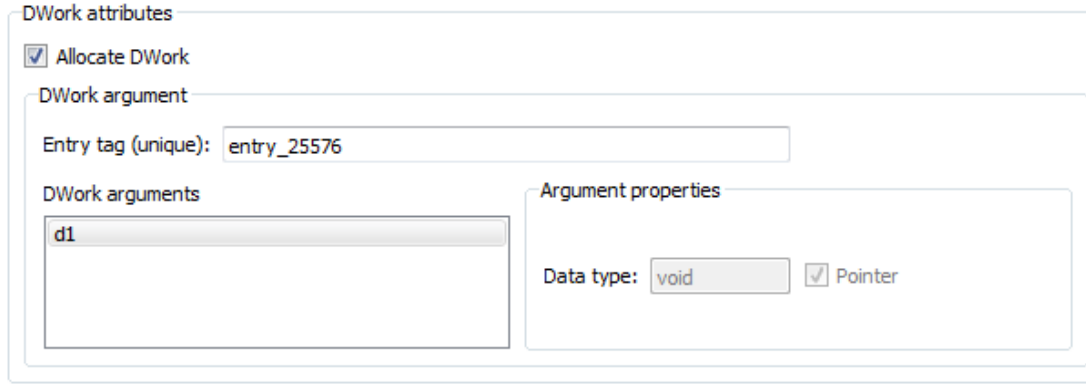
Generated mutex and semaphore code typically consists of these elements:

Code	Generated Code
Model initialization	Initialization function call that creates a mutex or semaphore function to control entry to a critical section of code.
Model step	• Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls reserve the critical section of code. • After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls release the critical section of code.

Code	Generated Code
Model termination	Optional destroy function call to delete the mutex or semaphore explicitly.

This example shows how to create code replacement table entries for a mutex replacement scenario. You configure a multicore target model for concurrent execution and for data transfer between tasks of differing rates, which Rate Transition blocks handle. In the generated code for the model, each Rate Transition block has a separate, unique mutex. Mutex lock and unlock operations within the Rate Transition block generated code share access to the same global data. They achieve this by using the unique mutex created for that Rate Transition block.

1. Open the Code Replacement Tool.
2. Create and open a new table.
3. Name the table `crl_table_rt_mutex`.
4. Create an entry for a mutex initialization function replacement.
   a. Select **File** > **New entry** > **Semaphore entry** to open a new table entry for configuring a semaphore or mutex replacement.
   b. In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Init`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
   c. In the **DWork attributes** section, the **Allocate DWork** option is selected. The dialog box provides a unique entry tag for the DWork argument `d1`.



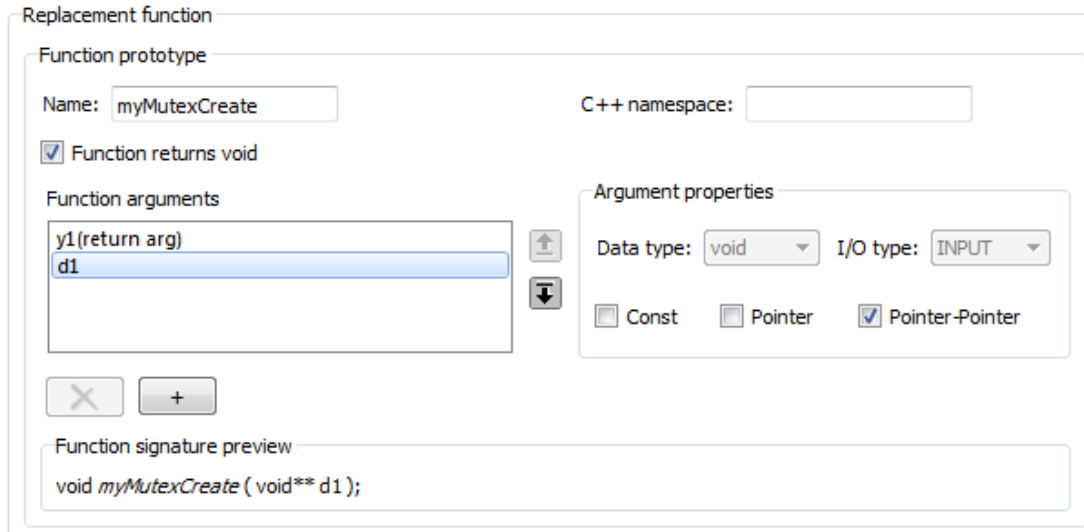
On the **DWork attributes** pane, configure a DWork argument to the replacement function. The DWork argument supports sharing of a semaphore or mutex between:

- Code that creates the semaphore or mutex
- Code that requests and relinquishes access
- Code that deletes the semaphore or mutex

In this example, the DWork argument for the `Mutex Init` function defines a unique entry tag, `entry_25576`. That function also defines DWork arguments for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy`, which reference the entry tag to share the DWork data.

The only data type supported for the DWork **Data type** parameter is `void*`.

d In the **Replacement function** section, enter a function name in the **Name** field. This example uses `myMutexCreate`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void**`.



The C function signature preview is:

```
void myMutexCreate (void** d1);
```

e In the **Replacement function** section, select **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values. Click **Apply**. Optionally, you can click **Validate entry** to validate the information entered in the **Mapping Information** tab.

   To create a sample table entry, configure the replacement function signature without the replacement function and its build information. If header and source files for these functions are available, select the **Build Information** table to specify them.

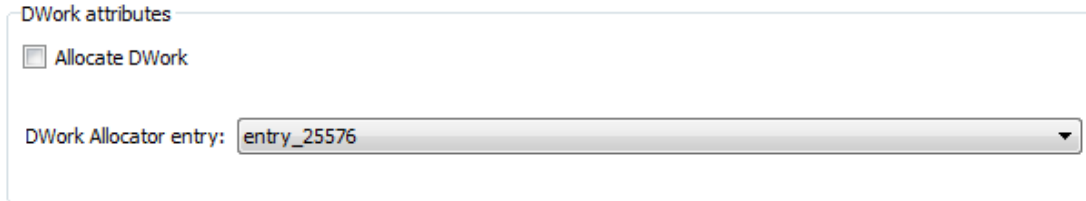
f The `Mutex Init` table entry is complete. Optionally, you can save the table to a file, and inspect the MATLAB code created for the table definition so far.

5 Repeat the following sequence to create the table entries for the mutex lock, unlock, and destroy function replacements. Each table entry references the DWork unique tag entry, `entry_25576`, defined in the `Mutex Init` table entry.

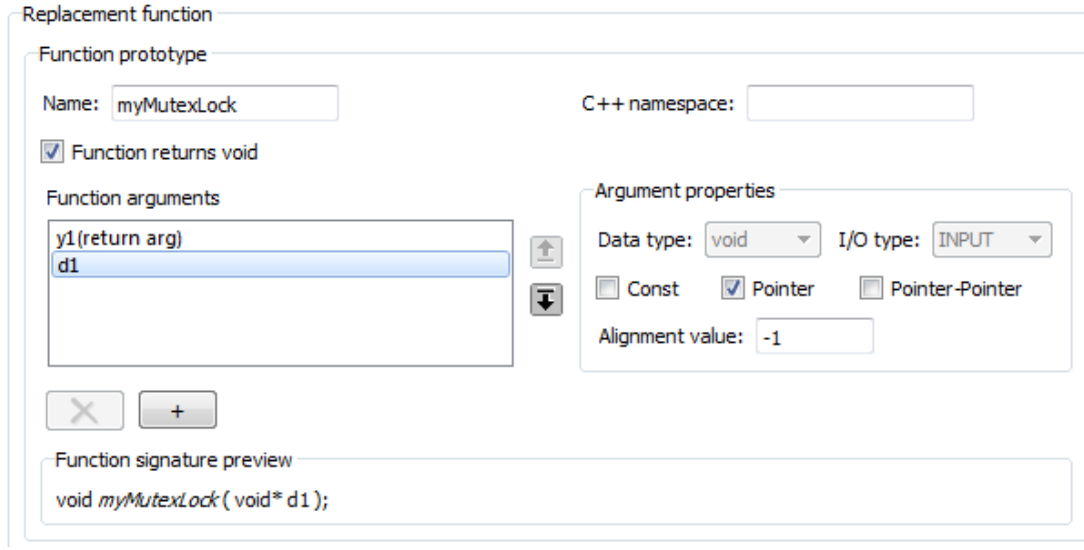
a Select **File** > **New entry** > **Semaphore entry**.

b In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Lock`, `Mutex Unlock`, or `Mutex Destroy`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.

c For a Rate Transition block mutex, the wait, post, and destroy functions operate on the DWork allocated at system startup by the mutex initialization function. In the **DWork attributes** section, verify that the **Allocate DWork** option is cleared. From the **DWork Allocator entry** drop-down list, select the entry tag matching the value in the `Mutex Init` table entry. In this example, the entry tag is `entry_25576`.



d In the **Replacement function** section, **Name** field, enter a function name. This example uses `myMutexLock`, `myMutexUnlock`, and `myMutexDelete`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void*`.

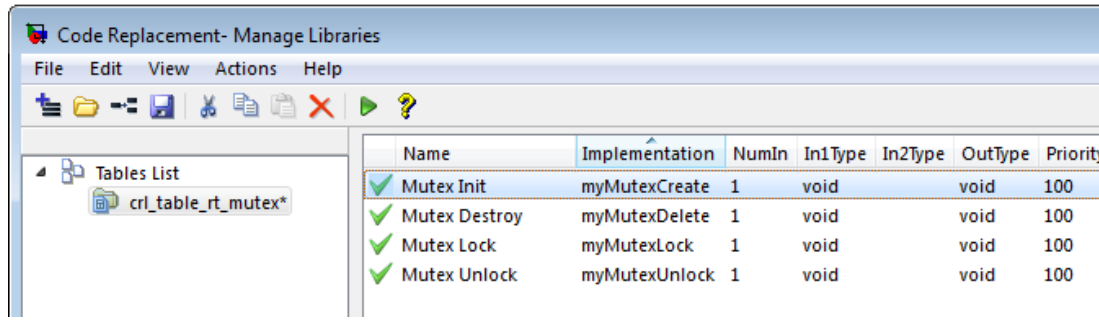


e In the **Implementation attributes** section, select the option **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values.

f Optionally, supply build information for the replacement function on the **Build Information** tab.

g Click **Apply**. In the middle pane, right-click the table entry and select **Validate entry(s)**.

6 When you have added the table entries for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy` to the entry for `Mutex Init`, the rate transition mutex replacement table is complete. In the left-most pane, right-click the table name and select **Validate table**. Address errors and repeat the table validation.

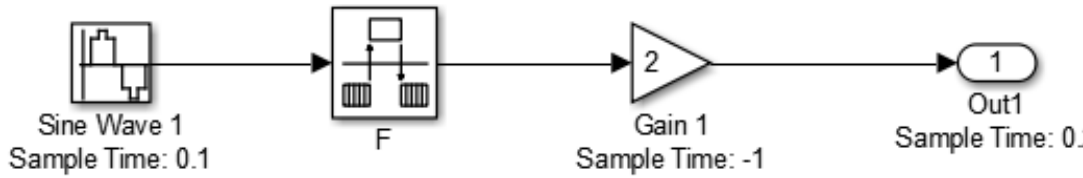


7 Save the table to a MATLAB file in your working folder, for example, using **File** > **Save table**. The name of the saved file is the table name, `crl_table_rt_mutex`, with an `.m` extension. Optionally, you can open the saved file and examine the MATLAB code for the code replacement table definition.

To test this example:

1 Register the code replacement mapping.

2 Create a model that contains a rate transition for which the build process generates mutex function calls. For example:



3 Configure the model for a multicore target environment and the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your mutex entry.

Algorithm-Based Code Replacement

For some math function blocks, you can control code replacement based on the computation or approximation algorithm configured for that block. For example, you can configure:

- The Reciprocal Sqrt block to use the `Newton-Raphson` or `Exact` computation method.
- The Trigonometric Function block, with **Function** set to `sin`, `cos`, or `sincos`, to use the approximation method `CORDIC` or `None`.

You can define code replacement entries to replace these functions for one or all of the available computation methods. For example, you can define an entry to replace only `Newton-Raphson` instances of the `rSqrt` function.

To set the algorithm for a function in an entry definition, use the `EntryInfoAlgorithm` property in a call to the function `setTflCFunctionEntryParameters`. The following table lists arguments for specifying the computation method to match during code generation.

Function	Argument
`rSqrt`	• `'RTW_DEFAULT'` (match the default computation method, `Exact`) • `'RTW_NEWTON_RAPHSON'` • `'RTW_UNSPECIFIED'` (match any computation method)

`sin`
`cos`
`sincos`
	• `'RTW_CORDIC'`
	• `'RTW_DEFAULT'` (match the default approximation method, `None`)
	• `'RTW_UNSPECIFIED'` (match any approximation method)

For example, to replace only `Newton-Raphson` instances of the `rSqrt` function, create an entry as follows:

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_rsqrt()
%CRL_TABLE_RSQRT - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
% Create entry for rsqrt function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4 Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(fcn_entry, ...
  'Key',                    'rSqrt', ...
  'Priority',               80, ...
  'ImplementationName',     'rsqrt_newton', ...
  'ImplementationHeaderFile', 'rsqrt.h', ...
  'EntryInfoAlgorithm',     'RTW_NEWTON_RAPHSON');
```

5 Create conceptual arguments `y1` and `u1`. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
  'Name',         'y1', ...
  'IOType',       'RTW_IO_OUTPUT', ...
  'DataTypeMode', 'double');

createAndAddConceptualArg(e, 'RTW.TflArgNumeric', ...
  'Name',         'u1', ...
  'DataTypeMode', 'double');
```

6 Copy the conceptual arguments to the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

The generated code for a `Newton-Raphson` instance of the `rSqrt` function looks like the following code:

```
/* Model step function */
```

```
void mrsqrt_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   *  Sqrt:   '<Root>/rSqrtBlk'
   */
  mrsqrt_Y.Out1 = rsqrt_newton(mrsqrt_U.In1);
}
```

Lookup Table Function Code Replacement

You can configure the algorithm for table lookup operations and index searches to better meet your application code requirements. Use the **Algorithm** tab of lookup table blocks. For example, you can specify the interpolation, extrapolation, and index search methods.

Lookup Table Algorithm Replacement

If the code generated for available algorithm options does not meet requirements for your application, create custom code replacement table entries to replace generated algorithm code. You can create the table entries programmatically or interactively by using the Code Replacement Tool.

For more information about using lookup table blocks, see "Nonlinearity" (Simulink).

Lookup Table Function Signatures

To create code replacement table entries for a function corresponding to a lookup table algorithm, you must have:

- Information about the conceptual function signature.
- Relevant algorithm parameters.

The following table provides the conceptual function signature information.

Conceptual Function Signature	Argument Summary
`y1 = interp1D(u1, u2, u3, u4)`	`y1` – output `u1` – index `u2` – fraction `u3` – table data `u4` – table dimension length
`y1 = interp2D(u1, u2, u3, u4, u5, u6, u7)`	`y1` – output `u1, u3` – index `u2, u4` – fraction `u5` – table data `u6, u7` – table dimension lengths
`y1 = interp3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)`	`y1` – output `u1, u3, u5` – index

Conceptual Function Signature	Argument Summary
	`u2, u4, u6` – fraction `u7` – table data `u8, u9, u10` – table dimension lengths
`y1 = interp4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)`	`y1` – output `u1, u3, u5, u7` – index `u2, u4, u6, u8` – fraction `u9` – table data `u10, u11, u12, u13` – table dimension lengths
`y1 = interp5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)`	`y1` – output `u1, u3, u5, u7, u9` – index `u2, u4, u6, u8, u10` – fraction `u11` – table data `u12, u13, u14, u15, u16` – table dimension lengths
`y1 = interpND({ui, uf,}... ut, un...)`	`y1` – output `ui`, `uf` is an index and fraction pair per dimension `ut` – table data `un` – table dimension lengths
Explicit values `y1 = lookup1D(u1, u2, u3, u4)`	`y1` – output `u1` – input `u2` – breakpoint data `u3` – table data `u4` – table dimension length
Even spacing `y1 = lookup1D(u1, u2, u3, u4, u5)`	`y1` – output `u1` – input `u2` – first point of breakpoint data `u3` – spacing of breakpoints `u4` – table data `u5` – table dimension length

Conceptual Function Signature	Argument Summary
Explicit values `y1 = lookup2D(u1, u2, u3, u4, u5, u6, u7)`	`y1` – output `u1, u2` – input `u3, u4` – breakpoint data `u5` – table data `u6, u7` – table dimension lengths
Even spacing `y1 = lookup2D(u1, u2, u3, u4, u5, u6, u7, u8, u9)`	`y1` – output `u1, u2` – input `u3, u5` – first point of breakpoint data `u4, u6` – spacing of breakpoints `u7` – table data `u8, u9` – table dimension lengths
Explicit spacing `y1 = lookup3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)`	`y1` – output `u1, u2, u3` – input `u4, u5, u6` – breakpoint data `u7` – table data `u8, u9, u10` – table dimension lengths
Even spacing `y1 = lookup3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)`	`y1` – output `u1, u2, u3` – input `u4, u6, u8` – first point of breakpoint data `u5, u7, u9` – spacing of breakpoints `u10` – table data `u11, u12, u13` – table dimension lengths
Explicit values `y1 = lookup4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)`	`y1` – output `u1, u2, u3, u4` – input `u5, u6, u7, u8` – breakpoint data `u9` – table data `u10, u11, u12, u13` – table dimension lengths

Conceptual Function Signature	Argument Summary
Even spacing `y1 = lookup4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17)`	`y1` – output `u1, u2, u3, u4` – input `u5, u7, u9, u11` – first point of breakpoint data `u6, u8, u10, u12` – spacing of breakpoints `u13` – table data `u14, u15, u16, u17` – table dimension lengths
Explicit values `y1 = lookup5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)`	`y1` – output `u1, u2, u3, u4, u5` – input `u6, u7, u8, u9, u10` – breakpoint data `u11` – table data `u12, u13, u14, u15, u16` – table dimension lengths
Even spacing `y1 = lookup5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17, u18, u19, u20, u21)`	`y1` – output `u1, u2, u3, u4, u5` – input `u6, u8, u10, u12, u14` – first point of breakpoint data `u7, u9, u11, u13, u15` – spacing of breakpoints `u16` – table data `u17, u18, u19, u20, u21` – table dimension lengths
Explicit values `y1 = lookupND(u`*n*`,..., u`*b*`,..., u`*t*`, u`*n*`...)`	`y1` – output `u`*n*, input per dimension `u`*b*, breakpoint per dimension `u`*t* – table data `u`*n* – table dimension lengths

Conceptual Function Signature	Argument Summary
Even spacing `y1 = lookupND(un,..., {ufn, usn,}... ut, un...)`	`y1` – output `un` – input per dimension `ufn` – first point of breakpoint data per dimension `usn` – spacing of breakpoint per dimension `ut` – table data `un` – table dimension lengths
`y1 = lookupND_Direct(u1, u2,...ui, ui+1)`	`y1` – output `u1...ui` – input `ui+1` – table data
Explicit values `y1, y2 = prelookup(u1, u2, u3)`	`y1` – index `y2` – fraction `u1` – input `u2` – breakpoint data `u3` – number of breakpoints
Evenly spaced `y1, y2 = prelookup(u1, u2, u3, u4)`	`y1` – index `y2` – fraction `u1` – input `u2` – first point of breakpoint data `u3` – spacing of breakpoints `u4` – number of breakpoints

When defining a table entry programmatically, you might also need to change the values of required (primary) and optional algorithm parameters.

- Set values for required parameters to achieve code replacement.
- If you do not set a value for an optional parameter, the algorithm parameter software applies `don't care`. The code replacement software ignores the parameter while searching for matches.

To look up algorithm parameter information for a lookup table function:

1. Create a table entry for a function.

   ```
   tableEntry = RTW.TflCFunctionEntry;
   ```

2 Identify the lookup table function in the table entry. Use the `Key` table entry parameter in a call to `setTflCFunctionEntryParameters`. The following example identifies an entry for the `prelookup` function.

```
setTflCFunctionEntryParameters(tableEntry, ...
    'Key', 'prelookup', ...
    'Priority', 100, ...
    'ImplementationName', 'myPrelookup');
```

3 Get the algorithm parameter set for the entry with a call to `getAlgorithmParameters`.

```
algParams = getAlgorithmParameters(tableEntry);

algParams =

  Prelookup with properties:

            ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
                 RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
       IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
       UseLastBreakpoint: [1x1 coder.algorithm.parameter.UseLastBreakpoint]
   RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
```

4 Examine information available for each parameter.

```
algParams.ExtrapMethod

ans =

  ExtrapMethod with properties:

       Name: 'ExtrapMethod'
    Options: {'Linear'  'Clip'}
    Primary: 1
      Value: {'Linear'}

algParams.RndMeth

ans =

  RndMeth with properties:

       Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
      Value: {1x7 cell}

algParams.RndMeth.Value

ans =

  Columns 1 through 6

    'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'    'Simplest'

  Column 7

    'Zero'

algParams.IndexSearchMethod
```

```
ans =

  IndexSearchMethod with properties:

       Name: 'IndexSearchMethod'
    Options: {'Linear search'  'Binary search'  'Evenly spaced points'}
    Primary: 0
      Value: {'Binary search'  'Evenly spaced points'  'Linear search'}

algParams.UseLastBreakpoint

ans =

  UseLastBreakpoint with properties:

       Name: 'UseLastBreakpoint'
    Options: {'off'  'on'}
    Primary: 0
      Value: {'off'  'on'}

algParams.RemoveProtectionInput

ans =

  RemoveProtectionInput with properties:

       Name: 'RemoveProtectionInput'
    Options: {'off'  'on'}
    Primary: 0
      Value: {'off'  'on'}
```

Interactive Mapping with Code Replacement Tool

This example shows how to specify a code replacement table entry for a lookup table algorithm by using the Code Replacement Tool.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder `matlab/toolbox/rtw/rtwdemos/crl_demo`:

- `myLookup1D.h`
- `myLookup1D.c`

Place a copy of these files in your working folder.

Open and examine the code for `myLookup1D.h`.

```
#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
```

Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
  real_T y;
  uint16_T frac;
  uint32_T bpIdx;
  uint32_T maxIndex=tdl-1;

  if (u0 <= bp0[0U]) {
    bpIdx = 0U;
    frac = 0U;
  } else if (u0 < bp0[maxIndex]) {
    bpIdx = maxIndex >> 1U;
    while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
      bpIdx--;
    }

    while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
      bpIdx++;
    }

    frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
      bp0[bpIdx]) * 32768.0);
  } else {
    bpIdx = maxIndex;
    frac = 0U;
  }

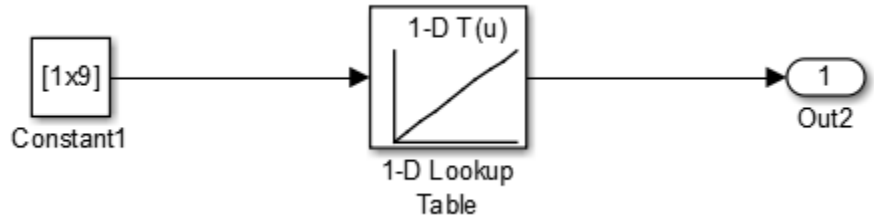
  if (bpIdx == maxIndex) {
    y = table[bpIdx];
  } else {
    y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
      table[bpIdx];
  }

  return y;
}
```

Open and Examine the Example Model

This example uses the model rtwdemo_crllookup1D to test your code replacement specification. Place a copy of the model in your working folder and name it `my_lookup1d.slx`.

Open and examine the model. Note input and output specifications and block parameter settings. To achieve a match, you must specify conceptual arguments based on how the 1-D Lookup Table block is configured in the example model.



Create Code Replacement Table

1. At the command prompt, enter `crtool` to open the Code Replacement Tool.
2. Add a new table, select that table, and add a new function entry.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. Look up the call signature and algorithm parameter information for the lookup table function that you want to update with an algorithm replacement. See "Lookup Table Function Signatures" on page 51-112.

   For this example, you replace the algorithm for the conceptual function associated with the 1-D Lookup Table block. The signature for that function is:

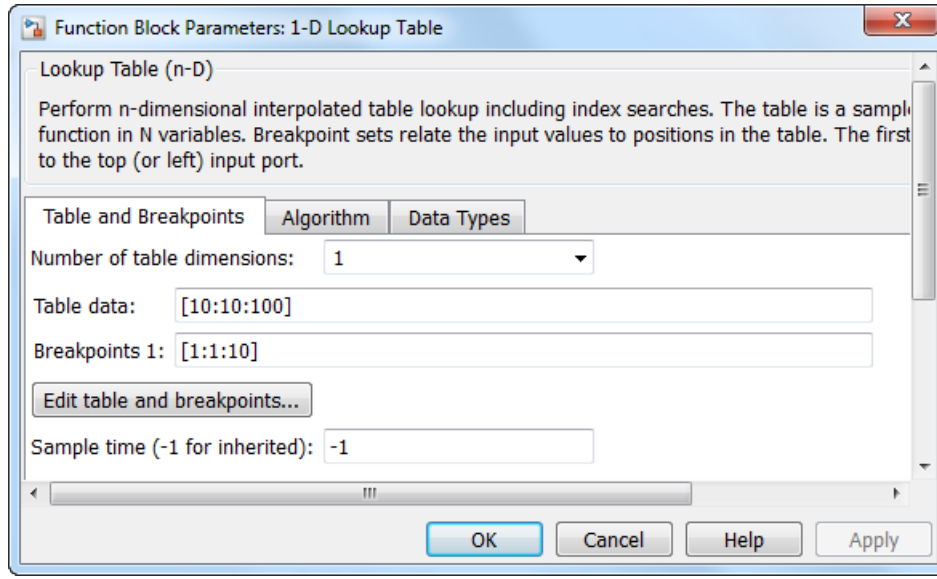
   ```
   y1 = lookup1D(u1, u2, u3, u4)
   ```

   Arguments `u1`, `u2`, `u3`, `u4` represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to `y1`.
5. To the right of the **Function** drop-down list, in the function-name text box, enter the name of the Simulink lookup table function. For this example, type the name `lookup1D`. Type the name exactly as it appears in the documented signature, including character casing. Press **Enter**.

   The tool displays algorithm parameter settings that trigger a match for the 1-D Lookup Table block in the example model. Required parameters appear with only one value. For this example, do not change the values. Optional parameters appear with multiple values. Changes to optional parameters do not affect the match process.
6. Specify the conceptual arguments. Under the **Conceptual arguments** list box, click **+** to add the arguments that are in the documented function signature. The `lookup1D` function takes one output argument and four input arguments. Click **+** five times.

The tool creates an output argument *y1* and four input arguments *u1*, *u2*, *u3*, and *u4*. By default, the four arguments are scalars of type `double`.

You can adjust the conceptual argument properties. For this example, you do not make changes for `y1` and `u1`. However, as the block parameter dialog box for the example model shows, you must adjust the argument properties for the breakpoint and table data arguments.



Adjust the conceptual argument properties by using the following table. Click **Apply**.

Signature Argument Name	Conceptual Argument Name	Data type	I/O type	Argument type	Lower range	Upper range
`y`	`y1`	`double`	`OUTPUT`	`Scalar`	Not applicable	Not applicable
`u1`	`u1`	`double`	`INPUT`	`Scalar`	Not applicable	Not applicable
`bp1`	`u2`	`double`	`INPUT`	`Matrix`	`[0 0]`	`[Inf Inf]`

Signature Argument Name	Conceptual Argument Name	Data type	I/O type	Argument type	Lower range	Upper range
`table`	`u3`	`double`	`INPUT`	`Matrix`	`[0 0]`	`[Inf Inf]`
`tdl`	`u4`	`uint32`	`INPUT`	`Scalar`	Not applicable	Not applicable

7 Enter information for the replacement function prototype. The prototype for the example function is:

```
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
```

In the **Replacement function** > **Function prototype** section, type the function name `my_Lookup1D_Repl` in the **Name** text box.

8 Specify the arguments for the replacement function. Under the **Function arguments** list box, click **+** five times to add five implementation arguments.

You might need to adjust the function argument properties. As the replacement function signature shows, adjust the argument properties for the breakpoint, table data, and table dimension length arguments. For `u2` (breakpoints) and `u3` (table), select the **Const** check box. For `u4`, set **Data type** to `uint32`.

The function signature preview should appear as follows:

```
double my_Lookup1D_Repl(double u1, const double* u2, const double* u3, uint32 u4)
```

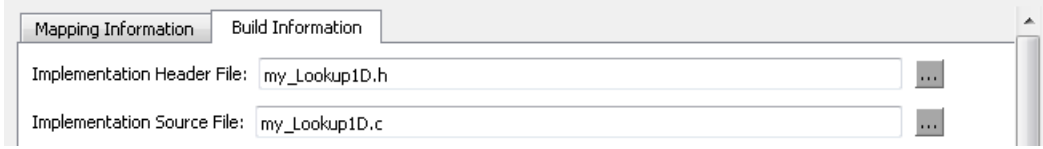
9 Set relevant implementation attributes. Use the default settings.

10 Validate the entry. If the tool reports errors, fix them, and retry the validation. Repeat the procedure until the tool does not report errors.

11 Save the code replacement table in your working folder as `my_lookup_replacement_table.m`.

Specify Build Information

On the **Build Information** tab, specify information relevant to generating C or C++ code and building an executable from the model. Enter `myLookup1D.h` for **Implementation Header File** and `myLookup1D.c` for **Implementation Source File**.



If you copied the example files to a folder other than the working folder containing the test model, `lookup1d.slx`, specify the source and header file paths. Otherwise, leave the other **Build Information** parameters set to default values. Click **Apply**.

Test the Entry

To test this example:

1. Register the code replacement mapping.
2. Use the example model rtwdemo_crllookup1D.
3. Configure the model with the following settings:
   - On the **Solver** pane, select a fixed-step solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation** > **Interface** pane, select the code replacement library that contains your lookup table function entry.

Programmatic Specification

This example shows how to specify code replacement table entries for lookup table functions programmatically.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder `matlab/toolbox/rtw/rtwdemos/crl_demo`:

- `myLookup1D.h`
- `myLookup1D.c`

Place a copy of these files in your working folder.

Open and examine the code for `myLookup1D.h`.

```
#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
```

Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
  real_T y;
  uint16_T frac;
  uint32_T bpIdx;
  uint32_T maxIndex=tdl-1;

  if (u0 <= bp0[0U]) {
    bpIdx = 0U;
    frac = 0U;
  } else if (u0 < bp0[maxIndex]) {
    bpIdx = maxIndex >> 1U;
    while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
      bpIdx--;
    }

    while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
      bpIdx++;
    }

    frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
      bp0[bpIdx]) * 32768.0);
  } else {
    bpIdx = maxIndex;
    frac = 0U;
  }

  if (bpIdx == maxIndex) {
    y = table[bpIdx];
  } else {
    y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
      table[bpIdx];
  }

  return y;
}
```

Review Lookup Function Signature

Look up the call signature information for the lookup function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 51-112.

Replace the algorithm for the function associated with the 1–D Lookup Table block. The signature for that function is:

```
y1 = lookup1D(u1, u2, u3, u4)
```

Arguments `u1`, `u2`, `u3`, and `u4` represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to `y1`.

Create Code Replacement Entry

Create a code replacement table file as a MATLAB function, that describes the lookup table function code replacement table entries. Place a copy of the file `matlab/toolbox/rtw/rtwdemos/crl_demo/crl_table_lookup1D.m` in your working folder. This file defines a code replacement table for the C function `my_Lookup1D_Repl`.

Open `crl_table_lookup1D.m` and examine the definition.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = my_lookup_replacement_table
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hLib = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function. The function key, implementation name, and header and source files in the function call identify the Simulink lookup table function name, `lookup1D`, and the following information for replacement function `my_Lookup1D_Repl`:

   - Function name
   - Header file
   - Source file

   Specify the Simulink lookup table function name exactly as it appears in the documented signature, including character casing (see “Lookup Table Function Signatures” on page 51-112). If you copied the example files to a folder other than the working folder that contains the test model, rtwdemo_crllookup1D, specify the source and header file paths.

   ```
   setTflCFunctionEntryParameters(hEnt, ...
             'Key',                    'lookup1D', ...
             'Priority',               100, ...
             'ImplementationName',     'my_Lookup1D_Repl', ...
             'ImplementationHeaderFile', 'myLookup1D.h', ...
             'ImplementationSourceFile', 'myLookup1D.c', ...
             'GenCallback',            'RTW.copyFileToBuildDir');
   ```

5 Create conceptual arguments and add them to the entry. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

The example defines five conceptual arguments for the `lookup1D` function, one output argument *`y1`* and four input arguments *`u1`*, *`u2`*, *`u3`*, and *`u4`*. Arguments *`y1`* and *`u1`* are defined as scalar `double` data. Arguments *`u2`* and *`u3`* represent *`bp1`* and *`table`* in the signature and are defined as 1x10 matrices of `double` data. Argument *`u4`* represents *`tdl`* and is defined as scalar of `uint32` data. This definition triggers a match with the example model.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT',  'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u4','uint32');
addConceptualArg(hEnt, arg);
```

6 Review the algorithm parameter information for the lookup function that you want to update with an algorithm replacement. Use the `getAlgorithmParameters` function to display the parameter information.

```
algParams = getAlgorithmParameters(hEnt)

algParams =

  Lookup with properties:

                InterpMethod: [1x1 coder.algorithm.parameter.InterpMethod]
                ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
                     RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
           IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
           UseLastTableValue: [1x1 coder.algorithm.parameter.UseLastTableValue]
       RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
  SaturateOnIntegerOverflow: [1x1 coder.algorithm.parameter.SaturateOnIntegerOverflow]
    SupportTunableTableSize: [1x1 coder.algorithm.parameter.SupportTunableTableSize]
            BPPower2Spacing: [1x1 coder.algorithm.parameter.BPPower2Spacing]
```

Examine the information for each parameter. The `Options` property lists possible values. `Primary` indicates whether a parameter is required (1) or optional (0). The

`Value` property specifies the current value. For required parameters, initially, `Value` is set to the default value for a given lookup table function.

```
algParams.InterpMethod

ans =

  InterpMethod with properties:

       Name: 'InterpMethod'
    Options: {'Linear'  'Flat'  'Nearest'}
    Primary: 1
      Value: {'Linear'}

algParams.RndMeth

ans =

  RndMeth with properties:

       Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
      Value: {1x7 cell}

algParams.RndMeth.Options

ans =

  Columns 1 through 5

    'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'

  Columns 6 through 7

    'Simplest'    'Zero'

algParams.RndMeth

ans =

  RndMeth with properties:

       Name: 'RndMeth'
    Options: {1x7 cell}
```

```
    Primary: 0
      Value: {1x7 cell}
.
.
.
```

7 Set the algorithm properties for the `lookup1D` table entry. Assign a value to each parameter. Update the parameter settings for the entry by calling the function `setAlgorithmParameters`. The following parameter settings trigger a match with the example model.

```
algParams.InterpMethod = 'Linear';
algParams.ExtrapMethod = 'Clip';
algParams.RndMeth = 'Round';
algParams.IndexSearchMethod = 'Linear search';
algParams.UseLastTableValue = 'Evenly spaced point';
algParams.RemoveProtectionInput = 'off';
algParams.SaturateOnIntegerOverflow = 'off';
algParams.SupportTunableTableSize = 'off';
algParams.BPPower2Spacing = 'off';
setAlgorithmParameters(hEnt, algParams);

ans =

  RndMeth with properties:

       Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
      Value: {1x7 cell}
.
.
.
```

To verify your changes, call `getAlgorithmParameters` to get the parameter set for the table entry. Examine the value of each parameter.

```
getAlgorithmParameters(hEnt, algParams);
algParams.InterpMethod.Value

ans =

    'Linear'

algParams.ExtrapMethod.Value
```

```
ans =

    'Clip'

algParams.RndMeth.Value

ans =

    'Round'
.
.
.
```

8 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create five implementation arguments that map to arguments in the replacement function prototype: one output argument *y1* and four input arguments *u1*, *u2*, *u3*, and *u4*. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32');
hEnt.Implementation.addArgument(arg);
```

9 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

Test the Entry

To test this example:

1. Register the code replacement mapping.
2. Use the example model rtwdemo_crllookup1D.
3. Configure the model with the following settings:
   - On the **Solver** pane, select a fixed-step solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation** > **Interface** pane, select the code replacement library that contains your lookup table function entry.

Sample Code Replacement Definition for the `lookup2D` Function

The following code shows a replacement definition for the `lookup2D` function.

```
function hLib = my_2dlookup_replacement_table

hLib = RTW.TflTable;

hEnt = RTW.TflCFunctionEntry;
setTflCFunctionEntryParameters(hEnt, ...
          'Key',                      'lookup2D', ...
          'Priority',                 100, ...

          'ImplementationName',       'custom_lookup2d', ...
          'ImplementationHeaderFile', 'custom_lookup2d.h', ...
          'ImplementationSourceFile', 'custom_lookup2d.c', ...
          'GenCallback',              'RTW.copyFileToBuildDir');

% Conceptual Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u2','double');
addConceptualArg(hEnt, arg);
```

```
arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT',  'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u4', 'RTW_IO_INPUT',  'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u5', 'RTW_IO_INPUT',  'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u6','uint32');
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u7','uint32');
addConceptualArg(hEnt, arg);

% Algorithm Parameters

addAlgorithmProperty(hEnt, 'ExtrapMethod','Clip');
addAlgorithmProperty(hEnt, 'IndexSearchMethod','Linear search');
addAlgorithmProperty(hEnt, 'InterpMethod','Linear');
addAlgorithmProperty(hEnt, 'RemoveProtectionInput','off');
addAlgorithmProperty(hEnt, 'UseLastTableValue','on');

% Implementation Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','double*');
```

```
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6','uint32');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u7','uint32');
hEnt.Implementation.addArgument(arg);

hLib.addEntry(hEnt);
```

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance. To configure data alignment for a function implementation:

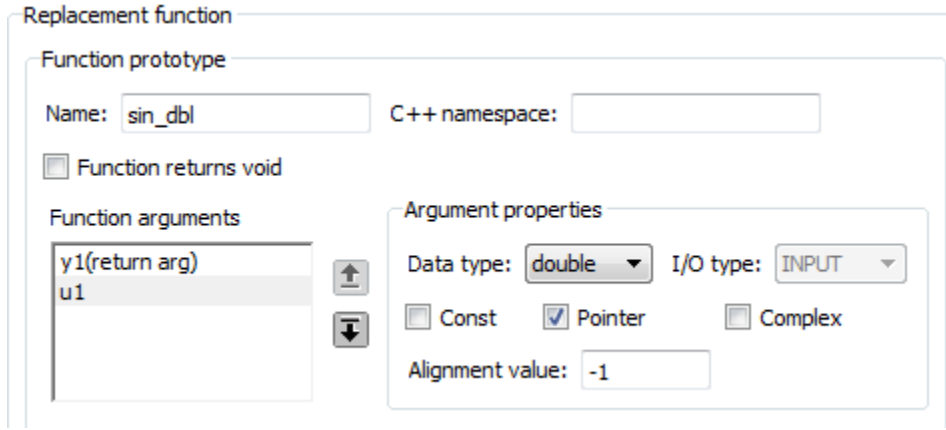
1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See "Specify Data Alignment Requirements for Function Arguments" on page 51-133.
2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See "Provide Data Alignment Specifications for Compilers" on page 51-135.
3. Register the library containing the table entry and alignment specification object.
4. Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see "Basic Example of Code Replacement Data Alignment" on page 51-139 and the "Data Alignment for Function Implementations" section of the "Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®" example page.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the argument `Descriptor` property.
- If you are defining a replacement function using the Code Replacement Tool, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.



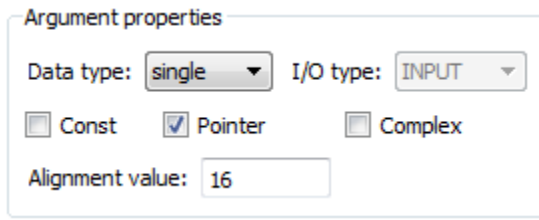
The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- `-1` (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.



Note: If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

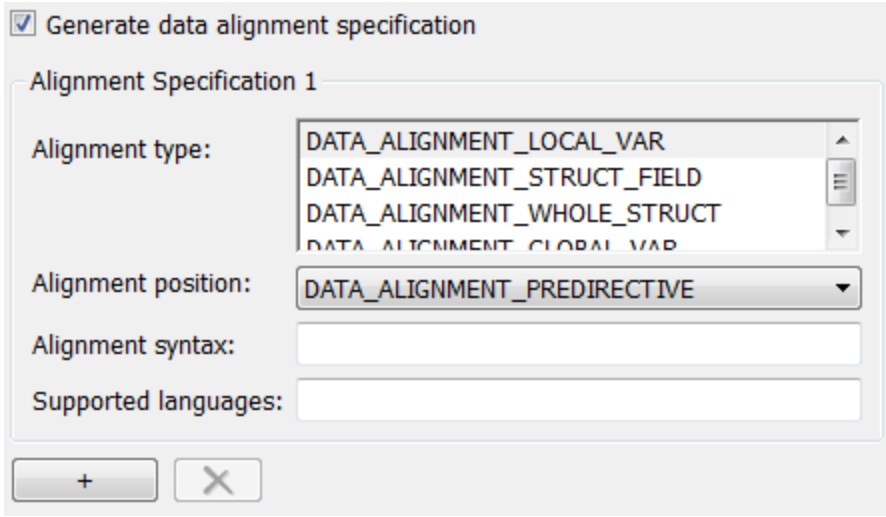
To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

  The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.



Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

`Alignment-Specification` Property	**Dialog Box Parameter**	**Description**
`AlignmentType`	**Alignment type**	Cell array of predefined enumerated strings, specifying which types of alignment this specification supports. • `DATA_ALIGNMENT_LOCAL_VAR` — Local variables. • `DATA_ALIGNMENT_GLOBAL_VAR` — Global variables. • `DATA_ALIGNMENT_STRUCT_FIELD` — Individual structure fields. • `DATA_ALIGNMENT_WHOLE_STRUCT` — Whole structure, with padding (individual structure field alignment, if

Alignment-Specification Property	Dialog Box Parameter	Description
		specified, is favored and takes precedence over whole structure alignment). Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.
AlignmentPosition	**Alignment position**	Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT: • DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before `struct st_tag{…}`, as part of the type definition statement (for example, MSVC). • DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after `struct st_tag{…}`, as part of the type definition statement (for example, gcc). • DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. • DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.

Alignment-Specification Property	Dialog Box Parameter	Description
`AlignmentSyntax-Template`	**Alignment syntax**	Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported: • `%n` — Replaced by the alignment boundary for the replacement function argument. • `%s` — Replaced by the aligned symbol, usually the identifier of a variable. For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`.
`SupportedLanguage`	**Supported languages**	Cell array specifying the languages to which this alignment specification applies, among `c` and `c++`. Sometimes alignment syntax and position differ between languages for a compiler. .

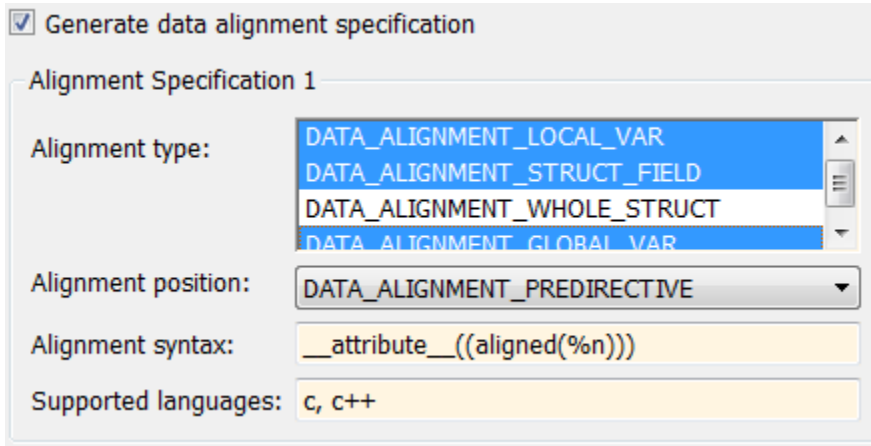
Here is a data alignment specification for the GCC compiler:

```
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                    'DATA_ALIGNMENT_STRUCT_FIELD', ...
                    'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.



Basic Example of Code Replacement Data Alignment

A simple example of the complete workflow for data alignment specified for code replacement is:

1. Create and save the following code replacement table definition file, `crl_table_mmul_4x4_single_align.m`. This table defines a replacement entry for the * (multiplication) operator, the `single` data type, and input dimensions `[4,4]`. The entry also specifies a data alignment boundary of 16 bytes for each replacement function argument. The entry expresses the requirement that the starting memory address for the data allocated for the function arguments during code generation is a multiple of 16.

```
function hLib = crl_table_mmul_4x4_single_align
%CRL_TABLE_MMUL_4x4_SINGLE_ALIGN - Describe matrix operator entry with data alignment

hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(entry, ...
    'Key',                  'RTW_OP_MUL', ...
    'Priority',             90, ...
    'ImplementationName',   'matrix_mul_4x4_s');

% conceptual arguments
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
                                 'Name',         'y1', ...
                                 'IOType',       'RTW_IO_OUTPUT', ...
                                 'BaseType',     'single', ...
                                 'DimRange',     [4 4]);
```

```
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
                                 'Name',          'u1', ...
                                 'BaseType',      'single', ...
                                 'DimRange',      [4 4]);

createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
                                 'Name',          'u2', ...
                                 'BaseType',      'single', ...
                                 'DimRange',      [4 4]);

% implementation arguments
arg = getTflArgFromString(hLib, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hLib, 'y1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hlib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u2','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

hLib.addEntry(entry);
```

2 Create and save the following registration file, `rtwTargetInfo.m`. If you want to compile the code generated in this example, first modify the `AlignmentSyntaxTemplate` property for the compiler that you use. For example, for the MSVC compiler, replace the gcc template character vector `__attribute__((aligned(%n)))` with `__declspec(align(%n))`.

```
function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
% for use with  code generation

  % Register the CRL defined in local function locCrlRegFcn
  cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_mmul_4x4_single_align
function thisCrl = locCrlRegFcn

  % create an alignment specification object, assume gcc
```

```
    as = RTW.AlignmentSpecification;
    as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                        'DATA_ALIGNMENT_GLOBAL_VAR', ...
                        'DATA_ALIGNMENT_STRUCT_FIELD'};
    as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
    as.SupportedLanguages={'c', 'c++'};

    % add the alignment specification object
    da = RTW.DataAlignment;
    da.addAlignmentSpecification(as);

    % add the data alignment object to target characteristics
    tc = RTW.TargetCharacteristics;
    tc.DataAlignment = da;

    % Instantiate a CRL registry entry
    thisCrl = RTW.TflRegistry;

    % Define the CRL properties
    thisCrl.Name = 'Data Alignment Example';
    thisCrl.Description = 'Example of replacement with data alignment';
    thisCrl.TableList = {'crl_table_mmul_4x4_single_align'};
      thisCrl.TargetCharacteristics = tc;

end % End of LOCCRLREGFCN
```

3. To register your library with code generator without having to restart MATLAB, enter this command:

   ```
   RTW.TargetRegistry.getInstance('reset');
   ```

4. Configure the code generator to use your code replacement library.
5. Generate code and a code generation report.
6. Review the code replacements. For example, check whether a multiplication operation is replaced with a `matrix_mul_4x4_s` function call. In `mmalign.h`, check whether the gcc alignment directive `__attribute__((aligned(16)))` is generated to align the function variables.

Replace MATLAB Functions with Custom Code Using `coder.replace`

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace `coder.ceval` Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in "Interactive External Function Call Replacement Specification with Code Replacement Tool" on page 52-107 and "Programmatic External Function Call Replacement Specification" on page 52-108 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
  return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2)  %#codegen

y=0.0;

if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
```

```
  y= in1+in2;
else
% Executing in generated code, call C function my_add
  y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;

y = call_my_add(in1, in2);

disp('Output')
disp('y =')
disp(y);
```

- Replacement C function `my_add_replacement.c`.

```
/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
  return in1 + in2;
}
```

- Replacement C header file `my_add_replacement.h`.

```
/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);
```

Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval`, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 52-106.

2. In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see "Define Code Replacement Mappings" on page 52-30.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.
5. Under the **Conceptual arguments** list box, click **+** to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.
6. In the **Replacement function** > **Function prototype** section, type the name `my_add_replacement` in the **Name** text box.
7. Under the **Function arguments** list box, click **+** to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type double. Use the default settings.
8. In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:

   ```
   double my_add_replacement(double u1, double u2);
   ```
9. On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.
10. Click **Validate entry**.
11. Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `crl_table_my_add.m`.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in "Example Files" on page 52-106.
2. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = crl_table_my_add
   ```
3. Within the function body, create the table by calling the function `RTW.TflTable`.
4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```
5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   hEnt.setTflCFunctionEntryParameters( ...
             'Key', 'my_add', ...
             'Priority', 100, ...
             'ImplementationName', 'my_add_replacement', ...
             'ImplementationHeaderFile', 'my_add_replacement.h', ...
             'ImplementationSourceFile', 'my_add_replacement.c');
   ```
6. Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```
7. Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

8. Add the entry to a code replacement table with a call to the `addEntry` function.

   ```
   hLib.addEntry(hEnt);
   ```

9. Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Replace MATLAB Functions Specified in MATLAB Function Blocks

This example shows how to use code replacement to replace a **MATLAB** function specified in a MATLAB Function block.

1. Open the `ex_replace` model. At the command prompt, enter:

   ```
   addpath(fullfile(docroot,'toolbox','ecoder','examples'))
   ex_replace
   ```

2. View the MATLAB Function Block code. In the model, double-click the MATLAB Function block to view the code in the MATLAB editor.

   ```
   function y = customFcn(u1, u2) %#codegen
   % This block supports MATLAB for code generation.

   % Replace this MATLAB function with CRL replacement function and if no
   % CRL replacement is found, generate an error during code generation.
   coder.replace('-errorifnoreplacement');

   assert(isa(u1,'int32'));
   assert(isa(u2,'int32'));

   y = power(u1,u2);
   ```

   The `coder.replace('-errorifnoreplacement')` statement instructs the code generator to replace this MATLAB function with a code replacement library function. The code generator produces an error if it does not find a match.

3. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_coderreplace()
   ```

4. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

5. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```

6. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   setTflCFunctionEntryParameters(hEnt, ...
       'Key',                    'customFcn', ...
   ```

```
    'Priority',                100, ...
    'ImplementationName',      'scalarFcnReplacement', ...
    'ImplementationHeaderFile', 'MyMath.h', ...
    'ImplementationSourceFile', 'MyMath.c')
```

7 Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hEnt, 'y1','int32');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','int32');
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u2','int32');
addConceptualArg(hent, arg);
```

8 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument *`void`*, input arguments *`u1`* and *`u2`*, and output argument *`y1`*. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```
arg = getTflArgFromString(hEnt, 'void','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt, 'u1','int32');
hEnt.Implementation.addArgument(arg);

arg = getTflArgFromString(hEnt, 'u2','int32');
hEnt.Implementation.addArgument(arg);

arg = getTflArgFromString(hEnt, 'y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);
```

9 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the code replacement mapping.
2. Create files `MyMath.c` and `MyMath.h` that define the replacement function, `scalarFcnReplacement`, which has two `int32` inputs and one `int32` output.

   `MyMath.c`

   ```
   #include "MyMath.h"

   void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1 ) {
       *y1 = u1^u2;
   }
   ```

   `MyMath.h`

   ```
   #ifndef _ScalarMath_h
   #define _ScalarMath_h

   #include "rtwtypes.h"

   #ifdef __cplusplus
   extern "C" {
   #endif

   extern void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1);

   #ifdef __cplusplus
   }
   #endif

   #endif
   ```
3. Open the `ex_replace` model.
4. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
5. Generate the replacement code and a code generation report.
6. Review the code replacements. In the code generation report, view the generated code for `ex_replace.c`.

   ```
   void ex_replace_step(void)
   {
      int32_T y;
      scalarFcnReplacement(ex_replace_U.In1, ex_replace_U.In2, &y);
      ex_replace_Y.Out1 = y;
   ```

```
}
```

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

More About

- “Code You Can Replace From Simulink Models” on page 51-7
- “Customize Match and Replacement Process” on page 51-153
- “Define Code Replacement Mappings” on page 51-42
- “Develop a Code Replacement Library” on page 51-27

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from `RTW.TflCFunctionEntryML (for function replacement)` or `RTW.TflCOperationEntryML` (for operator replacement).
2. In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:

    - Add match criteria that the base class does not provide. The base class provides a match based on:

        - Argument number
        - Argument name
        - Signedness
        - Word size
        - Slope (if not specified with wildcards)
        - Bias (if not specified with wildcards)
        - Math modes, such as saturation and rounding

    - Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
3. Create code replacement entries that instantiate the custom entry class.
4. Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

Customize Code Match and Replacement for Functions

This example shows how to use custom code replacement table entries to refine the match and replacement logic for functions. The example shows how to:

- Modify a sine function replacement only if the integer size on the current target platform is 32 bits.
- Change the replacement such that the implementation function passes in a degrees-versus-radians flag as an input argument.

1. To exercise the table entries that you create in this example, create an ERT-based model with a sine function block. For example:

   In the Inport block parameters, set the signal **Data type** to `double`. If the value selected for **Configuration Parameters** > **Hardware Implementation** > **Device type** supports an integer size other than 32, do one of the following:

   - Select a temporary target platform with a 32-bit integer size.
   - Modify the code to match the integer size of your target platform.
2. Create a class, for example `TflCustomFunctionEntry`, that is derived from the base class `RTW.TflCFunctionEntryML`. The derived class defines a `do_match` method with the signature:

```
function ent = do_match(hThis, ...
        hCSO, ...
        targetBitPerChar, ...
        targetBitPerShort, ...
        targetBitPerInt, ...
        targetBitPerLong, ...
        targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned either as empty (indicating that the match failed) or as a `TflCFunctionEntry` handle.
- `hThis` is a handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds required additional match criteria that the base class does not provide.
- Makes required modifications to the implementation signature.

In this case, the `do_match` method must match only `targetBitPerInt`, representing the number of bits in the C `int` data type for the current target, to the value 32. If the code generator finds a match, the method sets the return handle and creates and adds an input argument. The input argument represents whether units are expressed as degrees or radians, to the replacement function signature.

Alternatively, create and add the additional implementation function argument for passing a units flag in each code replacement table definition file that instantiates this class. In that case, this class definition code does not create the argument. That code sets only the argument value. For an example of creating and adding additional implementation function arguments in a table definition file, see “Customize Code Match and Replacement for Scalar Operations” on page 51-161.

```
classdef TflCustomFunctionEntry < RTW.TflCFunctionEntryML
  methods
    function ent = do_match(hThis, ...
        hCSO, ... %#ok
        targetBitPerChar, ... %#ok
```

```
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok
      % DO_MATCH - Create a custom match function. The base class
      % checks the types of the arguments prior to calling this
      % method. This will check additional data and perhaps modify
      % the implementation function.

      ent = []; % default the return to empty, indicating the match failed.

      % Match sine function only if the target int size is 32 bits
      if targetBitPerInt == 32
        % Need to modify the default implementation, starting from a copy
        % of the standard TflCFunctionEntry.
        ent = RTW.TflCFunctionEntry(hThis);

        % If the target int size is 32 bits, the implementation function
        % takes an additional input flag argument indicating degress vs.
        % radians. The additional argument can be created and added either
        % in the CRL table definition file that instantiates this class, or
        % here in the class definition, as follows:
        createAndAddImplementationArg(ent, 'RTW.TflArgNumericConstant', ...
                                      'Name',           'u2', ...
                                      'IsSigned',       true, ...
                                      'WordLength',     32, ...
                                      'FractionLength', 0, ...
                                      'Value',          1);
      end
    end
  end
end
```

Exit the class folder and return to the previous working folder.

3 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a function table entry for sine with `double` input and output. This entry instantiates the derived class from the previous step, `TflCustomFunctionEntry`.

```
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

%% Add TflCustomFunctionEntry
fcn_entry = TflCustomFunctionEntry;
setTflCFunctionEntryParameters(fcn_entry, ...
    'Key',                    'sin', ...
    'Priority',               30, ...
    'ImplementationName',     'mySin', ...
    'ImplementationHeaderFile', 'mySin.h', ...
    'ImplementationSourceFile', 'mySin.c');
```

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
     'Name',          'y1', ...
     'IOType',        'RTW_IO_OUTPUT', ...
     'DataTypeMode', 'double');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
     'Name',          'u1', ...
     'IOType',        'RTW_IO_INPUT', ...
     'DataTypeMode', 'double');

% TflCustomFunctionEntry class do_match method will create and add
% an implementation function argument during code generation if
% the supported integer size on the current target is 32 bits.
copyConceptualArgsToImplementation(fcn_entry);

addEntry(hTable, fcn_entry);
```

4 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = crl_table_custom_sinfcn_double
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(crl_table_custom_sinfcn_double)
  ```

Customize Code Match and Replacement for Nonscalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a nonscalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

This example restricts the match criteria for an element-wise multiplication replacement to entries with a specific dimension range. When a match occurs, the custom `do_match` method modifies the replacement signature to pass the number of elements into the function.

Files for developing and testing this code replacement library example are available in `matlab/help/toolbox/ecoder/examples/code_replacement/custom_elemmult`:

- `do_match` method — `@MyElemMultEntry/MyElemMultEntry.m`
- Replacement function source and header files — `src/myMulImplLib.c` and `src/myMulImplLib.h`
- Model — `myElemMul.slx`

- Code replacement table definition — `myElemMultCrlTable.m`
- Registration file — `rtwTargetInfo.m`

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example `MyElemMultEntry`, which is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

   ```
   function ent = do_match(hThis, ...
       hCSO, ...
       targetBitPerChar, ...
       targetBitPerShort, ...
       targetBitPerInt, ...
       targetBitPerLong, ...
       targetBitPerLongLong)
   ```

   In the `do_match` signature:

   - `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
   - `hThis` is the handle to the derived instance.
   - `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
   - Remaining arguments are the number of bits for various data types of the current target.

   The `do_match` method:

   - Adds match criteria that the base class does not provide.
   - Makes changes to the implementation signature.

   The `do_match` method relies on the base class for checking data types and dimension ranges. If the code generator finds a match, `do_match`:

   - Sets the return handle.
   - Uses the conceptual arguments to compute the number of elements in the array. In the replacement entry returned, sets the value of the constant implementation argument as the number of elements of the array.

- Updates the code replacement entry such that it matches CSOs that have the same argument dimensions.

```
classdef MyElemMulyEntry < RTW.TflCOperationEntryML
    methods
        function obj = MyElemMultEntry(varargin)
            mlock;
            obj@RTW.TflCOperationEntryML(varargin{:});
        end

        function ent = do_match(hThis, ...
            hCSO, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong ) %#ok

            %  Fourth implementation arg represents number of elements for producing matches.
            assert(strcmp(hThis.Implementation.Arguments(4).Name,'numElements'));

            ent = RTW.TflCOperationEntry(hThis);

            % Calculate number of elements and set value of injected constant.
            ent.Implementation.Arguments(4).Value = prod(hCSO.ConceptualArgs(1).DimRange(1,:));

            % Since implementation has been modified for specific DimRange, update
            % returned entry to match similar CSOs only.
            for idx =1:3
                ent.ConceptualArgs(idx).DimRange = hCSO.ConceptualArgs(idx).DimRange;
            end
        end
    end
end
```

2 Create and save the following code replacement table definition file, `myElemMultCrlTable.m`. This file defines a code replacement table that contains an operator entry generator for element-wise multiplication. The table entry:

- Instantiates the derived class `myElemMultEntry` from the previous step.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Creates conceptual arguments `y1`, `u1`, and `u2`. The argument class `RTW.TflArgMatrix` specifies matrix arguments to match. The three arguments are set up to match 2-dimensional matrices with at least two elements in each dimension.

- Calls the `getTflArgFromString` function to create a return value and four implementation arguments. Arguments `u1` and `u2` are the operands, `y1` is the product, and the fourth argument is the number of elements.

  Alternatively, the `do_match` method of the derived class `myElemMultEntry` can create and add the implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```
function hLib = myElemMultCrlTable

libPath = fullfile(fileparts(which(mfilename)),'src');

hLib = RTW.TflTable;
%---------- entry: RTW_OP_ELEM_MUL -----------
hEnt = MyElemMultEntry;
hEnt.setTflCOperationEntryParameters( ...
          'Key', 'RTW_OP_ELEM_MUL', ...
          'Priority', 100, ...
          'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
          'ImplementationName', 'myElemMul_s32', ...
          'ImplementationSourceFile', 'myMulImplLib.c', ...
          'ImplementationSourcePath', libPath, ...
          'ImplementationHeaderFile', 'myMulImplLib.h', ...
          'ImplementationHeaderPath', libPath, ...
          'SideEffects', true, ...
          'GenCallback','RTW.copyFileToBuildDir');

% Conceptual Args

arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT',  'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT',  'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);
```

```
% Implementation Args

arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',0);
hEnt.Implementation.addArgument(arg);

hLib.addEntry( hEnt );
```

3 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = myElemMultCrlTable
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(myElemMultCrlTable)
  ```

Customize Code Match and Replacement for Scalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1 Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
        hCSO, ...
        targetBitPerChar, ...
        targetBitPerShort, ...
        targetBitPerInt, ...
        targetBitPerLong, ...
        targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
  methods
    function ent = do_match(hThis, ...
        hCSO, ... %#ok
        targetBitPerChar, ... %#ok
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok

      % DO_MATCH - Create a custom match function. The base class
      % checks the types of the arguments prior to calling this
      % method. This class will check additional data and can
      % modify the implementation function.

      % The base class checks word size and signedness. Slopes and biases
      % have been wildcarded, so the only additional checking to do is
      % to check that the biases are zero and that there are only three
      % conceptual arguments (one output, two inputs)

      ent = []; % default the return to empty, indicating the match failed

      if length(hCSO.ConceptualArgs) == 3 && ...
          hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
          hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
          hCSO.ConceptualArgs(3).Type.Bias == 0

        % Modify the default implementation. Since this is a
        % generator entry, a concrete entry is created using this entry
        % as a template. The type of entry being created is a standard
        % TflCOperationEntry. Using the standard operation entry
        % provides required information, and you do not need
        % a custom match function.
        ent = RTW.TflCOperationEntry(hThis);

        % Since this entry is modifying the implementation for specific
        % fraction-length values (arguments 3, 4, and 5), the conceptual argument
        % wild cards must be removed (the wildcards were inherited from the
        % generator when it was used as a template for the concrete entry).
        % This concrete entry is now for a specific slope and bias.
        % hCSO holds the slope and bias values (created by the code generator).
        for idx=1:3
          ent.ConceptualArgs(idx).CheckSlope = true;
          ent.ConceptualArgs(idx).CheckBias = true;

          % Set the specific Slope and Biases
```

```
            ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
            ent.ConceptualArgs(idx).Type.Bias = 0;
          end

          % Set the fraction-length values in the implementation function.
          ent.Implementation.Arguments(3).Value = ...
             -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
          ent.Implementation.Arguments(4).Value = ...
             -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
          ent.Implementation.Arguments(5).Value = ...
             -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
        end
      end
    end
  end
```

Exit the class folder and return to the previous working folder.

2 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;

%% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName',       'myFixptAdd', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',       'y1', ...
     'IOType',     'RTW_IO_OUTPUT', ...
     'CheckSlope', false, ...
     'CheckBias',  false, ...
     'DataType',   'Fixed', ...
     'Scaling',    'BinaryPoint', ...
     'IsSigned',   false, ...
     'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
      'Name',       'u1', ...
      'IOType',     'RTW_IO_INPUT', ...
      'CheckSlope', false, ...
      'CheckBias',  false, ...
      'DataType',   'Fixed', ...
      'Scaling',    'BinaryPoint', ...
      'IsSigned',   false, ...
      'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
       'Name',       'u2', ...
       'IOType',     'RTW_IO_INPUT', ...
       'CheckSlope', false, ...
       'CheckBias',  false, ...
       'DataType',   'Fixed', ...
```

```
        'Scaling',    'BinaryPoint', ...
        'IsSigned',   false, ...
        'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u1', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u2', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',         'fl_in1', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',         0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',         'fl_in2', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',         0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
```

```
    'Name',        'fl_out', ...
    'IOType',      'RTW_IO_INPUT', ...
    'IsSigned',    false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',        0);

addEntry(hTable, op_entry);
```

3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = crl_table_custom_sinfcn_double
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(crl_table_custom_sinfcn_double)
  ```

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the `setTflCOperationEntryParameters` function.

   ```
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 90, ...
                       'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
                       'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                       'ImplementationName',       'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg );

   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg );
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(op_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

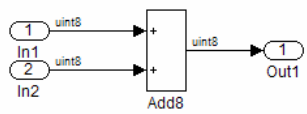
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes an Add block, such as this model.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

4 Generate code and a code generation report.

5 Review the code replacements.

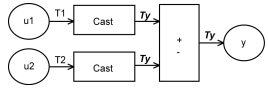
Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

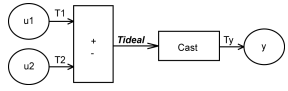
Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.



- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.



Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an **Algorithm** menu. Use that menu to specify the `Cast before operation` or `Cast after operation` algorithm for that entry.

Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- `Key` to `RTW_OP_ADD` or `RTW_OP_MINUS`
- `ImplementationName` to the name of your replacement function
- `EntryInfoAlgorithm` to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                  'Key',                      'RTW_OP_ADD', ...
                  'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
                  'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

`single`	`single`	`single`	`double`	—
`single`	`single`	`double`	`single`	—
`single`	`single`	`double`	`double`	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: • Operation type is `double`. • Operation type is `single` and input types are `single` or fixed-point.
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: • Accumulator type equals output type (`Tacc == Tout`). • Output type is a superset of input types (`Tacc >= {Tin1, Tin2}`) and accumulator type is a superset of output type (`Tacc >= Tout`). • Operation does not incur range or precision loss.
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see "Addition" or "Subtraction" in "Fixed-Point Operator Code Replacement" on page 52-146 (for MATLAB code) or "Fixed-Point Operator Code Replacement" on page 51-195 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 –> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

Limitations

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the `double` data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create table entry for matrix_sum_2x2_double
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCOperationEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_ADD', ...
       'Priority',               30, ...
       'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
       'ImplementationName',     'matrix_sum_2x2_double', ...
       'ImplementationHeaderFile', 'MatrixMath.h', ...
       'ImplementationSourceFile', 'MatrixMath.c', ...
       'ImplementationHeaderPath', LibPath, ...
       'ImplementationSourcePath', LibPath, ...
       'AdditionalIncludePaths',   {LibPath}, ...
       'GenCallback',            'RTW.copyFileToBuildDir', ...
       'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument

class `RTW.TflArgMatrix`. Specify the base type and the dimensions for which the argument is valid. The first table entry specifies `[2 2]` and the second table entry specifies `[3 3]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Create the entry for the second operator mapping.

```
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',       'matrix_sum_3x3_double', ...
```

```
        'ImplementationHeaderFile', 'MatrixMath.h', ...
        'ImplementationSourceFile', 'MatrixMath.c', ...
        'ImplementationHeaderPath', LibPath, ...
        'ImplementationSourcePath', LibPath, ...
        'AdditionalIncludePaths',   {LibPath}, ...
        'GenCallback',              'RTW.copyFileToBuildDir', ...
        'SideEffects',              true);

    % Specify operands and result
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                              'Name',         'y1', ...
                              'IOType',       'RTW_IO_OUTPUT', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                              'Name',         'u1', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                              'Name',         'u2', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);

    % Specify replacement function signature
    arg = getTflArgFromString(hTable, 'y2', 'void');
    arg.IOType = 'RTW_IO_OUTPUT';
    op_entry.Implementation.setReturn(arg);
    arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
    op_entry.Implementation.addArgument(arg);
    arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
    op_entry.Implementation.addArgument(arg);
    arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
    arg.IOType = 'RTW_IO_OUTPUT';
    op_entry.Implementation.addArgument(arg);

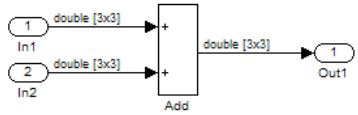
    addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes an Add block.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

4 In the Model Explorer, configure the **Signal Attributes** for the `In1` and `In2` source blocks. For each source block, set **Port dimensions** to `[3,3]`, and set **Data type** to `double`. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements. The code generator replaces the + operator with `matrix_sum_3x3_double` in the generated code.

7 Reconfigure **Port dimensions** for `In1` and `In2` to `[2 2]`, regenerate code. Observe that code containing the + operator is replaced with `matrix_sum_2x2_double`.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of $C = a(op(A) * op(B)) + bC$. $op(X)$ means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of $C = op(A) * op(B)\ (a = 1.0, b = 0.0)$. Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of $y = a(op(A) * x) + by$, code replacement libraries support only the limited case of $y = op(A) * x\ (a = 1.0, b = 0.0)$.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_tmwblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

   ```
   % Define library path for Windows or UNIX
   arch = computer('arch');
   if ~ispc
       LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
   else
       % Use Stateflow to get the compiler info
       compilerInfo = sf('Private','compilerman','get_compiler_info');
       compilerName = compilerInfo.compilerName;
       if strcmp(compilerName, 'msvc90') || ...
               strcmp(compilerName, 'msvc80') || ...
               strcmp(compilerName, 'msvc71') || ...
               strcmp(compilerName, 'msvc60'), ...
               compilerName = 'microsoft';
       end
       LibPath = fullfile('$(MATLAB_ROOT)', 'extern', 'lib', arch, compilerName);
   end
   ```

4 Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

```
% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;
```

5 Set operator entry parameters with a call to the `setTflCFunctionEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCFunctionEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

```
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',       {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath}, ...
    'SideEffects',              true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
```

```
                            'IOType',       'RTW_IO_OUTPUT', ...
                            'BaseType',     'double', ...
                            'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                            'Name',         'u1', ...
                            'BaseType',     'double', ...
                            'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                            'Name',         'u2', ...
                            'BaseType',     'double', ...
                            'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%        type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
%  RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
%  RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for dgemv32
op_entry = RTW.TflBlasEntryGenerator;
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_MUL', ...
    'Priority',               100, ...
    'ImplementationName',     'dgemv32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',     {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath},...
    'SideEffects',            true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(char* TRANS, int* M, int* N,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* INCX,
%        type* BETA, type* y, int* INCY)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY, and insert them into the
% generated code. TRANS will be set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANS');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX','integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

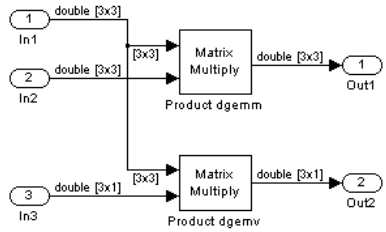
arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1. Register the code replacement mapping.
2. Create a model that includes two Product blocks.



3. For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.
4. Configure the model with the following settings:
   - On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.
5. In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For `In1` and `In2`, set **Port dimensions** to `[3 3]` and set the **Data type** to `double`. For `In3`, set **Port dimensions** to `[3 1]` and set the **Data type** to `double`.
6. Generate code and a code generation report.
7. Review the code replacements.

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of $C = a(op(A) * op(B)) + bC$. $op(X)$ means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of $C = op(A) * op(B)\ (a = 1.0, b = 0.0)$. Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of $y = a(op(A) * x) + by$, code replacement libraries support only the limited case of $y = op(A) * x\ (a = 1.0, b = 0.0)$.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

   ```
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                      'RTW_OP_MUL', ...
   ```

```
    'Priority',                100, ...
    'ImplementationName',      'cblas_dgemm', ...
    'ImplementationHeaderFile', 'cblas.h', ...
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',             'RTW.copyFileToBuildDir', ...
    'SideEffects',             true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`. The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',          'y1', ...
                          'IOType',        'RTW_IO_OUTPUT', ...
                          'BaseType',      'double', ...
                          'DimRange',      [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',          'u1', ...
                          'BaseType',      'double', ...
                          'DimRange',      [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',          'u2', ...
                          'BaseType',      'double', ...
                          'DimRange',      [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
%        type ALPHA, type* u1, int LDA, type* u2, int LDB,
```

```
%        type BETA, type* y, int LDC)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'cblas_dgemv', ...
    'ImplementationHeaderFile', 'cblas.h', ...
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, int M, int N,
%        type ALPHA, type* u1, int LDA, type* u2, int INCX,
%        type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.
```

```
% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M','integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

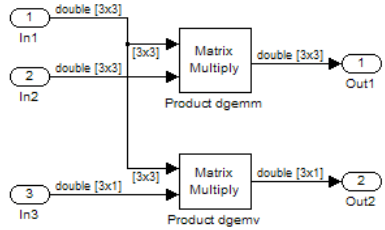
addEntry(hTable, op_entry);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes two Product blocks.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

4 For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.

5 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For `In1` and `In2`, set **Port dimensions** to `[3 3]`. Set the **Data type** to `double`. For `In3`, set **Port dimensions** to `[3 1]`. Set the **Data type** to `double`.

6 Generate code and a code generation report.

7 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

Note: Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 90, ...
                       'ImplementationName',       'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
                       'SideEffects',              true );
   ```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg );

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg );
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

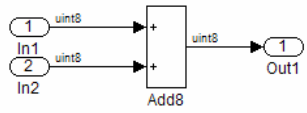
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes an Add block.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.
- On the **All Parameters** tab, set the **Optimize global data access** parameter to `Use global to hold temporary results` to reduce data copies in the generated code.

4 Generate code and a code generation report.

5 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point binary-point-only scaling. • `FractionLength`: Specify a fraction length (for example, 3).
A specific slope bias scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function:

Match	Create entry	Minimally specify parameters
		• `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point [slope bias] scaling. • `Slope` (or `SlopeAdjustmentFactor/FixedExponent` equivalent): Specify a slope value (for example, `15`). • `Bias`: Specify a bias value (for example, `2`).
Net slope between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntryGenerator_NetSlope`	`setTflCOperationEntryParameters` function: • `NetSlopeAdjustmentFactor`: Specify the slope adjustment factor (`F`) part of the net slope, $F2^E$ (for example, `1.0`). • `NetFixedExponent`: Specify the fixed exponent (`E`) part of the net slope, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.

Match	Create entry	Minimally specify parameters
Relative scaling between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntryGenerator`	`setTflCOperationEntryParameters` function: • `RelativeScalingFactorF`: Specify the slope adjustment factor (`F`) part of the relative scaling factor, $F2^E$ (for example, `1.0`). • `RelativeScalingFactorE`: Specify the fixed exponent (`E`) part of the relative scaling factor, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.
Equal slope and zero net bias across operator inputs and output (addition and subtraction).	`RTW.TflCOperationEntryGenerator`	`setTflCOperationEntryParameters` function: • `SlopesMustBeTheSame`: Specify the value `true`. • `MustHaveZeroNetBias`: Specify the value `true`. `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`.

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- V is an arbitrarily precise real-world value.
- $\tilde{V}$ is the approximate real-world value that results from fixed-point representation.
- Q is an integer that encodes $\tilde{V}$, referred to as the *quantized integer*.
- S is a coefficient of Q, referred to as the *slope*.
- B is an additive correction, referred to as the *bias*.

The general equation for an operation between fixed-point operands is:

$$\left(S_O Q_O + B_O\right) = \left(S_1 Q_1 + B_1\right) < op > (S_2 Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

Addition

The operation $V_0 = V_1 + V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right) Q_1 + \left(\frac{S_2}{S_0}\right) Q_2 + \left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left(\frac{B_1 + B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Subtraction

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0} \right) Q_1 - \left(\frac{S_2}{S_0} \right) Q_2 + \left(\frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left(\frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. Use the `TflCOperationEntry` class

and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 * V_2$ implies, for binary-point-only scaling, that

$$S_0Q_0 = (S_1Q_1)(S_2Q_2)$$
$$Q_0 = \left(\frac{S_1S_2}{S_0}\right)Q_1Q_2$$
$$Q_0 = S_nQ_1Q_2$$

where S_n is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.) For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

Note: When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. For this, use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. For this, use a net slope entry or create a custom entry (see "Customize Match and Replacement Process" on page 51-153).

The operation $V_0 = (V_1 / V_2)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{S_2 Q_2} \right)$$

$$Q_0 = S_n \left(\frac{Q_1}{Q_2} \right)$$

where S_n is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.) For the `s16_netslopeOp5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

Note: When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Data Type Conversion (Cast)

The data type conversion operation $V_0 = V_1$ implies, for binary-point-only scaling, that

$$Q_0 = \left(\frac{S_1}{S_0} \right) Q_1$$

$$Q_0 = S_n Q_1$$

where S_n is the net slope.

Shift

The shift left or shift right operation $V_0 = (V_1 / 2^n)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{2^n} \right)$$

$$Q_0 = \left(\frac{S_1}{S_0} \right) + \left(\frac{Q_1}{2^n} \right)$$

$$Q_0 = S_n \left(\frac{Q_1}{2^n} \right)$$

where S_n is the net slope.

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_MUL', ...
       'Priority',               90, ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
       'ImplementationName',     's32_mul_s16_s16_binarypoint', ...
       'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
       'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a

fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 13);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (`int32`). The input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     32, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

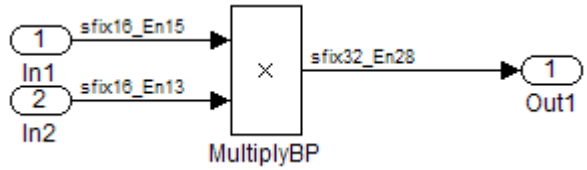
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `fixdt(1,16,15)`.
- Set the Inport 2 **Data type** to `fixdt(1,16,13)`.
- In the Product block:
  - Set **Output data type** to `fixdt(1,32,28)`.
  - Select the option **Saturate on integer overflow**.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                    'RTW_OP_DIV', ...
      'Priority',               90, ...
      'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
      'RoundingModes',          {'RTW_ROUND_CEILING'}, ...
      'ImplementationName',     's16_div_s16_s16_slopebias', ...
      'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
      'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          15, ...
   'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          15, ...
   'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'u2', ...
   'IOType',         'RTW_IO_INPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          13, ...
   'Bias',           5);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

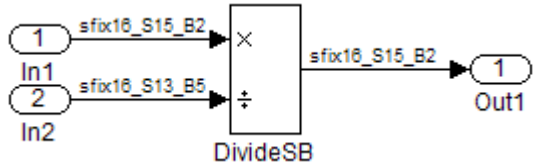
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `fixdt(1,16,15,2)`.
- Set the Inport 2 **Data type** to `fixdt(1,16,13,5)`.
- In the Divide block:
  - Set **Output data type** to `Inherit: Inherit via back propagation`.
  - Set **Integer rounding mode** to `Ceiling`.
  - Select the option **Saturate on integer overflow**.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_netslopesaturate
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```
   wv = [16,32];
   for iy = 1:2
     for inum = 1:2
       for iden = 1:2
         hTable = getDivOpEntry(hTable, ...
            fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
       end
     end
   end

   %------------------------------------------------------------
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %------------------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified

   funcStr = sprintf('user_div_%s_%s_%s',...
           typeStrFunc(dty),...
           typeStrFunc(dtnum),...
           typeStrFunc(dtden));
   ```

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW',...
   'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'},...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         0.0, ...
   'ImplementationName',       funcStr, ...
   'ImplementationHeaderFile', [funcStr,'.h'], ...
   'ImplementationSourceFile', [funcStr,'.c']);
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',           'y1',...
   'IOType',         'RTW_IO_OUTPUT',...
   'CheckSlope',     false,...
   'CheckBias',      false,...
   'DataTypeMode',   'Fixed-point: slope and bias scaling',...
   'IsSigned',       dty.Signed,...
   'WordLength',     dty.WordLength,...
   'Bias',           0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT',...
   'CheckSlope',     false,...
   'CheckBias',      false,...
   'DataTypeMode',   'Fixed-point: slope and bias scaling',...
   'IsSigned',       dtnum.Signed,...
   'WordLength',     dtnum.WordLength,...
   'Bias',           0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',           'u2', ...
```

```
    'IOType',          'RTW_IO_INPUT',...
    'CheckSlope',      false,...
    'CheckBias',       false,...
    'DataTypeMode',    'Fixed-point: slope and bias scaling',...
    'IsSigned',        dtden.Signed,...
    'WordLength',      dtden.WordLength,...
    'Bias',            0);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2',typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Define functions that determine the data type word length.

```
%------------------------------------------------------------
function str = typeStrFunc(dt)
%------------------------------------------------------------

if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);

%------------------------------------------------------------
function str = typeStrBase(dt)
%------------------------------------------------------------

if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Multiplication and Division with Rounding Mode and Additional Implementation Arguments

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netsloperound
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the relative scaling factor $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'NetSlopeAdjustmentFactor',   1.0, ...
   'NetFixedExponent',           0.0, ...
```

```
    'ImplementationName',       's16_div_s16_s16', ...
    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
                                  'Name',           'y1', ...
                                  'IOType',         'RTW_IO_OUTPUT', ...
                                  'IsSigned',       true, ...
                                  'WordLength',     16, ...
                                  'FractionLength', 0);
```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                                'Name',           'u1', ...
                                'IOType',         'RTW_IO_INPUT', ...
                                'IsSigned',       true, ...
                                'WordLength',     16, ...
                                'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                                'Name',           'u2', ...
                                'IOType',         'RTW_IO_INPUT', ...
                                'IsSigned',       true, ...
                                'WordLength',     16, ...
                                'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

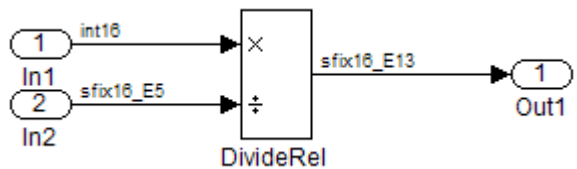
8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `int16`.
- Set the Inport 2 **Data type** to `fixdt(1,16,-5)`.
- In the Divide block:
  - Set **Output data type** to `fixdt(1,16,-13)`.
  - Set **Integer rounding mode** to `Ceiling`.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.

- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values. Map relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

   ```
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. `SlopesMustBeTheSame` and `MustHaveZeroNetBias` are set to `true`, indicating that slopes must be equal and net bias must be zero across the addition inputs and output.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                   'RTW_OP_ADD', ...
       'Priority',               90, ...
       'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
       'SlopesMustBeTheSame',    true, ...
       'MustHaveZeroNetBias',    true, ...
       'ImplementationName',      'u16_add_SameSlopeZeroBias', ...
       'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
       'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (`uint16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

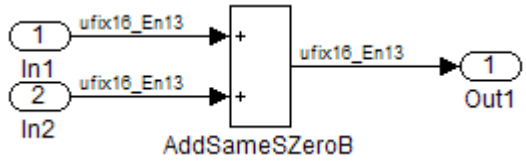
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `fixdt(0,16,13)`.
- Set the Inport 2 **Data type** to `fixdt(0,16,13)`.
- In the Add block:
  - Verify that **Output data type** is set to its default, `Inherit via internal rule`.
  - Set **Integer rounding mode** to `Zero`.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

Casts from `int32` To `int16`

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cast_int32_to_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_sat_cast`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_CAST', ...
       'Priority',               50, ...
       'ImplementationName',     'my_sat_cast', ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_FLOOR'}, ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Casts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type

of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                     'RTW_OP_CAST', ...
   'Priority',                50, ...
   'SaturationMode',          'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',           {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',        (OutFL - InFL), ...
   'ImplementationName',      'my_fxp_cast', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',         'u1', ...
     'IOType',       'RTW_IO_INPUT', ...
     'CheckSlope',   false, ...
     'CheckBias',    false, ...
     'DataTypeMode', 'Fixed-point: binary point scaling', ...
     'IsSigned',     InSgn, ...
     'WordLength',   InWL, ...
     'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and

`createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       InSgn, ...
    'WordLength',     InWL, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

Shift Lefts for `int16` Data

This example creates a code replacement entry to replace shift left operations for `int16` data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_SL', ...
       'Priority',               50, ...
       'ImplementationName',     'my_shift_left', ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```

6 Create the `int16` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as an implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTflArgFromString` is called to create an `int8` input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

  ```
  addEntry(hTable, op_entry);
  ```
- Save the table definition file. Use the name of the table definition function to name the file.

Shift Lefts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_SL', ...
   'Priority',                 50, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         (OutFL - InFL),...
   'ImplementationName',       'my_fxp_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
```

```
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',          'u1', ...
    'IOType',        'RTW_IO_INPUT', ...
    'CheckSlope',    false, ...
    'CheckBias',     false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',      InSgn, ...
    'WordLength',    InWL, ...
    'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',           'u1', ...
     'IOType',         'RTW_IO_INPUT', ...
     'IsSigned',       InSgn, ...
     'WordLength',     InWL, ...
     'FractionLength', 0);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Code Replacement Customization for MATLAB Code

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator's match and replacement process for functions

To get started, "Quick Start Library Development" on page 51-28.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority
3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
4. Uses the C or C++ replacement function prototype in the code replacement object to generate code.

Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 52-64.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 52-47.
- Addition and subtraction operation replacements—See “Addition and Subtraction Operator Code Replacement” on page 52-122for relevant limitations.
- `coder.replace` function — See `coder.replace` for relevant limitations.
- `coder.dataAlignment` function — See `coder.dataAlignment` for relevant limitations.

Code You Can Replace from MATLAB Code

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

In this section...

Math Functions

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`abs`[1]	Floating point	Scalar	Real
`acos`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`acosd`	Floating point	Scalar Vector Matrix	Real Complex
`acot`	Floating point	Scalar Vector Matrix	Real Complex
`acotd`	Floating point	Scalar Vector Matrix	Real Complex
`acoth`	Floating point	Scalar	Real

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Vector Matrix	Complex
`acsc`	Floating point	Scalar Vector Matrix	Real Complex
`acscd`	Floating point	Scalar Vector Matrix	Real Complex
`acsch`	Floating point	Scalar Vector Matrix	Real Complex
`asec`	Floating point	Scalar Vector Matrix	Real Complex
`asecd`	Floating point	Scalar Vector Matrix	Real Complex
`asech`	Floating point	Scalar Vector Matrix	Real Complex
`asin`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`asind`	Floating point	Scalar Vector Matrix	Real Complex
`atan`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`atan2`	Floating point	Scalar Vector Matrix	Real
`atan2d`	Floating point	Scalar Vector Matrix	Real
`atand`	Floating point	Scalar Vector Matrix	Real Complex
`cos`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`ceil`	• Floating-point • Scalar	• Floating-point • Scalar	• Floating-point • Scalar
`cosd`	Floating point	Scalar Vector Matrix	Real Complex
`cosh`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`cot`	Floating point	Scalar Vector Matrix	Real Complex
`cotd`	Floating point	Scalar Vector Matrix	Real Complex
`coth`	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`csc`	Floating point	Scalar Vector Matrix	Real Complex
`cscd`	Floating point	Scalar Vector Matrix	Real Complex
`csch`	Floating point	Scalar Vector Matrix	Real Complex
`exp`	Floating point	Scalar	Real
`fix`	Floating point	Scalar	Real
`floor`	• Floating-point • Scalar	• Floating-point • Scalar	• Floating-point • Scalar
`hypot`	Floating point	Scalar Vector Matrix	Real
`ldexp`	Floating point	Scalar	Real
`log`	Floating point	Scalar Vector Matrix	Real Complex
`log10`	Floating point	Scalar Vector Matrix	Real Complex
`log2`	Floating point	Scalar Vector Matrix	Real Complex
`max`	Integer Floating point	Scalar	Real
`min`	Integer Floating point	Scalar	Real
`pow`	Floating point	Scalar	Real

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`rem`	Floating point	Scalar	Real
`round`	Floating point	Scalar	Real
`sec`	Floating point	Scalar Vector Matrix	Real Complex
`secd`	Floating point	Scalar Vector Matrix	Real Complex
`sech`	Floating point	Scalar Vector Matrix	Real Complex
`sign`	Floating point	Scalar	Real
`sin`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`sind`	Floating point	Scalar Vector Matrix	Real Complex
`sinh`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`sqrt`	Floating point	Scalar	Real
`tan`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`tand`	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`tanh`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
[1] Wrap on integer overflow only			

Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`memcmp`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memcpy`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset2zero`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

Operators

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code

generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates you can specify different data types of different inputs.

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Addition (+)[1]	`RTW_OP_ADD`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Subtraction (-)[1]	`RTW_OP_MINUS`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*)[2]	`RTW_OP_MUL`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Division (/)	`RTW_OP_DIV`	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	`RTW_OP_CAST`	Integer Floating point[3] Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	`RTW_OP_SL`	Integer Fixed-point Mixed	Scalar Vector Matrix	Real
Shift right arithmetic (>>)[4]	`RTW_OP_SRA`	Integer Fixed-point Mixed	Scalar Vector Matrix	Real
Shift right logical (>>)	`RTW_OP_SRL`	Integer Fixed-point	Scalar Vector	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Mixed	Matrix	
Element-wise matrix multiplication (`.*`)[5]	`RTW_OP_ELEM_MUL`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Complex conjugation	`RTW_OP_CONJUGATE`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Transposition (`.'`)	`RTW_OP_TRANS`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Hermitian (complex conjugate) transposition (`'`)	`RTW_OP_HERMITIAN`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with transposition[2]	`RTW_OP_TRMUL`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with Hermitian transposition[2]	`RTW_OP_HMMUL`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication followed by shift right arithmetic (`u1*u2>>u3`)[6]	`RTW_OP_MUL_SRA`	Integer Fixed-point	Scalar	Real
Multiplication followed by division (`u1*u2/u3`)[7]	`RTW_OP_MULDIV`	Integer Fixed-point	Scalar	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Greater than (>)	RTW_OP_GREATER_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Greater than or equal (>=)	RTW_OP_GREATER_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than (<)	RTW_OP_LESS_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than or equal (<=)	RTW_OP_LESS_THAN_OR_EUQAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Equal (==)	RTW_OP_EUQAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Not equal (!=)	RTW_OP_NOT_EUQAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support

[1] See "Addition and Subtraction Operator Code Replacement" on page 52-122 for details to consider when defining mappings for addition and subtraction code replacements.

[2] Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

[3] Scaled floating point is not supported.

[4] Code replacement libraries that provide arithmetic shift right implementations should also provide logical shift right implementations, because some arithmetic shift rights are converted to logical shift rights during code generation.

[5] Use the multiplication (`*`) operator (`RTW_OP_MUL`) for scalar multiplication.

[6] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope` and `Mul_output_slope == output_slope_of_shift_operation`).

[7] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope`).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. "Identify Code Replacement Requirements" on page 52-26
2. "Prepare for Code Replacement Library Development" on page 52-29
3. "Define Code Replacement Mappings" on page 52-30
4. "Specify Build Information for Replacement Code" on page 52-47
5. "Register Code Replacement Mappings" on page 52-56
6. "Verify Code Replacements" on page 52-64
7. "Deploy Code Replacement Library" on page 52-81

To get started, see "Identify Code Replacement Requirements" on page 52-26.

To experiment with the process and tools, see "Quick Start Library Development" on page 52-16.

More About

- "Identify Code Replacement Requirements" on page 52-26
- "Code You Can Replace from MATLAB Code" on page 52-5
- "Quick Start Library Development" on page 52-16
- "What Is Code Replacement Customization?" on page 52-3

Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the Code Replacement Tool.

Prerequisites

To complete this example, install the following software:

- MATLAB
- MATLAB Coder
- Embedded Coder
- C compiler

For instructions on installing MathWorks products, see "Installation and Activation" (Installation, Licensing, and Activation). If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

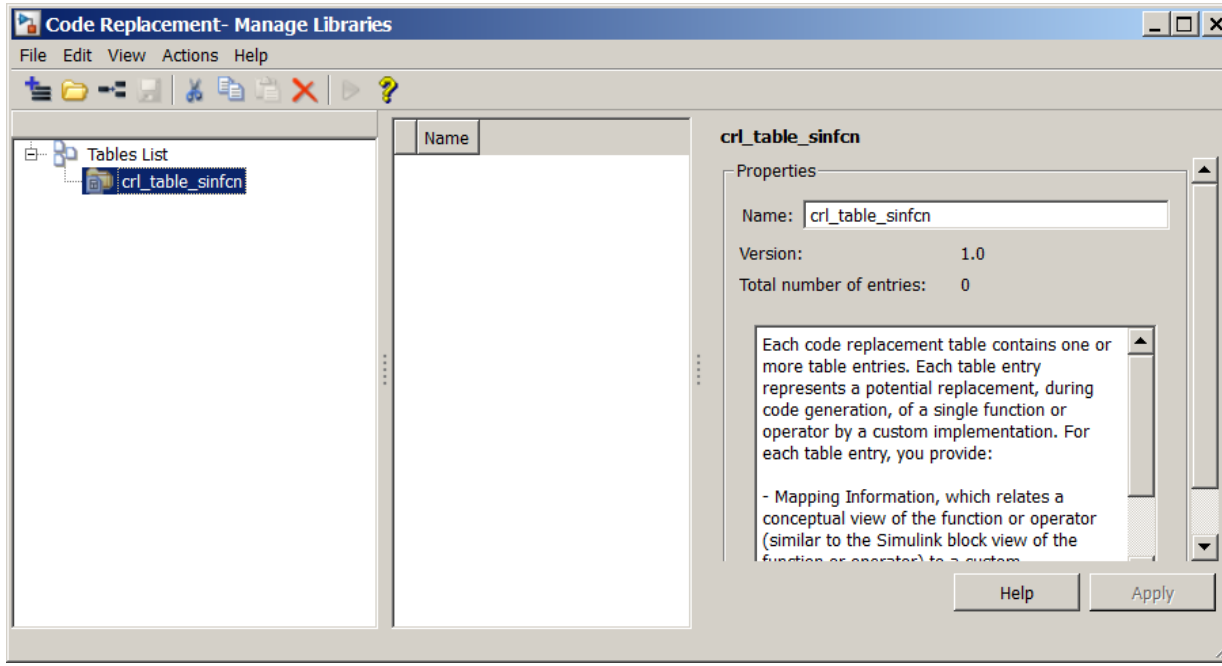
For a list of supported compilers, see http://www.mathworks.com/support/compilers/current_release/.

Open the Code Replacement Tool

1. Start a new MATLAB session.
2. Create or navigate (`cd`) to an empty folder.
3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

Create Code Replacement Table

1. In the Code Replacement Tool window, select **File > New table**.
2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.



Create Table Entry

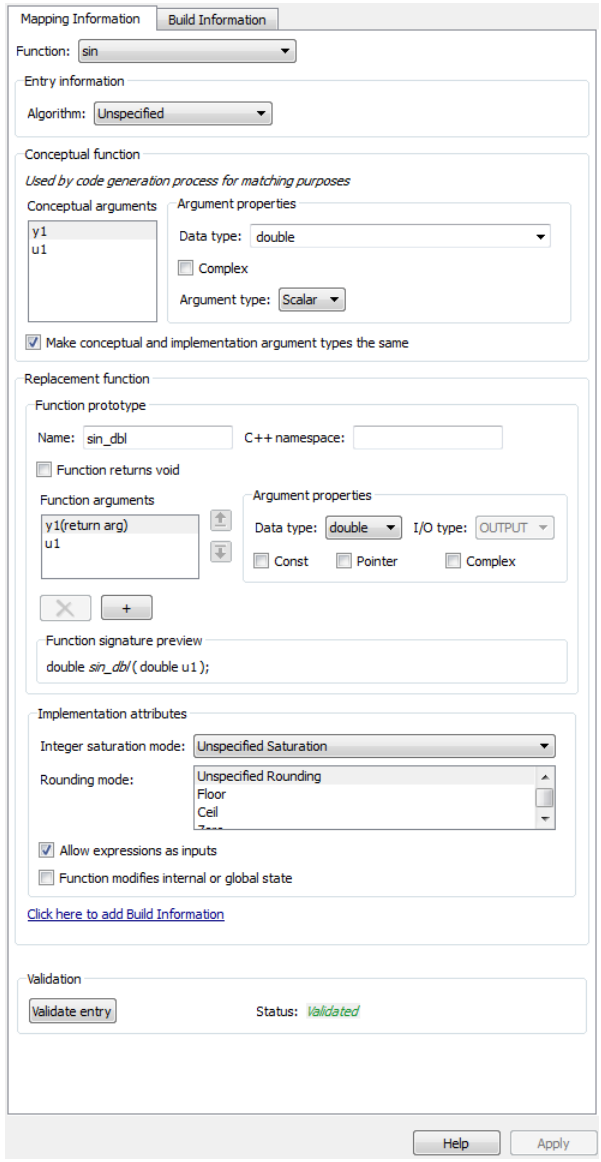
Create a table entry that maps a `sin` function with `double` input and `double` output to a custom implementation function.

1. In the left pane, select table `crl_table_sinfcn`. Then, select **File** > **New entry** > **Function**. The new entry appears in the middle pane, initially without a name.
2. In the middle pane, select the new entry.
3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
4. Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.
5. In the **Replacement function** group, name the replacement function `sin_dbl`.
6. Leave the remaining parameters in the **Replacement function** group set to default values.

7 Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.

8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

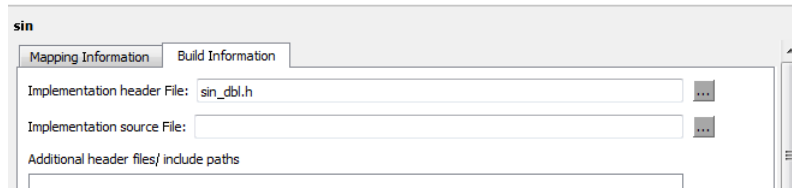
The following figure shows the completed mapping information.



Mapping Information
Build Information
Function: sin
Entry information
Algorithm: Unspecified
Conceptual function
Used by code generation process for matching purposes
Conceptual arguments
y1
u1
Argument properties
Data type: double
Complex
Argument type: Scalar
Make conceptual and implementation argument types the same
Replacement function
Function prototype
Name: sin_dbl
C++ namespace:
Function returns void
Function arguments
y1(return arg)
u1
Argument properties
Data type: double
I/O type: OUTPUT
Const
Pointer
Complex
Function signature preview
double sin_dbl(double u1);
Implementation attributes
Integer saturation mode: Unspecified Saturation
Rounding mode:
Unspecified Rounding
Floor
Ceil
Allow expressions as inputs
Function modifies internal or global state
Click here to add Build Information
Validation
Validate entry
Status: Validated
Help
Apply

Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
2. Leave the remaining parameters set to default values.
3. Click **Apply**.



4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.
2. Select **Edit** > **Copy**
3. Select **Edit** > **Paste**
4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

Validate the Code Replacement Table

1. Select **Actions** > **Validate table**.

2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

	Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
✓	sin	sin_dbl	1	double		double		100
✓	sin	sin_sgl	1	single		double		100

Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File** > **Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

Review the Code Replacement Table Definition

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

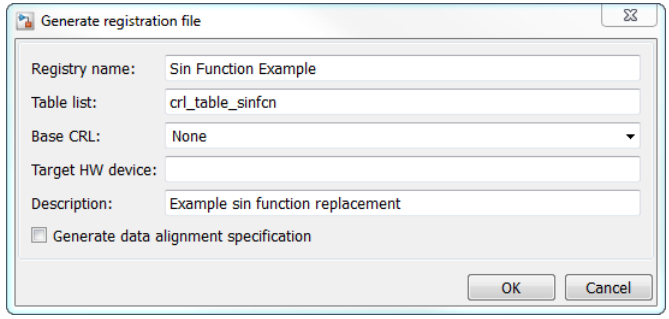
To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1 In the Code Replacement Tool, select **File** > **Generate registration file**.

2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.



3 In the **Select location** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

Register the Code Replacement Table

At the command prompt, enter:

```
RTW.TargetRegistry.getInstance('reset');
```

Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1 Check for errors. At the command line, invoke the table definition file . For example:

```
tbl = crl_table_sinfcn

tbl =

  TflTable with properties:

               Version: '1.0'
       ReservedSymbols: []
    StringResolutionMap: []
             AllEntries: [2x1 RTW.TflCFunctionEntry]
           EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message to appear. Fix the error and try again.

2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

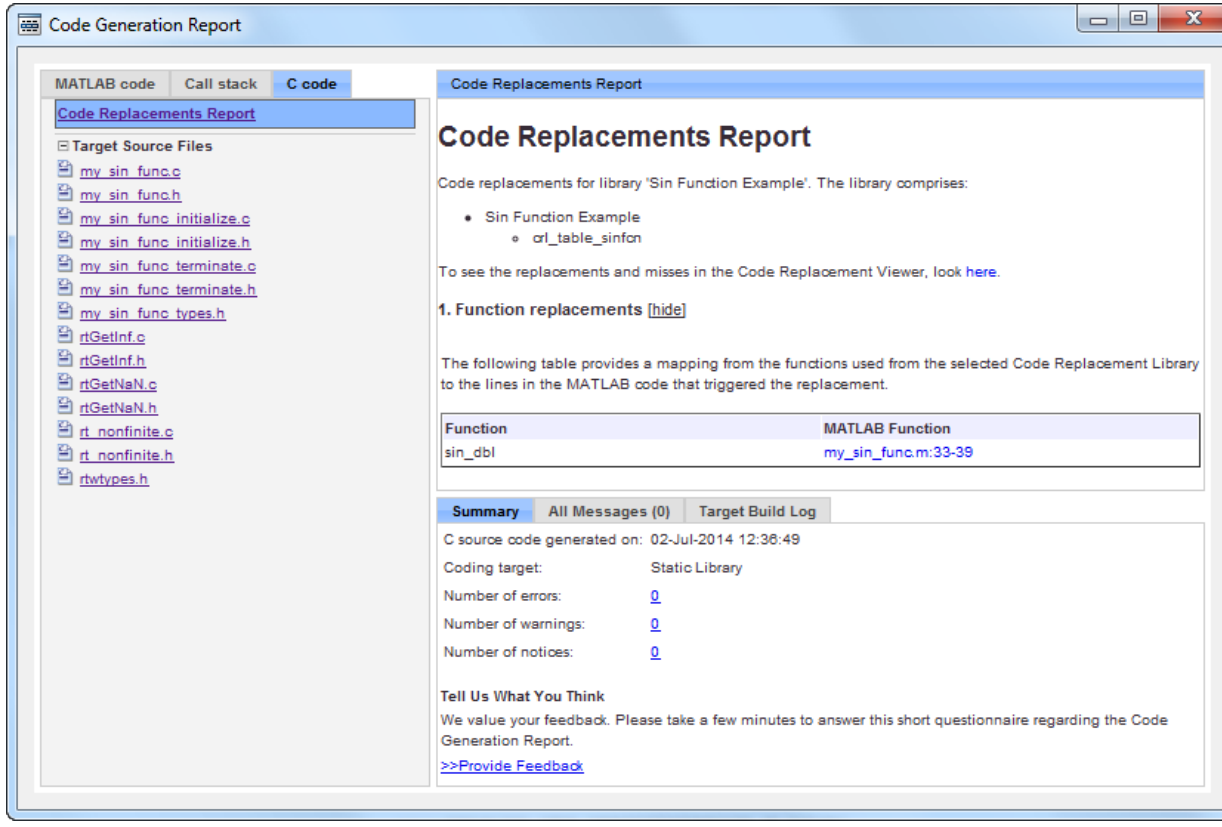
- Incorrect argument order.
- Conceptual argument names that do not match what is expected by the code generator.

- Incorrect priority settings.

3. Identify existing or create new MATLAB code that calls the `sin` function. For example:

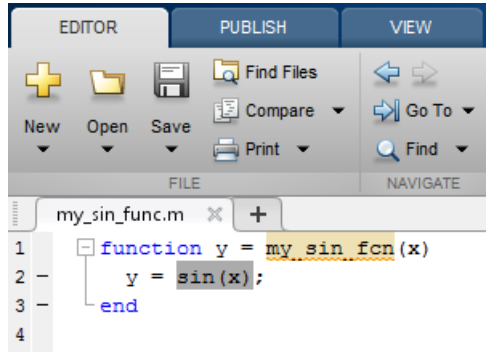
```
function y = my_sin_fnc(x)
  y = sin(x);
end
```

4. Open the MATLAB Coder app.
5. Add the function that includes a call to the `sin` function as an entry-point file. For example, add `my_sin_func.m`. The app creates a project named `my_sin_func.prj`.
6. Click **Next** to go to the **Define Input Type** step. Define the types for the entry-point function inputs.
7. Click **Next** to go to the **Check for Run-Time Issues** step. This step is optional. However, it is a best practice to perform this step. Provide a test file that calls your entry-point function. The app generates a MEX function from your entry-point function. Then, the app runs the test file, replacing calls to the MATLAB function with calls to the generated MEX function.
8. Click **Next** to go to the **Generate Code** step. To open the **Generate** dialog box, click the **Generate** arrow  .
9. Set **Build type** to generate a library or executable.
10. Click **More Settings**.
11. Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For example, `Sin Function Example`.
12. Configure the code generation report. On the **Debugging** tab, set the **Always create a code generation report**, **Code replacements**, and **Automatically launch a report if one is generated** parameters.
13. Configure the code generator to generate code only. On the **Generate** dialog box, select the **Generate code only** check box. You want to review your code replacements in the generated code before building an executable.
14. Click **Generate** to generate C code and a report.
15. Review code replacement results in the Code Replacements Report section of the code generation report.



The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

16 Review the code replacements. In the report, under **Function replacements**, click the MATLAB function that triggered the replacement, `my_sin_func.m`. The MATLAB Editor opens and highlights the function call that triggers the code replacement.



More About

- "What Is Code Replacement Customization?" on page 52-3

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for your code replacement library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?

Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.

- Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3

Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

Situation	Approach
Defining mappings for the first time.	Code Replacement Tool.
Rapid prototyping mappings.	Code Replacement Tool to quickly generate, register, and test mappings.
Developing a mapping as a template or starting point for defining similar mappings.	Code Replacement Tool to generate definition code that you can copy and modify.
Modifying a registration file, including copying and pasting content.	MATLAB Editor to update the programming interface directly.
Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).	Programming interface.
Reusing existing code for new mappings by copying, pasting, and editing existing mappings.	Programming interface.

Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to **All Parameters** > **Code Generation** > **Code replacement library** and click **Custom**.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select **View** > **Show dialog pane** to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select **Hide** to remove the column from the display. (You cannot hide the **Name** column.)

Create a Code Replacement Table

1. In the Code Replacement Tool window, select **File** > **New table**.
2. In the right pane, name the table and click **Apply**. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.

Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select **File** > **New entry** > **entry-type**, where **entry-type** is one of:

   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.
3. In the middle pane, select the new entry.
4. In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.
5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (`Cast before operation` or `Cast after operation`).
6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

   If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that

specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`. In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select `Custom` for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click **Apply**.

Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can address them and retry the validation. Repeat the process until the tool does not report errors.

To	Do
Validate table entries	Select an entry, scroll to the bottom of the **Mapping Information** tab, and click **Validate entry**. Alternatively, select one or more entries, right-click, and select **Validate entries**.
Validate a table	Select the table. Then, select **Actions** > **Validate table**.

Save a Table

When you save a table, the tool validates unvalidated content.

1. Select **File** > **Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
3. Click **Save**.

Open and Modify Tables

After saving a code replacement table, to make changes in the table:

1. Select **File** > **Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

Define Mappings Programmatically

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for

- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

Create Code Replacement Table

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_sinfcn()
   ```
2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1 Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

Entry Type	Function
Math operation	`RTW.TflCOperationEntry`
Function	`RTW.TflCFunctionEntry`
BLAS operation	`RTW.TflBlasEntryGenerator`
CBLAS operation	`RTW.TflCBlasEntryGenerator`
Fixed-point addition and subtraction operations (support for `SlopesMustBeTheSame` and `ZeroNetBias` parameters)	`RTW.TflCOperationEntryGenerator`
Net slope fixed-point operation	`RTW.TflCOperationEntryGenerator_NetSlope`
Semaphore or mutex entry	`RTW.TflCSemaphoreEntry`
Custom function entry	*`MyCustomFunctionEntry`* (where *`MyCustomFunctionEntry`* is a class derived from `RTW.TflCFunctionEntryML`)
Custom operation entry	*`MyCustomOperationEntry`* (where *`MyCustomOperationEntry`* is a class derived from `RTW.TflCOperationEntryML`)

For example:

```
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a

single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator's default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:

```
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
   'sin_dbl', 'double', 'sin_dbl.h','','');
```

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector specifications.

For example:

```
hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

Entry Type	Function
Math operation	`setTflCOperationEntryParameters`
Function	`setTflCFunctionEntryParameters`
BLAS operation	`setTflCOperationEntryParameters`
CBLAS operation	`setTflCOperationEntryParameters`
Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for `SlopesMustBeTheSame` and `ZeroNetBias` parameters)	`setTflCOperationEntryParameters`
Net slope fixed-point operation	`setTflCOperationEntryParameters`
Semaphore or mutex entry	`setTflCSemaphoreEntryParameters`
Custom function entry	`setTflCFunctionEntryParameters`
Custom operation entry	`setTflCOperationEntryParameters`

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```
hEnt = RTW.TflCFunctionEntry
```

```
hEnt =

  TflCFunctionEntry with properties:

             Implementation: [1x1 RTW.CImplementation]
        SlopesMustBeTheSame: 0
          BiasMustBeTheSame: 0
            AlgorithmParams: []
                   ImplType: 'FCN_IMPL_FUNCT'
      AdditionalHeaderFiles: {0x1 cell}
      AdditionalSourceFiles: {0x1 cell}
```

```
      AdditionalIncludePaths: {0x1 cell}
       AdditionalSourcePaths: {0x1 cell}
          AdditionalLinkObjs: {0x1 cell}
     AdditionalLinkObjsPaths: {0x1 cell}
         AdditionalLinkFlags: {0x1 cell}
      AdditionalCompileFlags: {0x1 cell}
                 SearchPaths: {0x1 cell}
                         Key: ''
                    Priority: 100
               ConceptualArgs: [0x1 handle]
                    EntryInfo: []
                 GenCallback: ''
                 GenFileName: ''
               SaturationMode: 'RTW_SATURATE_UNSPECIFIED'
                RoundingModes: {'RTW_ROUND_UNSPECIFIED'}
          TypeConversionMode: 'RTW_EXPLICIT_CONVERSION'
             AcceptExprInput: 1
                 SideEffects: 0
                  UsageCount: 0
          RecordedUsageCount: 0
                 Description: ''
    StoreFcnReturnInLocalVar: 0
                TraceManager: [1x1 RTW.TflTraceManager]
```

To see the implementation parameters, enter:

```
hEnt.Implemenation
```

```
ans =

  CImplementation with properties:

             HeaderFile: ''
             SourceFile: ''
             HeaderPath: ''
             SourcePath: ''
                 Return: []
          StructFieldMap: []
                   Name: ''
              Arguments: [0x1 handle]
    ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```
setTflCFunctionEntryParameters(hEnt, ...
          'Key', 'sin', ...
          'ImplementationName', 'sin_dbl');
```

Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.
- Specify argument names that comply with code generator argument naming conventions:
  - `y1` for a return argument
  - `u1`, `u2`, ..., `un` for input arguments
- Specify data types that are familiar to the code generator.
- The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
- The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1. Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the `sin` function, open the tool, create a table, create a function entry, and in the **Function** menu select `sin`.
2. Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

If	Then

You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).	Call the function `createAndAddConceptualArg`. For example:
	`createAndAddConceptualArg(hEnt, ...`
	`  'RTW.TflArgNumeric', ...`
	`  'Name', 'y1',...`
	`  'IOType', 'RTW_IO_OUTPUT',...`
	`  'DataTypeMode', 'double');`

If	Then
	The second argument specifies whether the argument is scalar (`RTW.TflArgNumeric` or`RTW.TflArgMatrix`) .

You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).	Call `getTflArgFromString` to create the argument. Then, call `addConceptualArg` to add the argument to the entry.
	`arg = getTflArgFromString(hEnt, 'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`addConceptualArg(hEnt, arg);`

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	`hEnt = createCRLEntry(hTable, ...`
	`'double y1 = sin(double u1)', ...`
	`'mySin');`

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```
% Conceptual Args

arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.

- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
- For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, `y1=u1+u2`, the conceptual arguments are `y1`, `u1`, and `u2`, in that order. If the signature of your implementation function is `t myAdd(t u2, t u1)`, where `t` is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, `u1`, to the second implementation argument of `myAdd`. The code generator passes the value of the second conceptual argument, `u2`, to the first implementation argument of `myAdd`.
- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.
2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want to populate implementation arguments as copies of previously created matching conceptual arguments	Call the function `copyConceptualArgsToImplementation`. For example: `copyConceptualArgsToImplementation(hEnt);`

You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order	Call functions `createAndSetCImplementationReturn` and`createAndAddImplementationArg` . For example:
	`createAndSetCImplementationReturn(hEnt,`
	`'RTW.TflArgNumeric', ...`
	`'Name', 'y1', ...`
	`'IOType', 'RTW_IO_OUTPUT', ...`
	`'IsSigned', true, ...`
	`'WordLength', 32, ...`
	`'FractionLength', 0);`
	
	`createAndAddImplementationArg(op_entry,`
	`'RTW.TflArgNumeric',...`
	`'Name', 'u1', ...`

If	Then

	`'IOType', 'RTW_IO_INPUT',...`
	`'IsSigned', true,...`
	`'WordLength', 32, ...`
	`'FractionLength', 0 );`

If	Then

You want to minimize the amount of code, or specify constant arguments to pass to the implementation function	Create the argument with a call to the function `getTflArgFromString`. Then, use the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument and to add the argument to the entry's array of implementation arguments. For example:
	
	`arg = getTflArgFromString(hEnt, 'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setReturn(arg);`
	
	`arg = getTflArgFromString(hEnt, 'u1','double');`
	`hEnt.Implementation.addArgument(arg);`
	
	The following call to `getTflArgFromString` passes the constant `0` to argument `u2`:
	
	`arg = getTflArgFromString(hEnt, 'u2', 'int16', 0)`
	`hEnt.Implementation.addArgument(arg);`
	
	For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example:
	
	`arg = getTflDWorkFromString('d1', 'void*')`
	`hEnt.addDWorkArg(arg);`
	
	`arg = hEnt.getTflArgFromString('y1', 'void');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setRetrurn(arg);`
	
	`arg = hEnt.getTflArgFromString('u1', 'integer');`
	`hEnt.Implementation.addArgument(arg);`
	
	`arg = hEnt.getTflArgFromString('d1', 'void**');`
	`hEnt.Implementation.addArgument(arg);`

If	Then

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	`hEnt = createCRLEntry(hTable, ...`
	`'double y1 = sin(double u1)', ...`
	`'mySin');`

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```
% Implementation Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```
addEntry(hTable, hEnt);
```

Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```
hTbl = crl_table_sinfcn

hTbl =

RTW.TflTable
    Version: '1.0'
    AllEntries: [2x1 RTW.TflCFunctionEntry]
    ReservedSymbols: []
```

```
    StringResolutionMap: []
```

If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```
hTbl = crl_table_sinfcn

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Save Table

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Build Information

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

Situation	Approach
Creating code replacement entries for the first time.	Code Replacement Tool.
You used the Code Replacement Tool to create the entries for which the build information applies.	Code Replacement Tool to specify the build information quickly .
Rapid prototyping entries.	Code Replacement Tool to generate, register, and test entries quickly.

Situation	Approach
Developing an entry to use as a template or starting point for defining similar entries.	Code Replacement Tool to generate entry code that you can copy and modify.
Modifying existing mappings.	MATLAB Editor to update the programming interface directly.

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGo` function to relocate static and generated code files to another development environment:
  - In the call to `packNGo`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGo` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector or cell array of character vectors in the MATLAB workspace that you enclose with dollar signs (`$`*`variable`*`$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$\folder1`, where `myfolder` is a character vector variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

1 Determine the information that you must specify.

2. Open the Code Replacement Tool.
3. Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4. In the right pane, select the **Build Information** tab.
5. On the **Build Information** tab, specify your build information.

Parameter	Specify
Implementation header file	File name and extension for the header file the code generator needs to generate the replacement code. For example, `sin_dbl.h`.
Implementation source file	File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, `sin_dbl.c`.
Additional header files/include paths	Paths and file names for additional header files the code generator needs to generate the replacement code. For example, `C:\libs\headerFiles` and `C:\libs\headerFiles\common.h`. This parameter adds `-I` to the compile line in the generated makefile.
Additional source files/ paths	Paths and file names for additional source files the code generator needs to generate the replacement code. For example, `C:\libs\srcFiles` and `C:\libs\srcFiles\common.c`. This parameter adds `-I` to the compile line in the generated makefile.
Additional object files/ paths	Paths and file names for additional object files the linker needs to build the replacement code. For example, `C:\libs\objFiles` and `C:\libs\objFiles\common.obj`.
Additional link flags	Flags the linker needs to generate an executable file for the replacement code.
Additional compile flags	Flags the compiler needs to generate object code for the replacement code.
Copy files to build directory	Whether to copy header, source, or object files, which are required to generate replacement

Parameter	Specify
	code, to the build folder before code generation. If you specify files with **Additional header files/include paths** or **Additional source files/ paths** and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

6 Click **Apply**.

7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.

8 Save the table that includes the entry that you just modified.

Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1 Identify or create the code replacement entry that you want to specify the build information.

2 Determine what information to specify.

3 Specify your build information.

Specify	Action

Implementation header file	Use one of the following:
	• Set properties `ImplementationHeaderFile` and `ImplementationHeaderPath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`

Specify	Action

	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`
	• Set argument `headerFile` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry`

Implementation source file	Set properties `ImplementationSourceFile` and `ImplementationSourcePath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.c', ...`
	`'ImplementationHeaderPath', 'D:/lib/sourceFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`

Additional header files/include paths	For each file, specify the file name and path in calls to the functions `addAdditionalHeaderFile` and `addAdditionalIncludePath`. For example:
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	`hEnt = RTW.TflCFunctionEntry;`
	`addAdditionalHeaderFile(hEnt, 'common.h');`
	`addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));`
	These functions add `-I` to the compile line in the generated makefile.

Specify	Action

Additional source files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalSourceFile` and `addAdditionalSourcePath`. For example:
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	`hEnt = RTW.TflCFunctionEntry;`
	`addAdditionalSourceFile(hEnt, 'common.c');`
	`addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));`
	These functions add `-I` to the compile line in the generated makefile.

Additional object files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalLinkObj` and `addAdditionalLinkObjPath`. For example:
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	`hEnt = RTW.TflCFunctionEntry;`
	`addAdditionalLinkObj(hEnt, 'sin.o');`
	`addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));`

Compile flags	Set the entry property `AdditionalCompileFlags` to a cell array of character vectors representing the required compile flags. For example:
	`hEnt = RTW.TflCFunctionEntry;`
	`hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-O3'};`

Link flags	Set the entry property `AdditionalLinkFlags` to a cell array of character vectors representing the required link flags. For example:
	`hEnt = RTW.TflCFunctionEntry;`
	`hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};`

Specify	Action

Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation	Use one of the following:
	• Set property `GenCallback` to `'RTW.copyFileToBuildDir'` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`
	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl'`
	`'GenCallback', 'RTW.copyFileToBuildDir');`
	• Set argument `genCallback` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` to `'RTW.copyFileToBuildDir'`.
	If a match occurs for a table entry, a call to the function `RTW.copyFileToBuildDir` copies required files to the build folder.
	If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the `genCallback` property to `'RTW.copyFileToBuildDir'` in the call to the `setTflCOperationEntryParameters` function. In this example, the header file `s32_mul.h` contains an inlined function that invokes assembly functions contained in `s32_mul.s`. If a match occurs for the table

entry, the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```
function hTable = make_my_crl_table

hTable = RTW.TflTable;

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_MUL', ...
                'Priority',                 100, ...
                'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_mul_s32_s32_sat', ...
                'ImplementationHeaderFile', 's32_mul.h', ...
                'ImplementationSourceFile', 's32_mul.s', ...
                'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'GenCallback',              'RTW.copyFileToBuildDir');
.
.
.
addEntry(hTable, op_entry);
```

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_ADD', ...
                'Priority',                 90, ...
                'SaturationMode',           'RTW_SATURATE_UNSPECIFIED', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_add_s32_s32', ...
                'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
                'ImplementationSourceFile', 's32_add_s32_s32.c'...
                'GenCallback',              'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
.
```

```
.
.
addEntry(hTable, op_entry);
```

Next, include your code replacement table in a code replacement library and register the library with the code generator.

More About

- “Define Code Replacement Mappings” on page 52-30
- “Register Code Replacement Mappings” on page 52-56
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3
- “Code You Can Replace from MATLAB Code” on page 52-5

Register Code Replacement Mappings

After you define code replacement entries in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

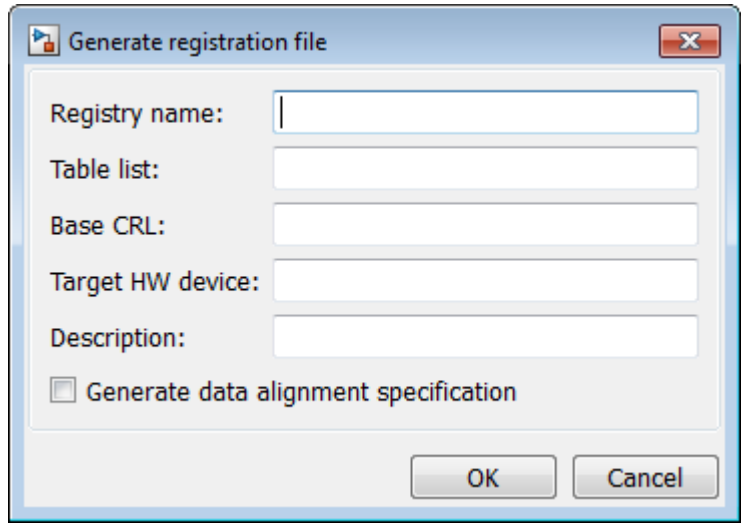
The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

If...	Then...
Registering a code replacement table for the first time	Use the Code Replacement Tool.
You used the Code Replacement Tool to create the table	Use the Code Replacement Tool to quickly register the table.
Rapid prototyping code replacement	Use the Code Replacement Tool to quickly generate, register, and test entries.
Creating registration file to use as a template or starting point for defining similar registration files	Use the Code Replacement Tool to generate code that you can copy and modify.
Modifying existing registration files	Use the MATLAB Editor to update the registration file.
Defining multiple code replacement libraries in one registration file	Use the MATLAB Editor to create a new or extend an existing registration file.
Defining code replacement library hierarchy in a registration file	Use the MATLAB Editor to create a new or extend an existing registration file.

Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1 After you validate and save a code replacement table, select **File > Generate registration file** to open the **Generate registration file** dialog box.



2 Enter the registration information. Minimally, specify:

For...	Specify...
Registry name	Text naming the code replacement library. For example, `Sin Function Example`.
Table list	Text naming one or more code replacement tables to include in the library. Specify each table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)`

For...	Specify...
	You can specify multiple tables. If you do, separate the table specifications with a comma. For example: `crl_table_sinfcn, c:/work_crl/crl_table_muldiv` See "Registration Files That Define Multiple Code Replacement Libraries" on page 52-61 for examples of each type of table specification.

Optionally, you can specify:

For...	Specify...
Description	Text that describes the purpose and content of the library.
Target HW device	Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, `TI C28x, TI C62x`.
Base CRL	Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.
Generate data alignment specification	Flag that enables data alignment specification.

Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1. Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'crl-name';
this(1).TableList = {'table',...};
```

For...	Replace...
`this(1).Name = 'crl-name';`	*`crl-name`* with text naming the code replacement library. For example, `Sin Function Example`.
`this(1).TableList = {'table',...};`	*`table`* with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)` You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

For...	Replace...
`this(1).Description = '`*`text`*`'`	*`text`* with text that describes the purpose and content of the library.
`this(1).TargetHWDeviceType = {'`*`device-type`*`',...}`	*`device-type`* with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, `TI C28x, TI C62x`. To support all device types, enter an asterisk (*).
`this(1).BaseTfl = '`*`base-lib`*`'`	*`base-lib`* with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device` library as the base library for a `TI C28x device` library. See "Registration Files That Define Code Replacement Library Hierarchies" on page 52-61 for an example.

For example:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'Sin Function Example';
this(1).TableList = {'crl_table_sinfcn'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example - sin function replacement';
```

2 Save the file with the name `rtwTargetInfo.m`.

3 Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, you must refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```
sl_refresh_customizations
```

Registration Files That Define Multiple Code Replacement Libraries

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The `TableList` fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library for use with model: rtwdemo_crladdsub
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Addition & Subtraction Examples';
  thisCrl(1).Description = 'Example of addition/subtraction op replacement';
  thisCrl(1).TableList = {'crl_table_addsub'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlmuldiv
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'Multiplication & Division Examples';
  thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
  thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
  thisCrl(2).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlfixpt
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'Fixed-Point Examples';
  thisCrl(3).Description = 'Example of fixed-point operator replacement';
  thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)', ...
     'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
  thisCrl(3).TargetHWDeviceType = {'*'};
```

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code

replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library that includes common entries
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Common Replacements';
  thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
  thisCrl(1).TableList = {'crl_table_general'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for TI devices
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'TI Device Replacements';
  thisCrl(2).Description = 'Code replacement entries shared across TI devices';
  thisCrl(2).TableList = {'crl_table_TI_devices'};
  thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
  thisCrl(1).BaseTfl = 'Common Replacements'

  % Register a code replacement library for TI c6xx devices
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'TI c6xx Device Replacements';
  thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
  thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
  thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

  % Register a code replacement library for the TI c67x device
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'TI c67x Device Replacements';
  thisCrl(3).Description = 'Code replacement entries for the TI C67x device';
  thisCrl(3).TableList = {'crl_table_TIC67x_device'};
  thisCrl(3).TargetHWDeviceType = {'TI 67x'};
```

After registering your code replacement mappings, verify that code replacements occur.

More About

- “Troubleshoot Code Replacement Library Registration” on page 52-63
- “Specify Build Information for Replacement Code” on page 52-47
- “Verify Code Replacements” on page 52-64
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3
- “Code You Can Replace from MATLAB Code” on page 52-5

Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (`RTW.TargetRegistry.getInstance('reset');` or for the Simulink environment,`sl_refresh_customizations`).
- See whether the registration file, `rtwTargetInfo.m`, contains an error.

More About

- "Register Code Replacement Mappings" on page 52-56

Verify Code Replacements

After you create or modify a code replacement table, use the following techniques to examine and validate the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.

Validate a Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```
isvalid(crl_table_sinfcn)

ans =

      1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```
isvalid(crl_table_sinfcn)

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Review Library Content

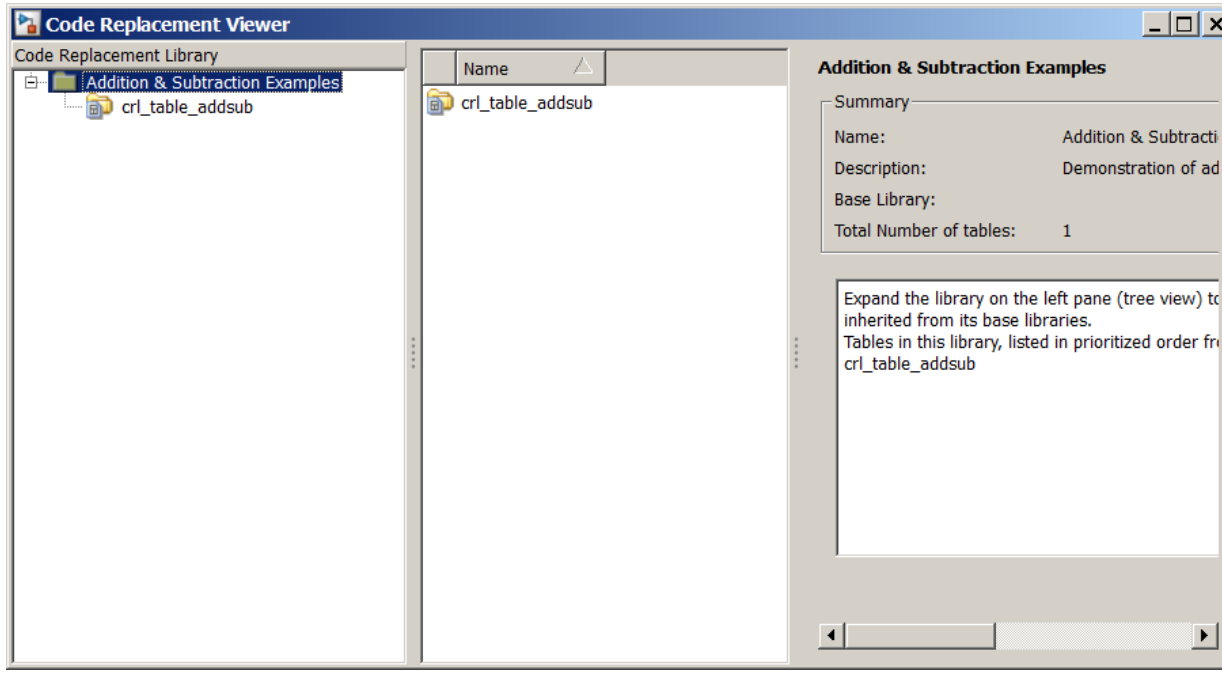
After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

1 Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```
crviewer('library')
```

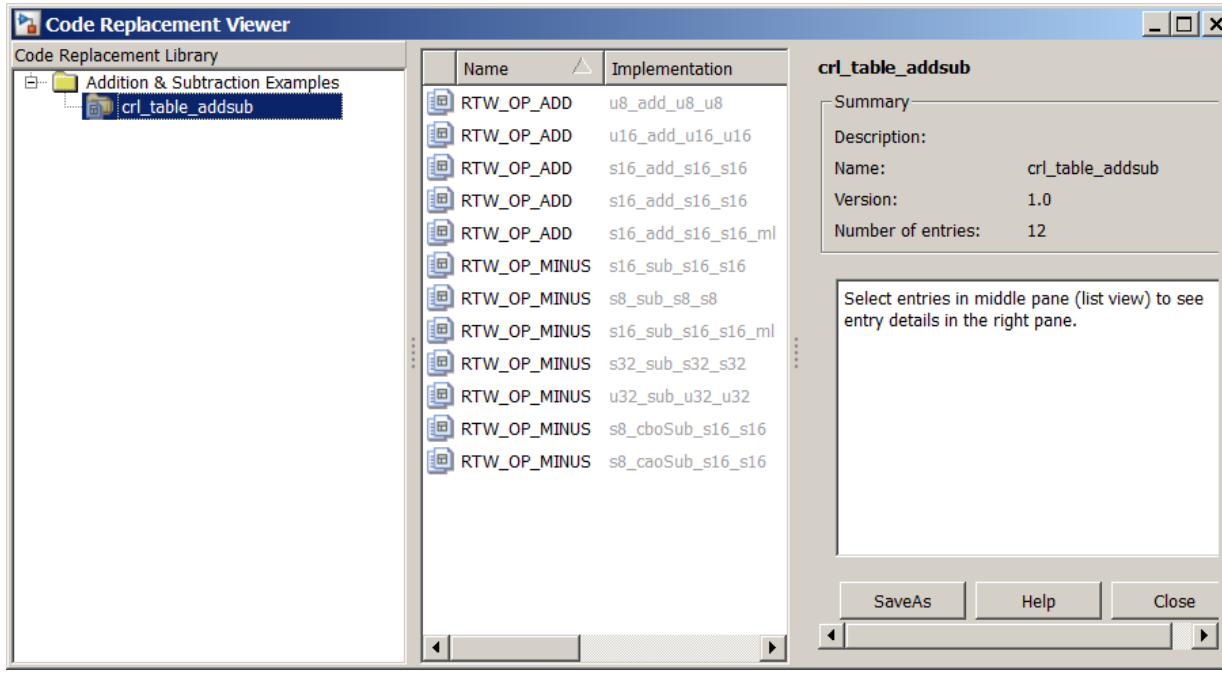
For example:

```
crviewer('Addition & Subtraction Examples')
```



2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.

3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?



Review Table Content

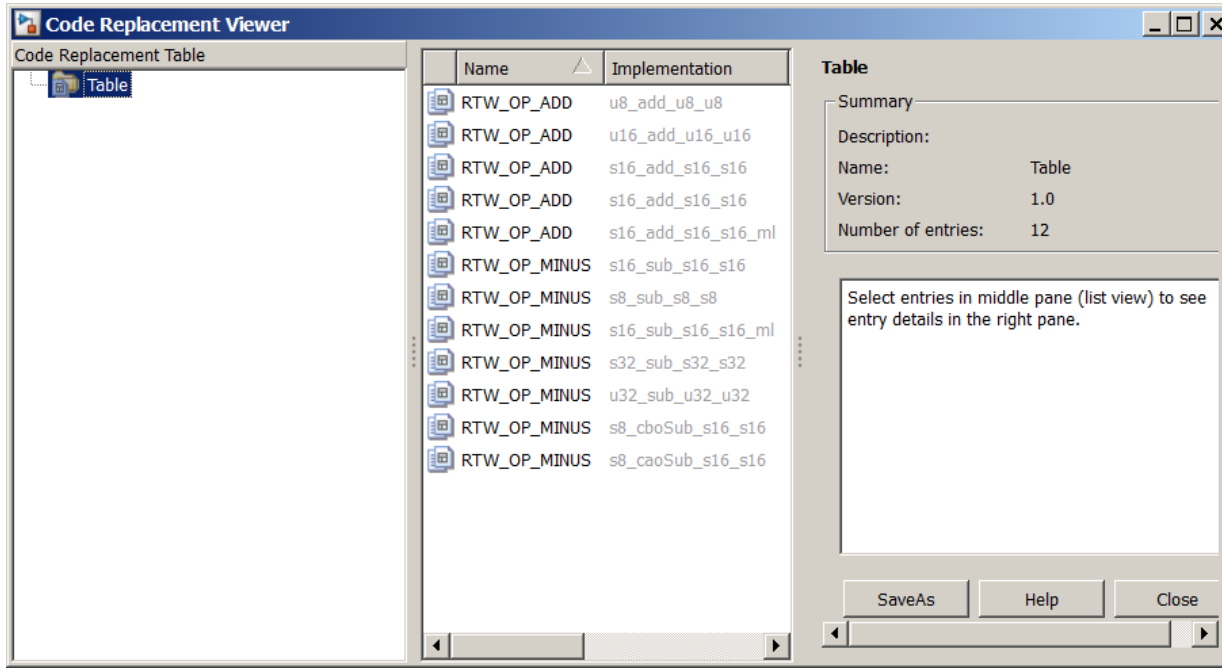
After you create or modify a code replacement table, use the Code Replacement Viewer to review and verify table entries.

1 Open the viewer to display the contents of your table. At the command prompt, enter the following command. *`table`* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

```
crviewer(table)
```

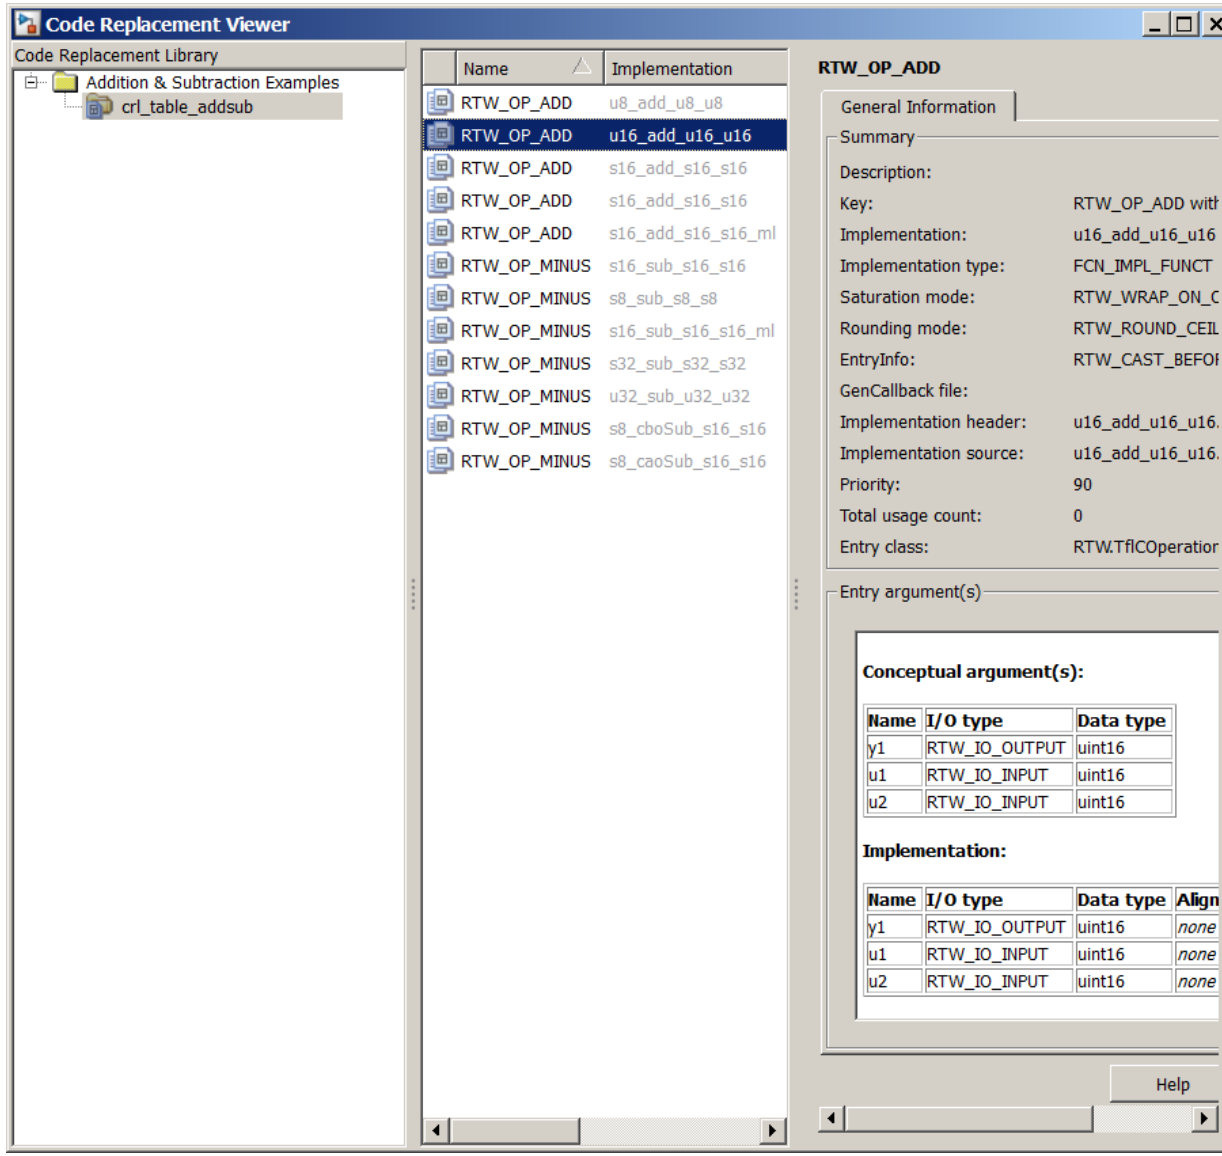
For example:

```
crviewer(crl_table_addsub)
```



2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.

3 In the center pane, click each entry and verify the entry information in the right pane.



- Argument order is correct.

- Conceptual argument names match code generator naming conventions.
- Implementation argument names are correct.
- Algorithm properties (for example, saturation and rounding mode) are set correctly.
- Header or source file specification is not missing.
- I/O types are correct.
- Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the line of MATLAB code that triggered the replacement. The Code Replacements report is not available for generated MEX functions.

The following example illustrates two complementary approaches for reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
- Trace code replacements.

1. Identify the MATLAB function where you anticipate that a function or operator replacement occurs. This example uses the function matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m.

   ```
   function [y1, y2] = addsub_two_int16(u1, u2)

   y1 = int16(u1 + u2);
   y2 = int16(u1 - u2);
   ```

2. Identify or create code or a script to exercise the function. For example, consider test file `addsub_to_int16_test.m`, which includes the following code:

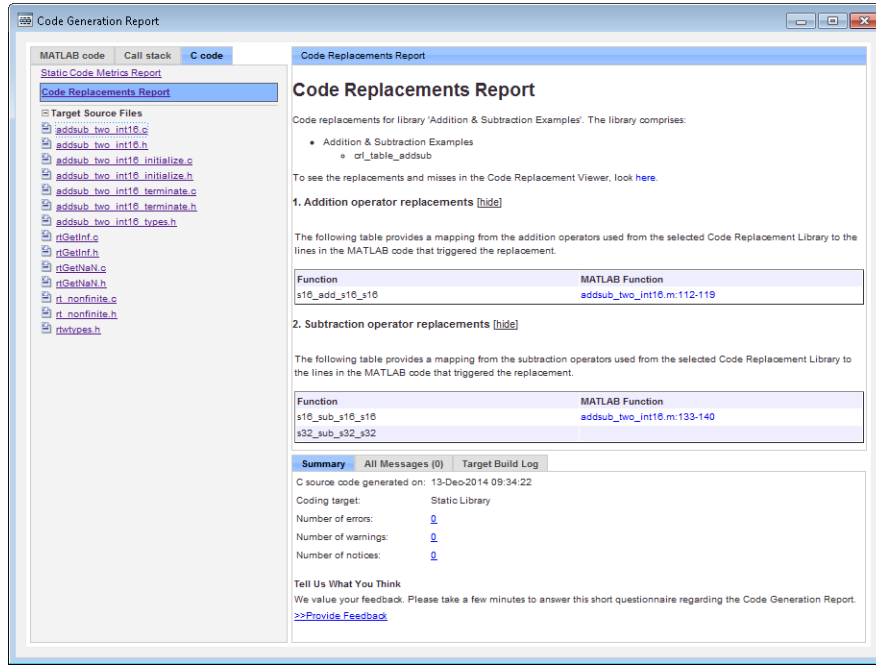
   ```
   disp('Input')
   u1 = int16(10)
   ```

```
u2 = int16(10)

[y1, y2] = addsub_two_int16(u1, u2);

disp('Output')
disp('y1 =')
disp(y1);
disp('y2 =')
disp(y2);
```

3. Open the MATLAB Coder app.
4. On the **Select Source Files** page, add your function to the project. For this example, add function `addsub_two_int16`. Click **Next**.
5. On the **Define Input Types** page, use the test file `addsub_to_int16_test` to automatically define the input types. Click **Next**.
6. On the **Check for Run-Time Issues** page, specify the test file `addsub_to_int16_test`. The app runs the test file, replacing calls to `addsub_to_int16_test` with calls to a MEX version of `addsub_to_int16_test`. Click **Next**.
7. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
8. Set **Build type** to generate source code. Before you build an executable, you want to review your code replacements in the generated code.
9. In the Generate dialog box, click **More Settings**.
10. Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For this example, set the library to `Addition & Subtraction Examples`.
11. Configure the code generation report to include the Code Replacements Report. On the **Debugging** tab, select:
    - **Always create a code generation report**
    - **Code replacements**
    - **Automatically launch a report if one is generated**
12. To generate code and a report, click **Generate**.
13. Open the **Code Replacements Report** section of the code generation report.



That report lists the replacement functions that the code generator used. The report provides a mapping between each replacement instance and the MATLAB code that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each code link to see the source that triggered the reported code replacement.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 52-74.

- "Troubleshoot Code Replacement Misses" on page 52-74
- "Register Code Replacement Mappings" on page 52-56
- "Deploy Code Replacement Library" on page 52-81
- "Develop a Code Replacement Library" on page 52-15
- "What Is Code Replacement Customization?" on page 52-3

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

```
1. Mismatched data types (argument name, CSO value, table entry value)
```

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

```
1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32
```

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
- Information missing from the code replacement table entry or a source parameter setting.

- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.
  - Input casts resulting in loss of bits.

Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your MATLAB code.

1 Review the code generated for a specific code element, looking for expected code replacement. Regenerate or reopen the code generation report for your MATLAB code. If you already generated the code generation report that includes the Code Replacements Report for matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m, open the file `codegen/lib/addsub_two_int16/html/index.html`. For information on how to regenerate the report, see "Verify Code Replacements" on page 52-64.

   To examine the code generated for function, from the code generation report, open the generated file `addsub_two_int16.c`.

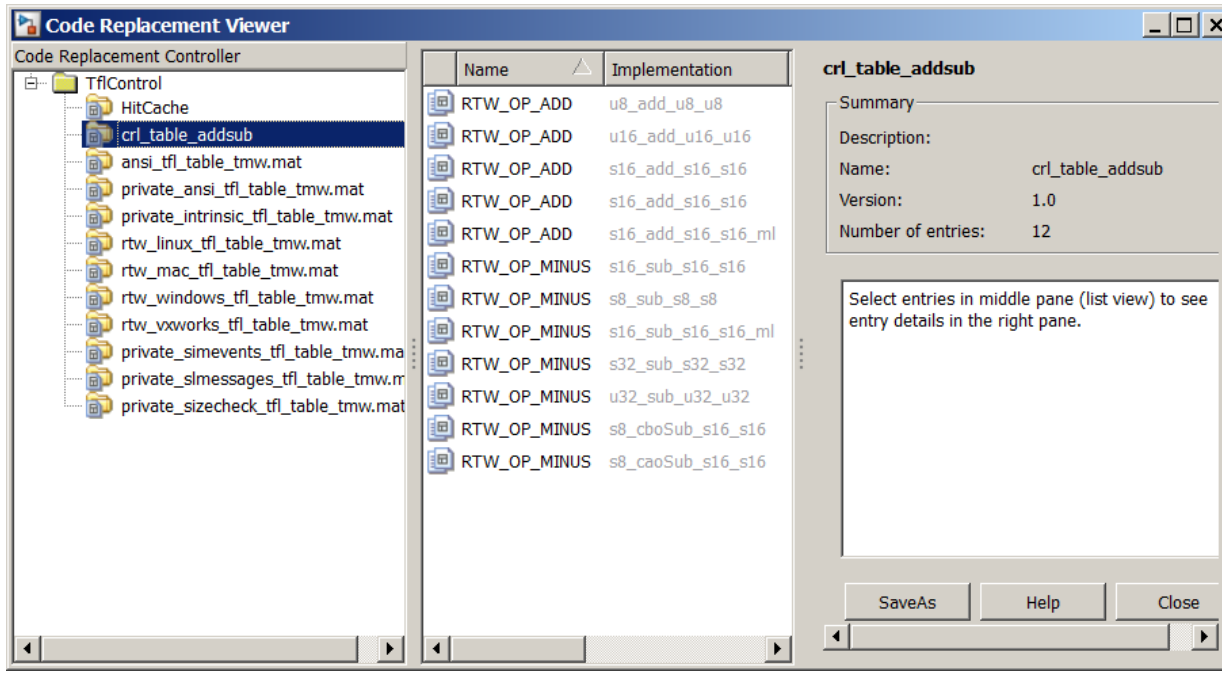
```
21    */
22   void addsub_two_int16(short u1, short u2, short *b_y1, short *y2)
23   {
24     *b_y1 = s16_add_s16_s16(u1, u2);
25     *y2 = s16_sub_s16_s16(u1, u2);
26   }
```

The code generator replaced code, but the replacement is for the signed version of the 16-bit addition and subtraction operations. You expected code replacements for operations on unsigned data.

2 Open the Code Replacements Report for the MATLAB code.

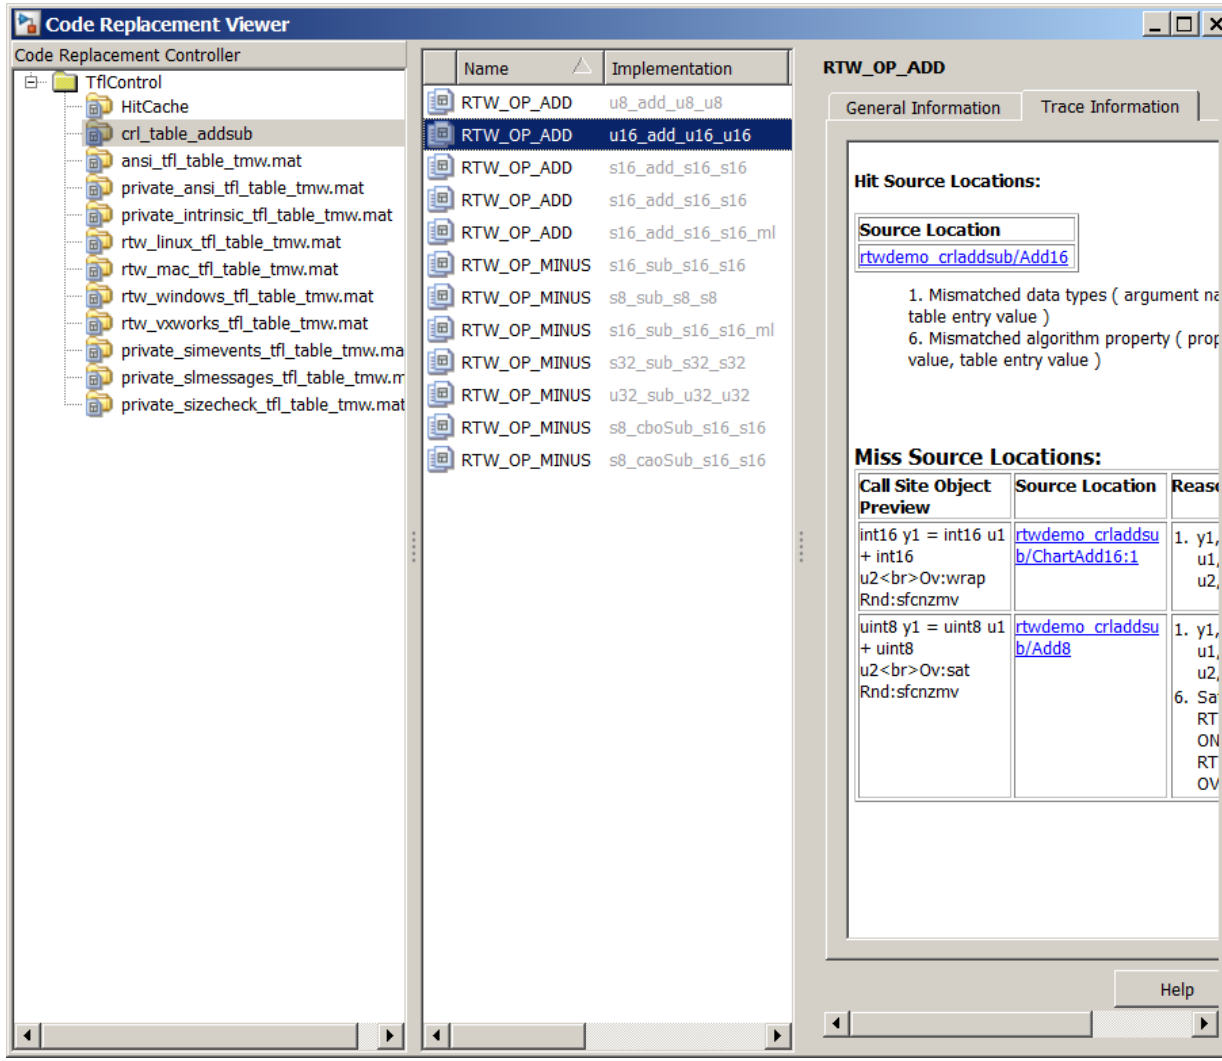
3 Click the link to open the Code Replacement Viewer.

4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `crl_table_addsub`.



5 In the middle pane, select table entry `RTW_OP_ADD` with implementation function `u16_add_u16_u16`.

6 In the right pane, select the **Trace Information** tab.



The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of addition operator. The code generator uses this object to query the code replacement library for a match.

- A link to the source location in the MATLAB function where the code generator considered replacing code.
- The reasons that the miss occurred. See “Miss Reason Messages” on page 52-74.

For this example, the report shows misses for function `addsub_two_int16.m`.

7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or a source parameter setting. For a list of conditions to consider, see“Miss Reason Messages” on page 52-74.

For this example, determine why code for function `addsub_two_int16` is not replaced with code for an unsigned 16-bit addition operation. The miss reasons for the function indicate data type and algorithm mismatches. For the three arguments:

- The data type in the call site object is a signed 16-bit integer. The code replacement entry specifies an unsigned 16-bit integer.
- The algorithm property in the call site object is `RTW_SATURATE_ON_OVERFLOW` while the code replacement entry specifies `RTW_WRAP_ON_OVERFLOW`.

8 Correct the specified MATLAB code and relevant specifications or code replacement table entry. If the issue concerns the MATLAB code, use the source location in the trace information to find the code to correct. For this example, you expected an unsigned addition operation to occur for the `addsub_two_int16` function.

To fix the mismatches, in the test file `addsub_to_int16_test`, change the data types definitions for `u1` and `u2` as follows:

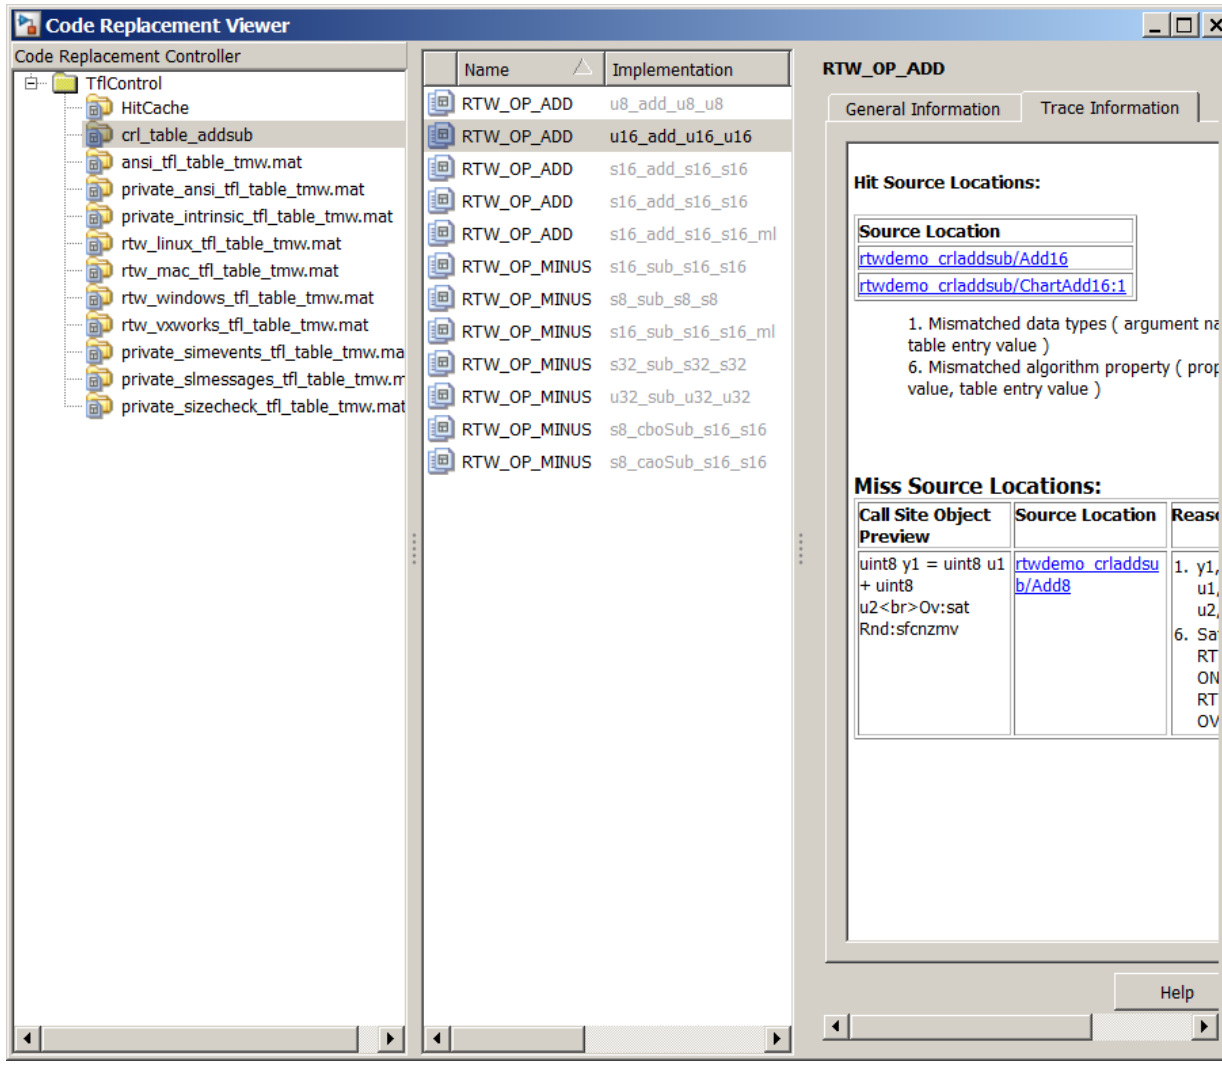
```
u1 = uint16(10)
u2 = uint16(10)
```

In the MATLAB Coder app:

- Open the project that contains the `addsub_to_int16` function.
- Use the updated test file `addsub_to_int16_test` to automatically redefine the input types.
- Run the test file.
- In the project settings dialog box, on the **Speed** tab, clear the check box for the **Saturate on integer overflow** parameter.

- Regenerate code and a report.

9 From the Code Replacements Report, open the Code Replacement Viewer. Use the Code Replacement Viewer trace information to verify that your MATLAB code or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for function `addsub_two_int16`.



More About

- "Verify Code Replacements" on page 52-64

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
3. Register the library customizations or restart MATLAB.
4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
5. Inform users that the libraries are available and provide direction on when and how to apply them.

More About

- "Verify Code Replacements" on page 52-64

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
% Create entry for sin function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(fcn_entry, ...
                               'Key',                    'sin', ...
                               'Priority',               30, ...
                               'ImplementationName',     'mySin', ...
                               'ImplementationHeaderFile', 'basicMath.h',...
                               'ImplementationSourceFile', 'basicMath.c');
```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'y1',...
                          'IOType',       'RTW_IO_OUTPUT',...
                          'DataTypeMode', 'double');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'u1', ...
                          'IOType',       'RTW_IO_INPUT',...
                          'DataTypeMode', 'double');
```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_memcpy()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   % Set SideEffects to 'true' for function returning void to prevent it from
   % being optimized away.
   setTflCFunctionEntryParameters(fcn_entry, ...
                                  'Key',                    'memcpy', ...
                                  'Priority',               90, ...
                                  'ImplementationName',     'memcpy_int', ...
                                  'ImplementationHeaderFile', 'memcpy_int.h',...
                                  'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

More About

- "Code You Can Replace from MATLAB Code" on page 52-5

- "Customize Match and Replacement Process" on page 52-112
- "Develop a Code Replacement Library" on page 52-15

Specify In-Place Code Replacement

In-place code replacement is an optimization technique that uses a single buffer, that is, the same memory, to store function input and output data, as in `x=foo(x)`.

When you generate C or C++ code from MATLAB code, the code generator supports in-place function argument code replacement. When you interactively create a code replacement table entry with the Code Replacement Tool, you can specify in-place function argument replacement. You can also specify in-place function argument replacement programmatically with the Code Replacement Library API.

Argument Specification Requirements

- The argument must be a pointer.
- An argument can be in-place with only one other argument.
- Specify an input argument as in-place (shares memory) with an output argument or an output argument as in-place with an input argument.

Interactive Argument Replacement Specification with Code Replacement Tool

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function with the Code Replacement Tool. The tool enforces in-place argument specification requirements as you add arguments and modify argument properties.

1. Create the following MATLAB function, `customFunction.m`.

   ```
   function x = customFunction(x)
   % Function that updates the input and returns it as an output

   coder.replace('-errorifnoreplacement');
   x = sin(x);
   ```

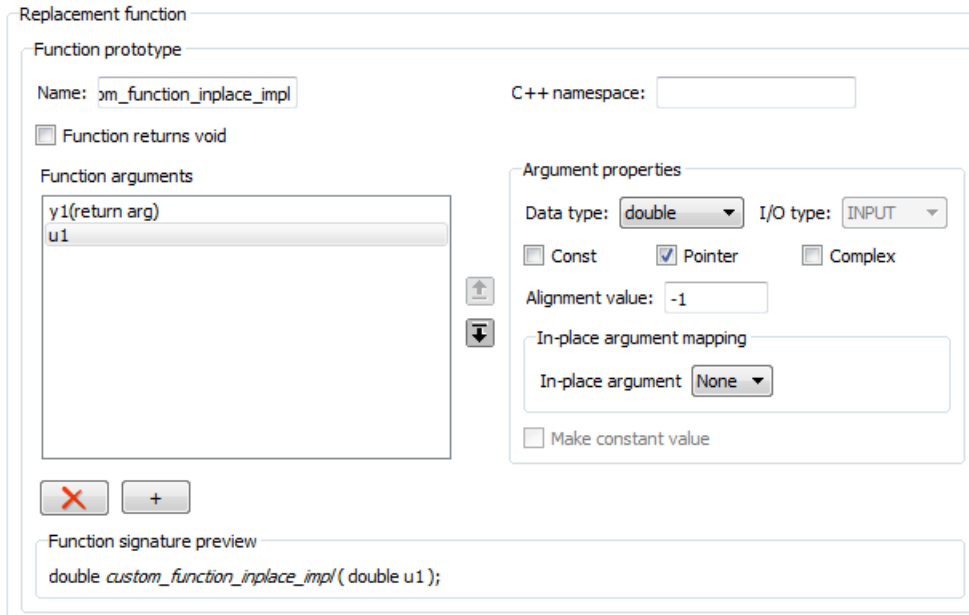
2. In the Code Replacement Tool, add a new table, select that table, and add a new function entry. For more information, see “Define Code Replacement Mappings” on page 52-30.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. In the **function-name** text box, name the custom function. For this example, type the name `customFunction`.

5 Under the **Conceptual arguments** list box, click **+** to add two arguments. By default, the tool creates an output argument *y1* and an input argument *u1*, both of type `double`.

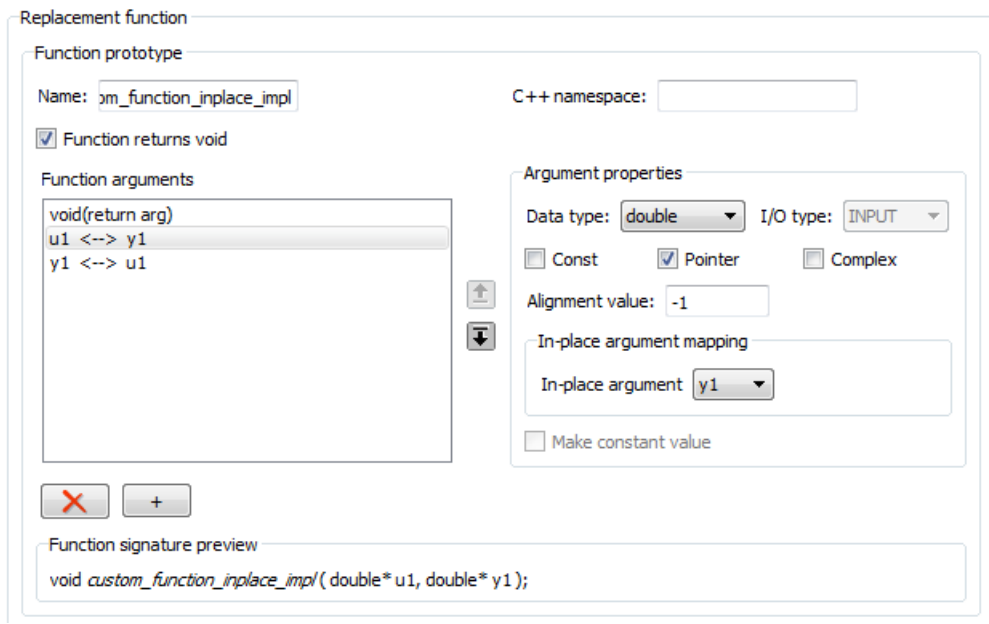
6 In the **Replacement function** > **Function prototype** section, type the name `custom_function_inplace_impl` in the **Name** text box.

7 Under the **Function arguments** list box, click **+** to add two function implementation arguments. By default, the tool creates an output argument *y1* and an input argument *u1*, both of type `double`.

8 For each input argument that you want to specify as in-place with a corresponding output argument, in the **Argument properties** box, select the **Pointer** check box. The **Argument properties** section of the dialog box expands to include an **In-place argument** drop-down list. For this example, in the **Function arguments** list, select input argument *u1*, and then select the **Pointer** check box.



9 From the **In-place argument** list, select *y1*, the output argument for the code replacement mapping. The **Function arguments** list box is updated to show possible in-place argument mappings.



10 Select and delete one of the two possible argument mappings. For this example, delete the mapping `y1<-->u1`.

11 In the **Function signature preview** box, if the function signature appears as expected, click **Apply**. Otherwise, make adjustments, and then click **Apply**. The function signature for this example, appears as

```
void custom_function_inplace_impl(double* u1);
```

12 Click **Validate entry**.

13 Save the code replacement table in the same folder as `customFunction.m`. Name the file `htfl_inplace_table.m`.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate the replacement code and a code generation report.

4 Review the code replacements.

Programmatic Argument Replacement Specification

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function programmatically. For the input implementation argument that shares the memory buffer, the example:

- Sets the name of the implementation argument to the same name as the corresponding conceptual argument.
- Associates the corresponding implementation argument with the argument property `ArgumentForInPlaceUse`.

1. Create the following MATLAB function, `customFunction.m`.

```
function y = customFunction(x)
% Function that updates the input and returns it as an output

coder.replace('-errorifnoreplacement');
x = sin(x);
```

2. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_inplace()
```

3. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
hEnt = RTW.TflCFunctionEntry;
```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(hEnt, ...
    'Key', 'customFunction', ...
    'Priority', 100, ...
    'ImplementationName', 'custom_function_inplace_impl', ...
    'SideEffects', true);
```

6. Create conceptual arguments `y1` and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

```
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

7 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument *y1* and input argument *u1*. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hEnt, 'y2','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt, 'u1','double*');
arg.ArgumentForInPlaceUse = 'y1';
hEnt.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate the replacement code and a code generation report.

4 Review the code replacements.

- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance when using MATLAB Coder. To configure data alignment for a function implementation:

1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See "Specify Data Alignment Requirements for Function Arguments" on page 51-133.
2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See "Provide Data Alignment Specifications for Compilers" on page 51-135.
3. Register the library containing the table entry and alignment specification object.
4. Configure the code generator to use the code replacement library and generate code. Observe the results.

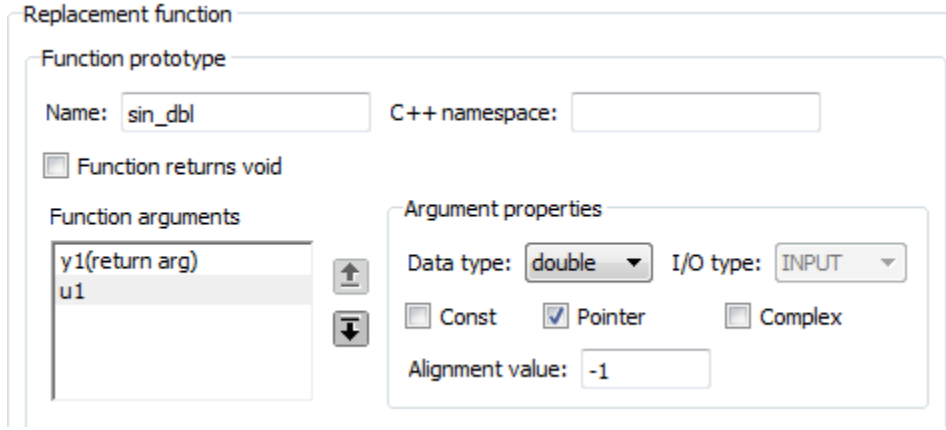
For examples, see "Basic Example of Code Replacement Data Alignment" on page 51-139 and the "Data Alignment for Function Implementations" section of the "Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®" example page.

Note If replacement that requires alignment uses imported data (for example, I/O of an entry-point function or exported function), specify the data alignment with `coder.dataAlignment` statements in the MATLAB code. Specify alignment separately for each instance of imported data. See "Specify Data Alignment in MATLAB Code for Imported Data" on page 52-98.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the argument `Descriptor` property.
- If you are defining a replacement function using the Code Replacement Tool, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.



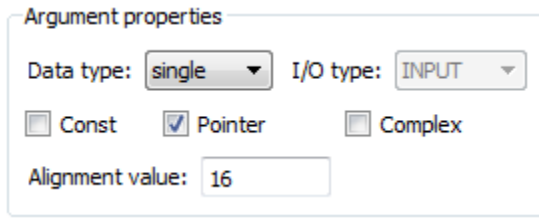
The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- `-1` (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.



Note: If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

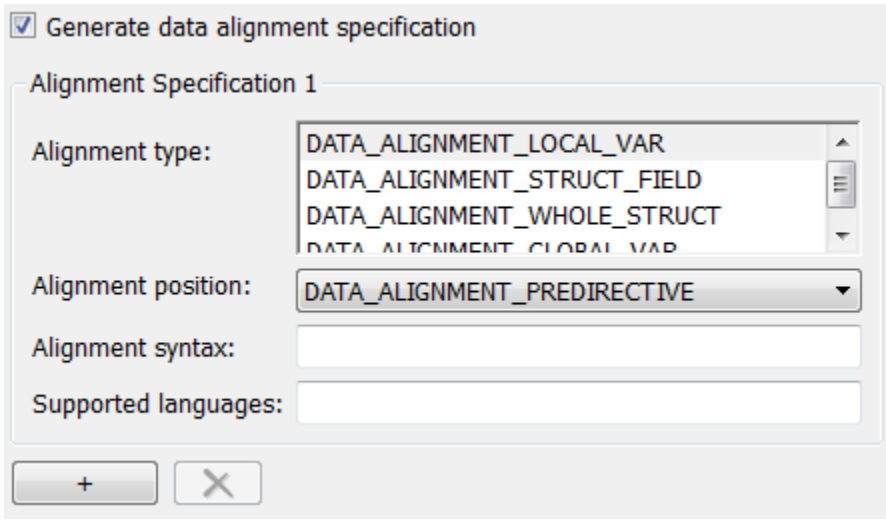
- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

  The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation

for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.



Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

`AlignmentSpecification` Property	**Dialog Box Parameter**	**Description**
`AlignmentType`	**Alignment type**	Cell array of predefined enumerated strings, specifying which types of alignment this specification supports. • `DATA_ALIGNMENT_LOCAL_VAR` — Local variables.

Alignment-Specification Property	Dialog Box Parameter	Description
		• DATA_ALIGNMENT_GLOBAL_VAR — Global variables. • DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields. • DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment). Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentPosition	**Alignment position**	Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT: • DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before struct st_tag{…}, as part of the type definition statement (for example, MSVC). • DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after struct st_tag{…}, as part of the type definition statement (for example, gcc). • DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. • DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentSyntax-Template	**Alignment syntax**	Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported: • `%n` — Replaced by the alignment boundary for the replacement function argument. • `%s` — Replaced by the aligned symbol, usually the identifier of a variable. For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`.
SupportedLanguage	**Supported languages**	Cell array specifying the languages to which this alignment specification applies, among `c` and `c++`. Sometimes alignment syntax and position differ between languages for a compiler. .

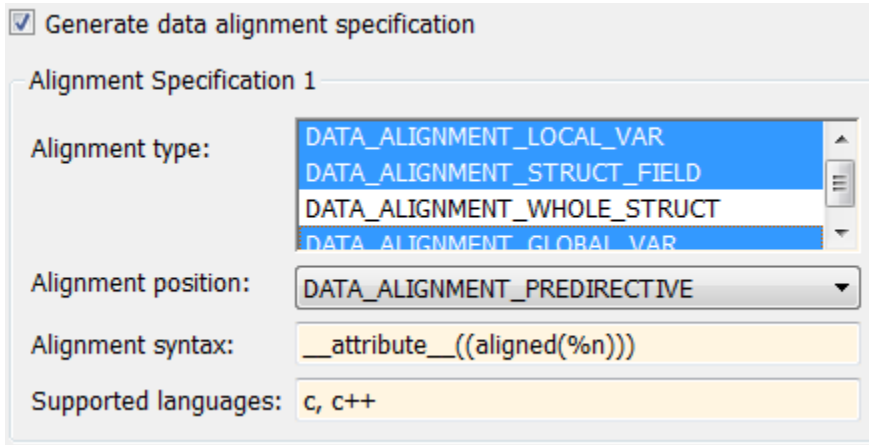
Here is a data alignment specification for the GCC compiler:

```
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                    'DATA_ALIGNMENT_STRUCT_FIELD', ...
                    'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.



Specify Data Alignment in MATLAB Code for Imported Data

If MATLAB Coder code replacements that require data alignment use imported data, such as an entry-point or exported function I/O, specify data alignment to external code with `coder.dataAlignment` statements in the MATLAB code.

If MATLAB Coder code replacements occur that require data alignment (uses imported data), such as an entry-point or exported function with I/O, specify code replacement data alignment with `coder.DataAlignment` statements in the MATLAB code.

To specify the data alignment requirements for imported data in a MATLAB code:

- For each instance of imported data that requires data alignment, specify the alignment in the function with a `coder.dataAlignment` statement of the form:

  ```
  coder.dataAlignment('varName', align_value)
  ```

- The *`varName`* is a character array of the variable name that requires alignment information specification. The *`align_value`* is an integer number which should be a power of 2, from 2 through 128. This number specifies the power-of-2 byte alignment boundary.
- An example function that specifies data alignment is:

  ```
  function y = testFunction(x1,x2)

  coder.dataAlignment('x1',16);   % Specifies information
  ```

```
coder.dataAlignment('x2',16);    % Specifies information
coder.dataAlignment('y',16);     % Specifies information

y = x1 + x2;

end
```

If `testFunction` is an entry-point or exported function, imported data `x1`, `x2`, and `y` are not aligned automatically by the code generator. The `coder.DataAlignment` statements for these variables are only meant as information for the code generator. The call sites allocating memory for the data need to ensure that the data is aligned as specified.

You also can specify code replacement data alignment for exported data, such as a `global` variable or an `ExportedGlobal` custom storage class. For more information, see "Introduction to Custom Storage Classes" on page 23-2.

Replacing Math Functions and Operators with Implementations that require Data Alignment - MATLAB®

This example shows how to develop and use code replacement library entries for target-specific function implementations that require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
- Specify the data alignment capabilities and syntax for your compiler. Attach an AlignmentSpecification object to the TargetCharacteristics object of the registry entry specified in your rtwTargetInfo.m file.

If externally allocated data (e.g. entry-point function arguments) are used in an operation that can be replaced with an implementation that requires alignment, use the coder.dataAlignment directive to specify alignment so that replacement occurs.

This example is configured to use either the GCC, Clang, or MSVC compilewhosrs.

Create a New Folder and Copy Relevant Files

The following code creates a folder in your current working folder (pwd). The new folder will contain the files that are relevant for this example. If you do not want to affect the

current folder (or if you cannot generate files in this folder), you should change your working folder.

Run Command: Create a New Folder and Copy Relevant Files

```
coderdemo_setup('coderdemo_crlalign');
cleanupObj = {};
mlpath = addpath(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crlali
cleanupObj{end+1} = onCleanup(@()path(mlpath));
```

Check selected compiler

This example is configured to use either GCC, Clang, or MSVC to compile the generated code.

```
cc = rtwprivate('getMexCompilerInfo');
isDaDemoSupported = strcmpi(cc.comp.Manufacturer,'GNU') || ...
                    strcmpi(cc.comp.Manufacturer,'Apple') || ...
                    strcmpi(cc.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
  recMsg = ['Use "mex -setup" to select either GCC, Clang, or MSVC and restart this '
            'example'];
  warning(['Example %s is configured to use either GCC, Clang, or MSVC to compile ' ..
           'the generated code. %s.'], mfilename,recMsg);
end
```

Set MATLAB Coder options

Set up the configuration object and define the function input types.

```
cfg = coder.config('lib','ecoder',true);
cfg.GenerateReport = false;
cfg.LaunchReport = false;
cfg.VerificationMode = 'SIL';
cfg.CodeExecutionProfiling = true;

len = 400000;
args = {coder.typeof(single(0),[len,1]), ...
        coder.typeof(single(0))};
global g1;
g1 = single(zeros([len,1]));
```

Generate code using the SIMD Examples Code Replacement Library

To see the code replacement table definition file, look here.

```
RTW.TargetRegistry.getInstance('reset');

mcode_da16 = 'biased_sum_of_square_differences_da16';
cfg.CodeReplacementLibrary = 'SIMD Examples';
codegen('-config',cfg, mcode_da16,'-args',args,'-global',{'g1',g1});
```

Inspect the MATLAB Coder Generated Code

After compiling, you may want to explore the generated source code.
matlab:edit(fullfile(pwd,'codegen','lib','biased_sum_of_square_differences_da16','sum_of_square_differ

Performance Gain from Data Alignment

Compare performance of normal ANSI code against the earlier generated code that used SIMD intrinsics.

```
% Generate ansi code
mcode_noda = 'biased_sum_of_square_differences';
cfg.CodeReplacementLibrary = 'None';
codegen('-config',cfg, mcode_noda,'-args',args,'-global',{'g1',g1});

% Run SIMD executable and collect execution profile information
coder.runTest('run_biased_ssd_da16',[mcode_da16,'_sil.',mexext])
pause(120);
clear([mcode_da16,'_sil']); % stop simulation
executionProfile_simd = getCoderExecutionProfile(mcode_da16);
idx_section = find(strcmp(mcode_da16,{executionProfile_simd.Sections.Name}),1);
avg_selftime_simd = executionProfile_simd.Sections(idx_section).TotalSelfTimeInTicks/ex

% Run ANSI executable and collect execution profile information
coder.runTest('run_biased_ssd',[mcode_noda,'_sil.',mexext])
pause(120);
clear([mcode_noda,'_sil']); % stop simulation
executionProfile_ansi = getCoderExecutionProfile(mcode_noda);
idx_section = find(strcmp(mcode_noda,{executionProfile_ansi.Sections.Name}),1);
avg_selftime_ansi = executionProfile_ansi.Sections(idx_section).TotalSelfTimeInTicks/ex

% Compare execution profile results
barObj = bar([avg_selftime_ansi; ...
    avg_selftime_simd]);
axesObj = barObj.Parent;
figObj = axesObj.Parent;
axesObj.XTickLabel = {'ANSI SSD', 'SIMD SSD'};
axesObj.YLabel.String = 'Average Execution Time (Timer Ticks)';
```

```
axesObj.YLim = [min([0,avg_selftime_ansi,avg_selftime_simd]), ...
                max(avg_selftime_ansi,avg_selftime_simd)*1.3];

percent_perf_gain = 100 * (avg_selftime_ansi-avg_selftime_simd)/avg_selftime_ansi;
annotation(figObj, 'textbox',axesObj.Position, ...
    'String',sprintf('Execution speed increased by %d%% on average',percent_perf_gain),
    'FontWeight', 'bold', 'FontSize', 12, 'HorizontalAlignment', 'center', ...
    'FitBoxToText','On');

### Starting SIL execution for 'biased_sum_of_square_differences_da16'
    To terminate execution: <a href="matlab: targets_hyperlink_manager('run',1);">clear

Replace MATLAB Functions with Custom Code Using `coder.replace`

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace `coder.ceval` Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in "Interactive External Function Call Replacement Specification with Code Replacement Tool" on page 52-107 and "Programmatic External Function Call Replacement Specification" on page 52-108 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
  return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2)  %#codegen

y=0.0;

if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
```

```
  y= in1+in2;
else
% Executing in generated code, call C function my_add
  y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;

y = call_my_add(in1, in2);

disp('Output')
disp('y =')
disp(y);
```

- Replacement C function `my_add_replacement.c`.

```
/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
  return in1 + in2;
}
```

- Replacement C header file `my_add_replacement.h`.

```
/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);
```

Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval`, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 52-106.

2. In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see "Define Code Replacement Mappings" on page 52-30.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.
5. Under the **Conceptual arguments** list box, click **+** to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.
6. In the **Replacement function** > **Function prototype** section, type the name `my_add_replacement` in the **Name** text box.
7. Under the **Function arguments** list box, click **+** to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type double. Use the default settings.
8. In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:

   ```
   double my_add_replacement(double u1, double u2);
   ```
9. On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.
10. Click **Validate entry**.
11. Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `crl_table_my_add.m`.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in "Example Files" on page 52-106.
2. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = crl_table_my_add
   ```
3. Within the function body, create the table by calling the function `RTW.TflTable`.
4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```
5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   hEnt.setTflCFunctionEntryParameters( ...
             'Key', 'my_add', ...
             'Priority', 100, ...
             'ImplementationName', 'my_add_replacement', ...
             'ImplementationHeaderFile', 'my_add_replacement.h', ...
             'ImplementationSourceFile', 'my_add_replacement.c');
   ```
6. Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```
7. Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
hLib.addEntry(hEnt);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate code and the report.

4 Review the code replacements.

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

More About

- “Code You Can Replace from MATLAB Code” on page 52-5
- “Customize Match and Replacement Process” on page 52-112
- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from `RTW.TflCFunctionEntryML (for function replacement) or RTW.TflCOperationEntryML` (for operator replacement).
2. In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:

    - Add match criteria that the base class does not provide. The base class provides a match based on:

        - Argument number
        - Argument name
        - Signedness
        - Word size
        - Slope (if not specified with wildcards)
        - Bias (if not specified with wildcards)
        - Math modes, such as saturation and rounding

    - Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
3. Create code replacement entries that instantiate the custom entry class.
4. Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

Customize Match and Replacement Process for Operators

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
        hCSO, ...
        targetBitPerChar, ...
        targetBitPerShort, ...
        targetBitPerInt, ...
```

```
        targetBitPerLong, ...
        targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
  methods
    function ent = do_match(hThis, ...
        hCSO, ... %#ok
        targetBitPerChar, ... %#ok
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok

      % DO_MATCH - Create a custom match function. The base class
```

```
        % checks the types of the arguments prior to calling this
        % method. This class will check additional data and can
        % modify the implementation function.

        % The base class checks word size and signedness. Slopes and biases
        % have been wildcarded, so the only additional checking to do is
        % to check that the biases are zero and that there are only three
        % conceptual arguments (one output, two inputs)

        ent = []; % default the return to empty, indicating the match failed

        if length(hCSO.ConceptualArgs) == 3 && ...
            hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
            hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
            hCSO.ConceptualArgs(3).Type.Bias == 0

          % Modify the default implementation. Since this is a
          % generator entry, a concrete entry is created using this entry
          % as a template. The type of entry being created is a standard
          % TflCOperationEntry. Using the standard operation entry
          % provides required information, and you do not need
          % a custom match function.
          ent = RTW.TflCOperationEntry(hThis);

          % Since this entry is modifying the implementation for specific
          % fraction-length values (arguments 3, 4, and 5), the conceptual argument
          % wild cards must be removed (the wildcards were inherited from the
          % generator when it was used as a template for the concrete entry).
          % This concrete entry is now for a specific slope and bias.
          % hCSO holds the slope and bias values (created by the code generator).
          for idx=1:3
            ent.ConceptualArgs(idx).CheckSlope = true;
            ent.ConceptualArgs(idx).CheckBias = true;

            % Set the specific Slope and Biases
            ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
            ent.ConceptualArgs(idx).Type.Bias = 0;
          end

          % Set the fraction-length values in the implementation function.
          ent.Implementation.Arguments(3).Value = ...
             -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
          ent.Implementation.Arguments(4).Value = ...
             -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
          ent.Implementation.Arguments(5).Value = ...
             -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
        end
      end
    end
  end
```

Exit the class folder and return to the previous working folder.

2 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table

that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;

%% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...

       'Scaling',    'BinaryPoint', ...
       'IsSigned',   false, ...
       'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'y1', ...
    'IOType',     'RTW_IO_OUTPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u1', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
```

```
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u2', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',       'fl_in1', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',       'fl_in2', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',       'fl_out', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

addEntry(hTable, op_entry);
```

3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = crl_table_custom_sinfcn_double
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(crl_table_custom_sinfcn_double)
  ```

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the `setTflCOperationEntryParameters` function.

   ```
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 90, ...
                       'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
                       'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                       'ImplementationName',       'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg );

   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg );
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(op_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

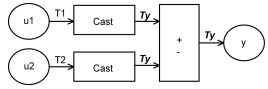
Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

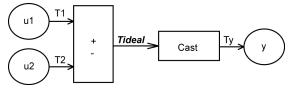
Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.



- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.



Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an **Algorithm** menu. Use that menu to specify the `Cast before operation` or `Cast after operation` algorithm for that entry.

Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- `Key` to `RTW_OP_ADD` or `RTW_OP_MINUS`
- `ImplementationName` to the name of your replacement function
- `EntryInfoAlgorithm` to `RTW_CAST_BEFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                  'Key',                      'RTW_OP_ADD', ...
                  'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
                  'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
`double`	`double`	`double`	`double`	CBO, CAO
`double`	`double`	`double`	`single`	—
`double`	`double`	`single`	`double`	—
`double`	`double`	`single`	`single`	CBO
`double`	`single`	`double`	`double`	CBO, CAO

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
`double`	`single`	`double`	`single`	—
`double`	`single`	`single`	`double`	—
`double`	`single`	`single`	`single`	CBO
`single`	`single`	`single`	`single`	CBO, CAO
`single`	`single`	`single`	`double`	—
`single`	`single`	`double`	`single`	—
`single`	`single`	`double`	`double`	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: • Operation type is `double`. • Operation type is `single` and input types are `single` or fixed-point.
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: • Accumulator type equals output type (`Tacc == Tout`). • Output type is a superset of input types (`Tacc >= {Tin1, Tin2}`) and accumulator type is a superset of output type (`Tacc >= Tout`). • Operation does not incur range or precision loss.
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see "Addition" or "Subtraction" in "Fixed-Point Operator Code Replacement" on page 52-146 (for MATLAB code) or "Fixed-Point Operator Code Replacement" on page 51-195 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 -> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

Limitations

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the `double` data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create table entry for matrix_sum_2x2_double
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCOperationEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_ADD', ...
       'Priority',               30, ...
       'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
       'ImplementationName',     'matrix_sum_2x2_double', ...
       'ImplementationHeaderFile', 'MatrixMath.h', ...
       'ImplementationSourceFile', 'MatrixMath.c', ...
       'ImplementationHeaderPath', LibPath, ...
       'ImplementationSourcePath', LibPath, ...
       'AdditionalIncludePaths',   {LibPath}, ...
       'GenCallback',            'RTW.copyFileToBuildDir', ...
       'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument

class `RTW.TflArgMatrix`. Specify the base type and the dimensions for which the argument is valid. The first table entry specifies `[2 2]` and the second table entry specifies `[3 3]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Create the entry for the second operator mapping.

```
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',       'matrix_sum_3x3_double', ...
```

```
        'ImplementationHeaderFile', 'MatrixMath.h', ...
        'ImplementationSourceFile', 'MatrixMath.c', ...
        'ImplementationHeaderPath', LibPath, ...
        'ImplementationSourcePath', LibPath, ...
        'AdditionalIncludePaths',   {LibPath}, ...
        'GenCallback',              'RTW.copyFileToBuildDir', ...
        'SideEffects',              true);

    % Specify operands and result
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                              'Name',         'y1', ...
                              'IOType',       'RTW_IO_OUTPUT', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                              'Name',         'u1', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                              'Name',         'u2', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);

    % Specify replacement function signature
    arg = getTflArgFromString(hTable, 'y2', 'void');
    arg.IOType = 'RTW_IO_OUTPUT';
    op_entry.Implementation.setReturn(arg);
    arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
    op_entry.Implementation.addArgument(arg);
    arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
    op_entry.Implementation.addArgument(arg);
    arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
    arg.IOType = 'RTW_IO_OUTPUT';
    op_entry.Implementation.addArgument(arg);

    addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of $C = a(op(A) * op(B)) + bC$. $op(X)$ means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of $C = op(A) * op(B)\ (a = 1.0, b = 0.0)$. Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of $y = a(op(A) * x) + by$, code replacement libraries support only the limited case of $y = op(A) * x\ (a = 1.0, b = 0.0)$.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_tmwblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

   ```
   % Define library path for Windows or UNIX
   arch = computer('arch');
   if ~ispc
       LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
   else
       % Use Stateflow to get the compiler info
       compilerInfo = sf('Private','compilerman','get_compiler_info');
       compilerName = compilerInfo.compilerName;
       if strcmp(compilerName, 'msvc90') || ...
               strcmp(compilerName, 'msvc80') || ...
               strcmp(compilerName, 'msvc71') || ...
               strcmp(compilerName, 'msvc60'), ...
               compilerName = 'microsoft';
       end
       LibPath = fullfile('$(MATLAB_ROOT)', 'extern', 'lib', arch, compilerName);
   end
   ```

4 Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

```
% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;
```

5 Set operator entry parameters with a call to the `setTflCFunctionEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCFunctionEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

```
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',       {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath}, ...
    'SideEffects',              true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
```

```
                            'IOType',       'RTW_IO_OUTPUT', ...
                            'BaseType',     'double', ...
                            'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                            'Name',         'u1', ...
                            'BaseType',     'double', ...
                            'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                            'Name',         'u2', ...
                            'BaseType',     'double', ...
                            'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%        type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
%  RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
%  RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for dgemv32
op_entry = RTW.TflBlasEntryGenerator;
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_MUL', ...
    'Priority',               100, ...
    'ImplementationName',     'dgemv32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',     {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath},...
    'SideEffects',            true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(char* TRANS, int* M, int* N,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* INCX,
%        type* BETA, type* y, int* INCY)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY, and insert them into the
% generated code. TRANS will be set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANS');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX','integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of $C = a(op(A) * op(B)) + bC$. $op(X)$ means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of $C = op(A) * op(B)\ (a = 1.0, b = 0.0)$. Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of $y = a(op(A) * x) + by$, code replacement libraries support only the limited case of $y = op(A) * x\ (a = 1.0, b = 0.0)$.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

   ```
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                      'RTW_OP_MUL', ...
   ```

```
    'Priority',                100, ...
    'ImplementationName',      'cblas_dgemm', ...
    'ImplementationHeaderFile', 'cblas.h', ...
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',             'RTW.copyFileToBuildDir', ...
    'SideEffects',             true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`. The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
%        type ALPHA, type* u1, int LDA, type* u2, int LDB,
```

```
%        type BETA, type* y, int LDC)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'cblas_dgemv', ...

    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, int M, int N,
%        type ALPHA, type* u1, int LDA, type* u2, int INCX,
%        type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.
```

```
% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M','integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```

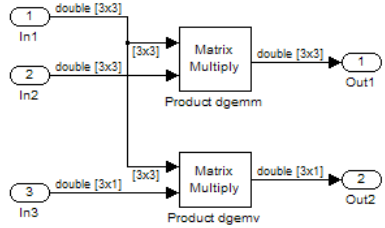
10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses two Product blocks. For example:

1 Create a model that includes two Product blocks, such as the following:



2 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

3 For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.

4 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For `In1` and `In2`, set **Port dimensions** to `[3 3]` and set the **Data type** to `double`. For `In3`, set **Port dimensions** to `[3 1]` and set the **Data type** to `double`.

5 Generate code and a code generation report.

6 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

Note: Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 90, ...
                       'ImplementationName',       'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
                       'SideEffects',              true );
   ```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg );

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg );
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

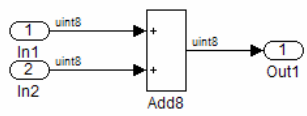
7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses an Add block. For example:

1 Create a model that includes an Add block, such as the following:



2 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.
- On the **All Parameters** tab, set the **Optimize global data access** parameter to `Use global to hold temporary results`. This reduces data copies in the generated code.

3 Generate code and a code generation report.

4 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point binary-point-only scaling. • `FractionLength`: Specify a fraction length (for example, 3).
A specific slope bias scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function:

Match	Create entry	Minimally specify parameters
		• `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point [slope bias] scaling. • `Slope` (or `SlopeAdjustmentFactor/FixedExponent` equivalent): Specify a slope value (for example, `15`). • `Bias`: Specify a bias value (for example, `2`).
Net slope between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntryGenerator_NetSlope`	`setTflCOperationEntryParameters` function: • `NetSlopeAdjustmentFactor`: Specify the slope adjustment factor (`F`) part of the net slope, $F2^E$ (for example, `1.0`). • `NetFixedExponent`: Specify the fixed exponent (`E`) part of the net slope, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.

Match	Create entry	Minimally specify parameters
Relative scaling between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntryGenerator`	`setTflCOperationEntryParameters` function: • `RelativeScalingFactorF`: Specify the slope adjustment factor (`F`) part of the relative scaling factor, $F2^E$ (for example, `1.0`). • `RelativeScalingFactorE`: Specify the fixed exponent (`E`) part of the relative scaling factor, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.
Equal slope and zero net bias across operator inputs and output (addition and subtraction).	`RTW.TflCOperationEntryGenerator`	`setTflCOperationEntryParameters` function: • `SlopesMustBeTheSame`: Specify the value `true`. • `MustHaveZeroNetBias`: Specify the value `true`. `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`.

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- V is an arbitrarily precise real-world value.
- $\tilde{V}$ is the approximate real-world value that results from fixed-point representation.
- Q is an integer that encodes $\tilde{V}$, referred to as the *quantized integer*.
- S is a coefficient of Q, referred to as the *slope*.
- B is an additive correction, referred to as the *bias*.

The general equation for an operation between fixed-point operands is:

$$\left(S_O Q_O + B_O\right) = \left(S_1 Q_1 + B_1\right) < op > (S_2 Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

Addition

The operation $V_0 = V_1 + V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right) Q_1 + \left(\frac{S_2}{S_0}\right) Q_2 + \left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left(\frac{B_1 + B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Subtraction

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0} \right) Q_1 - \left(\frac{S_2}{S_0} \right) Q_2 + \left(\frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left(\frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. Use the `TflCOperationEntry` class

and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 * V_2$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = (S_1 Q_1)(S_2 Q_2)$$
$$Q_0 = \left(\frac{S_1 S_2}{S_0} \right) Q_1 Q_2$$
$$Q_0 = S_n Q_1 Q_2$$

where S_n is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.) For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

Note: When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. For this, use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. For this, use a net slope entry or create a custom entry (see "Customize Match and Replacement Process" on page 51-153).

The operation $V_0 = (V_1 / V_2)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{S_2 Q_2} \right)$$

$$Q_0 = S_n \left(\frac{Q_1}{Q_2} \right)$$

where S_n is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.) For the `s16_netslopeOp5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

Note: When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Data Type Conversion (Cast)

The data type conversion operation $V_0 = V_1$ implies, for binary-point-only scaling, that

$$Q_0 = \left(\frac{S_1}{S_0} \right) Q_1$$

$$Q_0 = S_n Q_1$$

where S_n is the net slope.

Shift

The shift left or shift right operation $V_0 = (V_1 / 2^n)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{2^n} \right)$$

$$Q_0 = \left(\frac{S_1}{S_0} \right) + \left(\frac{Q_1}{2^n} \right)$$

$$Q_0 = S_n \left(\frac{Q_1}{2^n} \right)$$

where S_n is the net slope.

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_MUL', ...
       'Priority',               90, ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
       'ImplementationName',     's32_mul_s16_s16_binarypoint', ...
       'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
       'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a

fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 13);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (`int32`). The input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     32, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                    'RTW_OP_DIV', ...
      'Priority',               90, ...
      'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
      'RoundingModes',          {'RTW_ROUND_CEILING'}, ...
      'ImplementationName',     's16_div_s16_s16_slopebias', ...
      'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
      'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'Slope',          15, ...
    'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'Slope',          15, ...
    'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'Slope',          13, ...
    'Bias',           5);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_netslopesaturate
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```
   wv = [16,32];
   for iy = 1:2
     for inum = 1:2
       for iden = 1:2
         hTable = getDivOpEntry(hTable, ...
            fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
       end
     end
   end

   %------------------------------------------------------------
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %------------------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified

   funcStr = sprintf('user_div_%s_%s_%s',...
           typeStrFunc(dty),...
           typeStrFunc(dtnum),...
           typeStrFunc(dtden));
   ```

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW',...
   'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'},...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         0.0, ...
   'ImplementationName',       funcStr, ...
   'ImplementationHeaderFile', [funcStr,'.h'], ...
   'ImplementationSourceFile', [funcStr,'.c']);
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',           'y1',...
   'IOType',         'RTW_IO_OUTPUT',...
   'CheckSlope',     false,...
   'CheckBias',      false,...
   'DataTypeMode',   'Fixed-point: slope and bias scaling',...
   'IsSigned',       dty.Signed,...
   'WordLength',     dty.WordLength,...
   'Bias',           0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT',...
   'CheckSlope',     false,...
   'CheckBias',      false,...
   'DataTypeMode',   'Fixed-point: slope and bias scaling',...
   'IsSigned',       dtnum.Signed,...
   'WordLength',     dtnum.WordLength,...
   'Bias',           0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',           'u2', ...
```

```
    'IOType',          'RTW_IO_INPUT',...
    'CheckSlope',      false,...
    'CheckBias',       false,...
    'DataTypeMode',    'Fixed-point: slope and bias scaling',...
    'IsSigned',        dtden.Signed,...
    'WordLength',      dtden.WordLength,...
    'Bias',            0);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2',typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Define functions that determine the data type word length.

```
%--------------------------------------------------------------
function str = typeStrFunc(dt)
%--------------------------------------------------------------

if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);

%--------------------------------------------------------------
function str = typeStrBase(dt)
%--------------------------------------------------------------

if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Multiplication and Division with Rounding Mode and Additional Implementation Arguments

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netsloperound
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the relative scaling factor $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'NetSlopeAdjustmentFactor',   1.0, ...
   'NetFixedExponent',           0.0, ...
```

```
    'ImplementationName',       's16_div_s16_s16', ...
    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
                                  'Name',           'y1', ...
                                  'IOType',         'RTW_IO_OUTPUT', ...
                                  'IsSigned',       true, ...
                                  'WordLength',     16, ...
                                  'FractionLength', 0);
```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                              'Name',           'u1', ...
                              'IOType',         'RTW_IO_INPUT', ...
                              'IsSigned',       true, ...
                              'WordLength',     16, ...
                              'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                              'Name',           'u2', ...
                              'IOType',         'RTW_IO_INPUT', ...
                              'IsSigned',       true, ...
                              'WordLength',     16, ...
                              'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values. Map relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

   ```
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. `SlopesMustBeTheSame` and `MustHaveZeroNetBias` are set to `true`, indicating that slopes must be equal and net bias must be zero across the addition inputs and output.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                   'RTW_OP_ADD', ...
       'Priority',               90, ...
       'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
       'SlopesMustBeTheSame',    true, ...
       'MustHaveZeroNetBias',    true, ...
       'ImplementationName',      'u16_add_SameSlopeZeroBias', ...
       'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
       'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (`uint16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cast_int32_to_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_sat_cast`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_CAST', ...
       'Priority',               50, ...
       'ImplementationName',     'my_sat_cast', ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_FLOOR'}, ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   ```

```
op_entry.Implementation.setReturn(arg);
```

6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...
   'Priority',                 50, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         (OutFL - InFL), ...
   'ImplementationName',       'my_fxp_cast', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',         'u1', ...
     'IOType',       'RTW_IO_INPUT', ...
     'CheckSlope',   false, ...
     'CheckBias',    false, ...
     'DataTypeMode', 'Fixed-point: binary point scaling', ...
     'IsSigned',     InSgn, ...
     'WordLength',   InWL, ...
     'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       InSgn, ...
    'WordLength',     InWL, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for `int16` data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_SL', ...
       'Priority',               50, ...
       'ImplementationName',     'my_shift_left', ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```

6. Create the `int16` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg`

functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as an implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTflArgFromString` is called to create an `int8` input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

  ```
  addEntry(hTable, op_entry);
  ```
- Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_SL', ...
   'Priority',                 50, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         (OutFL - InFL),...
   'ImplementationName',       'my_fxp_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u1', ...
```

```
    'IOType',       'RTW_IO_INPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     InSgn, ...
    'WordLength',   InWL, ...
    'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',           'u1', ...
     'IOType',         'RTW_IO_INPUT', ...
     'IsSigned',       InSgn, ...
     'WordLength',     InWL, ...
     'FractionLength', 0);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Performance

Optimizations for Generated Code in Simulink Coder

Increase Code Generation Speed

In this section...

The amount of time it takes to generate code for a model depends on the size and configuration settings of the model. For instance, if you are working with a large model, it can take awhile to generate code. To decrease the amount of time for code generation of a model, try one or more of the following methods:

- Build a model in increments
- Build large model reference hierarchies in parallel
- Minimize memory requirements during code generation
- Generate only code
- Disable the creation of a code generation report

Build a Model in Increments

You can use the `rtwbuild` (Simulink Coder) command to build a model and generate code. By default, when rebuilding a model, `rtwbuild` provides an incremental model build, which only rebuilds a model or submodels that have changed since the most recent model build. Incremental model build saves code generation time. Use the **Rebuild** parameter on the **Model Referencing** pane to change the method that Simulink uses to determine when to rebuild code for referenced models. For more information on the **Rebuild** parameter, see “Rebuild” (Simulink).

Build Large Model Reference Hierarchies in Parallel

In a parallel computing environment, whenever conditions allow, you can increase the speed of code generation and compilation by building models containing large model reference hierarchies in parallel. For example, if you have Parallel Computing Toolbox software, you can distribute code generation and compilation for each referenced

model across the cores of a multicore host computer. If you have MATLAB Distributed Computing Server software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Distributed Computing Server configuration.

The performance gain realized by using parallel builds for referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- Parallel computing resources such as the number of local and remote workers available
- The hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For more information, see "Reduce Build Time for Referenced Models" (Simulink Coder).

Minimize Memory Requirements During Code Generation

Models that have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow code generation. The code generator copies this data to the *`model`*`.rtw` file. The *`model`*`.rtw` file is a partial representation of the model that the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language (for example, C). The Target Language Compiler (TLC) is an integral part of the code generator. The code generator copies parameters and data into *`model`*`.rtw`, whether they originate in the model or come from variables or objects in a workspace.

You can improve code generation speed by specifying the maximum number of elements that data vectors can have for the code generator to copy this data to *`model`*`.rtw`. When a data vector exceeds the specified size, the code generator places a reference key in *`model`*`.rtw`. The TLC uses this key to access the data from Simulink and format it into the generated code. Reference keys result in maintaining only one copy of large data vectors in memory.

The default value above which the code generator uses reference keys in place of actual data values is 10 elements. You can verify this value. In the Command Window, type the following command:

```
get_param(0, 'RTWDataReferencesMinSize')
```

To set the threshold to a different value, in the Command Window, type the following `set_param` function:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which the code generator uses reference keys in place of actual data values.

Generate Only Code

You can increase code generation speed by specifying that the build process generate code and a makefile, but not invoke the make command. When the code generator invokes the make command, the build process takes longer because the code generator generates code, compiles code, and creates an executable file.

On the **Code Generation** pane in the Model Configuration Parameters dialog box, you can specify that the build process generate only code by selecting the **Generate code only** parameter. You can specify that the code generation process build a makefile by selecting the **Generate makefile** parameter on the **All Parameters** tab.

No Creation of a Code Generation Report

You can speed up code generation by not generating a code generation report as a part of the build process. To disable the creation of a code generation report, on the **Code Generation** > **Report** pane, clear the **Create code generation report** parameter. After the build process, you can generate a code generation report by doing this procedure, “Generate Code Generation Report After Build Process” (Simulink Coder).

- “Reduce Build Time for Referenced Models” on page 40-50

Control Compiler Optimizations

To control compiler optimizations for a makefile build at the GUI level, use the **Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- Target-independent values `Optimizations on (faster runs)` and `Optimizations off (faster builds)`, which allow you to easily toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at the Simulink GUI level, rather than editing compiler flags into template makefiles (TMFs) or supplying compiler flags to build process make commands

The default setting is `Optimizations off (faster builds)`. Selecting the value `Custom` enables the **Custom compiler optimization flags** field, in which you can enter custom compiler optimization flags (for example, `-O2`).

Note: If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

For more information about the **Compiler optimization level** parameter and its values, see "Compiler optimization level" (Simulink Coder) and "Custom compiler optimization flags" (Simulink Coder).

Optimization Tools and Techniques

Use the Model Advisor to Optimize a Model for Code Generation

You can use the Model Advisor to analyze a model for code generation and identify aspects of your model that impede production deployment or limit code efficiency. You can select from a set of checks to run on a model's current configuration. The Model Advisor analyzes the model and generates check results providing suggestions for improvements in each area. Most Model Advisor diagnostics do not require the model to be in a compiled state; those that do are noted.

Before running the Model Advisor, select the target you plan to use for code generation. The Model Advisor works most effectively with ERT and ERT-based system target files.

Use the following examples to investigate optimizing models for code generation using the Model Advisor:

- `rtwdemo_advisor1`
- `rtwdemo_advisor2`
- `rtwdemo_advisor3`

Note: Example models `rtwdemo_advisor2` and `rtwdemo_advisor3` require Stateflow and Fixed-Point Designer software.

For more information on using the Model Advisor, see “Run Model Checks” (Simulink). For more information about the checks, see “Simulink Coder Checks” (Simulink Coder).

Design Tips for Optimizing Generated Code for Stateflow Objects

Do Not Access Machine-Parented Data In a Graphical Function

This restriction prevents long parameter lists from appearing in the code generated for a graphical function. You can access local data that resides in the same chart as the graphical function.

For more information, see “Reuse Logic Patterns Using Graphical Functions” (Stateflow).

Be Explicit About the Inline Option of a Graphical Function

When you use a graphical function in a Stateflow chart, select `Inline` or `Function` for the property **Function Inline Option**. Otherwise, the code generated for a graphical function may not appear as you want.

For more information, see "Specify Graphical Function Properties" (Stateflow).

Avoid Using Multiple Edge-Triggered Events in Stateflow Charts

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart.

For more information, see "Define Stateflow Structures" (Stateflow).

Combine Input Signals of a Chart Into a Single Bus Object

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart.

For more information, see "Define Stateflow Structures" (Stateflow).

Use Charts with Discrete Sample Times

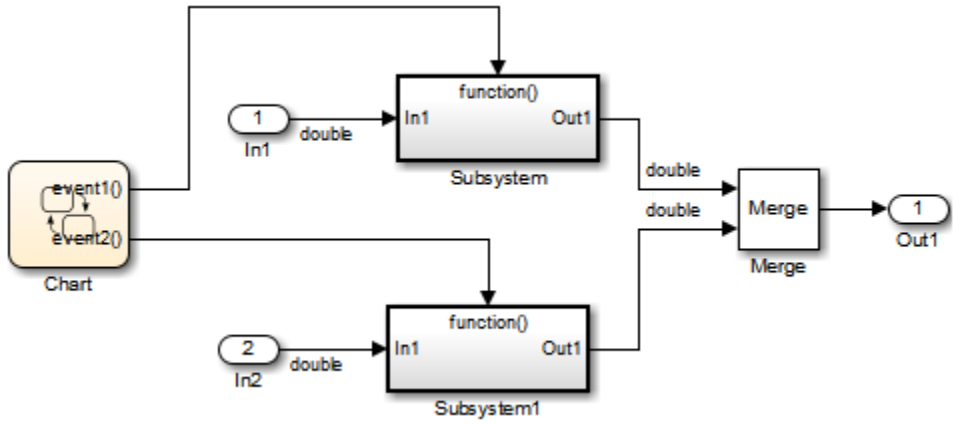
The code generated for discrete charts that are not inside a triggered or enabled subsystem uses integer counters to track time instead of Simulink provided time. This allows for more efficient code generation in terms of overhead and memory, as well as enabling this code for use in Software-in-the-Loop(SIL) and Processor-in-the-Loop(PIL) simulation modes.

Additional Optimization Techniques

You can apply the following techniques to optimize a model for code generation:

- Use the Upgrade Advisor to upgrade older models (saved by prior versions or the current version) to use current features. For details, see "Model Upgrades" (Simulink).
- Before building, set optimization flags for the compiler (for example, `-O2` for `gcc`, `-Ot` for the Microsoft Visual C++ compiler).
- Directly inline C/C++ S-functions into the generated code by writing a TLC file for the S-function. For more information, see "Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target" (Simulink Coder) and see "Inline C MEX S-Functions" (Simulink Coder).

- Use a Simulink data type other than `double` when possible. The available data types are `Boolean`, signed and unsigned 8-, 16-, and 32-bit integers, and 32- and 64-bit floats (a `double` is a 64-bit float). For more information, see "About Data Types in Simulink" (Simulink). For a block-by-block summary, click showblockdatatypetable or type the command in the Command Window.
- For tunable block parameters that you configure to store in memory in the generated code, you can match parameter data types with signal data types to eliminate unnecessary typecasts and C shifts. Where possible, store parameter values in small integer data types. See "Parameter Data Types in the Generated Code" on page 19-79.
- Remove repeated values in lookup table data.
- Use the Merge block to merge the output of signals wherever possible. This block is particularly helpful when you need to control the execution of function-call subsystems with a Stateflow chart. The following model shows an example of how to use the Merge block.



When more than one signal connected to a Merge block has a non-`Auto` storage class, all non-`Auto` signals connected to that block must *be identically labeled* and *have the same storage class*. When Merge blocks connect directly to one another, these rules apply to the signals connected to any of the Merge blocks in the group.

Control Memory Allocation for Time Counters

The **Application lifespan (days)** parameter lets you control the allocation of memory for absolute and elapsed time counters. Such counters exist in the code for blocks that use absolute or elapsed time. For a list of such blocks, see "Absolute Time Limitations" (Simulink Coder).

The size of the time counters in generated code is 8, 16, 32, or 64 bits. The size is set automatically to the minimum that can accommodate the duration value specified by **Application lifespan (days)** given the step size specified in the Configuration Parameters **Solver** pane. To minimize the amount of RAM used by time counters, specify the smallest lifespan possible and the largest step size possible.

An application runs to its specified lifespan. It may be able to run longer. For example, running a model with a step size of one millisecond (0.001 seconds) for one day requires a 32-bit timer, which could continue running without overflow for 49 days more.

To maximize application lifespan, specify **Application lifespan (days)** as `inf`. This value allocates 64 bits (two `uint32` words) for each timer. Using 64 bits to store timing data would allow a model with a step size of 0.001 microsecond (10E-09 seconds) to run for more than 500 years, which would rarely be required. 64-bit counters do not violate the usual code generator length limitation of 32 bits because the value of a time counter does not provide the value of a signal, state, or parameter.

Execution Profiling for Generated Code

Use code execution profiling to:

- Determine whether the generated code meets execution time requirements for real-time deployment on your target hardware.
- Identify code sections that require performance improvements.

The following tasks represent a general workflow that uses code execution profiling:

1. With the Simulink model, design and optimize your algorithm.
2. Configure the model for code execution profiling, and generate code.
3. Execute generated code on target. For example, you can:
   - Run a software-in-the-loop (SIL) simulation on your development computer.
   - Run a processor-in-the-loop (PIL) simulation using a target support package or custom PIL target.
   - Perform real-time execution with Simulink Real-Time or a target support package.
4. Analyze performance through code execution profiling plots and reports. For example, check that the algorithm code satisfies execution time requirements for real-time deployment:
   - If the algorithm code easily meets the requirements, consider enhancing your algorithm to exploit available processing power.
   - If the code cannot be executed in real time, look for ways to reduce execution time.

     Identify the tasks that require the most time. For these tasks, investigate whether trade-offs between functionality and speed are possible.

     If your target is a multicore processor, distribute the execution of algorithm code across available cores.
5. If required, refine the model and return to step 2.

To find information about code execution profiling with Simulink products, use the following table.

Optimize Generated Code by Combining Multiple `for` Constructs

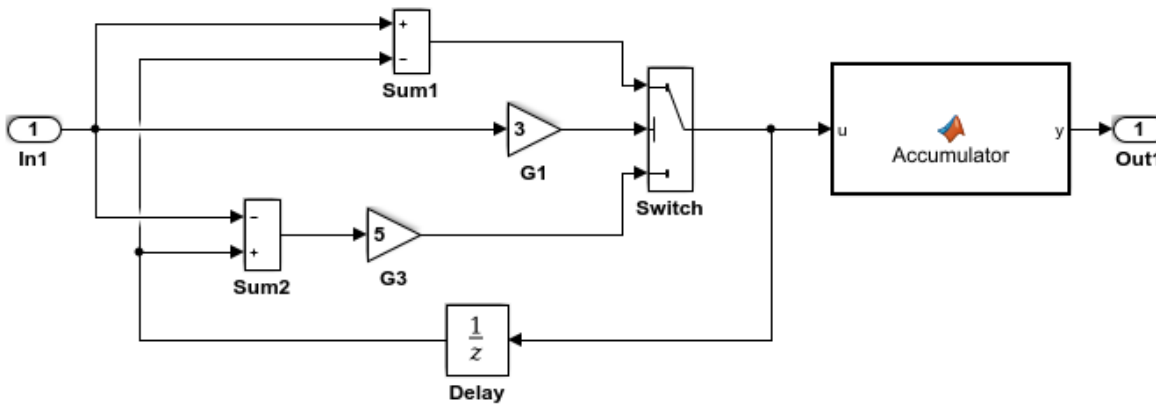
This example shows how the code generator combines `for` loops. The generated code uses `for` constructs to represent a variety of modeling patterns, such as a matrix signal or Iterator blocks. Using data dependency analysis, the code generator combines `for` constructs to reduce static code size and runtime branching.

The benefits of optimizing `for` loops are:

- Reducing ROM and RAM consumption.
- Increasing execution speed.

`for` Loop Modeling Patterns

In the model, rtwdemo_forloop, the Switch block and MATLAB Function block represent `for` constructs. In the `In1` Block Parameters dialog box, the **Port dimensions** parameter is set to `10` .



This model shows how Simulink Coder optimizes for-loops by combining multiple blocks into the same for-loop, improving code efficiency and readability. The for-loop fusion optimization complements expression folding. To see the vector widths in this model, select Edit > Update Diagram.

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Generate Code

In the model, there are no data dependencies across the `for` loop iterations. Therefore, the code generator combines all `for` loops into one loop. Build the model and view the generated code.

```
### Starting build procedure for model: rtwdemo_forloop
### Successful completion of build procedure for model: rtwdemo_forloop
```

The generated file, `rtwdemo_forloop.c`, contains the code for the single `for` loop.

```
/* Model step function */
void rtwdemo_forloop_step(void)
{
  int32_T k;

  /* MATLAB Function: '<Root>/Accum' */
  /* MATLAB Function 'Accum': '<S1>:1' */
  /* '<S1>:1:3' */
  /* '<S1>:1:4' */
  rtwdemo_forloop_Y.Out1 = 0.0;

  /* '<S1>:1:5' */
  for (k = 0; k < 10; k++) {
    /* Switch: '<Root>/Switch' incorporates:
     *  Gain: '<Root>/G1'
     *  Gain: '<Root>/G3'
     *  Inport: '<Root>/In1'
     *  Sum: '<Root>/Sum1'
     *  Sum: '<Root>/Sum2'
     *  UnitDelay: '<Root>/Delay'
     */
    if (3.0 * rtwdemo_forloop_U.In1[k] >= 0.0) {
      rtwdemo_forloop_DW.Delay_DSTATE[k] = rtwdemo_forloop_U.In1[k] -
        rtwdemo_forloop_DW.Delay_DSTATE[k];
    } else {
      rtwdemo_forloop_DW.Delay_DSTATE[k] = (rtwdemo_forloop_DW.Delay_DSTATE[k] -
        rtwdemo_forloop_U.In1[k]) * 5.0;
    }

    /* End of Switch: '<Root>/Switch' */

    /* MATLAB Function: '<Root>/Accum' */
    /* '<S1>:1:5' */
```

```
    /* '<S1>:1:6' */
    rtwdemo_forloop_Y.Out1 += (1.0 + (real_T)k) +
      rtwdemo_forloop_DW.Delay_DSTATE[k];
  }
}
```

Close the model.

Subnormal Number Performance

Subnormal numbers, formerly known as denormal numbers in floating-point literature, fill the underflow gap around zero in floating-point arithmetic. Subnormal values are a special category of floating-point values that are too close to `0.0` to be represented as a normalized value. The leading significand (mantissa) of a subnormal number is zero. When adding and subtracting floating-point numbers, subnormal numbers prevent underflow.

Using subnormal numbers provides precision beyond the normal representation by using leading zeros in the significand to represent smaller values after the representation reaches the minimum exponent. As the value approaches `0.0`, you trade off precision for extended range. Subnormal numbers are useful if your application requires extra range.

However, in a real-time system, using subnormal numbers can dramatically increase execution latency, resulting in excessive design margins and real-time overruns. If the simulation or generated code performs calculations that produce or consume subnormal numbers, the execution of these calculations can be up to 50 times slower than similar calculations on normal numbers. The actual simulation or code execution time for subnormal number calculations depends on your computer operating environment. Typically, for desktop processors, the execution time for subnormal number calculations is five times slower than similar calculations on normal numbers.

To minimize the possibility of execution slowdowns or overruns due to subnormal number calculation latency, do one of the following:

- In your model, manually flush to zero any incoming or computed subnormal values at inputs and key operations, such as washouts and filters. For an example, see “Flush Subnormal Numbers to Zero” on page 53-20.

  To detect a subnormal value for a single precision, 32-bit floating-point number:

  1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

     ```
     >> SmallestNormalSingle = realmin('single')
     ```

     In the C language, `FLT_MIN` , defined in `float.h`, is equivalent to `realmin('single')`.

  2. Look for values in range:

     ```
     0 < fabsf(x) < SmallestNormalSingle
     ```

To detect a subnormal value for a double precision, 64-bit floating-point number:

1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

   ```
   >> SmallestNormalDouble = realmin('double')
   ```
   In the C language, `DBL_MIN` , defined in `float.h`, is equivalent to `realmin('double')`.

2. To detect a subnormal value, look for values in this range:

   ```
   0 < fabs(x) < SmallestNormalDouble
   ```

- On your processor, set flush-to-zero mode or, with your compiler, specify an option to disable subnormal numbers. Flush-to-zero modes treat a subnormal number as 0 when it is an input to a floating-point operation. Underflow exceptions do not occur in flush-to-zero mode.

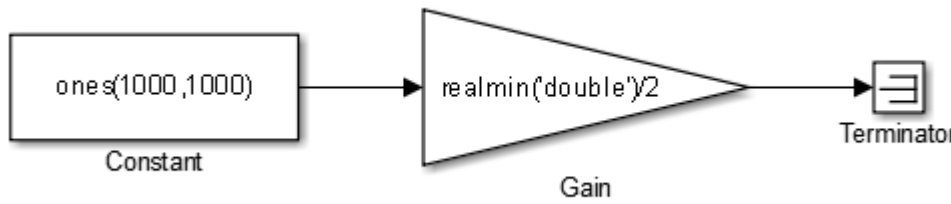
  For example, in Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register control floating-point calculations. For the gcc compiler on Linux, `-ffast-math` sets abrupt underflow (FTZ), flush-to-zero, while `-O3 -ffast-math` reverts to gradual underflow, using subnormal numbers.

For more information, see the IEEE Standard 754, *IEEE Standard for Floating-Point Arithmetic*.

Simulation Time With and Without Subnormal Numbers

This model shows how using subnormal numbers increases simulation time by ~5 times.

1. Open the model ex_subnormal. The Gain is set to subnormal value `realmin('double')/2`.



2 To run a simulation, in the Command Window, type `for k=1:5, tic; sim('ex_subnormal'); toc,end`. Observe the elapsed times for simulation using subnormals, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 9.909326 seconds.
Elapsed time is 9.617966 seconds.
Elapsed time is 9.797183 seconds.
Elapsed time is 9.702397 seconds.
Elapsed time is 9.893946 seconds.
```

3 Set the Gain to a number, 2, that is not a subnormal value:

```
>> set_param('ex_subnormal/Gain', 'Gain', '2');
```

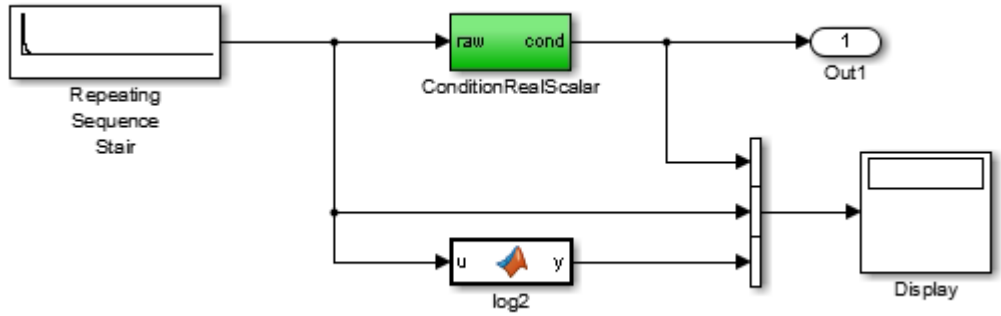
4 To run a simulation, in the Command Window, type `for k=1:5, tic; sim('ex_subnormal'); toc,end`. Observe elapsed times for simulations that do not use subnormal values, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 2.045123 seconds.
Elapsed time is 1.796598 seconds.
Elapsed time is 1.758458 seconds.
Elapsed time is 1.721721 seconds.
Elapsed time is 1.780569 seconds.
```

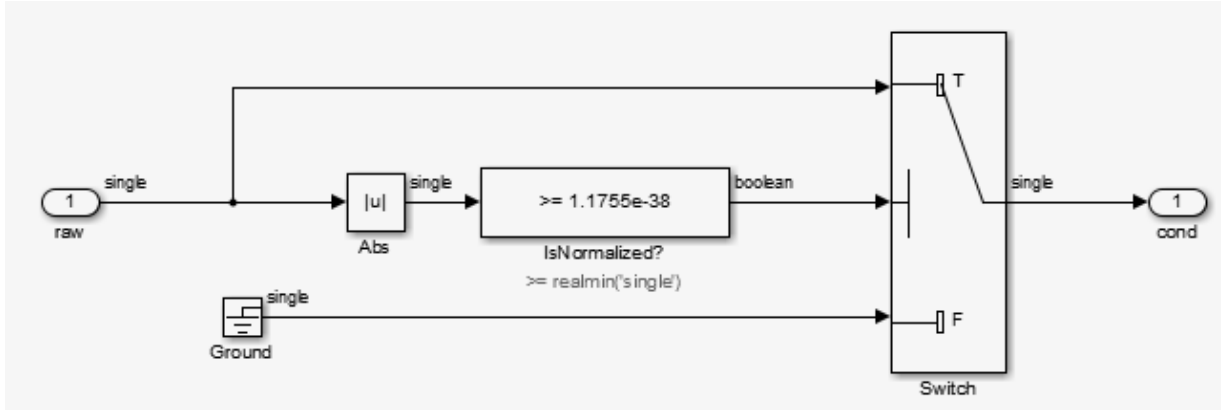
Flush Subnormal Numbers to Zero

This example shows how to flush single precision subnormal numbers to zero.

1 Open the model ex_flush_to_zero:



- `Repeating Sequence Stair` generates a sequence of numbers from two raised to the power of 0 through two raised to the power of -165. The sequence approaches zero.
- `ConditionRealScalar` flushes subnormal single precision values that are less than `realmin('single')` to zero.



- MATLAB function block `log2` generates the base 2 logarithm of the `Repeating Sequence Stair` output. Specifically, `log2` generates the numbers 0 through -165.

2 On the **Simulation > Stepping Options** pane:

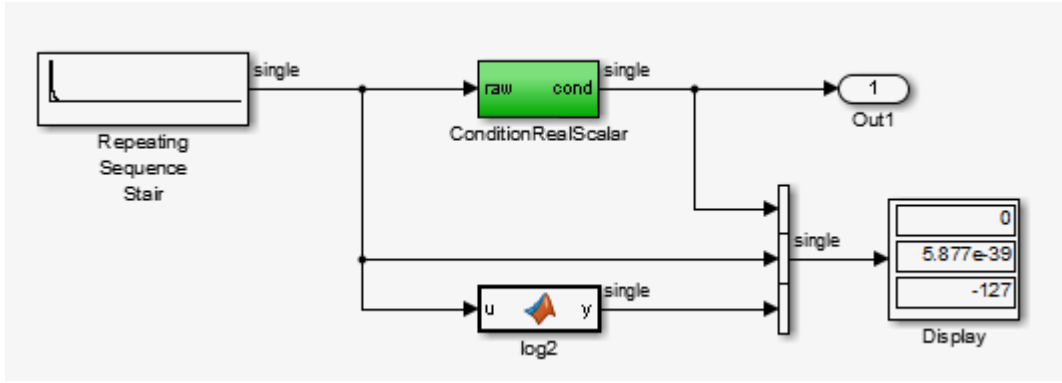
- Select **Enable stepping back**.

- Select **Pause simulation when time reaches** and enter `121`.

3 In the model window, run the simulation. The simulation pauses at `T=121`. The displayed values:

- `ConditionRealScalar` output approaches zero.
- `Repeating Sequence Stair output` approaches zero.

4 Step the simulation forward to `T=127`. `ConditionRealScalar` flushes the subnormal value output from `Repeating Sequence Stair` to zero.



5 Continue stepping the simulation forward. `ConditionRealScalar` flushes the subnormal single precision values output from `Repeating Sequence Stair` to zero. When `T=150`, the output of `Repeating Squence Stair` is itself zero.

Remove Code From Floating-Point to Integer Conversions That Wraps Out-of-Range Values

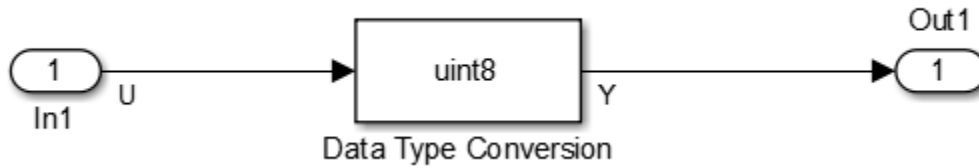
In this section...

This example shows how to remove code for out-of-range floating-point to integer conversions. Without this code, there might be a mismatch between simulation and code generation results. Standard C does not define the behavior of out-of-range floating-point to integer conversions, while these conversions are well-defined during simulation. In Standard C and during simulation, floating-point to integer conversions are well-defined for input values in the range of the output type.

If the input values in your application are in the range of the output type, remove code for out-of-range floating-point to integer conversions. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a `double` to a `uint8`. A `uint8` can support values from 0 to 255. If the input signal has a value outside of this range, an out-of-range conversion occurs. In this example, the model is named `conversion_ex`.



1 Use Inport, Outport, and Data Type Conversion blocks to create the example model.

2. Open the Inport Block Parameters dialog box and select the **Signal Attributes** tab. For the **Data Type** parameter, select `double`.
3. Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.
4. For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `U`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.
5. For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `Y`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select `Fixed-step`.
2. On the **Code Generation > Report** pane, select **Create code generation report**.
3. On the **Code Generation** pane, select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.
4. In the Code Generation report, select the `conversion_ex.c` file and view the model step function. The code generator applies the `fmod` function to handle out-of range-results.

```
/* Model step function */
void conversion_ex_step(void)
{
  real_T tmp;

  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<>/In1'
   */
  tmp = floor(U);
  if (rtIsNaN(tmp) || rtIsInf(tmp)) {
    tmp = 0.0;
  } else {
    tmp = fmod(tmp, 256.0);
  }

  Y = (uint8_T)(tmp < 0.0 ? (int32_T)(uint8_T)-(int8_T)(uint8_T)-tmp : (int32_T)
                (uint8_T)tmp);
```

Generate Code with Optimization

1. Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove code from floating-point to integer conversions that wraps out-of-range values**. Generate code.
2. In the code generation report, select the `conversion_ex.c` file and view the model step function. The generated code does not contain code that protects against out-of-range values.

```
/* Model step function */
void conversion_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<Root>/In1'
   */
  Y = (uint8_T)U;
```

The generated code is more efficient without this protective code, but it is possible that the execution of generated code does not produce the same results as simulation for values not in the range of 0 to 255.

Remove Code That Maps NaN to Integer Zero

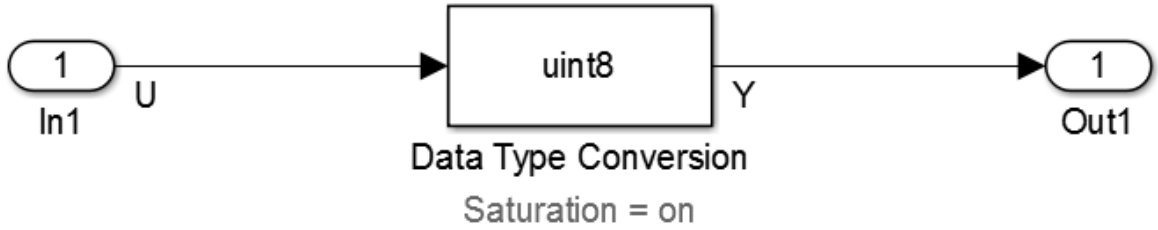
In this section...

This example shows how to remove code that maps `NaN` to integer zero. For floating-point to integer conversions involving saturation, Simulink converts `NaN` to integer zero during simulation. If your model contains an input value of `NaN`, you can specify that the code generator produce code that maps `NaN` to zero. Without this code, there is a mismatch between simulation and code generation results because in Standard C, every condition involving `NaN` evaluates to false.

If there are no input values of `NaN` in your application, you can remove code that maps `NaN` to integer zero. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a `double` to a `uint8`. In this example, the model is named `conversion_ex`.



1. Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2. Open the Inport Block Parameters dialog box and click the **Signal Attributes** tab. For the **Data Type** parameter, select `double`.
3. Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.

4. Select **Saturate on integer overflow**. Selecting this parameter specifies that an out-of-range signal value equals either the minimum or maximum value that the data type can represent.
5. For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of `U`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.
6. For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of `Y`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

Generate Code

1. Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select `Fixed-step` .
2. Open the Model Configuration Parameters dialog box. On the **All Parameters** tab, clear **Remove code from floating-point to integer conversions with saturation that maps NaN to zero**.
3. On the **Code Generation** > **Report** pane, select **Create code generation report**.
4. On the **Code Generation** pane, select **Generate code only** and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.
5. In the Code Generation report, select the `nan_int_ex.c` file and view the model step function. For an input value of `NaN`, there is agreement between the generated code and simulation because `NaN` maps to integer zero.

```
/* Model step function */
void nan_int_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (U < 256.0) {
    if (U >= 0.0) {
      Y = (uint8_T)U;
    } else {
      Y = 0U;
    }
  } else if (U >= 256.0) {
```

```
    Y = MAX_uint8_T;
  } else {
    Y = 0U;
  }
```

Generate Code with Optimization

1. Open the Configuration Parameters dialog box. On the **All Parameters** tab, select **Remove code from floating-point to integer conversions that wraps out-of-range values**. Generate code.
2. In the Code Generation report, select the `nan_int_ex.c` section and view the model step function. The generated code maps `NaN` to 255 and not integer zero. The generated code is more efficient without the extra code that maps `NaN` to integer zero, but the execution of the generated code does not produce the same results as simulation for `NaN` values.

```
/* Model step function */
void nan_int_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (U < 256.0) {
    if (U >= 0.0) {
      Y = (uint8_T)U;
    } else {
      Y = 0U;
    }
  } else {
    Y = MAX_uint8_T;
  }

  /* End of DataTypeConversion: '<Root>/Data Type Conversion' */
```

Disable Nonfinite Checks or Inlining for Math Functions

When the code generator produces code for math functions:

- If the model option **Support non-finite numbers** is selected, nonfinite number checking is generated uniformly for math functions, without the ability to specify that nonfinite number checking should be generated for some functions, but not for others.
- By default, inlining is applied uniformly for math functions, without the ability to specify that inlining should be generated for some functions, while invocations should be generated for others.

You can use code replacement library (CRL) customization entries to:

- Selectively disable nonfinite checks for math functions. This can improve the execution speed of the generated code.
- Selectively disable inlining of math functions. This can increase code readability and decrease code size.

The functions for which these customizations are supported include the following:

- Floating-point only: `atan2`, `copysign`, `fix`, `hypot`, `log`, `log10`, `round`, `sincos`, and `sqrt`
- Floating-point and integer: `abs`, `max`, `min`, `mod`, `rem`, `saturate`, and `sign`

The general workflow for disabling nonfinite number checking and/or inlining is as follows:

1. If you can disable nonfinite number checking for a particular math function, or if you want to disable inlining for a particular math function and instead generate a function invocation, you can copy the following MATLAB function code into a MATLAB file with an `.m` file name extension, for example, `crl_table_customization.m`.

```
function hTable = crl_table_customization

% Create an instance of the Code Replacement Library table for controlling
% function intrinsic inlining and nonfinite support

hTable = RTW.TflTable;

% Inline - true (if function needs to be inline)
%          false (if function should not be inlined)
% SNF (support nonfinite) - ENABLE (if non-finite checking should be performed)
%                           DISABLE (if non-finite checking should NOT be performed)
%                           UNSPECIFIED (Default behavior)
```

```
% registerCustomizationEntry(hTable, ...
%       Priority, numInputs, key, inType, outType, Inline, SNF);

registerCustomizationEntry(hTable, ...
        100, 2, 'atan2', 'double', 'double', false, 'UNSPECIFIED');

        100, 1, 'sign', 'int8',   'integer', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'sign', 'uint32', 'uint32',  true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'sign', 'uint16', 'uint16',  true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'sign', 'uint8',  'uint8',   true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'sign', 'integer','integer', true, 'UNSPECIFIED');

registerCustomizationEntry(hTable, ...
```

```
        100, 1, 'sqrt', 'double', 'double', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'sqrt', 'single', 'single', true, 'UNSPECIFIED');

registerCustomizationEntry(hTable, ...
        100, 1, 'fix', 'double', 'double', false, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'fix', 'single', 'single', false, 'UNSPECIFIED');

registerCustomizationEntry(hTable, ...
        100, 1, 'copysign', 'double', 'double', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'copysign', 'single', 'single', true, 'UNSPECIFIED');
```

2. To reduce the size of the file, you can delete the `registerCustomizationEntry` lines for functions for which the default nonfinite number checking and inlining behavior is acceptable.
3. For each remaining entry,

   - Set the `Inline` argument to `true` if the function should be inlined or `false` if it should not be inlined.
   - Set the `SNF` argument to `ENABLE` if nonfinite checking should be generated, `DISABLE` if nonfinite checking should not be generated, or `UNSPECIFIED` to accept the default behavior based on the model option settings.

   Save the file.
4. Optionally, perform a quick check of the syntactic validity of the customization table entries by invoking the table definition file at the MATLAB command line (`>> tbl = crl_table_customization`). Fix syntax errors that are flagged.
5. Optionally, view the customization table entries in the Code Replacement Viewer (`>> crviewer(crl_table_customization)`). For more information about viewing code replacement tables, see "Choose a Code Replacement Library" (Simulink Coder).
6. To register these changes and make them appear in the **Code replacement library** drop-down list located on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, first copy the following MATLAB function code into an instance of the file `rtwTargetInfo.m`.

Note: For the example below, specify the argument `'RTW'` if a GRT target is selected for your model, otherwise omit the argument.

```
function rtwTargetInfo(cm)
```

```
% rtwTargetInfo function to register a code replacement library (CRL)

  % Register the CRL defined in local function locCrlRegFcn
  cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_customization
function thisCrl = locCrlRegFcn

  % Instantiate a CRL registry entry - specify 'RTW' for GRT
  thisCrl = RTW.TflRegistry('RTW');

  % Define the CRL properties
  thisCrl.Name = 'CRL Customization Example';
  thisCrl.Description = 'Example  of CRL Customization';
  thisCrl.TableList = {'crl_table_customization'};
  thisCrl.TargetHWDeviceType = {'*'};

end % End of LOCCRLREGFCN
```

You can edit the `Name` field to specify the library name that appears in the **Code replacement library** drop-down list. Also, the file name in the `TableList` field must match the name of the file you created in step 1.

To register your changes, with both of the MATLAB files you created present in the MATLAB path, enter the following command at the MATLAB command line:

```
sl_refresh_customizations
```

7. Create or open a model that generates function code corresponding to one of the math functions for which you specified a change in nonfinite number checking or inlining behavior.
8. Open the Configuration Parameters dialog box, go to the **Code Generation > Interface** pane, and use the **Code replacement library** drop-down list to select the code replacement entry you registered in step 6, for example, `CRL Customization Example`.
9. Generate code for the model and examine the generated code to verify that the math functions are generated as expected.

Minimize Computations and Storage for Intermediate Results at Block Outputs

In this section...

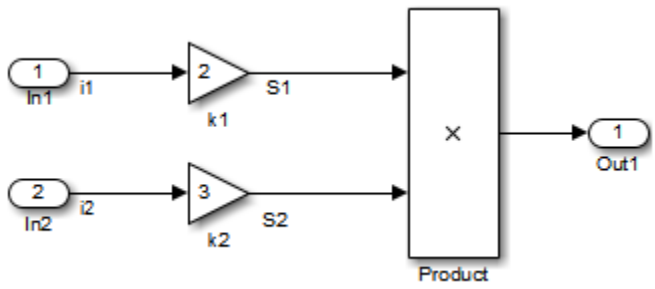
Expression Folding

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in the model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

You can use expression folding in your own inlined S-function blocks. For more information, see "S-Functions That Support Expression Folding" (Simulink Coder).

Example Model



Generate Code

With expression folding off, in the `explfld.c` file, the code generator generates this code.

```
/* Model step function */
void exprfld_step(void)
{
  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  exprfld_B.S1 = exprfld_P.Gain_Gain * exprfld_U.i1;

  /* Gain: '<Root>/Gain1' incorporates:
   *  Inport: '<Root>/In2'
   */
  exprfld_B.S2 = exprfld_P.Gain1_Gain * exprfld_U.i2;

  /* Outport: '<Root>/Out1' incorporates:
   *  Product: '<Root>/Product'
   */
  exprfld_Y.Out1 = exprfld_B.S1 * exprfld_B.S2;
}
```

There are separate code statements for both Gain blocks. Before final output, these code statements compute temporary results for the Gain blocks.

Enable Optimization

Expression folding is on by default. To see if expression folding is on for an existing model:

1. Open the Configuration Parameters dialog box and select the **All Parameters** tab.
2. Expression folding is available only when the **Signal storage reuse** parameter is set to `on` because expression folding operates only on expressions involving local variables. On the **All Parameters** tab, select **Signal storage reuse**.
3. When you select **Signal storage reuse**, the **Enable local block outputs**, **Reuse local block outputs**, and **Eliminate superfluous local variables (expression folding)** parameters are all on by default.

Generate Code with Optimization

With expression folding, the code generator generates a single-line output computation, as shown in the `expfld.c` file. The generated comments document the block parameters that appear in the expression.

```
/* Model step function */
void exprfld_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Gain: '<Root>/Gain1'
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   *  Product: '<Root>/Product'
   */
  exprfld_Y.Out1 = exprfld_P.Gain_Gain * exprfld_U.i1 * (exprfld_P.Gain1_Gain *
    exprfld_U.i2);
}
```

For an example of expression folding in the context of a more complex model, click `rtwdemo_slexprfold` , or at the command prompt, type:

```
rtwdemo_slexprfold
```

For more information, see “Enable and Reuse Local Block Outputs in Generated Code” (Simulink Coder)

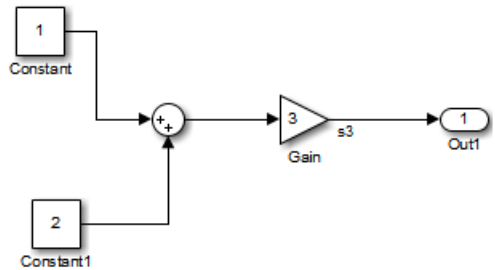
Inline Invariant Signals

You can optimize the generated code by selecting **Inline invariant signals** on the **Optimization** > **Signals and Parameters** pane. The generated code uses the numerical values of the invariant signals instead of their symbolic names.

An invariant signal is a block output signal that does not change during Simulink simulation. For example, the signal S3 is an invariant signal. An *invariant signal* is not the same as an *invariant constant*. The two constants (1 and 2) and the gain value of 3 are invariant constants. To inline invariant constants, set **Default parameter behavior** to `Inlined`.



Optimize Generated Code Using Inline Invariant Signals

This example shows how to use inline invariant signals to optimize the generated code. This optimization transforms symbolic names of invariant signals into constant values.

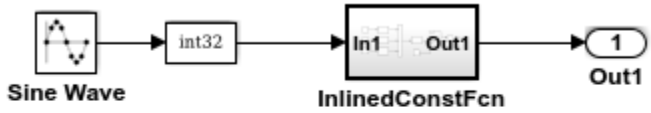
The `InlineInvariantSignals` optimization:

- Reduces ROM and RAM consumption.
- Improves execution speed.

Example Model

Consider the model matlab:rtwdemo_inline_invariant_signals.

```
model = 'rtwdemo_inline_invariant_signals';
open_system(model);
```



Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model using Simulink Coder.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signal
```

View the generated code without the optimization. These lines of code are in `rtwdemo_inline_invariant_signals.c`.

```
cfile = fullfile(cgDir,'rtwdemo_inline_invariant_signals_grt_rtw',...
    'rtwdemo_inline_invariant_signals.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
    '/* Model output', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline_InlinedConstFcn(int32_T rtu_In1,
  B_InlinedConstFcn_rtwdemo_inl_T *localB, const ConstB_InlinedConstFcn_rtwdem_T
  *localC)
{
  /* Product: '<S1>/Product' */
  localB->Product = rtu_In1 * localC->Sum_p;
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization->Signals and Parameters** pane, select **Inline Invariant Signals**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'InlineInvariantSignals', 'on');
```

Generate Code with Optimization

The generated code uses the numerical values of the folded constants instead of creating an additional structure (rtwdemo_inline_invariant_ConstB).

Build the model using Simulink Coder.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signal
```

View the generated code with the optimization. These lines of code are in `rtwdemo_minmax.c`.

```
rtwdemodbtype(cfile,'/* Output and update for atomic system', '/* Model output', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
  B_InlinedConstFcn_rtwdemo_inl_T *localB)
{
  /* Product: '<S1>/Product' */
  localB->Product = rtu_In1 << 5;
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Inline Numeric Values of Block Parameters

This example shows how to optimize the generated code by inlining the numeric values of block parameters. *Block parameters* include the **Gain** parameter of a Gain block and the table data and breakpoint sets of an n-D Lookup Table block.

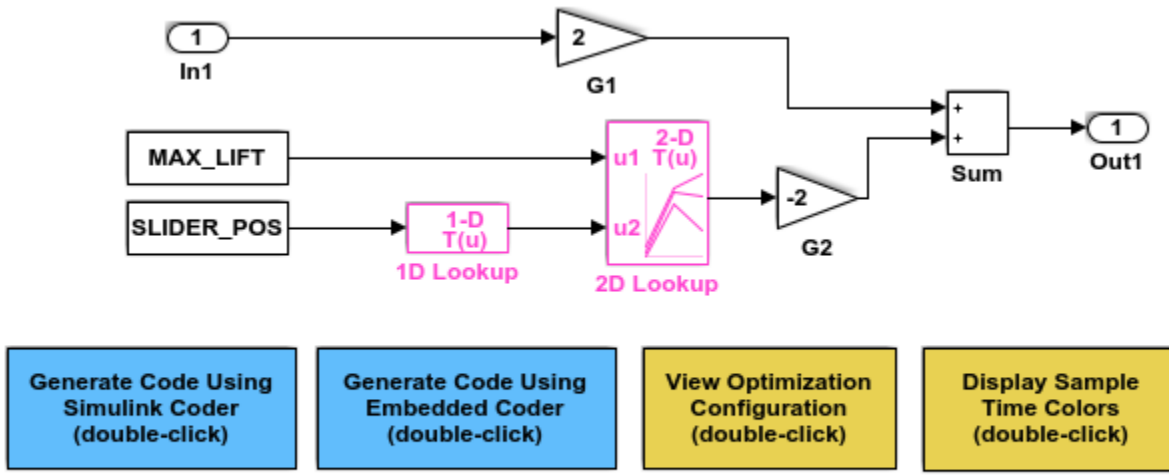
This optimization determines whether numeric block parameters occupy global memory in the generated code. The optimization can:

- Improve execution speed.
- Reduce RAM and ROM consumption.

Explore Example Model

Open the example model `rtwdemo_paraminline`.

```
open_system('rtwdemo_paraminline')
```



The model contains blocks that have these numeric parameters:

- The **Gain** parameters of the Gain blocks

- The **Constant value** parameters of the Constant blocks
- The table data and breakpoint sets of the n-D Lookup Table blocks

The output of the block G2, and the outputs of blocks upstream of G2, change only if you tune the values of the block parameters during simulation or during code execution. When you update the model diagram, these blocks and signal lines appear magenta in color.

Several blocks use `Simulink.Parameter` objects in the base workspace to set the values of their parameters. The parameter objects all use the storage class `Auto`, which means that you can configure the generated code to inline the parameter values.

Generate Code Without Optimization

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Disable the optimization by setting **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to `Tunable`.

```
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

In the code generation report, view the source file `rtwdemo_paraminline_data.c`. The code defines a global structure that contains the block parameter values. Each block parameter in the model, such as a lookup table array, breakpoint set, or gain, appears as a field of the structure.

```
cfile = fullfile(cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline_data.c');
rtwdemodbtype(cfile,'/* Block parameters (auto storage) */', '};', 1, 1);
```

```
/* Block parameters (auto storage) */
P_rtwdemo_paraminline_T rtwdemo_paraminline_P = {
  10.0,                                /* Variable: MAX_LIFT
                                        * Referenced by: '<Root>/Constant'
                                        */
```

```
  0.0,                                 /* Variable: SLIDER_POS
                                        * Referenced by: '<Root>/Constant1'
                                        */

  /*  Variable: T1Break
   * Referenced by: '<Root>/1D Lookup'
   */
  { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

  /*  Variable: T1Data
   * Referenced by: '<Root>/1D Lookup'
   */
  { -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 },

  /*  Variable: T2Break
   * Referenced by: '<Root>/2D Lookup'
   */
  { 1.0, 2.0, 3.0 },

  /*  Variable: T2Data
   * Referenced by: '<Root>/2D Lookup'
   */
  { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 },
  2.0,                                 /* Expression: 2
                                        * Referenced by: '<Root>/G1'
                                        */
  -2.0,                                /* Expression: -2
                                        * Referenced by: '<Root>/G2'
                                        */

  /*  Computed Parameter: uDLookup_maxIndex
   * Referenced by: '<Root>/2D Lookup'
   */
  { 2U, 2U }
};
```

You can tune the structure fields during code execution because they occupy global memory. However, at each step of the generated algorithm, the code must calculate the output of each block, including the outputs of the block G2 and the upstream blocks. View the algorithm in the model `step` function in the file `rtwdemo_paraminline.c`.

```
cfile = fullfile(cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(cfile,'/* Model step function */','/* Model initialize function */',1,0);
```

```
/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Constant: '<Root>/Constant'
   *  Constant: '<Root>/Constant1'
   *  Gain: '<Root>/G1'
   *  Gain: '<Root>/G2'
   *  Inport: '<Root>/In1'
   *  Lookup_n-D: '<Root>/1D Lookup'
   *  Lookup_n-D: '<Root>/2D Lookup'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = rtwdemo_paraminline_P.G1_Gain *
    rtwdemo_paraminline_U.In1 + rtwdemo_paraminline_P.G2_Gain * look2_binlx
    (rtwdemo_paraminline_P.MAX_LIFT, look1_binlx
     (rtwdemo_paraminline_P.SLIDER_POS, rtwdemo_paraminline_P.T1Break,
      rtwdemo_paraminline_P.T1Data, 10U), rtwdemo_paraminline_P.T2Break,
     rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Data,
     rtwdemo_paraminline_P.uDLookup_maxIndex, 3U);
}
```

Generate Code with Optimization

Set **Default parameter behavior** to `Inlined`.

```
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Inlined')
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

In the code generation report, view the algorithm in the file `rtwdemo_paraminline.c`.

```
rtwdemodbtype(cfile,'/* Model step function */','/* Model initialize function */',1,0)
```

```
/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/G1'
```

```
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = 2.0 * rtwdemo_paraminline_U.In1 + 150.0;
}
```

The code does not allocate memory for block parameters or for parameter objects that use the storage class `Auto`. Instead, the code generator uses the parameter values from the model, and from the parameter objects, to calculate and inline the constant output of the block G2, `150.0`. The generator also inlines the value of the **Gain** parameter of the Gain block G1, `2.0`.

With the optimization, the generated code leaves out computationally expensive algorithmic code for blocks such as the lookup tables. The optimized code calculates the output of a block only if the output can change during execution. For this model, only the outputs of the Inport block In1, the Gain block G1, and the Sum block can change.

Close the model and the code generation report.

```
bdclose('rtwdemo_paraminline')
rtwdemoclean;
cd(currentDir)
```

Preserve Block Parameter Tunability

When you set **Default parameter behavior** to `Inlined`, you can preserve block parameter tunability by creating `Simulink.Parameter` objects for individual parameters. You can configure each object to appear in the code as a tunable field of the global parameter structure or as an individual global variable. You can change parameter values during code execution and interface the generated code with your own handwritten code. For more information, see “Block Parameter Representation in the Generated Code” (Simulink Coder).

Inline Invariant Signals

You can select the **Inline invariant signals** code generation option (which also places constant values in the generated code) only when you set **Default parameter behavior** to `Inlined`. See “Inline Invariant Signals” (Simulink Coder).

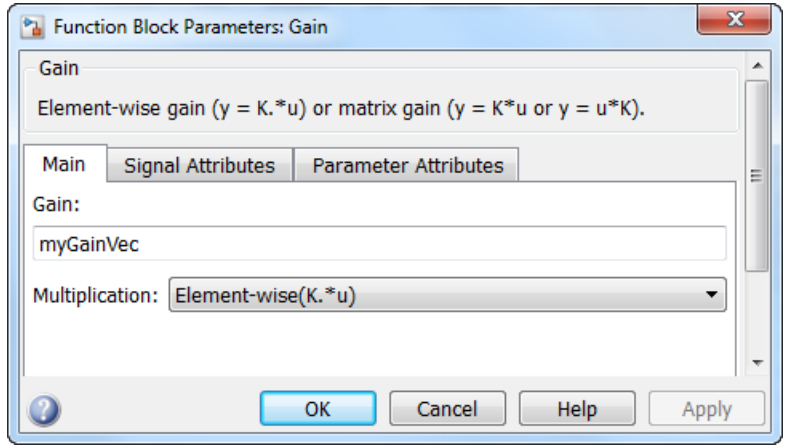
Configure Loop Unrolling Threshold

The **Loop unrolling threshold** parameter on the **Optimization > Signals and Parameters** pane determines when a wide signal or parameter should be wrapped into a `for` loop and when it should be generated as a separate statement for each element of the signal. The default threshold value is 5.

For example, consider the model below:

The gain parameter of the Gain block is the vector `myGainVec`.



Assume that the loop unrolling threshold value is set to the default, 5.

If `myGainVec` is declared as

```
myGainVec = [1:10];
```

an array of 10 elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters_`*`model`* data structure. The size of the gain array exceeds the loop unrolling threshold. Therefore, the code generated for the Gain block iterates over the array in a `for` loop, as shown in the following code:

```
{
    int32_T i1;

    /* Gain: '<Root>/Gain' */
    for(i1=0; i1<10; i1++) {
      myGainVec_B.Gain_f[i1] = rtb_foo *
        myGainVec_P.Gain_Gain[i1];
    }
  }
```

If `myGainVec` is declared as

```
myGainVec = [1:3];
```

an array of three elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters` data structure. The size of the gain array is below the loop unrolling threshold. The generated code consists of inline references to each element of the array, as in the code below.

```
/* Gain: '<Root>/Gain' */
  myGainVec_B.Gain_f[0] = rtb_foo * myGainVec_P.Gain_Gain[0];
  myGainVec_B.Gain_f[1] = rtb_foo * myGainVec_P.Gain_Gain[1];
  myGainVec_B.Gain_f[2] = rtb_foo * myGainVec_P.Gain_Gain[2];
```

See “Explore Variable Names and Loop Rolling” (Simulink Coder) for more information on loop rolling.

Note When a model includes Stateflow charts or MATLAB Function blocks, you can apply a set of Stateflow optimizations on the **Optimization > Stateflow** pane. The settings you select for the Stateflow options also apply to MATLAB Function blocks in the model. This is because the MATLAB Function blocks and Stateflow charts are built on top of the same technology and share a code base. You do not need a Stateflow license to use MATLAB Function blocks.

Use `memcpy` Function to Optimize Generated Code for Vector Assignments

In this section...

You can use the **Use memcpy for vector assignment** parameter to optimize generated code for vector assignments by replacing `for` loops with `memcpy` function calls. The `memcpy` function is more efficient than `for`-loop controlled element assignment for large data sets. This optimization improves execution speed.

Selecting the **Use memcpy for vector assignment** parameter enables the associated parameter **Memcpy threshold (bytes)**, which allows you to specify the minimum array size in bytes for which `memcpy` function calls should replace `for` loops in the generated code. For more information, see "Use memcpy for vector assignment" (Simulink) and "Memcpy threshold (bytes)" (Simulink). In considering whether to use this optimization,

- Verify that your target supports the `memcpy` function.
- Determine whether your model uses signal vector assignments (such as `Y=expression`) to move large amounts of data, for example, using the Selector block.

To apply this optimization,

1. Consider first generating code without this optimization and measuring its execution speed, to establish a baseline for evaluating the optimized assignment.
2. Select **Use memcpy for vector assignment** and examine the setting of **Memcpy threshold (bytes)**, which by default specifies 64 bytes as the minimum array size for which `memcpy` function calls replace `for` loops. Based on the array sizes used in your application's signal vector assignments, and target environment considerations that might bear on the threshold selection, accept the default or specify another array size.
3. Generate code, and measure its execution speed against your baseline or previous iterations. Iterate on steps 2 and 3 until you achieve an optimal result.

Note: The `memcpy` optimization may not occur under certain conditions, including when other optimizations have a higher precedence than the `memcpy` optimization, or when the

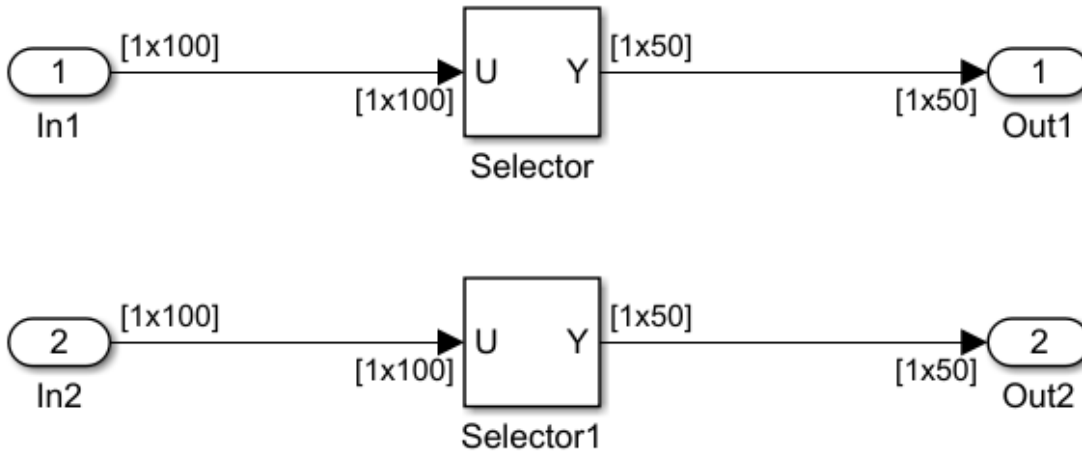
generated code is originating from Target Language Compiler (TLC) code, such as a TLC file associated with an S-function block.

Note: If you are licensed for Embedded Coder software, you can use a code replacement library (CRL) to provide your own custom implementation of the `memcpy` function to be used in generated model code. For more information, see "Memory Function Code Replacement" on page 51-96.

Example Model

To examine the result of using the **Use memcpy for vector assignment** parameter on the generated vector assignment code, create a model that generates signal vector assignments. For example,

1. Use In, Out, and Selector blocks to create the following model.



2. Open Model Explorer and configure the **Signal Attributes** for the `In1` and `In2` source blocks. For each, set **Port dimensions** to `[1,100]`, and set **Data type** to `int32`. Apply the changes and save the model. In this example, the model has the name `vectorassign`.
3. For each Selector block, set the **Index** parameter to `1:50`. Set the **Input port size** parameter to `100`.

Generate Code

1. The **Use memcpy for vector assignment** parameter is on by default. To turn off the parameter, go to the **Optimization > Signals and Parameters** pane and clear the **Use memcpy for vector assignment** parameter.
2. Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the **Create code generation report**. Then go to the **Code Generation** pane, select the **Generate code only** option, and generate code for the model. When code generation completes, the HTML code generation report is displayed.
3. In the HTML code generation report, click the `vectorassign.c` section and inspect the model step function. Notice that the vector assignments are implemented using `for` loops.

```
/* Model step function */
void vectorassign_step(void)
{
  int32_T i;
  for (i = 0; i < 50; i++) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In1'
     */
    vectorassign_Y.Out1[i] = vectorassign_U.In1[i];

    /* Outport: '<Root>/Out2' incorporates:
     *  Inport: '<Root>/In2'
     */
    vectorassign_Y.Out2[i] = vectorassign_U.In2[i];
  }
}
```

Generate Code with Optimization

1. Go to the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box and select the **Use memcpy for vector assignment** option. Leave the **Memcpy threshold (bytes)** option at its default setting of `64`. Apply the changes and regenerate code for the model. When code generation completes, the HTML code generation report again is displayed.
2. In the HTML code generation report, click the `vectorassign.c` section and inspect the model output function. Notice that the vector assignments now are implemented using `memcpy` function calls.

```
/* Model step function */
void vectorassign_step(void)
{
```

```
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   */
  memcpy(&vectorassign_Y.Out1[0], &vectorassign_U.In1[0], 50U * sizeof(real_T));

  /* Outport: '<Root>/Out2' incorporates:
   *  Inport: '<Root>/In2'
   */
  memcpy(&vectorassign_Y.Out2[0], &vectorassign_U.In2[0], 50U * sizeof(real_T));
}
```

Generate Target Optimizations Within Algorithm Code

Some application components are hardware-specific and cannot simulate on a host system. For example, consider a component that includes `pragmas` and assembly code for enabling hardware instructions for saturate on add operations or a Fast Fourier Transform (FFT) function.

The following table lists integration options to customize generated algorithm code with target-specific optimizations.

Note: Solutions marked with *EC only* require an Embedded Coder license.

If...	Then...	For More Information, See
You want to optimize the execution speed and memory of the model code by replacing default math functions and operators with target-specific code	*EC only*—Implement function and operator replacements by using the Code Replacement Tool, code replacement library (CRL) API, and Code Replacement Viewer to create, examine, validate, and register hardware-specific replacement tables	"Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®"
You want to control how code generation technology declares, stores, and represents signals, tunable parameters, block states, and data objects in generated code	*EC only*—Design (create) and apply custom storage classes	• `rtwdemo_cscpredef` • `rtwdemo_importstruct` • `rtwdemo_advsc` • "Custom Storage Classes"

Note: To simulate an algorithm that includes target-specific elements in a host environment, you must create code that is equivalent to the target code and can run in the host environment.

Remove Code for Blocks That Have No Effect on Computational Results

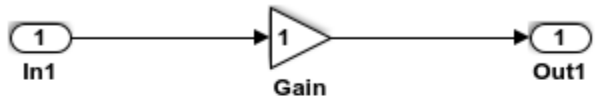
This example shows how the code generator optimizes generated code by removing code that has no effect on computational results. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

Example

In the model rtwdemo_blockreduction, a Gain block of value `1.0` is in between Inport and Outport blocks.

```
model = 'rtwdemo_blockreduction';
open_system(model);
```



Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
set_param(model,'BlockReduction','off');
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction
```

Here is the code from `rtwdemo_blockreduction.c`.

```
cfile = fullfile(cgDir,'rtwdemo_blockreduction_ert_rtw','rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */',...
    '/* Model initialize function */', 1, 0);
```

```
/* Model step function */
void rtwdemo_blockreduction_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In1'
   */
  rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **All Parameters** tab, select **Block reduction**. This optimization is on by default.

Alternately, use the command-line API to enable the optimization.

```
set_param(model,'BlockReduction','on');
```

Generate Code with Optimization

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction
```

Here is the optimized code from `rtwdemo_blockreduction.c`.

```
cfile = fullfile(cgDir,'rtwdemo_blockreduction_ert_rtw','rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */',...
    '/* Model initialize function */', 1, 0);
```

```
/* Model step function */
void rtwdemo_blockreduction_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
```

```
   *  Inport: '<Root>/In1'
   */
  rtwdemo_blockreduction_Y.Out1 = rtwdemo_blockreduction_U.In1;
}
```

Because multiplying the input signal by a value of `1.0` does not impact computational results, the code generator excludes the Gain block from the generated code. Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

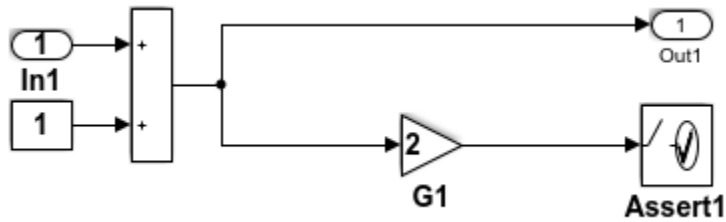
Eliminate Dead Code Paths in Generated Code

This example shows how the code generator eliminates dead (that is, unused) code paths from generated code. This optimization increases execution speed and conserves ROM and RAM consumption.

Example

In the model rtwdemo_deadpathElim, the signal leaving the Sum block divides into two separate code paths. The top path is not a dead code path. If the user disables the Assertion block, the bottom path becomes a dead code path.

```
model = 'rtwdemo_deadpathElim';
open_system(model);
```



Generate Code with an Enabled Assertion Block

1. For the Assertion block, open the block parameters dialog box.
2. Select the **Enable assertion** box. Alternatively, use the command-line API to enable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'on');
```

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_deadpathElim
```

```
### Successful completion of build procedure for model: rtwdemo_deadpathElim
```

Because the Assertion block is enabled, these lines of `rtwdemo_deadpathElim.c` include code for the Gain and Assertion blocks.

```
cfile = fullfile(cgDir,'rtwdemo_deadpathElim_grt_rtw','rtwdemo_deadpathElim.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize function */', 0, 1);
```

```
void rtwdemo_deadpathElim_step(void)
{
  /* Sum: '<Root>/Sum1' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Inport: '<Root>/In1'
   */
  rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

  /* Assertion: '<Root>/Assert1' incorporates:
   *  Gain: '<Root>/G1'
   */
  utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```

Generate Code with a Disabled Assertion Block

Disable the Assertion block to generate a dead code path. The code generator detects the dead code path and eliminates it from the generated code.

1. For the Assertion block, open the Block Parameters dialog box.
2. Deselect the **Enable assertion** box.

Alternatively, use the command-line API to disable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'off');
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_deadpathElim
### Successful completion of build procedure for model: rtwdemo_deadpathElim
```

Because the Assertion block is disabled, these lines of `rtwdemo_deadpathElim.c` do not include code for the Gain and Assertion blocks.

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize function */', 0, 1);
```

```
void rtwdemo_deadpathElim_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum1'
   */
  rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;
}
```

Close the model and clean-up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

For another example of how the code generator eliminates dead code paths in the generated code, see rtwdemo_deadpath.

Floating-Point Multiplication to Handle a Net Slope Correction

This example shows how to use floating-point multiplication to handle a net slope correction. When converting floating-point data types to fixed-point data types in the generated code, a net slope correction is one method of scaling fixed-point data types. Scaling the fixed-point data types avoids overflow conditions and minimizes quantization errors.

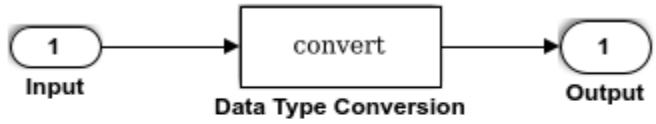
For processors that support efficient multiplication, using floating-point multiplication to handle a net slope correction improves code efficiency. If the net slope correction has a value that is not a power of two, using division improves precision.

Note: This example requires a Fixed-Point Designer™ license.

Example

In the model rtwdemo_float_mul_for_net_slope_correction, a Convert block converts an input signal from a floating-point data type to a fixed-point data type. The net slope correction has a value of 3.

```
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```



Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope
```

In these lines of `rtwdemo_float_mul_for_net_slope_correction.c` code, the code generator divides the input signal by `3.0F` .

```
cfile = fullfile(cgDir,'rtwdemo_float_mul_for_net_slope_correction_ert_rtw',...
    'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
  /* Outport: '<Root>/Output' incorporates:
   *  DataTypeConversion: '<Root>/Data Type Conversion'
   *  Inport: '<Root>/Input'
   */
  rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Use floating-point multiplication to handle net slope corrections**. This optimization is on by default.

Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'UseFloatMulNetSlope', 'on');
```

Generate Code with Optimization

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope
```

In the optimized code, the code generator multiplies the input signal by the reciprocal of `3.0F` , that is `0.333333343F` .

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
  /* Outport: '<Root>/Output' incorporates:
   *  DataTypeConversion: '<Root>/Data Type Conversion'
   *  Inport: '<Root>/Input'
   */
  rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input * 0.333333343F));
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

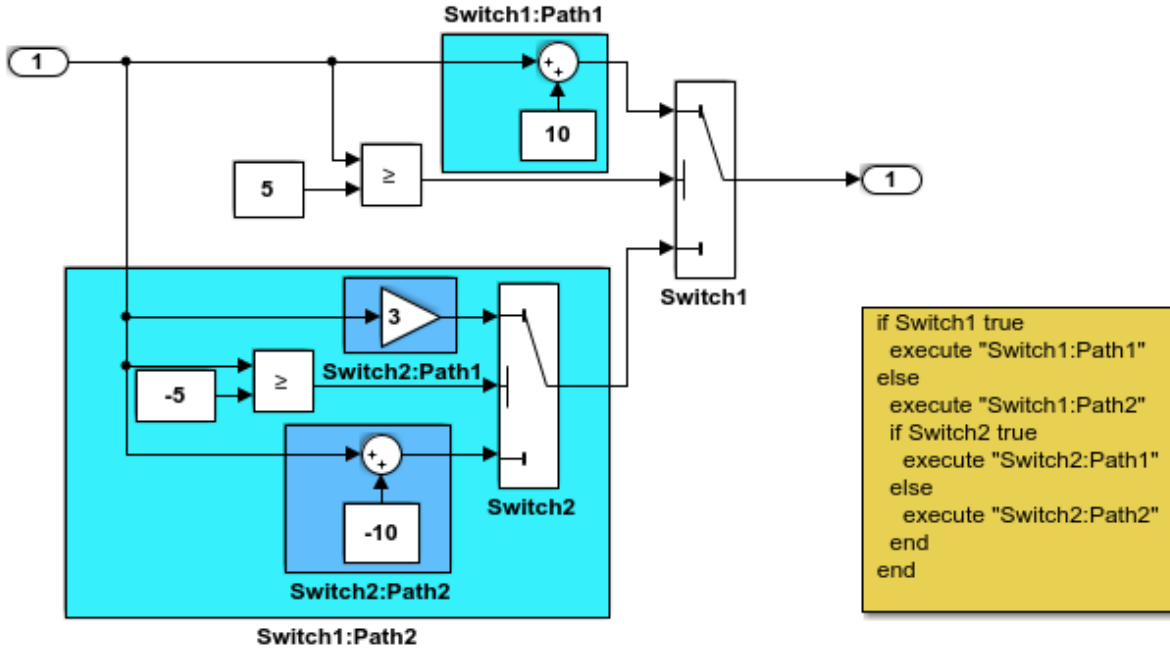
Use Conditional Input Branch Execution

This example shows how to optimize the generated code for a model that contains Switch and Multiport Switch blocks. When you select the model configuration parameter **Conditional input branch execution**, Simulink executes only blocks that compute the control input and data input that the control input selects. This optimization improves execution speed.

Example Model

In this example, switch paths are conditionally executed. If `Switch1` control input is true, `Switch1` executes blocks grouped in the `Switch1:Path1` branch. If `Switch1` control input is false, `Switch1` executes blocks grouped in the `Switch1:Path2` branch. If `Switch1` executes blocks in the `Switch1:Path2` branch and `Switch2` control input is true, `Switch2` executes blocks in the `Switch2:Path1` branch. If `Switch2` control input is false, `Switch2` executes blocks in the `Switch2:Path2` branch. The pseudo code shows this logic.

```
model='rtwdemo_condinput';
open_system(model);
```



This model shows conditional input branch execution performed by Simulink and Simulink Coder. Conditional input branch execution improves simulation and code generation execution performance. In this example, switch paths are conditionally executed. That is, if Switch1's control input is true, Switch1 executes blocks grouped in the "Switch1:Path1" branch. Otherwise, it executes blocks grouped in the "Switch1:Path2" branch. If blocks in "Switch1:Path2" are executed, Switch2 executes the "Switch2:Path1" branch if its control input is true. Otherwise, it executes the "Switch2:Path2" branch. This logic is illustrated by the pseudo code above.

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Generate Code

The **Conditional input branch execution** parameter is on by default. Enter the following command-line API to turn off the parameter.

```
set_param(model, 'ConditionallyExecuteInputs', 'off');
```

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_condinput
### Successful completion of build procedure for model: rtwdemo_condinput
```

View the generated code without the optimization. These lines of code are in the `rtwdemo_condinput.c` file.

```
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_condinput_step(void)
{
  /* Switch: '<Root>/ Switch2' incorporates:
   *  Constant: '<Root>/ C_10'
   *  Constant: '<Root>/C_5'
   *  Gain: '<Root>/  G3'
   *  Inport: '<Root>/input'
   *  RelationalOperator: '<Root>/Relational Operator'
   *  Sum: '<Root>/ Sum'
   */
  if (rtwdemo_condinput_U.input >= -5.0) {
    rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
  } else {
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
  }

  /* End of Switch: '<Root>/ Switch2' */
```

```
  /* Switch: '<Root>/Switch1' incorporates:
   *  Constant: '<Root>/C5'
   *  Inport: '<Root>/input'
   *  RelationalOperator: '<Root>/Relational Operator1'
   */
  if (rtwdemo_condinput_U.input >= 5.0) {
    /* Outport: '<Root>/output' incorporates:
     *  Constant: '<Root>/  C10'
     *  Sum: '<Root>/ Sum1'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
  }

  /* End of Switch: '<Root>/Switch1' */
}
```

The generated code contains an `if-else` statement for the `Switch1` block and an `if` statement for the `Switch2` block. Therefore, the generated code for `Switch1:Path2` executes even if the `if` statement for `Switch1:Path1` evaluates to true.

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **All Parameters** tab, select **Conditional input branch execution**. Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'ConditionallyExecuteInputs','on');
```

Generate Code with Optimization

```
rtwbuild(model)
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

### Starting build procedure for model: rtwdemo_condinput
### Successful completion of build procedure for model: rtwdemo_condinput

/* Model step function */
void rtwdemo_condinput_step(void)
{
  /* Switch: '<Root>/Switch1' incorporates:
   *  Constant: '<Root>/C5'
   *  Constant: '<Root>/C_5'
   *  Inport: '<Root>/input'
```

```
   *  RelationalOperator: '<Root>/Relational Operator'
   *  RelationalOperator: '<Root>/Relational Operator1'
   *  Switch: '<Root>/ Switch2'
   */
  if (rtwdemo_condinput_U.input >= 5.0) {
    /* Outport: '<Root>/output' incorporates:
     *  Constant: '<Root>/  C10'
     *  Sum: '<Root>/ Sum1'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
  } else if (rtwdemo_condinput_U.input >= -5.0) {
    /* Outport: '<Root>/output' incorporates:
     *  Gain: '<Root>/  G3'
     *  Switch: '<Root>/ Switch2'
     */
    rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
  } else {
    /* Outport: '<Root>/output' incorporates:
     *  Constant: '<Root>/ C_10'
     *  Sum: '<Root>/ Sum'
     *  Switch: '<Root>/ Switch2'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
  }

  /* End of Switch: '<Root>/Switch1' */
}
```

The generated code contains one `if` statement. The generated code for `Switch1:Path2` only executes if the `if` statement evaluates to false.

Close Model and Code Generation Report

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Optimize Generated Code for Complex Signals

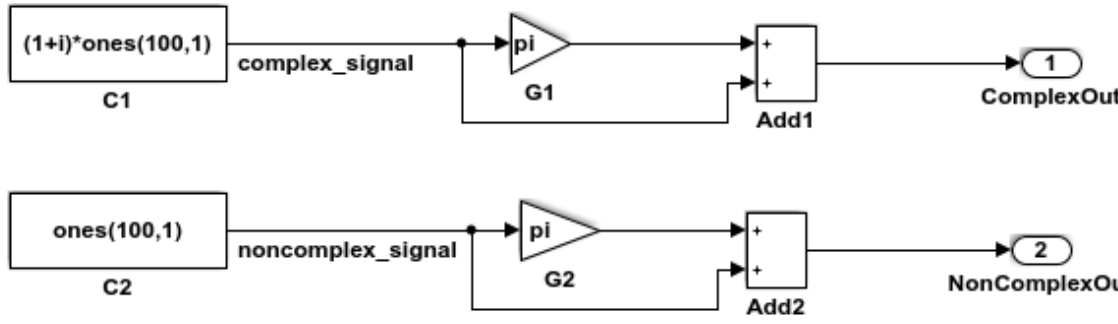
This example shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using **Simulation > Update Diagram**. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example:

- Expression Folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Example Model

```
model='rtwdemo_complex';
open_system(model);
```



This model shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using Simulation > Update Diagram. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example,

- o Expression folding: Gain and Sum operations on the complex signal are folded into a single expression.
- o For-loop fusion: Two separate for-loops, one for the complex signal and one for the noncomplex signal, are combined into a single for-loop.
- o Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Speed Up Linear Algebra in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain linear algebra functions in a MATLAB Function block, specify that the code generator produce LAPACK calls. LAPACK is a software library for numerical linear algebra. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet certain criteria, the code generator produces the LAPACK calls. Otherwise, the code generator produces code for the linear algebra functions.

The code generator uses the LAPACK library that you specify. Specify a LAPACK library that is optimized for your execution environment. See www.netlib.org/lapack/faq.html#_what_and_where_are_the_lapack_vendors_implementations.

Specify LAPACK Library

To generate LAPACK calls, you must have access to a LAPACK callback class. A LAPACK callback class specifies the LAPACK library and LAPACKE header file for the LAPACK calls. To indicate that you want to generate LAPACK calls and that you want to use a specific LAPACK library, specify the name of the LAPACK callback class. In the Configuration Parameters dialog box, in the **Code Generation** category, on the **All Parameters** tab, set **Custom LAPACK library callback** to the name of the callback class, for example, `useMyLAPACK`.

Write LAPACK Callback Class

To specify the locations of a particular LAPACK library and LAPACKE header file, write a LAPACK callback class. Share the callback class with others who want to use this LAPACK library for LAPACK calls in generated code.

The callback class must derive from the abstract class coder.LAPACKCallback. Use the following example callback class as a template.

```
classdef useMyLAPACK < coder.LAPACKCallback
    methods (Static)
        function hn = getHeaderFilename()
            hn = 'mylapacke_custom.h';
        end
```

```
        function updateBuildInfo(buildInfo, buildctx)
            buildInfo.addIncludePaths(fullfile(pwd,'include'));
            libName = 'mylapack';
            libPath = fullfile(pwd,'lib');
            [~,linkLibExt] = buildctx.getStdLibInfo();
            buildInfo.addLinkObjects([libName linkLibExt], libPath, ...
                '', true, true);
            buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
            buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
        end
    end
end
```

You must provide the `getHeaderFilename` and `updateBuildInfo` methods. The `getHeaderFilename` method returns the LAPACKE header file name. In the example callback class, replace `mylapacke_custom.h` with the name of your LAPACKE header file. The `updateBuildInfo` method provides the information required for the build process to link to the LAPACK library. Use code like the code in the template to specify the location of header files and the full path name of the LAPACK library. In the example callback class, replace `mylapack` with the name of your LAPACK library.

If your compiler supports only complex data types that are represented as structures, include these lines in the `updateBuildInfo` method.

```
buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
```

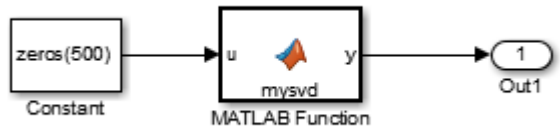
Generate LAPACK Calls by Specifying a LAPACK Callback Class

This example shows how to generate code that calls LAPACK functions in a specific LAPACK library. For this example, assume that the LAPACK callback class `useMyLAPACK` specifies the LAPACK library that you want.

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a linear algebra function. For example, add the function `mysvd` that calls the MATLAB function `svd`.

   ```
   function s = mysvd(A)
       %#codegen
       s = svd(A);
   end
   ```

4 Add a Constant block to the left of the MATLAB Function block. Set the value to `zeros(500)`.
5 Add an Outport block to the right of the MATLAB Function block.
6 Connect the blocks.



7 In the Configuration Parameters dialog box, in the **Code Generation** category, on the **All Parameters** tab, set **Custom LAPACK library callback** to `useMyLAPACK`.

   The callback class must be on the MATLAB path.
8 Build the model.

If the input to `mysvd` is large enough, the code generator produces a LAPACK call for `svd`. Here is an example of a call to the LAPACK library function for `svd`.

```
info_t = LAPACKE_dgesvd(LAPACK_COL_MAJOR, 'N', 'N', (lapack_int)500,
    (lapack_int)500, &A[0], (lapack_int)500, &S[0], NULL, (lapack_int)1, NULL,
    (lapack_int)1, &superb[0]);
```

Locate LAPACK Library in Execution Environment

The LAPACK library must be available in your execution environment. If your LAPACK library is shared, use environment variables or linker options to specify the location of the LAPACK library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD_LIBRARY_PATH environment variable or use the `rpath` linker option.
- On a Mac OS X, modify the DYLD_LIBRARY_PATH environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your coder.LAPACKCallback class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays.
- Disable dynamic memory allocation for MATLAB Function blocks.
- Modify the dynamic memory allocation threshold.

Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” (Simulink).

Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, on the **All Parameters** tab, in the **Simulation Target > Advanced parameters** category, clear or select the **Dynamic memory allocation in MATLAB Function blocks** check box.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, on the **All Parameters** tab, in the **Simulation Target > Advanced parameters** category, set the **Dynamic memory allocation threshold in MATLAB Function blocks** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to `0`.

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

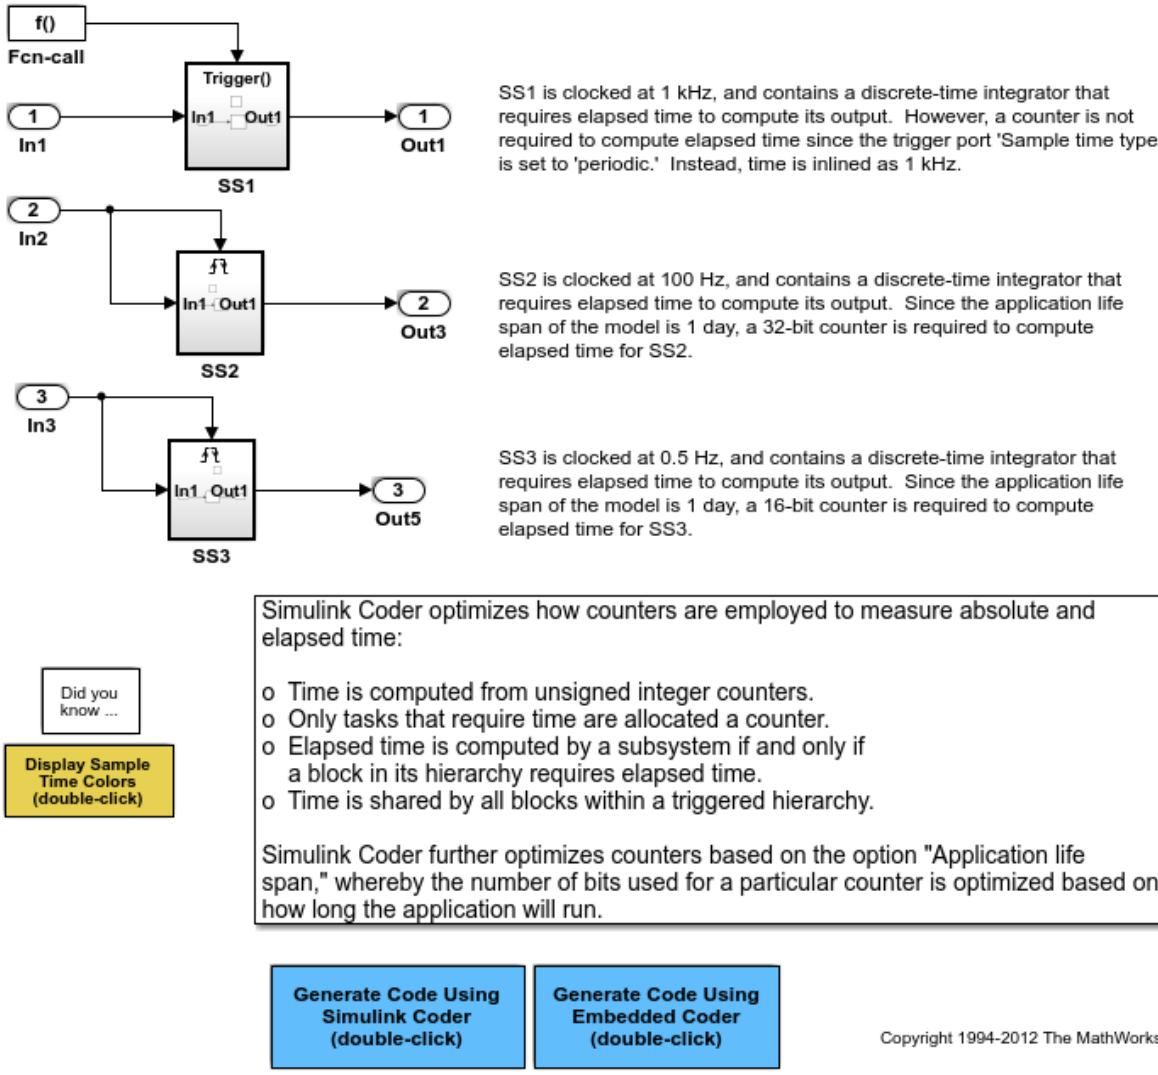
The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

Open Example Model

Open the example model `rtwdemo_abstime`.



The model consists of three subsystems `SS1`, `SS2`, and `SS3`. On the **Optimization** tab, the **Application lifespan (days)** parameter is set to the default, which is `auto`.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

Generate Code and Report

1. Create a temporary folder for the build and inspection process.

2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.

3. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review Generated Code

Open the generated source file `rtwdemo_abstime.c`.

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
    uint32_T clockTickH1;
    uint32_T clockTick2;
    uint32_T clockTickH2;
    struct {
```

```
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};
```

Four 32-bit unsigned integers, `clockTick1` , `clockTickH1` , `clockTick2` , and `clockTickH2` are counters for storing the elapsed time of subsystems `SS2` and `SS3`.

Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review the Regenerated Code

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
    uint16_T clockTick2;
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};
```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for `SS2`

- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for `SS3`

Minimize Memory Requirements During Code Generation

When the code generator produces code, it creates an partial representation of your model (called *`model`*`.rtw`), which the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language, (for example, C). Parameters and data are normally copied into the *`model`*`.rtw` file, whether they originate in the model itself or come from variables or objects in a workspace.

Models which have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow down code generation because of the need to copy their data to *`model`*`.rtw`. You can improve code generation speed by limiting the size of data that is copied by using a `set_param` command, described below.

Data vectors such as those for parameters, lookup tables, and constant blocks whose sizes exceed a specified value are not copied into the *`model`*`.rtw` file. In place of the data vectors, the code generator places a special reference key in the *`model`*`.rtw` file that enables the Target Language Compiler to access the data directly from the Simulink software and format it directly into the generated code. This results in maintaining only one copy of large data vectors in memory.

You can specify the maximum number of elements that a parameter or other data source can have for the code generator to represent it literally in the *`model`*`.rtw` file. Whenever this threshold size is exceeded, the product writes a reference to the data to the *`model`*`.rtw` file, rather than its values. The default threshold value is 10 elements, which you can verify with

```
get_param(0, 'RTWDataReferencesMinSize')
```

To set the threshold to a different value, type the following `set_param` function in the MATLAB Command Window:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which reference keys are to be used in place of actual data values.

Optimize Generated Code Using Boolean Data for Logical Signals

Optimize generated code by storing logical signals as Boolean data. When you select the model configuration parameter **Implement logic signals as Boolean data (vs. double)**, blocks that generate logic signals output Boolean signals.

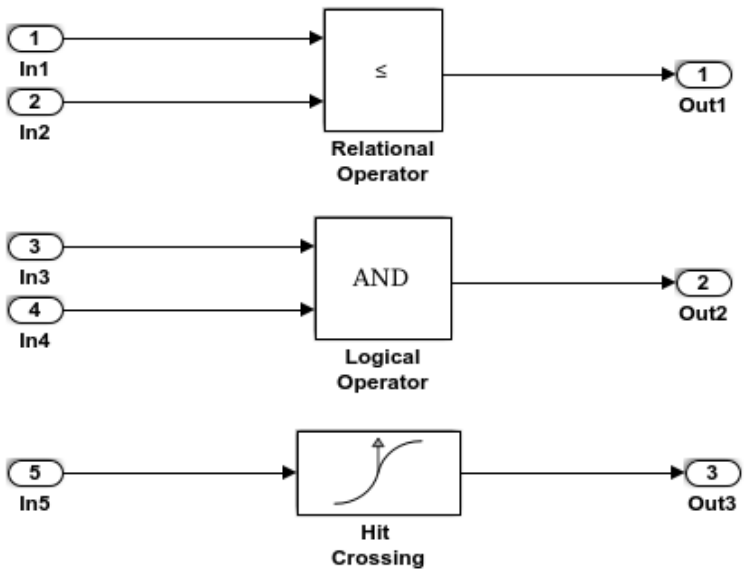
The optimization:

- Reduces the ROM and RAM consumption.
- Improves execution speed.

Example Model

Consider the model rtwdemo_logicalAsBoolean. The outputs of the `Relational Operator`, `Logical Operator` and `HitCrossing` blocks are `double`, even though they represent logical data.

```
model = 'rtwdemo_logicalAsBoolean';
open_system(model);
```



Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean
```

View the generated code without the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_logicalAsBoolean_ert_rtw',...
    'rtwdemo_logicalAsBoolean.h');
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (auto storage) */',1,0);
```

```
/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  real_T Out1;                         /* '<Root>/Out1' */
  real_T Out2;                         /* '<Root>/Out2' */
  real_T Out3;                         /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **All Parameters** tab, select **Implement logic signals as Boolean data (vs. double)**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleanDataType','on');
```

Generate Code with Optimization

The generated code stores the logical signal output as Boolean data.

Build the model.

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean
```

View the generated code with the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (auto storage) */',1,0);

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  boolean_T Out1;                      /* '<Root>/Out1' */
  boolean_T Out2;                      /* '<Root>/Out2' */
  boolean_T Out3;                      /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Memory Usage for Boolean and State Configuration Variables

1. Open the Model Configuration Parameters dialog box.
2. In the Model Configuration Parameters dialog box, select the **Optimization > Stateflow** pane.
3. Choose from these options:

   - **Use bitsets for storing state configuration** — Reduces the amount of memory that stores state configuration variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.
   - **Use bitsets for storing Boolean data** — Reduces the amount of memory that stores Boolean variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

   Note: You cannot use bitsets when you generate code for these cases:

   - An external mode simulation
   - A target that specifies an explicit structure alignment

Customize Stack Space Allocation

Your application might be constrained by limited memory. Controlling the maximum allowable size for the stack is one way to modify whether data is defined as local or global in the generated code. You can limit the use of stack space by specifying a positive integer value for the "Maximum stack size (bytes)" (Simulink) parameter, on the **Optimization > Signals and Parameters** pane of the Configuration parameter dialog box. Specifying the maximum allowable stack size provides control over the number of local and global variables in the generated code. Specifically, lowering the maximum stack size might generate more variables into global structures. The number of local and global variables help determine the required amount of stack space for execution of the generated code.

The default setting for "Maximum stack size (bytes)" (Simulink) is `Inherit from target`. In this case, the value of the maximum stack size is the smaller value of the following: the default value set by the code generator (200,000 bytes) or the value of the TLC variable `MaxStackSize` found in the system target file (`ert.tlc`).

To specify a smaller stack size for your application, select the `Specify a value` option of the **Maximum stack size (bytes)** parameter and enter a positive integer value. To specify a smaller stack size at the command line, use:

```
set_param(model_name, 'MaxStackSize', 65000);
```

Note: For overall executable stack usage metrics, you might want to do a target-specific measurement, such as using runtime (empirical) analysis or static (code path) analysis with object code.

It is recommended that you use the **Maximum stack size (bytes)** parameter to control stack space allocation instead of modifying the TLC variable, `MaxStackSize`, in the system target file. However, a target author might want to set the TLC variable, `MaxStackSize`, for a target. To set `MaxStackSize`, use `assign` statements in the system target file (`ert.tlc`), as in the following example.

```
%assign MaxStackSize = 4096
```

Write your `%assign` statements in the `Configure RTW code generation settings` section of the system target file. The `%assign` statement is described in "Target Language Compiler" (Simulink Coder).

See Also

"Maximum stack size (bytes)" (Simulink)

Optimize Generated Code Using `memset` Function

This example shows how to optimize the generated code by using the `memset` function to clear the internal storage. When you select the model configuration parameter **Use memset to initialize floats and doubles to 0.0**, the `memset` function clears internal storage, regardless of type, to the integer bit pattern `0` (that is, all bits are off).

If your compiler and target CPU both represent floating-point zero with the integer bit pattern `0`, consider setting this parameter to gain execution and ROM efficiency.

NOTE: The command-line values are the reverse of the settings values. 'on' in the command line corresponds to clearing the setting. `'off'` in the command line corresponds to selecting the setting.

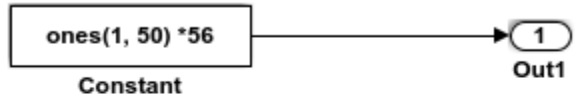
This optimization:

- Reduces ROM consumption.
- Improves execution speed.

Example Model

Consider the model matlab:rtwdemo_memset.

```
model = 'rtwdemo_memset';
open_system(model);
```



Generate Code

The code generator uses a loop to initialize the `Constant` block values.

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset
```

View the generated code without the optimization. These lines of code are in `rtwdemo_memset.c`.

```
cfile = fullfile(cgDir,'rtwdemo_memset_grt_rtw','rtwdemo_memset.c');
rtwdemodbtype(cfile,'/* Model initialize function */',...
    '/* Model terminate function */',1,0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

  /* external outputs */
  {
    int32_T i;
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 0.0;
    }
  }

  {
    int32_T i;

    /* ConstCode for Outport: '<Root>/Out1' */
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 56.0;
    }

    /* End of ConstCode for Outport: '<Root>/Out1' */
  }
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **All Parameters** tab, select **Use memset to initialize floats and doubles to 0.0**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'InitFltsAndDblsToZero','off');
```

Generate Code with Optimization

The code generator uses the `memset` function to initialize the `Constant` block values.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset
```

View the generated code with the optimization. These lines of code are in `rtwdemo_memset.c`.

```
rtwdemodbtype(cfile,'/* Model initialize function */',...
    '/* Model terminate function */',1,0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

  /* external outputs */
  (void) memset(&rtwdemo_memset_Y.Out1[0], 0,
                50U*sizeof(real_T));

  {
    int32_T i;

    /* ConstCode for Outport: '<Root>/Out1' */
    for (i = 0; i < 50; i++) {
```

```
      rtwdemo_memset_Y.Out1[i] = 56.0;
    }

    /* End of ConstCode for Outport: '<Root>/Out1' */
  }
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

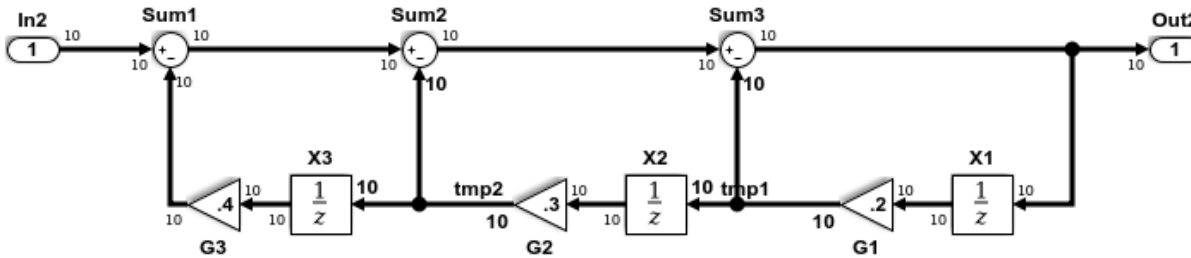
Vector Operation Optimization

This example shows how Simulink® Coder™ optimizes generated code by setting block output that generates vectors to scalars, for blocks such as the Mux, Sum, Gain, and Bus. This optimization reduces stack memory by replacing temporary local arrays with local variables.

Example Model

In the model, rtwdemo_VectorOptimization, the output of Gain blocks `G1` and `G2` are the vector signals `tmp1` and `tmp2`. These vectors have a width of 10.

```
model = 'rtwdemo_VectorOptimization';
open_system(model);
set_param(model, 'SimulationCommand', 'update')
```



Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_VectorOptimization
### Successful completion of build procedure for model: rtwdemo_VectorOptimization
```

The optimized code is in `rtwdemo_VectorOptimization.c`. The signals `tmp1` and `tmp2` are the local variables `rtb_tmp1` and `rtb_tmp2`.

```
cfile = fullfile(cgDir,'rtwdemo_VectorOptimization_grt_rtw',...
    'rtwdemo_VectorOptimization.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_VectorOptimization_step(void)
{
  int32_T i;
  real_T rtb_tmp2;
  real_T rtb_tmp1;
  real_T rtb_Sum3;
  for (i = 0; i < 10; i++) {
    /* Gain: '<Root>/G2' incorporates:
     *  UnitDelay: '<Root>/X2'
     */
    rtb_tmp2 = 0.3 * rtwdemo_VectorOptimization_DW.X2_DSTATE[i];

    /* Gain: '<Root>/G1' incorporates:
     *  UnitDelay: '<Root>/X1'
     */
    rtb_tmp1 = 0.2 * rtwdemo_VectorOptimization_DW.X1_DSTATE[i];

    /* Sum: '<Root>/Sum3' incorporates:
     *  Gain: '<Root>/G3'
     *  Inport: '<Root>/In2'
     *  Sum: '<Root>/Sum1'
     *  Sum: '<Root>/Sum2'
     *  UnitDelay: '<Root>/X3'
     */
    rtb_Sum3 = ((rtwdemo_VectorOptimization_U.In2[i] - 0.4 *
                 rtwdemo_VectorOptimization_DW.X3_DSTATE[i]) - rtb_tmp2) -
      rtb_tmp1;

    /* Outport: '<Root>/Out2' */
    rtwdemo_VectorOptimization_Y.Out2[i] = rtb_Sum3;

    /* Update for UnitDelay: '<Root>/X3' */
    rtwdemo_VectorOptimization_DW.X3_DSTATE[i] = rtb_tmp2;
```

```
    /* Update for UnitDelay: '<Root>/X2' */
    rtwdemo_VectorOptimization_DW.X2_DSTATE[i] = rtb_tmp1;

    /* Update for UnitDelay: '<Root>/X1' */
    rtwdemo_VectorOptimization_DW.X1_DSTATE[i] = rtb_Sum3;
  }
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

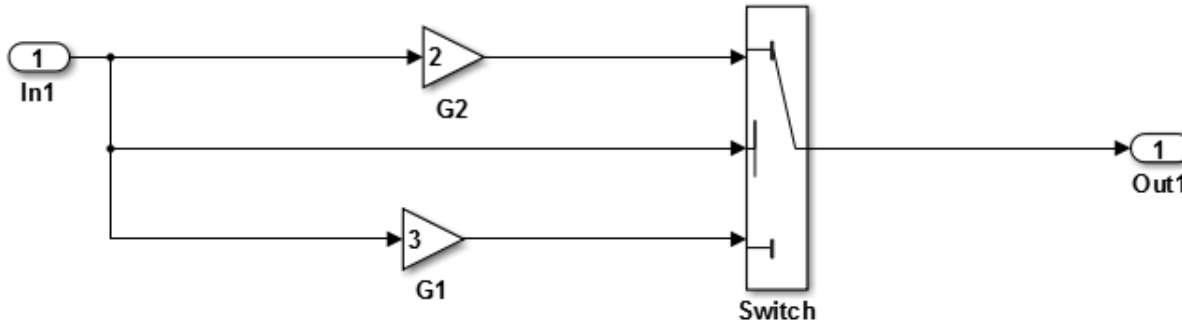
Enable and Reuse Local Block Outputs in Generated Code

In this section...

This example shows how to specify block output as local variables. The code generator can potentially reuse these local variables in the generated code. Declaring block output as local variables conserves ROM consumption. Reusing local variables conserves RAM consumption, reduces data copies, and increases execution speed.

Example Model

1 Use Inport, Outport, Gain, and Switch blocks to create the following model. In this example, the model is named `local_variable_ex`.



2 For `G2`, open the Gain Block Parameters dialog box. Enter a value of `2`.

3 For `G1`, enter a value of `3`.

4 For the Switch block, open the Block Parameters dialog box. For the **Criteria for passing first input** parameter, select `u2>=Threshold`.

Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. Select the **Solver** pane. For the **Type** parameter, select `Fixed-step`.
2. Select the **All Parameters** tab and clear **Signal Storage Reuse**.
3. Select the **Code Generation > Report** pane and select **Create code generation report**.
4. Select the **Code Generation** pane. Select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report appears.
5. In the code generation report, select the `local_variable_ex.c` section and view the model step function. The Gain block outputs are the global variables `local_variable_ex_B.G2` and `local_variable_ex_B.G1`.

```
/* Model step function */
void local_variable_ex_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (local_variable_ex_U.In1 >= 0.0) {
    /* Gain: '<Root>/G2' */
    local_variable_ex_B.G2 = 2.0 * local_variable_ex_U.In1;

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = local_variable_ex_B.G2;
  } else {
    /* Gain: '<Root>/G1' */
    local_variable_ex_B.G1 = 3.0 * local_variable_ex_U.In1;

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = local_variable_ex_B.G1;
  }

  /* End of Switch: '<Root>/Switch' */
```

Enable Local Block Outputs and Generate Code

1. Open the Model Configuration Parameters dialog box. On the **All Parameters** tab, select **Signal Storage Reuse**. **Signal Storage Reuse** enables the following optimization parameters:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Eliminate superfluous local variables (expression folding)**

2 Clear **Reuse local block outputs** and **Eliminate superfluous local variables (expression folding)**.

3 Generate code and view the model step function. There are three local variables in the model step function because you selected the optimization parameter **Enable Local Block Outputs**. The local variables `rtb_G2` and `rtb_G1` hold the outputs of the Gain blocks. The local variable `rtb_Switch` holds the output of the Switch block.

```
/* Model step function */
void local_variable_ex_step(void)
{
  real_T rtb_Switch;
  real_T rtb_G2;
  real_T rtb_G1;

  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (local_variable_ex_U.In1 >= 0.0) {
    /* Gain: '<Root>/G2' */
    rtb_G2 = 2.0 * local_variable_ex_U.In1;
    rtb_Switch = rtb_G2;
  } else {
    /* Gain: '<Root>/G1' */
    rtb_G1 = 3.0 * local_variable_ex_U.In1;
    rtb_Switch = rtb_G1;
  }

  /* End of Switch: '<Root>/Switch' */

  /* Outport: '<Root>/Out1' */
  local_variable_ex_Y.Out1 = rtb_Switch;
```

Reuse Local Block Outputs and Generate Code

1 Open the Model Configuration Parameters dialog box. On the **All Parameters** tab, select **Reuse local block outputs**.

2 Generate code. In the `local_variable_ex.c` section, view the model step function. There is one local variable, `rtb_G2`, that the code generator uses three times.

```
/* Model step function */
void local_variable_ex_step(void)
{
  real_T rtb_G2;

  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (local_variable_ex_U.In1 >= 0.0) {
    /* Gain: '<Root>/G2' */
    rtb_G2 = 2.0 * local_variable_ex_U.In1;
  } else {
    /* Gain: '<Root>/G1' */
    rtb_G2 = 3.0 * local_variable_ex_U.In1;
  }

  /* End of Switch: '<Root>/Switch' */

  /* Outport: '<Root>/Out1' */
  local_variable_ex_Y.Out1 = rtb_G2;
```

The extra temporary variable `rtb_Switch` and the associated data copy is not in the generated code.

Configuration in Embedded Coder

Specify Global Variable Localization

When you generate code for a model, the code generator can optimize variable references by replacing global variables with local variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM. Creating more local variables can increase stack usage.

Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries.
- Global signals across Simulink and Stateflow domains.
- Unused global state variables.
- Redundant local Data Store Memory block signals.

To enable the global variable localization analysis:

1. In the Configuration Parameters dialog box, on the **Code Generation** pane, in the **System target file** box, specify an ERT target.
2. Verify that the `OptimizeBlockIOStorage` parameter is set to '`on`':

   ```
   >> get_param(gcs,'OptimizeBlockIOStorage')
   ans =
         on
   ```

3. Verify that `AdvancedOptControl` is not set to '`-SLCI`':

   ```
   >> get_param(gcs,'AdvancedOptControl')
   ans =
         ''
   ```

4. Set the storage class for signals to `Auto`.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

Set Hardware Implementation Parameters

Specification of target hardware device characteristics (such as word sizes for `char`, `short`, `int`, and `long` data types, or desired rounding behaviors in integer operations) for generated code can be critical in embedded systems development. The **Hardware Implementation** category of parameters in a configuration set provides a way to control such characteristics in simulation and code generation.

By configuring the **Hardware Implementation** parameters of the active configuration set for a model to match the behaviors of your compiler and hardware, you can generate more efficient code. For example, if you specify the **Byte ordering** parameter, you can avoid generation of extra code that tests the byte ordering of the target CPU.

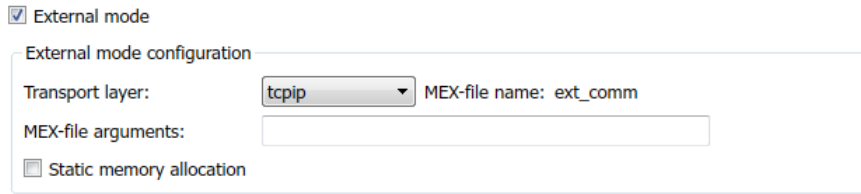
Before generating and deploying code, get familiar with the **Hardware Implementation** pane of the Configuration Parameters dialog box. By default, target hardware microprocessor device details are hidden. To view the details, click the **Device details** arrow. See “Hardware Implementation Pane” (Simulink) in the Simulink documentation and “Configure Run-Time Environment Options” (Simulink Coder) in the Simulink Coder documentation for more information.

You can use the example “Configure Target Hardware Characteristics” (Simulink Coder) to determine characteristics of your C or C++ compiler and target hardware. By using the example model with your target development system and debugger, you can observe the behavior of the code as it executes on the target hardware. You can then use the information to refine hardware target device parameters for your model.

Use External Mode with the ERT Target

Selecting the **External mode** option turns on generation of code to support external mode communication between host (Simulink) and target systems. The Embedded Coder software supports Simulink external mode simulation, as described in the Simulink Coder topic "Set Up and Use Host/Target Communication Channel" (Simulink Coder).

This section discusses external mode options that may be of special interest to embedded systems designers. The next figure shows the **External mode configuration** subpane of the Configuration Parameters dialog box, **Code Generation** > **Interface** pane, with **External mode** selected.



Memory Management

Consider the memory management option **Static memory allocation** before generating external mode code for an embedded target. Static memory allocation is generally desirable, as it reduces overhead and promotes deterministic performance.

When you select the **Static memory allocation** option, static external mode communication buffers are allocated in the target application. When **Static memory allocation** is deselected, communication buffers are allocated dynamically (with `malloc`) at run time.

Generation of Pure Integer Code with External Mode

The Embedded Coder software supports generation of pure integer code when external mode code is generated. To do this, select the **External mode** option and deselect the **Support: floating-point numbers** option on the **Code Generation** > **Interface** pane.

This selection lets you generate external mode code that is free of storage definitions of double or float data type, and allows your code to run on integer-only processors.

If you intend to generate pure integer code with **External mode** on, note the following requirements:

- All trigger signals must be of data type `int32`. Use a Data Type Conversion block if needed.
- When pure integer code is generated, the simulation stop time specified in the **Solver** options is ignored. To specify a stop time, run your target application from the MATLAB command line and use the `-tf` option. (See "Run the External Program" (Simulink Coder) in the Simulink Coder documentation.) If you do not specify this option, the application executes indefinitely (as if the stop time were `inf`).

  When executing pure integer target applications, the stop time specified by the `-tf` command line option is interpreted as the number of base rate ticks to execute, rather than as an elapsed time in seconds. The number of ticks is computed as

  ```
  stop time in seconds / base rate step size in seconds
  ```

Data Copy Reduction in Embedded Coder

Optimize Global Variable Usage

In this section...

To tune your application and choose tradeoffs for execution speed and memory usage, you can choose a global variable reference optimization for the generated code.

In the Configuration Parameters dialog box, on the **All Parameters** tab, in the **Optimize global data access** drop-down list, three parameter options control global variable usage optimizations.

- `None`. Use default optimizations. This choice works well for most models. The code generator balances the use of local and global variables. It generates code which balances RAM and ROM consumption and execution speed.
- `Use global to hold temporary results`. Reusing global variables improves code efficiency and readability. This optimization reuses global variables, which results in the code generator defining fewer variables. It reduces RAM and ROM consumption and data copies.
- `Minimize global data access`. Using local variables to cache global data reduces ROM consumption by reducing code size in certain cases, such as when the global variables are scalars. This optimization improves execution speed because the code uses fewer instructions for local variable references than for global variable references.

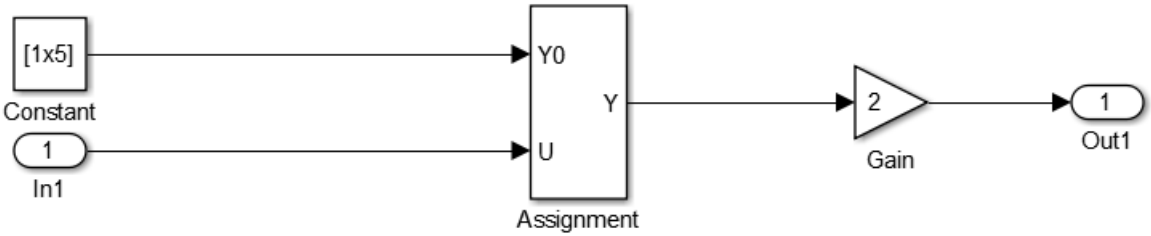
  Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see "Customize Stack Space Allocation" (Simulink Coder).

Use Global to Hold Temporary Results

The code generator uses global and local variables when you select `None` versus when you select `Use global to hold temporary results`.

Example Model

In the model matlab:rtwdemo_optimize_global_ebf, an Assignment block assigns values coming from the Inport and Constant blocks to an output signal. The output signal feeds into a Gain block.



```
model = 'rtwdemo_optimize_global_ebf';
load_system('rtwdemo_optimize_global_ebf')
```

Generate Code without Optimization

1. In the Configuration Parameters dialog box, on the All Parameters tab, verify that the **Signal storage reuse** parameter is selected.
2. In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select `None` or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process:

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_optimize_global_ebf
### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
    'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
  real_T rtb_Assignment[5];
  int32_T i;

  /* Assignment: '<Root>/Assignment' incorporates:
   *  Constant: '<Root>/Constant'
   *  Inport: '<Root>/In1'
   */
  for (i = 0; i < 5; i++) {
    rtb_Assignment[i] = rtCP_Constant_Value[i];
  }

  rtb_Assignment[1] = rtU.In1;

  /* End of Assignment: '<Root>/Assignment' */

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   */
  for (i = 0; i < 5; i++) {
    rtY.Out1[i] = 2.0 * rtb_Assignment[i];
  }

  /* End of Outport: '<Root>/Out1' */
}
```

The code assigns values to the local vector `rtb_Assignment`. The last statement copies the values in the local vector `rtb_Assignment` to the global vector `rtY.Out1`. Fewer global variable references result in improved execution speed. The code uses more instructions for global variable references than for local variable references.

In the Static Code Metrics Report, examine the Global Variables section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the `Global Variables` section.
3. Select the **[+]** sign before each variable to expand it.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[-] rtY	40	1	1
Out1	40	1	1
[-] rtU	8	1	1
In1	8	1	1
[-] rtM_	4	0*	0*
errorStatus	4	0	0
Total	**52**	**2**	

* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 2.

Generate Code with Optimization

In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select `Use global to hold temporary results`, or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf',...
    'GlobalVariableUsage','Use global to hold temporary results');
```

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_optimize_global_ebf
### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
    'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
```

```
  int32_T i;

  /* Assignment: '<Root>/Assignment' incorporates:
   *  Constant: '<Root>/Constant'
   *  Inport: '<Root>/In1'
   */
  for (i = 0; i < 5; i++) {
    rtY.Out1[i] = rtCP_Constant_Value[i];
  }

  rtY.Out1[1] = rtU.In1;

  /* End of Assignment: '<Root>/Assignment' */

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   */
  for (i = 0; i < 5; i++) {
    rtY.Out1[i] *= 2.0;
  }

  /* End of Outport: '<Root>/Out1' */
}
```

The code assigns values to the global vector `rtY.Out1` without using a local variable. This assignment improves ROM and RAM consumption and reduces data copies. The code places the value in the destination variable for each assignment instead of copying the value at the end. In the Static Code Metrics Report, examine the Global Variables section.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[-] rtY	40	4	4
Out1	40	4	4
[-] rtU	8	1	1
In1	8	1	1
[-] rtM_	4	0*	0*
errorStatus	4	0	0
Total	**52**	**5**	

* The global variable is not directly used in any function.

As a result of using global variables to hold local results, the total number of reads and writes for global variables has increased from 2 to 5. This optimization reduces data copies by reusing global variables.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

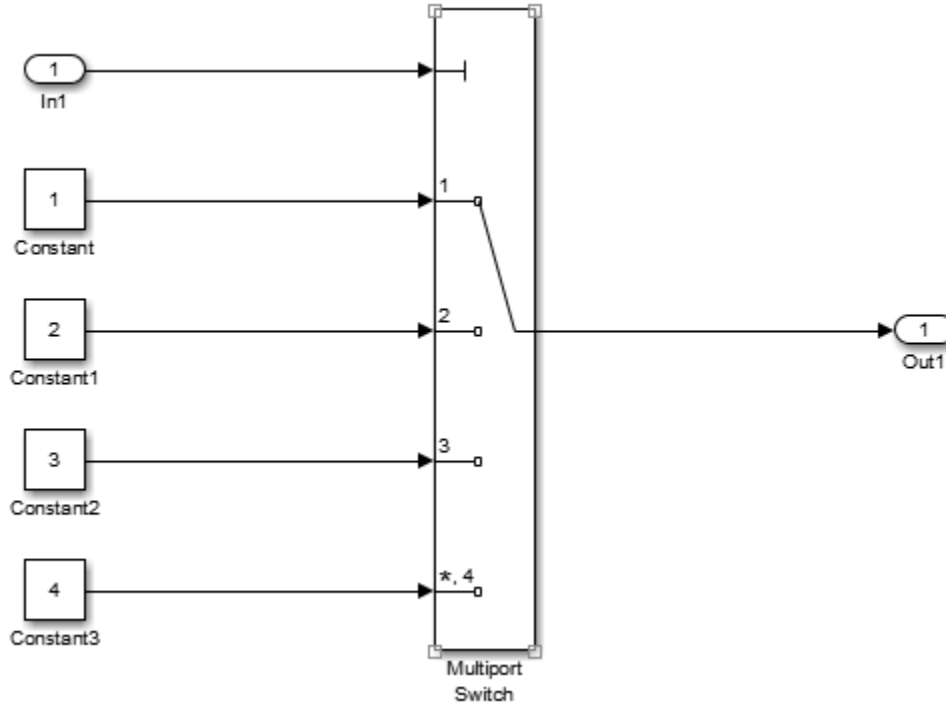
Minimize Global Data Access

Generate optimized code that reads from and writes to global variables less frequently.

Example Model

In the model matlab:rtwdemo_optimize_global, five signals feed into a Multiport Switch block.

```
model = 'rtwdemo_optimize_global';
load_system('rtwdemo_optimize_global')
```



Generate Code without Optimization

1. In the Configuration Parameters dialog box, on the **All Parameters** tab, verify that the **Signal storage reuse** parameter is selected.
2. In the Configuration Parameters dialog box, on the **All Parameters** tab, for the **Optimize global access** parameter, select `None` or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model);

### Starting build procedure for model: rtwdemo_optimize_global
### Successful completion of build procedure for model: rtwdemo_optimize_global
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
    'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  switch ((int32_T)rtU.In1) {
   case 1:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant'
     */
    rtY.Out1 = 1.0;
    break;

   case 2:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant1'
     */
    rtY.Out1 = 2.0;
    break;

   case 3:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant2'
     */
    rtY.Out1 = 3.0;
    break;

   default:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant3'
     */
```

```
    rtY.Out1 = 4.0;
    break;
  }

  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}
```

In the Static Code Metrics Report, examine the `Global Variables` section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the `Global Variables` section.
3. Select the **[+]** sign before each variable to expand it.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[−] rtU	8	1	1
In1	8	1	1
[−] rtY	8	4	4
Out1	8	4	4
[−] rtM	4	0*	0*
errorStatus	4	0	0
Total	**20**	**5**	

* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 5.

Enable Optimization and Generate Code

On the **All Parameters** tab, for the **Optimize global data access** parameter, select `Minimize global data access` or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global',...
    'GlobalVariableUsage','Minimize global data access');
```

Build the model.

```
rtwbuild(model);

### Starting build procedure for model: rtwdemo_optimize_global
### Successful completion of build procedure for model: rtwdemo_optimize_global
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
    'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
  real_T tmp_Out1;

  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  switch ((int32_T)rtU.In1) {
   case 1:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant'
     */
    tmp_Out1 = 1.0;
    break;

   case 2:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant1'
     */
    tmp_Out1 = 2.0;
    break;

   case 3:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant2'
     */
    tmp_Out1 = 3.0;
    break;

   default:
    /* Outport: '<Root>/Out1' incorporates:
```

```
     *  Constant: '<Root>/Constant3'
     */
    tmp_Out1 = 4.0;
    break;
  }

  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */

  /* Outport: '<Root>/Out1' */
  rtY.Out1 = tmp_Out1;
}
```

In `rtwdemo_optimize_global.c`, the code assigns a constant value to the local variable `tmp_Out1` in each case statement. The last statement in the code copies the value of `tmp_Out1` to the global variable `rtY.Out1`. Fewer global variable references result in fewer instructions and improved execution speed.

In the **Static Code Metrics Report**, examine the `Global Variables` section. As a result of minimizing global data accesses, the total number of reads and writes for global variables has decreased from 5 to 2.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[−] rtU	8	1	1
In1	8	1	1
[−] rtY	8	1	1
Out1	8	1	1
[−] rtM	4	0*	0*
errorStatus	4	0	0
Total	**20**	**2**	

* The global variable is not directly used in any function.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

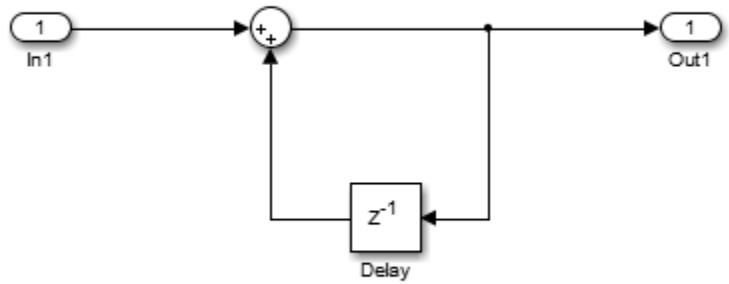
- "Reuse Global Block Outputs in the Generated Code" on page 55-14

Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

Example

In the Command Window, type rtwdemo_reuse_global.



Generate Code without Optimization

1. In the Configuration Parameters dialog box, on the **All Parameters** tab, verify that **Signal storage reuse** is selected.
2. Clear **Reuse global block outputs** and click **Apply**.
3. On the **Code Generation > Report** pane, select **Static code metrics**.
4. In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```
### Starting build procedure for model: rtwdemo_reuse_global
```

```
### Successful completion of build procedure for model: rtwdemo_reuse_global
```

View the generated code without the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
/* Model step function */
void rtwdemo_reuse_global_step(void)
{
  /* Sum: '<Root>/Sum' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.Delay_DSTATE += rtU.In1;

  /* Outport: '<Root>/Out1' */
  rtY.Out1 = rtDW.Delay_DSTATE;
}
```

The generated code contains a data copy to the global variable `rtDW.Delay_DSTATE`. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

Enable Optimization and Generate Code

1. On the **All Parameters** tab, select **Reuse global block outputs** and click **Apply**.
2. Generate code.
3. View the generated code with the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
  /* Sum: '<Root>/Sum' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtY.Out1 += rtU.In1;
}
```

The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

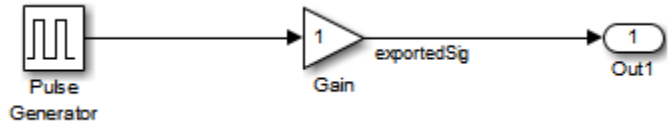
Virtualized Output Ports Optimization

The *virtualized output ports* optimization lets you store the signal entering the root output port as a global variable. Clearing the **MAT-file logging** option and setting the TLC variable `FullRootOutputVector` to `0`, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal `exportedSig` has `exportedGlobal` storage class.



In the default case, the output of the Gain block is written to the signal storage location, `exportedSig`. The code generator does not generate code or data for the `Out1` block, which has become a virtual block.

```
/* Gain Block: <Root>/Gain */
  exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;
```

In cases where you enable **MAT-file logging** or set `FullRootOutputVector = 1`, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with **MAT-file logging** enabled. The output port is represented as a member of the external outputs vector `VirtOutPortLogON_Y`. The Gain block output value is copied to `exportedSig` and to the external outputs vector.

```
/* Gain Block: <Root>/Gain */
  exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Outport Block: <Root>/Out1 */
  VirtOutPortLogON_Y.Out1 = exportedSig;
```

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of **MAT-file logging**) by setting the TLC variable `FullRootOutputVector` to `1`. Add the statement

```
%assign FullRootOutputVector = 1
```

to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see "Specify TLC for Code Generation" (Simulink Coder) and "Configure TLC" (Simulink Coder).

For more information on how to control signal storage in generated code, see "Signal Representation in Generated Code" (Simulink Coder).

- "Specify Buffer Reuse for Multiple Signals in a Path" on page 55-19
- "Optimize Global Variable Usage" on page 55-2

Specify Buffer Reuse for Multiple Signals in a Path

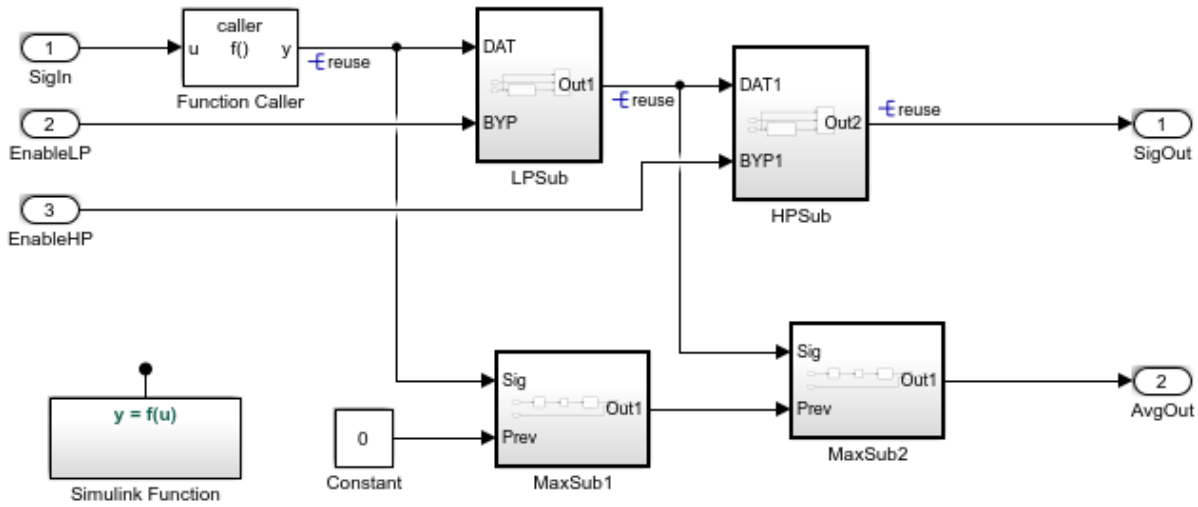
If your model has the optimal parameter settings for removing data copies, you may be able to remove additional data copies by using Simulink.Signal objects to specify buffer reuse. You specify signal objects on signal lines after studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible.

You can specify buffer reuse for multiple signals in a path that can include the root inport and outport signals. You can also specify reuse on just a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

Example Model

The model rtwdemo_reusable_csc_scheduling contains the nonreusable subsystems `LPSub` and `HPSub` and the reusable subsystems `MaxSub1` and `MaxSub2`.

```
model ='rtwdemo_reusable_csc_scheduling';
open_system(model);
set_param(model,'IncludeMdlTerminateFcn', 'on');
```



Specify a Simulink Signal Object for Reuse

1. Open the base workspace. The Simulink signal object `reuse` is for specifying which buffers to reuse in the generated code. To use a Simulink signal object for buffer reuse, the object must have a **Storage class** of `Reusable (Custom)`.
2. Right-click one of the signal lines that has the signal name `reuse`.
3. Specify a name for the **Signal name** parameter and select the checkbox **Signal name must resolve to Simulink signal object**.

Generate Code

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_reusable_csc_scheduling
### Successful completion of build procedure for model: rtwdemo_reusable_csc_scheduling
```

The `rtwdemo_reusable_csc_rescheduling.c` file contains this global variable for buffer reuse.

```
/* Definition for custom storage class: Reusable */

real_T reuse[256];
```

The `rtwdemo_reusable_csc_scheduling_step` function contains this code.

```
cfile = fullfile(cgDir,'rtwdemo_reusable_csc_scheduling_ert_rtw','rtwdemo_reusable_csc_
rtwdemodbtype(cfile,'/* Model step function', '/* Model initialize function ', 1, 0);
```

```
/* Model step function */
void rtwdemo_reusable_csc_scheduling_step(void)
{
  /* FunctionCaller: '<Root>/Function Caller' incorporates:
   *  Inport: '<Root>/SigIn'
   */
  f(rtU.SigIn, (&(reuse[0])));

  /* Outputs for Atomic SubSystem: '<Root>/MaxSub1' */
```

```
  /* Constant: '<Root>/Constant' incorporates:
   *  Outport: '<Root>/AvgOut'
   */
  MaxSub1((&(reuse[0])), 0.0, rtY.AvgOut);

  /* End of Outputs for SubSystem: '<Root>/MaxSub1' */

  /* Outputs for Atomic SubSystem: '<Root>/LPSub' */
  LPSub();

  /* End of Outputs for SubSystem: '<Root>/LPSub' */

  /* Outputs for Atomic SubSystem: '<Root>/MaxSub2' */

  /* Outport: '<Root>/AvgOut' */
  MaxSub2((&(reuse[0])), rtY.AvgOut, rtY.AvgOut);

  /* End of Outputs for SubSystem: '<Root>/MaxSub2' */

  /* Outputs for Atomic SubSystem: '<Root>/HPSub' */
  HPSub();

  /* End of Outputs for SubSystem: '<Root>/HPSub' */
}
```

All five functions in the `rtwdemo_reusable_csc_scheduling_step` function can reuse the variable `reuse` because calls to functions `MaxSub1` and `MaxSub2` happen before calls to function `LPSub` and `HPSub`, respectively.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Buffer Reuse for Unit Delay and Delay Blocks

To reuse the signal of a Unit Delay or Delay block

1. Use the same reusable custom storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay block or a Delay block.
2. Open the Unit Delay or Delay block parameters dialog box.
3. On the **State Attributes** tab, set the **State name** parameter to the name of the `Simulink.signal` that you want to reuse.

4 On the **State Attributes** tab, select **Signal name must resolve to Simulink signal object**.

5 On the **Main** tab, the **Delay length** parameter must have a value of `1`. The **Initial condition > Source parameter** must be set to `Dialog`.

Limitations for Root Inport and Outport Signals

The following limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals.

- The output ports cannot be conditional.
- If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the same model is a reference model, the code generator reports an error. To resolve the error, remove the Simulink.signal specification from the signal that connects to the outport port.
- When you run an executable produced by code generation, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results produced by the executable.

Limitations for the Model

The following limitations apply to a model in which you specify buffer reuse for signals.

- Signals that you specify for reuse must have the same data types and sampling rates.
- For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in which the code generator is unable to reorder block operations, buffer reuse does not occur.
- For models in which the code generator reorders block operations so that `Simulink.Signal` reuse can occur, you can observe the difference in the sorted order. In the model window, select **Display > Blocks > Sorted Execution Order**. To display the sorted execution order during simulation, select **Simulation > Update Diagram**. To display the execution order in the generated code, select **Code > C/C++ Code > Build Model**.

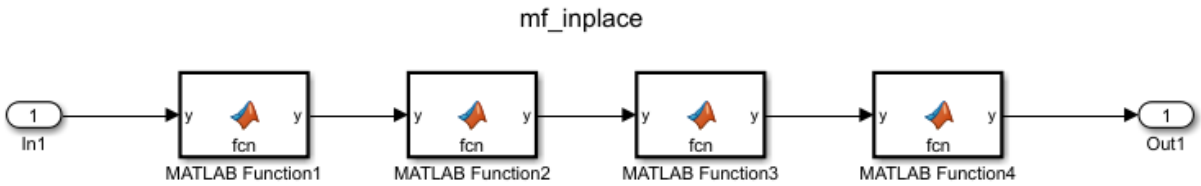
Specify Buffer Reuse for MATLAB Function Blocks in a Path

In this section...

You can specify buffer reuse across MATLAB Function blocks by using the same variable name for the input and output arguments. The code generator tries to reuse the output of one MATLAB Function block as the input to the next MATLAB Function block. This optimization conserves RAM and ROM consumption and reduces data copies.

Example Model

1 Use Inport, Outport, and MATLAB Function blocks to create the model `mf_inplace`.



2 Open each MATLAB Function block and copy the following code:

```
function y = fcn(y)
%#codegen

y=y+4;
```

3 Open the Configuration Parameters dialog box. On the **Code Generation** tab, change the **System target file** to `ert.tlc`.

4 On the **Solver** tab, change the **Type** parameter to `Fixed-step`.

Generate Code with Optimization

Generate code for the model. The `mf_inplace.c` file contains this code:

```
void mf_inplace_MATLABFunction(real_T *rty_y)
```

```
{
  *rty_y += 4.0;
}

void mf_inplace_step(void)
{
  real_T rtb_y_p5;
  rtb_y_p5 = mf_inplace_U.In1;
  mf_inplace_MATLABFunction(&rtb_y_p5);
  mf_inplace_MATLABFunction(&rtb_y_p5);
  mf_inplace_MATLABFunction(&rtb_y_p5);
  mf_inplace_Y.Out1 = rtb_y_p5;
  mf_inplace_MATLABFunction(&mf_inplace_Y.Out1);
}
```

The code generator reuses the variable `rtb_y_p5` for the input and output arguments of each MATLAB Function block.

Note: On the **Code Generation** tab in the Subsystem Block Parameters dialog box, if the **Function packaging** parameter is set to `Nonreusable function` and the **Function interface** parameter is set to `Allow arguments`, the code generator cannot reuse the input and output arguments.

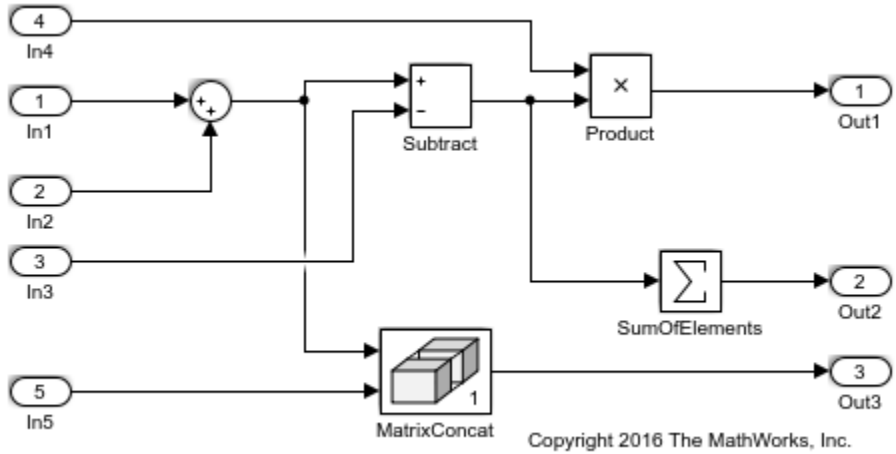
Remove Data Copies by Reordering Block Operations in the Generated Code

This example shows how to remove data copies by reordering block operations in the generated code. This optimization conserves RAM and ROM consumption and improves code execution speed.

Example Model

In the model matlab:rtwdemo_optimizeblockorder, the signal that leaves the Sum block enters a Subtract block and a Concatenate block. The signal that leaves the Subtract block enters a Product block and a Sum of Elements block.

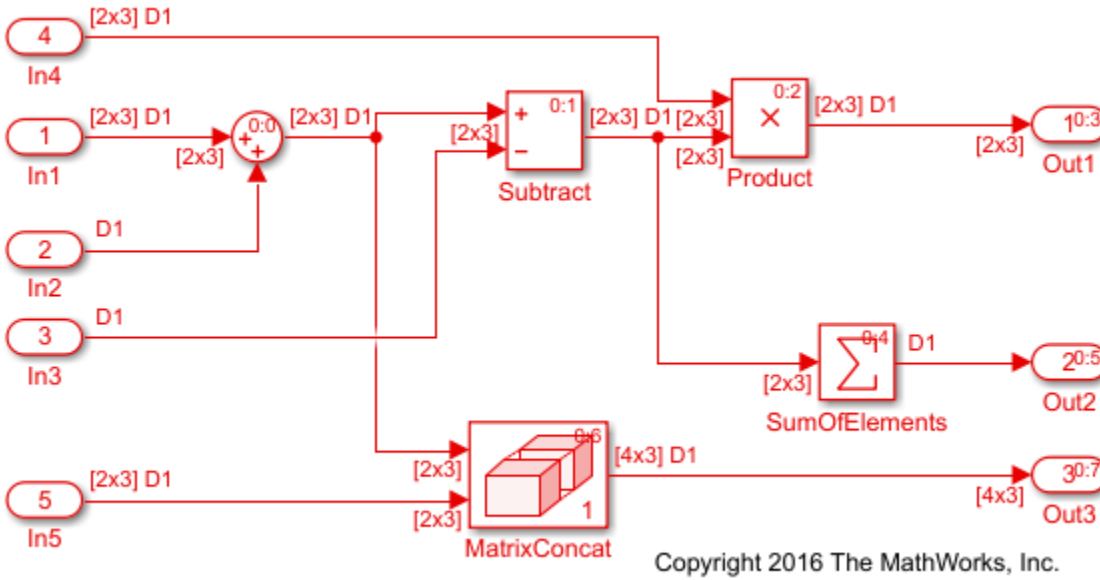


Generate Code without Optimization

In your system's temporary folder, create a folder for the build and inspection process and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

The image shows the default block order in the generated code. The Subtract block executes before the Concatenate block. The Product block executes before the Sum of Elements block.



View the generated code without the optimization. Here is `rtwdemo_optimizeblockorder.c`.

```
/* Model step function */
void rtwdemo_optimizeblockorder_step(void)
{
  real_T rtb_Sum2x3[6];
  int32_T i;
  real_T rtb_Sum2x3_d;
  real_T rtb_Subtract;

  /* Sum: '<Root>/SumOfElements' */
  rtY.Out2 = -0.0;
  for (i = 0; i < 6; i++) {
    /* Sum: '<Root>/Sum2x3' incorporates:
     *  Inport: '<Root>/In1'
     *  Inport: '<Root>/In2'
     */
    rtb_Sum2x3_d = rtU.In1[i] + rtU.In2;
```

```
    /* Sum: '<Root>/Subtract' incorporates:
     *  Inport: '<Root>/In3'
     */
    rtb_Subtract = rtb_Sum2x3_d - rtU.In3;

    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In4'
     *  Product: '<Root>/Product'
     */
    rtY.Out1[i] = rtU.In4[i] * rtb_Subtract;

    /* Sum: '<Root>/Sum2x3' */
    rtb_Sum2x3[i] = rtb_Sum2x3_d;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 += rtb_Subtract;
  }

  /* Concatenate: '<Root>/MatrixConcat ' */
  for (i = 0; i < 3; i++) {
    /* Outport: '<Root>/Out3' incorporates:
     *  Inport: '<Root>/In5'
     */
    rtY.Out3[i << 2] = rtb_Sum2x3[i << 1];
    rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
    rtY.Out3[1 + (i << 2)] = rtb_Sum2x3[(i << 1) + 1];
    rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
  }

  /* End of Concatenate: '<Root>/MatrixConcat ' */
}
```

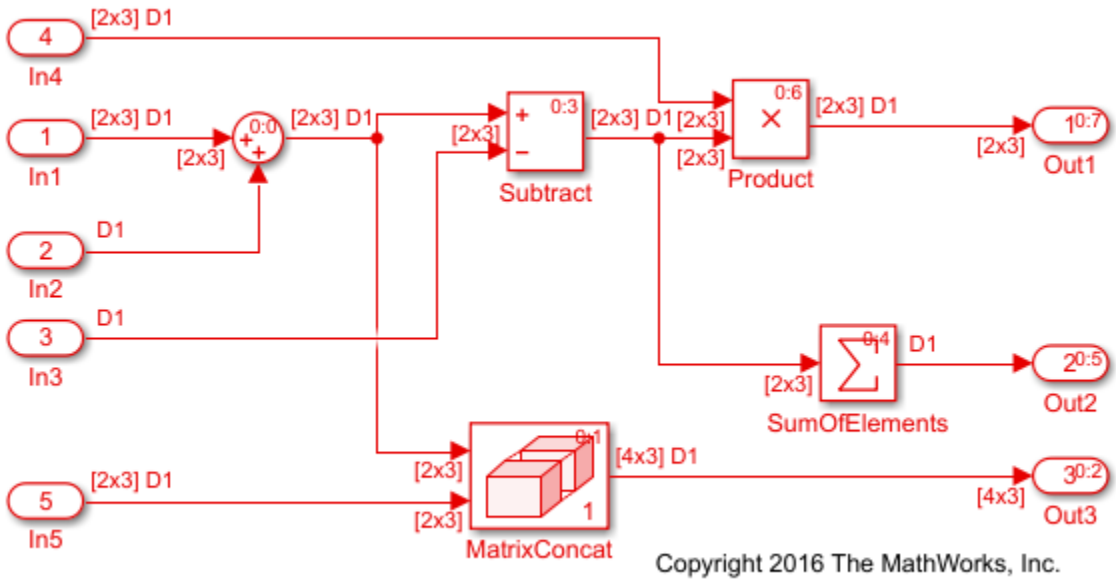
With the default order, the generated code contains three buffers, `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract`. The generated code contains these temporary variables and associated data copies because the Matrix Concatenate block must use the output from the Sum block and the Sum of Elements block must use the output from the Subtract block.

Generate Code with Optimization

1. In the Configuration Parameters dialog box, change the **Optimize block order in the generated code** parameter to `Improved Execution Speed`.
2. Generate code for the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

The image shows the optimized block order in the generated code. The Subtract block executes after the Concatenate block. The Product block executes after the Sum of Elements block.



View the generated code with the optimization. Here is `rtwdemo_optimizeblockorder.c`.

```
/* Model step function */
void rtwdemo_optimizeblockorder_step(void)
{
  int32_T i;

  /* Sum: '<Root>/Sum2x3' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
```

```
  for (i = 0; i < 6; i++) {
    rtY.Out1[i] = rtU.In1[i] + rtU.In2;
  }

  /* End of Sum: '<Root>/Sum2x3' */

  /* Concatenate: '<Root>/MatrixConcat ' */
  for (i = 0; i < 3; i++) {
    /* Outport: '<Root>/Out3' incorporates:
     *  Inport: '<Root>/In5'
     */
    rtY.Out3[i << 2] = rtY.Out1[i << 1];
    rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
    rtY.Out3[1 + (i << 2)] = rtY.Out1[(i << 1) + 1];
    rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
  }

  /* End of Concatenate: '<Root>/MatrixConcat ' */

  /* Sum: '<Root>/SumOfElements' */
  rtY.Out2 = -0.0;
  for (i = 0; i < 6; i++) {
    /* Sum: '<Root>/Subtract' incorporates:
     *  Inport: '<Root>/In3'
     */
    rtY.Out1[i] -= rtU.In3;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 += rtY.Out1[i];

    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In4'
     *  Product: '<Root>/Product'
     */
    rtY.Out1[i] *= rtU.In4[i];
  }
}
```

In the optimized code, the three buffers `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract` and their associated data copies are gone. The generated code does not require these temporary variables to hold the outputs of the Sum and Subtract blocks because the Subtract block executes after the Concatenate block and the Product block executes after the Sum of Elements block.

To implement buffer reuse, the code generator does not violate user-specified block priorities.

Execution Speed in Embedded Coder

Reduce Memory Requirements for Signals

To reduce the memory requirements of your real-time program, select the configuration parameter **Signal storage reuse**. Selecting **Signal storage reuse** enables parameters that provide the capability to reuse memory allocated for signals: **Reuse local block outputs**, **Reuse global block outputs**, and **Optimize global data access**. Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

When you select **Reuse local block outputs**, the code generator reuses local (function) variables for block outputs wherever possible. When you select **Reuse global block outputs**, the code generator reuses global (function) variables wherever possible.

The **Optimize global data access** parameter has the following settings `None`, `Use global to hold temporary results`, and `Minimize global data access`. When you select `None`, the code generator uses the default optimizations. The setting `Use global to hold temporary results` maximizes the use of global variables. The setting `Minimize global data access` minimizes the use of global variables by using local variables to hold intermediate values.

Remove Initialization Code

Consider selecting the “Remove root level I/O zero initialization” (Simulink) and “Remove internal data zero initialization” (Simulink) options on the **Optimization > General** pane.

These options (both off by default) control whether internal data (block states and block outputs) and external data (root inports and outports whose value is zero) are initialized. Initializing the internal and external data whose value is zero is a precaution and your application might not require it. Many embedded application environments initialize RAM to zero at startup, making generation of initialization code redundant.

However, be aware that if you select **Remove internal data zero initialization**, memory might not be in a known state each time the generated code begins execution. If you turn the option on, running a model (or a generated S-function) multiple times can result in different answers for each run.

This behavior is sometimes desirable. For example, you can turn on **Remove internal data zero initialization** if you want to test the behavior of your design during a warm boot (that is, a restart without full system reinitialization).

In cases where you have turned on **Remove internal data zero initialization** but still want to get the same answer on every run from an S-function produced by the code generator, you can use either of the following MATLAB commands before each run:

```
clear SFcnName
```

where *SFcnName* is the name of the S-function, or

```
clear mex
```

A related option, **Use memset to initialize floats and doubles**, lets you control the representation of zero used during initialization. See “Use memset to initialize floats and doubles to 0.0” (Simulink).

Note that the code still initializes data structures whose value is not zero when **Remove internal data zero initialization** and **Remove root level I/O zero initialization** are selected.

Note also that data of `ImportedExtern` or `ImportedExternPointer` storage classes are not initialized, regardless of the settings of these options.

Eliminate Zero Initialization Code for Internal Data

This example shows how to eliminate generated code that initializes internal data with zeroes, for example global DWork vectors, to reduce the size of the code and to accelerate model initialization.

Overview

During model initialization, generated code can initialize internal data by using assignments to zero. DWork vectors are an example of internal data.

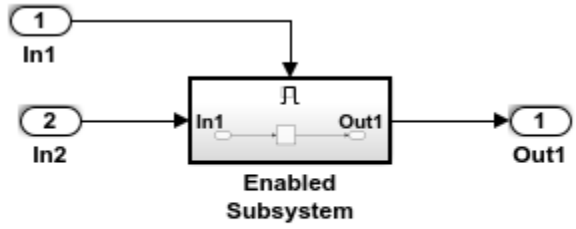
If the data are global variables in the generated code, and if the target environment already initializes global variables with zeroes, you can remove the corresponding lines of model initialization code.

This optimization removes unnecessary zero initialization code, providing these benefits:

- Reduction in size of generated code
- Increased execution speed of generated code

Open Example Model

Open the model rtwdemo_internal_init. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is 0.



Generate Code Without Optimization

Build the model using Embedded Coder.

```
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```

View the following code from the generated file `rtwdemo_internal_init.c`.

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtM, (NULL));

  /* states (dwork) */
  (void) memset((void *)&rtDWork, 0,
                sizeof(D_Work));

  /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
  /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
  rtDWork.UnitDelay_DSTATE = 0.0;

  /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}

/*
```

Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove internal data zero initialization**.

Alternatively, you can use the command prompt to enable the optimization. To enable the optimization, set the model parameter `ZeroInternalMemoryAtStartup` to `'off'`.

```
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

Generate Code with Optimization

Build the model using Embedded Coder.

```
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```

View the following code from the file `rtwdemo_internal_init.c`. The generated code does not initialize internal data by assignment to zero.

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
  /* (no initialization code required) */
}

/*
```

Generate Pure Integer Code If Possible

If your application uses only integer arithmetic, clear the **Support floating-point numbers** option in the **Software environment** section of the **Interface** pane so that the generated code contains no floating-point data or operations. When this option is cleared, an error is raised if noninteger data or expressions are encountered during code generation. The error message reports the offending blocks and parameters.

Disable MAT-File Logging

Disable MAT-file logging by clearing **Configuration Parameters > All Parameters > MAT-file logging**. This setting is the default, and is recommended for embedded applications because it eliminates the extra code and memory usage required to initialize, update, and clean up logging variables. In addition to these efficiencies, clearing the **MAT-file logging** parameter lets you exploit further efficiencies under certain conditions. See "Virtualized Output Ports Optimization" on page 55-17 for information.

Note also that code generated to support MAT-file logging invokes `malloc`, which can be undesirable for your application.

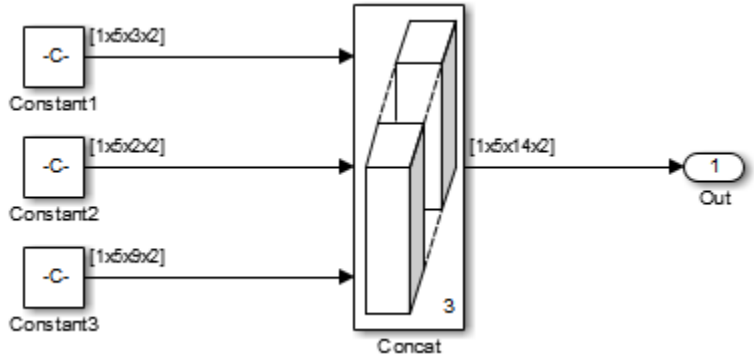
Simplify Multiply Operations in Array Indexing

In this section...

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter “Simplify array indexing” (Simulink) to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

Example Model

If you have the following model:



The Constant blocks have the following **Constant value**:

- `Const1`: `reshape(1:30,[1 5 3 2])`
- `Const2`: `reshape(1:20,[1 5 2 2])`
- `Const3`: `reshape(1:90,[1 5 9 2])`

The Concatenate block parameter **Mode** is set to `Multidimensional array`. The Constant blocks **Sample time** parameter is set to –1.

Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
  for (i_1 = 0; i_1 < 3; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
        ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
    }
  }
}

for (i = 0; i < 2; i++) {
  for (i_1 = 0; i_1 < 2; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
        ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
    }
  }
}

for (i = 0; i < 2; i++) {
  for (i_1 = 0; i_1 < 9; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
        ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
    }
  }
}
```

Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter on the **All Parameters** tab. Build the model again. In the generated code,

`[(i_0 + tmp_1) + tmp]` replaces a multiply operation in the array index, `[(i_0 + 5 * i_1) + 70 * i]`. The generated code is now:

```
int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
  tmp_1 = 0;
  for (i_1 = 0; i_1 < 3; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
        ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
    }

    tmp_1 += 5;
  }

  tmp += 70;
  tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
  tmp_1 = 0;
  for (i_1 = 0; i_1 < 2; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
        ex_arrayindex_P.Constant2_Value[(i_0 + tmp_1) + tmp_0];
    }

    tmp_1 += 5;
  }

  tmp += 70;
  tmp_0 += 10;
}
```

```
tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
  tmp_1 = 0;
  for (i_1 = 0; i_1 < 9; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
        ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
    }

    tmp_1 += 5;
  }

  tmp += 70;
  tmp_0 += 45;
}
```

Replace `boolean` with Specific Integer Data Type

Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of generated code. Select a specific integer data type to use for the built-in type `boolean`. Using data type replacement, in the generated code you can replace the `boolean` built-in data type with one of these integer types:

- `int8`
- `uint8`
- `int`*`n`*

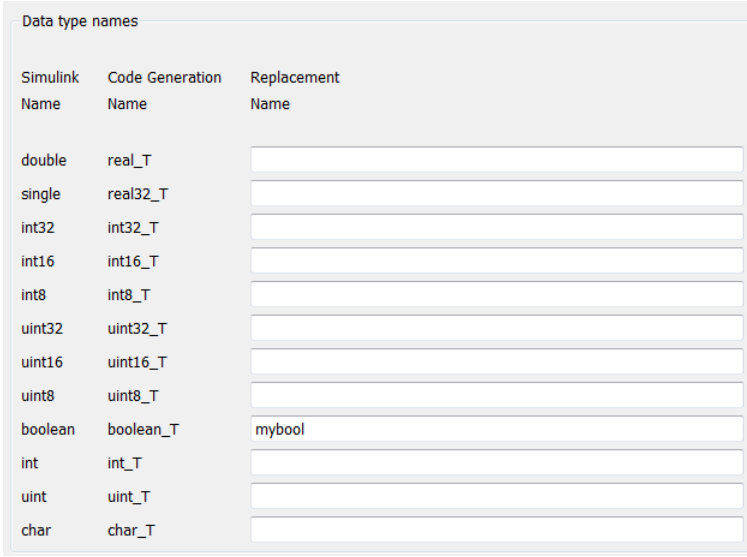
Replace *n* with `8`, `16`, or `32` to match the integer word size for the production hardware.

This example shows how to replace the data type `boolean` with the integer data type `int32` in the code generated for a 32-bit hardware target.

1. Define a `Simulink.AliasType` object with a base type of `int32`. Name the object using the replacement name that you want to appear in the generated code.

   ```
   mybool = Simulink.AliasType;
   mybool.BaseType = 'int32';
   ```

2. Open an ERT-based model. In the Configuration Parameters dialog box **Data Type Replacement** pane, specify the **Replacement Name** field for the data type `boolean` as `mybool`.



View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```
/* Generic type definitions ... */
...
typedef int boolean_T;
 ...
/* Define Simulink Coder replacement data types. */
typedef boolean_T mybool;    /* User defined replacement datatype for boolean_T */
```

View the generated file *`model`*`.c`. The code declares Boolean variables using the type `mybool`. For example, if the model has a Boolean output `Out1`, the generated code declares the corresponding variable using `mybool`.

```
  mybool Out1;                     /* '<Root>/Out1' */
```

Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division `INT_MIN/-1` operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization.

This optimization:

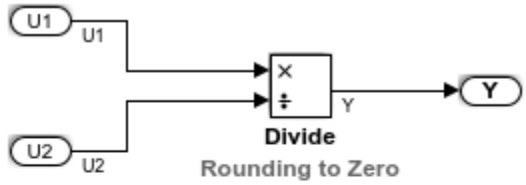
- Increases execution speed.
- Reduces ROM consumption.

NOTE: If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

Example Model

In the model rtwdemo_nzcheck, two signals of type `int8` feed into a divide block.

```
model = 'rtwdemo_nzcheck';
open_system(model);
```



Generate Code

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'NoFixptDivByZeroProtection', 'off');
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck
```

View the generated code without the optimization. Here is a portion of `rtwdemo_nzcheck.c`.

```
cfile = fullfile(cgDir,'rtwdemo_nzcheck_ert_rtw','rtwdemo_nzcheck.c');
rtwdemodbtype(cfile,'/* Real-time model','/* Model step function',1, 1);
```

```
/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;
int32_T div_s32(int32_T numerator, int32_T denominator)
{
  int32_T quotient;
  uint32_T tempAbsQuotient;
  if (denominator == 0) {
    quotient = numerator >= 0 ? MAX_int32_T : MIN_int32_T;

    /* Divide by zero handler */
  } else {
    tempAbsQuotient = (numerator < 0 ? ~(uint32_T)numerator + 1U : (uint32_T)
                       numerator) / (denominator < 0 ? ~(uint32_T)denominator +
      1U : (uint32_T)denominator);
    quotient = (numerator < 0) != (denominator < 0) ? -(int32_T)tempAbsQuotient :
      (int32_T)tempAbsQuotient;
  }

  return quotient;
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Remove code that protects against division arithmetic exceptions**.

Alternatively, you may use the command-line API to enable the optimization:

```
set_param(model, 'NoFixptDivByZeroProtection', 'on');
```

Generate Code with Optimization

The optimized code does not contain code that checks for whether or not the divisor has a value of zero.

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck
```

The following is a portion of `rtwdemo_nzcheck.c`. The code that protects against division arithmetic exceptions is not in the generated code.

```
rtwdemodbtype(cfile,'/* Real-time model','/* Model step function',1, 1);
```

```
/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Division Arithmetic Exceptions in Generated Code

The **Remove code that protects against division arithmetic exceptions** parameter in the **Optimization** pane of the Configuration Parameters dialog box controls the generation of code that protects against division arithmetic exceptions in integer and fixed-point operations. Division arithmetic exceptions include division by zero and `INT_MIN/-1`, which results in a quotient that cannot be represented.

When the parameter is selected, the generated code does not contain code that guards against these types of exceptions. This produces smaller, more efficient code, however it can affect numerical results. Select the parameter if you are sure that your model would not encounter these exceptions to optimize the efficiency of the generated code.

When the parameter is not selected, the generated code does not contain code that guards against division arithmetic exceptions. The added protection code checks that there is a numerical match between simulation and code generation for division operations at a cost of code size and performance.

Division by Zero

Division by zero is undefined and results in a runtime error in the generated code. When the **Remove code that protects against division arithmetic exceptions** parameter is selected, the code generator does not produce code that protects against division by zero. Select this option only when you are sure that your model will not produce such a division operation.

INT_MIN/-1

When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one (`INT_MAX + 1`), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time. When the **Remove code that protects against division arithmetic exceptions** parameter is selected, the code generator does not produce code that protects against this situation. Select this option only when you are sure that your model will not produce such a division operation.

The following illustrates an example of this type of exception:

```
a = int32(-2147483648);
b = a/-1
```

The ideal quotient of this operation is `2147483648`, but this is not representable in an `int32` data type, resulting in an exception at runtime.

Other Factors Affecting Generated Code of Division Operations

In addition to the **Remove code that protects against division arithmetic exceptions** parameter, there are several other factors that can affect the appearance of code generated for division operations. The manner in which this parameter controls code generated from blocks containing MATLAB code with integer or fixed-point division operations differs from the built-in Divide block in Simulink. Blocks containing MATLAB code include MATLAB Function blocks and Stateflow charts using MATLAB action language. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use `fi` objects and set the `fimath` properties to fit your needs. Usage of `fi` and `fimath` objects requires a Fixed-Point Designer license.

Rounding and overflow modes also affect the size and efficiency of the generated code. For more information, see "Optimize Generated Code with the Model Advisor" (Fixed-Point Designer).

Optimize Generated Code by Consolidating Redundant If-Else Statements

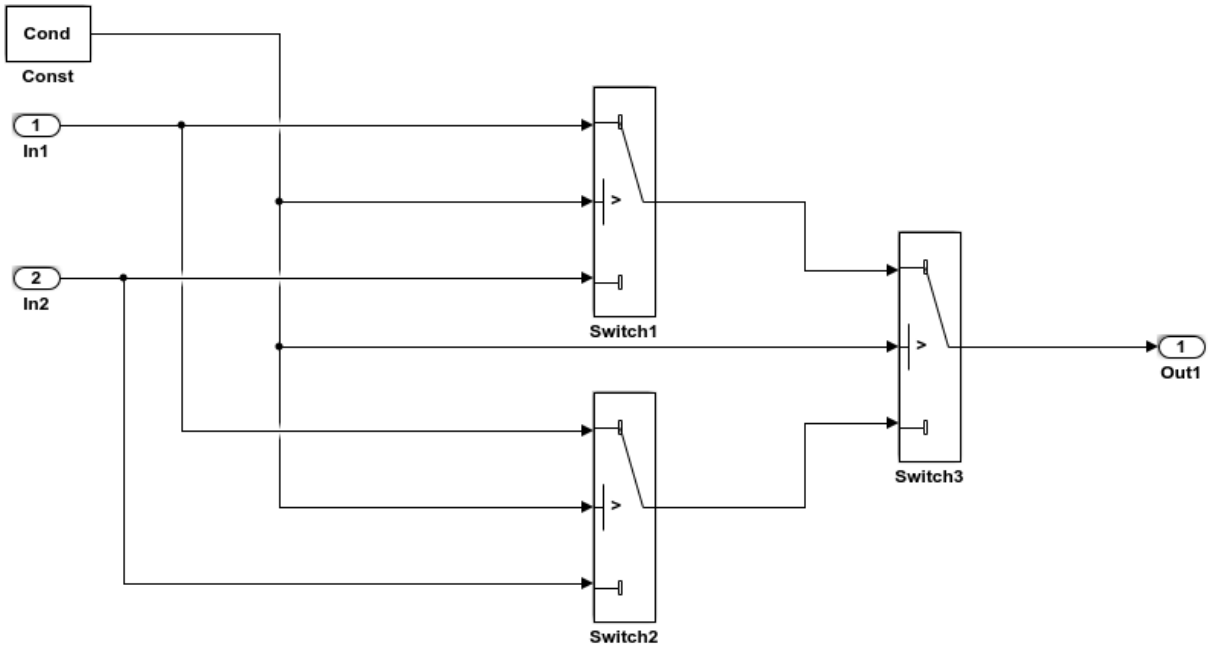
This example shows how to optimize generated code by combining `if-else` statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

Example

The model rtwdemo_controlflow_opt contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named `Cond` determines the value of the Constant block.

```
model = 'rtwdemo_controlflow_opt';
open_system(model);
```



Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

These lines of `rtwdemo_controlflow_opt.c` code show that in the generated code, two `if-else` statements and one `else-if` statement represent the three Switch blocks.

```
cfile = fullfile(cgDir,'rtwdemo_controlflow_opt_ert_rtw',...
    'rtwdemo_controlflow_opt.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
  /* Switch: '<Root>/Switch3' incorporates:
   *  Constant: '<Root>/Const'
   *  Switch: '<Root>/Switch2'
   */
  if (Cond) {
    /* Switch: '<Root>/Switch1' */
    if (Cond) {
      /* Outport: '<Root>/Out1' incorporates:
       *  Inport: '<Root>/In1'
       */
      rtY.Out1 = rtU.In1;
    } else {
      /* Outport: '<Root>/Out1' incorporates:
       *  Inport: '<Root>/In2'
       */
      rtY.Out1 = rtU.In2;
    }

    /* End of Switch: '<Root>/Switch1' */
  } else if (Cond) {
    /* Switch: '<Root>/Switch2' incorporates:
     *  Inport: '<Root>/In1'
     *  Outport: '<Root>/Out1'
     */
    rtY.Out1 = rtU.In1;
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In2'
     */
    rtY.Out1 = rtU.In2;
  }

  /* End of Switch: '<Root>/Switch3' */
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Code generation**-> **Code Style** pane, clear **Preserve condition expression in if statement**. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```
set_param(model, 'PreserveIfCondition', 'off');
```

Generate Code with Optimization

In the optimized code, the code generator consolidates the two `if-else` statements and one `else-if` statement into one `if-else` statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
  /* Switch: '<Root>/Switch1' incorporates:
   *  Constant: '<Root>/Const'
   *  Switch: '<Root>/Switch3'
   */
  if (Cond) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In1'
     */
    rtY.Out1 = rtU.In1;
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In2'
```

```
     */
    rtY.Out1 = rtU.In2;
  }

  /* End of Switch: '<Root>/Switch1' */
}
```

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Remove Initialization Code for Root-Level Inports and Outports Set to Zero

This example shows how to optimize generated code by removing initialization code for root-level inports and outports set to zero. If your embedded application does not require generating initialization code for external data whose value is zero, you can enable this optimization. For example, many embedded application environments initialize RAM to zero at startup, making generation of initialization code redundant. This optimization:

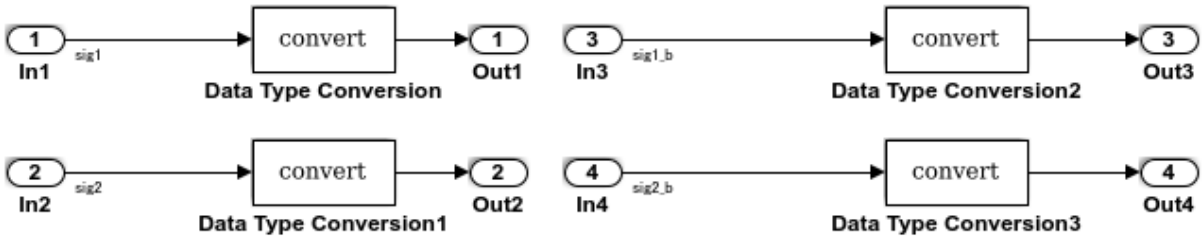
- Increases execution speed.
- Reduces ROM consumption.

Note: This example requires an Embedded Coder® license.

Example

In the model rtwdemo_rootlevel_zero_initialization, all of the input and output signals have a numeric value of zero. Because signals `sig1` and `sig2` have data types `int16` and `Boolean`, respectively, and all of the output signals have data type `double`, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of `0`, meaning that all bits are off. Signals `sig1_b` and `sig2_b` have a fixed-point data type with bias, so their initial value is not bitwise zero.

```
model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);
```



Generate Code

In your system temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'ZeroExternalMemoryAtStartup','on');
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initiali
```

These lines of `rtwdemo_rootlevel_zero_initialization.c` code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized as global variables. The four output signals are members of a global structure that the `memset` function initializes to bitwise zero.

```
cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',...
    'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',...
    'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
  /* Registration code */

  /* external inputs */
  sig1 = 0;
  sig2 = false;
  sig1_b = -3;
  sig2_b = -3;

  /* external outputs */
  (void) memset((void *)&rtY, 0,
                sizeof(ExternalOutputs));
}

/*
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Remove root level I/O zero initialization**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'ZeroExternalMemoryAtStartup','off');
```

Generate Code with Optimization

The optimized code does not contain initialization code for the input signals `sig1`, `sig2`, and the four output signals, because their initial values are bitwise zero.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initial
```

Here is the `rtwdemo_rootlevel_zero_initialization.c` optimized code in the initialization function.

```
cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',...
    'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',...
    'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
  /* Registration code */

  /* external inputs */
  sig1_b = -3;
  sig2_b = -3;
}

/*
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

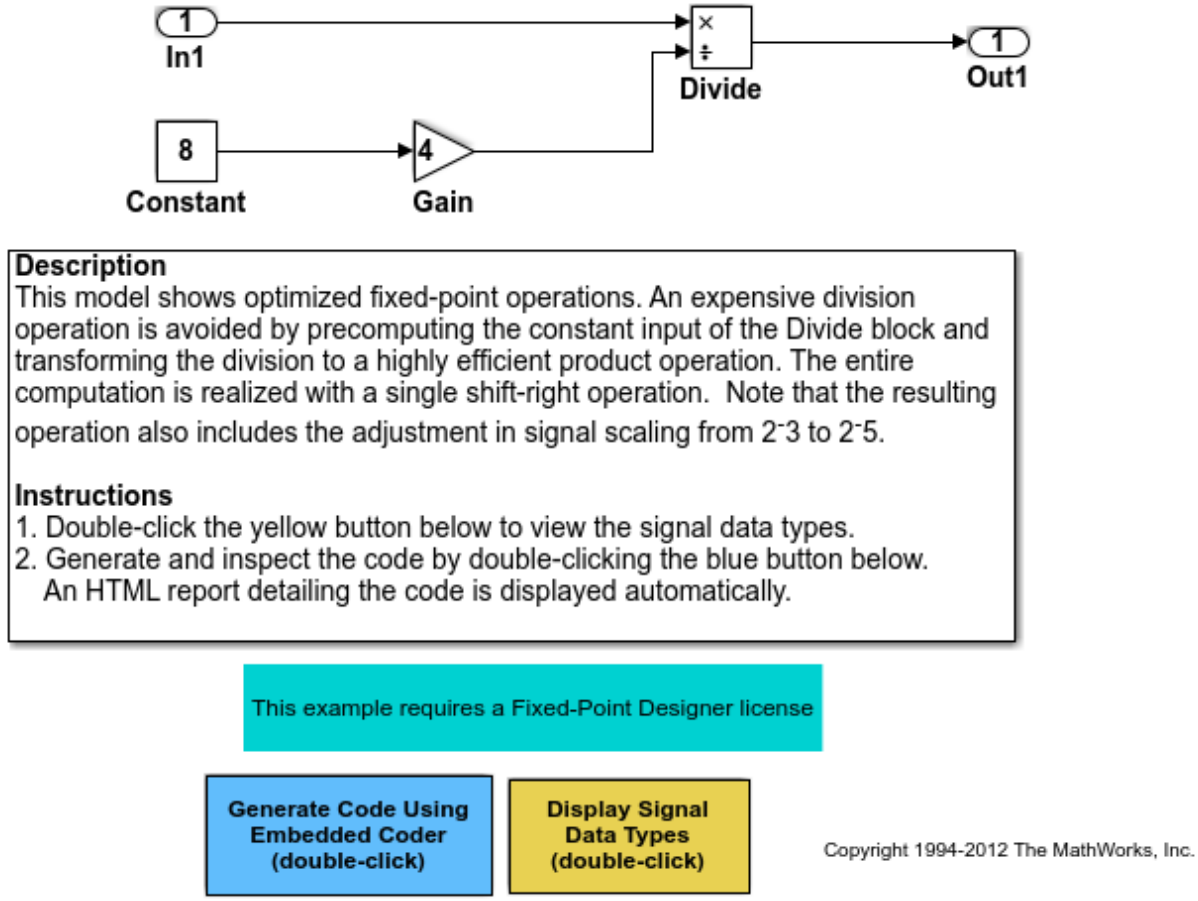
Optimize Generated Code for Fixed-Point Data Operations

This example shows how the code generater optimizes fixed-point operations by replacing expensive division operations with highly efficient product operations. This optimization improves execution speed.

Example Model

In the model rtwdemo_fixptdiv, two fixed point signals connect to a Product block. The **Number of inputs** parameter has the value `/*`.

```
model='rtwdemo_fixptdiv';
open(model);
```



Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model,'GenCodeOnly','on');
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_fixptdiv
### Successful completion of code generation for model: rtwdemo_fixptdiv
```

View the generated code. Here is a portion of `rtwdemo_fixptdiv.c`.

```
cfile = fullfile(cgDir,'rtwdemo_fixptdiv_ert_rtw','rtwdemo_fixptdiv.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_fixptdiv_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   *  Product: '<Root>/Divide'
   */
  rtY.Out1 = (int16_T)(rtU.In1 >> 3);
}
```

The generated code contains a highly efficient right shift operation instead of an expensive division operation. The generated code also contains the precomputed value for the constant input to the Product block.

Note that the resulting operation also includes the adjustment in signal scaling from 2^-3 to 2^-5.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Memory Usage in Embedded Coder

Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as *design minimum and maximum*, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, on the **Optimization** tab, when you select the **Optimize using specified minimum and maximum values** check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - `Simulink.Signal` objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

Enable Simulation Range Checking

1. In your model, select **Simulation** > **Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. In the Configuration Parameters dialog box, select **Diagnostics** > **Data Validity**.
3. On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to `warning` or `error`.

- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

Optimize Generated Code Using Specified Minimum and Maximum Values

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

Overview

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

NOTE: Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

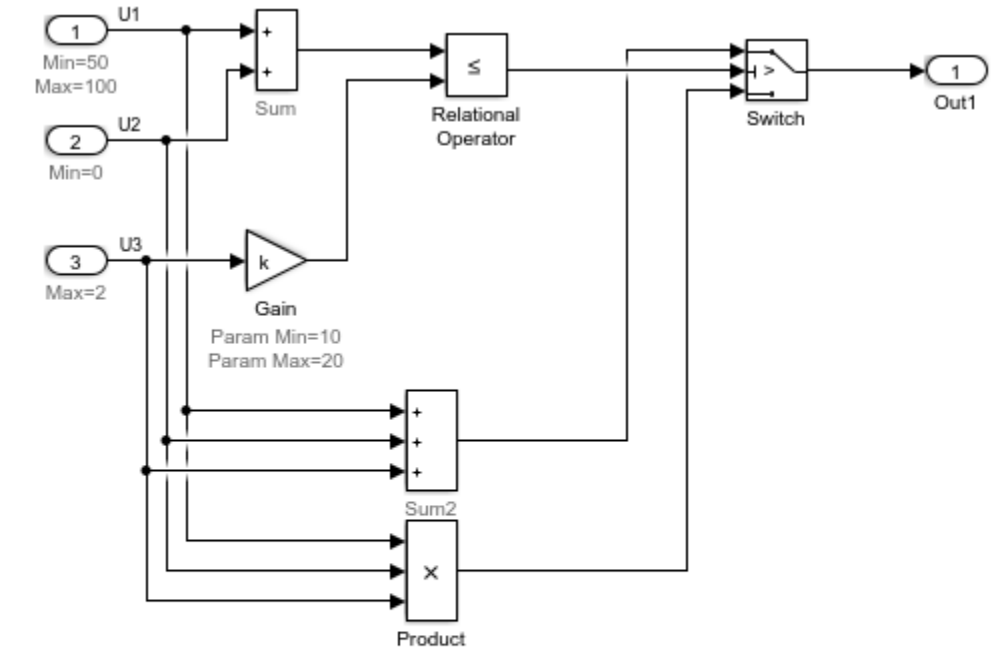
The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

Review Minimum and Maximum Information

Consider the model rtwdemo_minmax. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.

```
model = 'rtwdemo_minmax';
open_system(model);
```



Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_minmax
### Successful completion of build procedure for model: rtwdemo_minmax
```

A portion of `rtwdemo_minmax.c` is listed below.

```
cfile = fullfile(cgDir,'rtwdemo_minmax_ert_rtw','rtwdemo_minmax.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/U1'
   *  Inport: '<Root>/U2'
   *  Inport: '<Root>/U3'
   *  RelationalOperator: '<Root>/Relational Operator'
   *  Sum: '<Root>/Sum'
   */
  if (U1 + U2 <= k * U3) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Sum: '<Root>/Sum2'
     */
    rtY.Out1 = (U1 + U2) + U3;
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Product: '<Root>/Product'
     */
    rtY.Out1 = U1 * U2 * U3;
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Optimize using the specified minimum and maximum values**.

Alternatively, you can enable this optimization by setting the command-line parameter.

```
set_param(model, 'UseSpecifiedMinMax', 'on');
```

Generate Code With This Optimization

In the model, with the specified minimum and maximum values for U1 and U2, the sum of U1 and U2 has a minimum value of 50. Considering the range of U3 and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_minmax
### Successful completion of build procedure for model: rtwdemo_minmax
```

View the optimized code from `rtwdemo_minmax.c`.

```
cfile = fullfile(cgDir,'rtwdemo_minmax_ert_rtw','rtwdemo_minmax.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/U1'
   *  Inport: '<Root>/U2'
   *  Inport: '<Root>/U3'
   *  Product: '<Root>/Product'
   *  Switch: '<Root>/Switch'
   */
  rtY.Out1 = U1 * U2 * U3;
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
```

```
cd(currentDir)
```

Limitations

- This optimization does not take into account minimum and maximum values for:
  - Merge block inputs. To work around this issue, use a `Simulink.Signal` object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Outport block.

    Outport blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.
- If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

  Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for `Simulink.Signal` and `Simulink.Parameter` objects. In this example, to provide range information to the Polyspace software, use a `Simulink.Signal` object on the input of the division and specify a range that does not include zero.

  Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.
- If you are using double-precision data types and the **Code Generation > Interface > Support non-finite numbers** configuration parameter is selected, this optimization does not occur.
- If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not

occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.

- The Model Advisor DO-178C/DO-331 check **Check safety-related optimization settings** generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable. For more information about using the check to comply with DO-178C/DO-331, see Check safety-related optimization settings (Simulink Verification and Validation).

Flat Structures for Reusable Subsystem Parameters

This example shows how to increase the efficiency of code generated for reusable subsystems by generating a single flat parameter structure instead of a hierarchy of nested parameter structures.

By default, the code generated for reusable subsystems contains separate structures to define the parameters that each subsystem uses. If you use nested reusable subsystems, the generated code creates a hierarchy of nested parameter structures. Hierarchies of structures can reduce code efficiency due to compiler padding between word boundaries in memory.

This optimization is for only ERT-based targets. You must set the configuration parameter **Default parameter behavior** to `Inlined`.

Explore Example Model

Open the example model rtwdemo_paramstruct.

```
model = 'rtwdemo_paramstruct';
open_system(model);
```

The model contains two nested reusable subsystems. Each subsystem uses two of the parameters `A`, `B`, `C`, and `D` that are defined in the base workspace.

Generate Code with Hierarchical Parameter Structures

Create a temporary folder to contain the model build files. Generate code for the model using the default hierarchical data structure for reusable subsystems.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model)
```

In the code generation report, view the parameter structure definitions in the file `rtwdemo_paramstruct.h`.

```
cfile = fullfile(cgDir,'rtwdemo_paramstruct_ert_rtw','rtwdemo_paramstruct.h');
rtwdemodbtype(cfile,'/* Parameters for system: ''<S1>/SubsysZ'''',...
    '/* Parameters (auto storage)', 1, 0);
```

The code defines a parameter structure for each reusable subsystem and nests the structures.

Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization > Signals and Parameters** pane, select `Nonhierarchical` in the **Parameter structure** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'InlinedParameterPlacement', 'NonHierarchical');
```

Generate Code with Flat Parameter Structure

Generate code for the model using a flat parameter structure for reusable subsystems.

```
rtwbuild(model)
```

In the code generation report, view the parameter structure definition in the file `rtwdemo_paramstruct.h`.

```
rtwdemodbtype(cfile,'/* Parameters (auto storage) */',...
    '/* Real-time Model Data Structure */', 1, 0);
```

The code stores all of the parameters for the reusable subsystems in a single flat structure.

Close the model and delete build files.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Global Variables in Nonreusable Subsystem Functions

In this section...

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter "Function interface" (Simulink) provides this option. To compare the outputs for the **Function interface** options, first generate a function for a subsystem with a `void-void` interface, and then generate a function with arguments.

Generate `void-void` Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a `void-void` interface.

1. Open the example model `rtwdemo_roll`.
2. Right-click the subsystem `RollAngleReference`. From the list select `Block Parameter (Subsystem)`.
3. In the Block Parameter dialog box, confirm that the **Treat as atomic unit** check box is selected.
4. Click the **Code Generation** tab and set the **Function packaging** parameter to `Nonreusable function`.
5. The **Function interface** parameter is already set to `void_void`.
6. Click **Apply** and **OK**.
7. Repeat steps 2–6, for the other subsystems `HeadingMode` and `BasicRollMode`.
8. Generate code and the static code metrics report for `rtwdemo_roll`. This model is configured to generate a code generation report and to open the report automatically. For more information, see "Generate Static Code Metrics Report for Simulink Model" on page 35-38.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` contains a `void-void` function definition:

```
void rtwdemo_roll_RollAngleReference(void)
```

```
{
  ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `void_void` option, the number of bytes for global variables is `59`.

2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] rtwdemo_roll_U	26	14	6
[+] rtwdemo_roll_B	16	16	8
[+] rtwdemo_roll_DW	9	18	15
[+] rtwdemo_roll_M_	4	0*	0*
[+] rtwdemo_roll_Y	4	2	2
Total	**59**	**50**	

* The global variable is not directly used in any function.

Next, generate the same function with the `Allow arguments` option to compare the results.

Generate Function with Arguments

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

1. Open the Subsystem Block Parameter dialog box for `RollAngleReference`.
2. Click the **Code Generation** tab. Set the **Function interface** parameter to `Allow arguments`.
3. Click **Apply** and **OK**.
4. Repeat steps 2 and 3, for the other subsystems `HeadingMode` and `BasicRollMode`.
5. Generate code and the static code metrics report for `rtwdemo_roll`.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` now has arguments:

```
real32_T rtwdemo_roll_RollAngleReference(real32_T rtu_Turn_Knob,...
                                         boolean_T rtu_AP_Eng,...
                                         real32_T rtu_Phi)
 {
 ...
 }
```

In the static code metrics report, navigate to **Global Variables**. With the `Allow arguments` option set, the total number of bytes for global variables is now `47` bytes.

2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] rtwdemo_roll_U	26	11	8
[+] rtwdemo_roll_DW	9	18	15
[+] rtwdemo_roll_B	4	2	1
[+] rtwdemo_roll_M_	4	0*	0*
[+] rtwdemo_roll_Y	4	2	2
Total	**47**	**33**	

* The global variable is not directly used in any function.

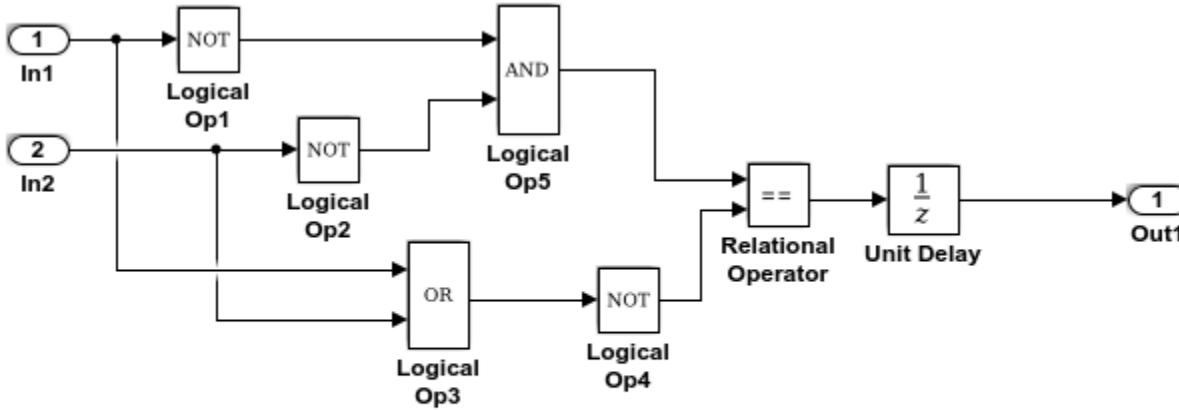
Optimize Generated Code By Packing Boolean Data Into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

Example Model

Consider the model rtwdemo_pack_boolean.

```
model = 'rtwdemo_pack_boolean';
open_system(model);
```



Disable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization > Signals and Parameters** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```
set_param(model,'BooleansAsBitfields','off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Generate Code Without Optimization

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean
```

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```
/* Block signals and states (auto storage) for system '<Root>' */
typedef struct {
  boolean_T LogicalOp1;                /* '<Root>/Logical Op1' */
  boolean_T LogicalOp2;                /* '<Root>/Logical Op2' */
  boolean_T LogicalOp5;                /* '<Root>/Logical Op5' */
  boolean_T LogicalOp3;                /* '<Root>/Logical Op3' */
  boolean_T LogicalOp4;                /* '<Root>/Logical Op4' */
  boolean_T RelationalOperator;        /* '<Root>/Relational Operator' */
  boolean_T UnitDelay_DSTATE;          /* '<Root>/Unit Delay' */
} DW;
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization > Signals and Parameters** pane, select **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleansAsBitfields','on');
```

Generate Code with Optimization

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean
```

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```
/* Block signals and states (auto storage) for system '<Root>' */
typedef struct {
  struct {
    uint_T LogicalOp1:1;               /* '<Root>/Logical Op1' */
    uint_T LogicalOp2:1;               /* '<Root>/Logical Op2' */
    uint_T LogicalOp5:1;               /* '<Root>/Logical Op5' */
    uint_T LogicalOp3:1;               /* '<Root>/Logical Op3' */
    uint_T LogicalOp4:1;               /* '<Root>/Logical Op4' */
    uint_T RelationalOperator:1;       /* '<Root>/Relational Operator' */
    uint_T UnitDelay_DSTATE:1;         /* '<Root>/Unit Delay' */
  } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

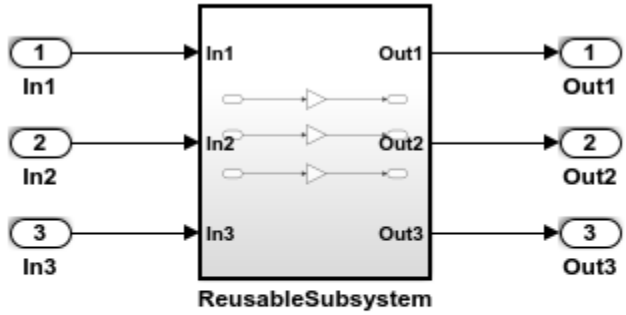
Optimize Generated Code By Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments instead of as a pointer to a structure stored in global memory optimizes the generated code. This optimization conserves RAM consumption and increases code execution speed by reducing global memory usage and eliminating data copies from local variables back to global block I/O structures.

Example Model

Consider the model rtwdemo_reusable_sys_outputs. In this model, the reusable subsystem outputs feed the root outputs of the model.

```
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```



Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
```

```
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs
```

The code snippet shows portions of `rtwdemo_reusable_sys_outputs.c`. Notice the global block I/O structure and in the model step function a data copy from this structure.

```
cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
'rtwdemo_reusable_sys_outputs.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
  DW_ReusableSubsystem *localDW)
{
  /* Gain: '<S1>/Gain' */
  localDW->Gain = 5.0 * rtu_In1;

  /* Gain: '<S1>/Gain1' */
  localDW->Gain1 = 6.0 * rtu_In2;

  /* Gain: '<S1>/Gain2' */
  localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

  /* Inport: '<Root>/In1' incorporates:
   *  Inport: '<Root>/In2'
   *  Inport: '<Root>/In3'
   */
  ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

  /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
```

```
  /* Outport: '<Root>/Out1' */
  rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;

  /* Outport: '<Root>/Out2' */
  rtY.Out2 = rtDW.ReusableSubsystem_d.Gain1;

  /* Outport: '<Root>/Out3' */
  rtY.Out3 = rtDW.ReusableSubsystem_d.Gain2;
}
```

Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization > Signals and Parameters** pane, set **Pass reusable subsystem outputs as** to `Individual arguments`.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

Generate Code With This Optimization

With this optimization, the `ReusableSubsystem` function has three output arguments, which are direct references to the external outputs. The `rtDW` global structure no longer exists, and the data copies from this structure to the `rtY` (external outputs) structure are not in the generated code.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs
```

The code snippet below is a portion of `rtwdemo_reusable_sys_outputs.c`. Observe the optimized code.

```
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3, real_T
  *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
```

```
  /* Gain: '<S1>/Gain' */
  *rty_Out1 = 5.0 * rtu_In1;

  /* Gain: '<S1>/Gain1' */
  *rty_Out2 = 6.0 * rtu_In2;

  /* Gain: '<S1>/Gain2' */
  *rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

  /* Inport: '<Root>/In1' incorporates:
   *  Inport: '<Root>/In2'
   *  Inport: '<Root>/In3'
   *  Outport: '<Root>/Out1'
   *  Outport: '<Root>/Out2'
   *  Outport: '<Root>/Out3'
   */
  ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

  /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace `for` loop controlled element assignments and `memcpy` function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than `for` loop controlled element assignments and `memcpy` function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

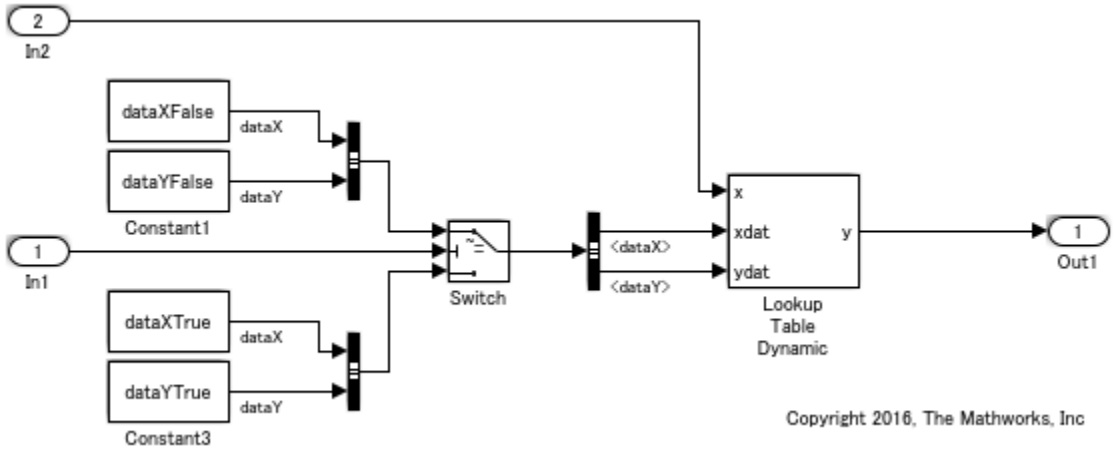
Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

1. Verify that your target supports the `memcpy` function.
2. Determine whether your model uses vector signal assignments (such as `Y=expression`) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
3. On the **Optimization > Signals and Parameters** pane, the **Use memcpy for vector assignment parameter**, which is on by default, enables the associated **Memcpy threshold (bytes)** parameter.
4. Examine the setting of **Memcpy threshold (bytes)**. By default, it specifies 64 bytes as the minimum array size for which `memcpy` function calls or pointer assignments can replace `for` loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

Example Model

Consider the following model named rtwdemo_pointer_conversion. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.



Generate Code without Optimization

1. In the Configuration Parameters dialog box, on the **All Parameters** tab, clear the **Use memcpy for vector assignment** parameter.
2. Create a temporary folder for the build and inspection process.
3. Press **Ctrl+B** to generate code.

```
### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion
```

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c` .

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
  int16_T rtb_dataX[100];
  int16_T rtb_dataY[100];
  int32_T i;

  /* Switch: '<Root>/Switch' incorporates:
   *  Constant: '<Root>/Constant'
   *  Constant: '<Root>/Constant1'
   *  Constant: '<Root>/Constant2'
   *  Constant: '<Root>/Constant3'
```

```
   *  Inport: '<Root>/In1'
   */
  for (i = 0; i < 100; i++) {
    if (rtU.In1) {
      rtb_dataX[i] = rtCP_Constant_Value[i];
      rtb_dataY[i] = rtCP_Constant1_Value[i];
    } else {
      rtb_dataX[i] = rtCP_Constant2_Value[i];
      rtb_dataY[i] = rtCP_Constant3_Value[i];
    }
  }

  /* End of Switch: '<Root>/Switch' */

  /* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
   *  Inport: '<Root>/In2'
   *  Outport: '<Root>/Out1'
   */
  /* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
   * Input0  Data Type:  Integer        S16
   * Input1  Data Type:  Integer        S16
   * Input2  Data Type:  Integer        S16
   * Output0 Data Type:  Integer        S16
   * Lookup Method: Linear_Endpoint
   *
   */
  LookUp_S16_S16( &(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}
```

Without the optimization, the generated code contains `for` loop controlled element assignments.

Enable Optimization and Generate Code

1. In the Configuration Parameter dialog box, on the **All Parameters** tab, select the **Use memcpy for vector assignment** parameter.
2. Generate code.

```
### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion
```

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
  const int16_T *rtb_dataX_0;
  const int16_T *rtb_dataY_0;

  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (rtU.In1) {
    /* Switch: '<Root>/Switch' incorporates:
     *  Constant: '<Root>/Constant'
     *  Constant: '<Root>/Constant1'
     */
    rtb_dataX_0 = &rtCP_Constant_Value[0];
    rtb_dataY_0 = &rtCP_Constant1_Value[0];
  } else {
    /* Switch: '<Root>/Switch' incorporates:
     *  Constant: '<Root>/Constant2'
     *  Constant: '<Root>/Constant3'
     */
    rtb_dataX_0 = &rtCP_Constant2_Value[0];
    rtb_dataY_0 = &rtCP_Constant3_Value[0];
  }

  /* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
   *  Inport: '<Root>/In2'
   *  Outport: '<Root>/Out1'
   */
  /* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
   * Input0  Data Type:  Integer        S16
   * Input1  Data Type:  Integer        S16
   * Input2  Data Type:  Integer        S16
   * Output0 Data Type:  Integer        S16
   * Lookup Method: Linear_Endpoint
   *
   */
  LookUp_S16_S16( &(rtY.Out1), &rtb_dataY_0[0], rtU.In2, &rtb_dataX_0[0], 99U);
}
```

Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

Remove Reset and Disable Functions from the Generated Code

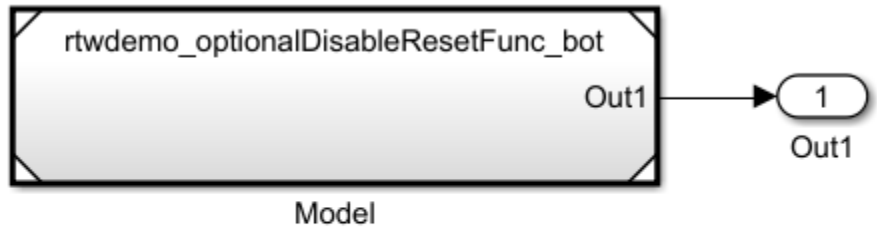
In this section...

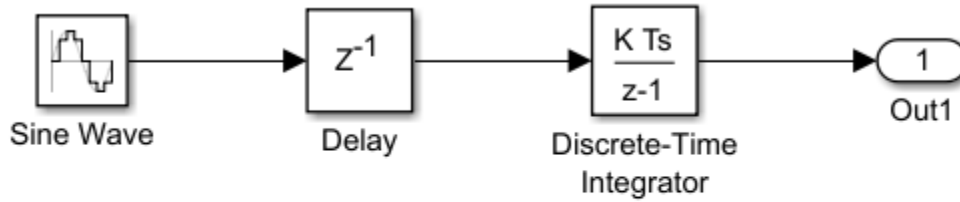
This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

Example Model

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.





Generate Code

1. Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.
2. In your system temporary folder, create a temporary folder for the build and inspection process.
3. Build the model.
4. Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.

The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```
/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset
  (DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
  /* InitializeConditions for Delay: '<Root>/Delay' */
  localDW->Delay_DSTATE = 0.0;

  /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
  localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1,
  DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
  /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
  localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}
```

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

Enable Optimization

1. Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
2. On the **All Parameters** tab, select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

Code Execution Profiling in Embedded Coder

Code Execution Profiling with SIL and PIL

In this section...

You can configure a software-in-the-loop (SIL) or processor-in-the-loop (PIL) on page 64-2 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the SIL or PIL application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

1. Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the *`model`*`_initialize` function.
2. In these tasks, investigate code sections that require the most time.
3. Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL or PIL simulation and compare the new metrics against previous metrics.

Note: Execution-time measurements depend greatly on the hardware that you use. For reliable results, collect execution-time metrics using hardware on which you plan to deploy the generated code, that is, run PIL simulations that execute code on your target hardware. SIL simulations, which execute code on your host computer, might not produce representative metrics.

When the SIL or PIL simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.
- Analyze the measurements within the MATLAB environment.

Configure Code Execution Profiling

To configure code execution profiling for a SIL or PIL simulation:

1. In your top model, open the Configuration Parameters dialog box, and select the **Code Generation** > **Verification** pane.
2. Select the **Measure task execution time** check box.
3. If you also want function execution times, select the **Measure function execution times** check box.
4. In the **Workspace variable** field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type `coder.profile.ExecutionTime`.

   If you select the **Data Import/Export** > **Single simulation output** check box, the software creates the variable in the `Simulink.SimulationOutput` object that you specify.
5. From the **Save options** drop-down list, select one of the following:

   - `Summary data only` — If you want to generate only a report and reduce memory usage, for example, during a long simulation.
   - `All data` — Allows you to generate a report and store execution-time profiles in the base workspace. After the simulation, you can use methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.
6. Click **OK**.

For a PIL simulation, you must configure a hardware-specific timer. When you set up the connectivity configuration for your target, create a timer object. This action is not required for a SIL simulation.

If you select `All data` from the **Save options** drop-down list, the metrics display window and generated report display Simulation Data Inspector icons  . When you click one of these icons, the software imports simulation results into the Simulation Data Inspector. You can then plot execution times and manage and compare plots from various simulations.

Profiling for Atomic Subsystems and Model Reference Hierarchies

To generate execution-time metrics for tasks only, on the **Code Generation** > **Verification** pane of the Configuration Parameters dialog box, select the **Measure task execution time** check box and clear the **Measure function execution times** check box.

To generate function execution data for atomic subsystems in the top model, on the **Code Generation** > **Verification** pane, select the **Measure task execution time** and **Measure function execution times** check boxes.

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the **Function packaging** field (on the **Code Generation** tab of the Function Block Parameters dialog box) to either `Nonreusable function` or `Reusable function`. If the field is set to `Auto`, then the insertion of probes depends on the packaging choice that results from the `Auto` setting. If the field is set to `Inline`, the software does not insert probes.

Note: In the generated code, the software wraps each function call with measurement probes except when:

- The call site cannot be wrapped because of expression folding (see "Minimize Computations and Storage for Intermediate Results at Block Outputs" (Simulink Coder)).
- The call site is located in the shared utility code (see "Sharing Utility Code" (Simulink Coder)).

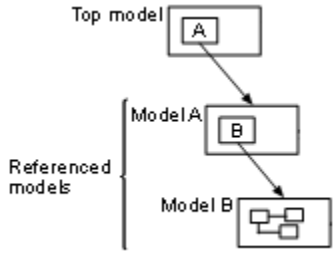
You might not want to generate profiles for specific subsystems. To disable code execution profiling for a subsystem in the top model:

1. Right-click the subsystem.
2. From the context menu, select **Properties**.
3. In the Block Properties dialog box, select the **General** tab.
4. In the **Tag** field, enter `DoNotProfile`.
5. Click **OK**.

To generate function execution data for model reference hierarchies:

1. In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
2. Select the **Measure task execution time** check box.
3. For each Model block that you want to profile, select **Measure function execution times** only at the reference level for which you require function execution data.

For example, consider a top model that has Model block A, which in turn contains Model block B.



If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and **Measure function execution times** for model B.

Note: By default, the Model block parameter **Code interface** is set to `Model reference`. If this block parameter is set to `Top model`, the configuration parameter **Measure task execution time** for the top model and the referenced model must be the same. Otherwise, the software produces an error.

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Blocks From Subsystems” on page 64-18. The execution profiling settings of your top model do not apply to the PIL block.

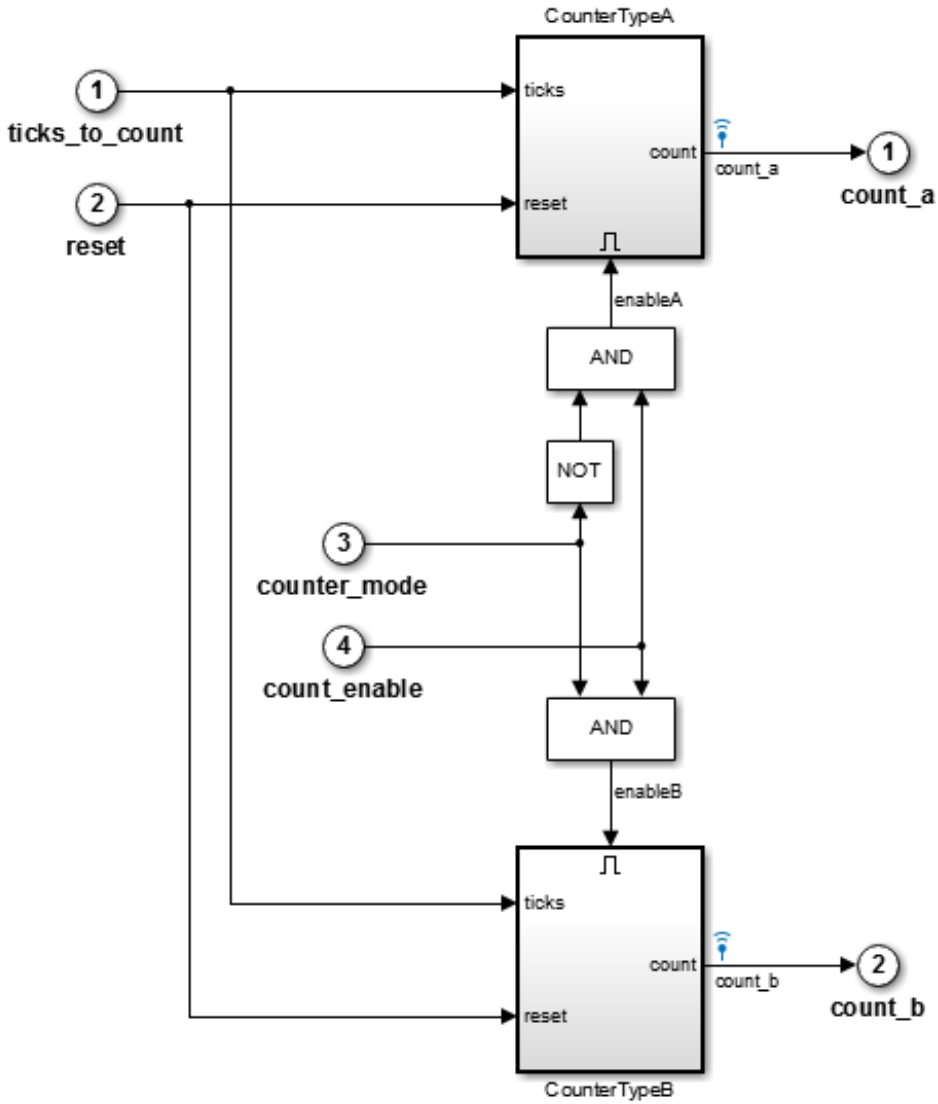
View and Compare Code Execution Times

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can use the Simulation Data Inspector to observe streamed execution times. At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for all profiled components.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

Consider the model `rtwdemo_sil_topmodel`, which has two subsystems `CounterTypeA` and `CounterTypeB`.



CounterTypeA
1
ticks_to_count
2
reset
ticks
reset
count
count_a
1
count_a
enableA
AND
NOT
3
counter_mode
4
count_enable
AND
enableB
ticks
reset
count
count_b
2
count_b
CounterTypeB

To measure code execution times for the subsystems, on the **Configuration Parameters > Code Generation > Verification** pane:

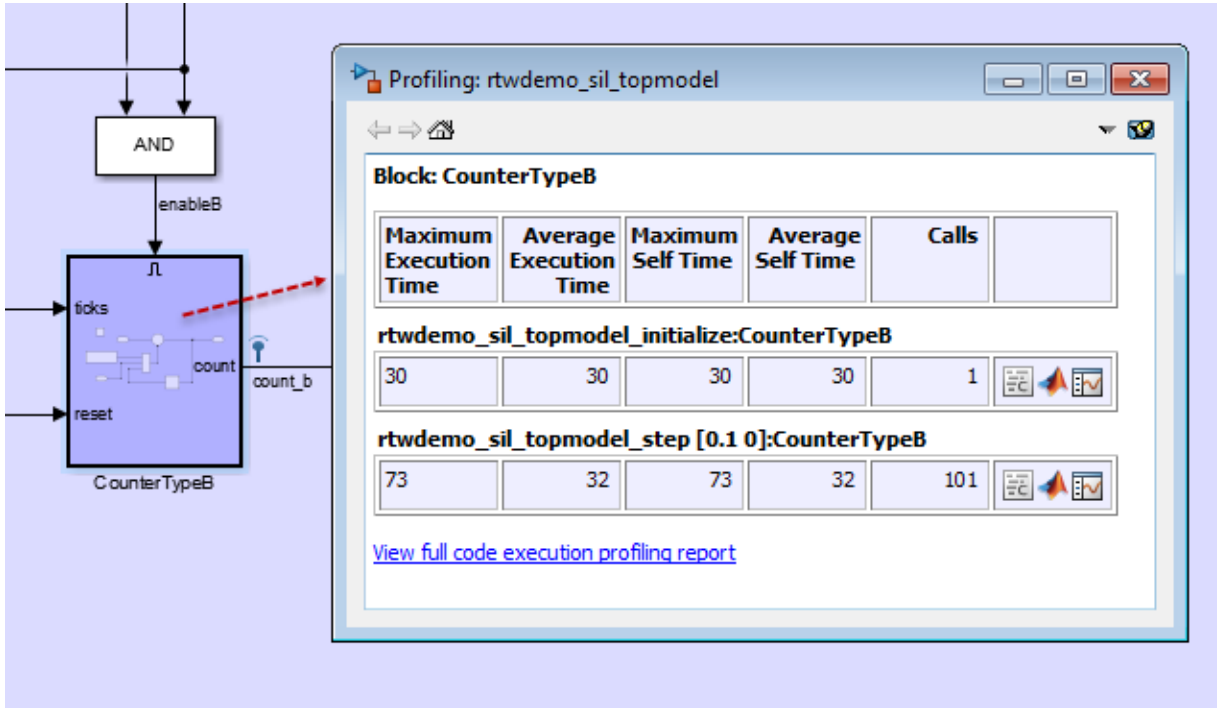
1. Select the following check boxes:
   - **Measure task execution time** — Provides execution-time metrics for the task generated from the top model `rtwdemo_sil_topmodel`.
   - **Measure function execution times** — Provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.
2. Specify a **Workspace variable**, for example, `executionProfile`.
3. From the **Save options** drop-down list, select `All data`.

The simulation generates the variable `executionProfile` in the MATLAB base workspace.

Note: If you select the **Data Import/Export > Single simulation output** check box, the simulation creates the variable in your specified `Simulink.SimulationOutput` object.

To view streamed execution times during the simulation, open the Simulation Data Inspector. On the Simulink Editor toolbar, click the Simulation Data Inspector button.

When the simulation is complete, the profiled model components are colored blue. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`.



The display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The profiled code section in the code generation report.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

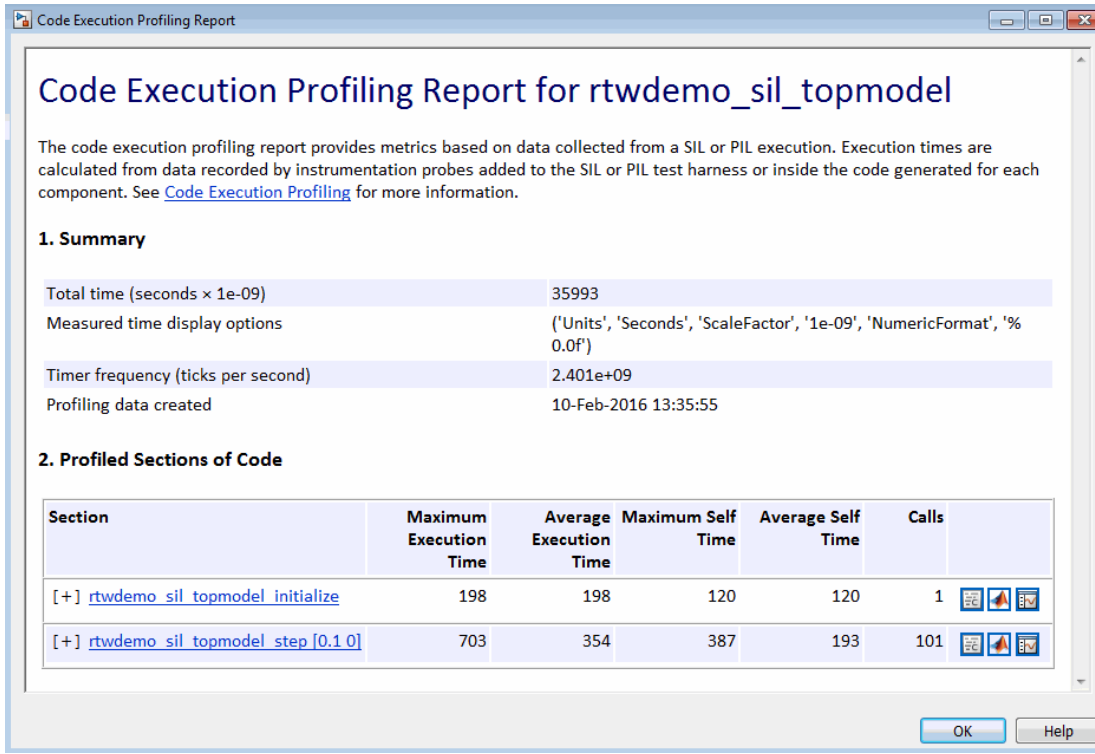
If you close the model or display window, you can reopen the colored model and display window with this line command:

```
>> annotate(executionProfile)
```

Code Execution Profiling Report

At the end of the simulation, you can open this report through the metrics display window or with this line command:

```
>> report(executionProfile)
```



Part 1 provides a summary. Part 2 contains information about profiled code sections.

Expand and collapse profiled sections in Part 2 by clicking [+] and [–] respectively. This graphic shows fully expanded sections.

2. Profiled Sections of Code

Section	Maximum Execution Time	Average Execution Time	Maximum Self Time	Average Self Time	Calls	
[−] rtwdemo_sil_topmodel_initialize	198	198	120	120	1	
CounterTypeA	52	52	52	52	1	
CounterTypeB	27	27	27	27	1	
[−] rtwdemo_sil_topmodel_step [0.1 0]	703	354	387	193	101	
CounterTypeA	257	116	257	116	101	
CounterTypeB	87	45	87	45	101	

The report contains time measurements for:

- The model initialization function `rtwdemo_sil_topmodel_initialize`.
- A task represented by the step function `rtwdemo_sil_topmodel_step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

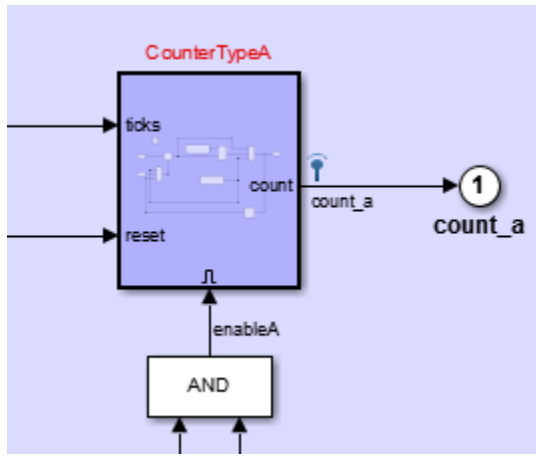
You can go to a profiled code section in the Generated Code view of the Code Generation Report. In the Code Execution Profiling Report, on a code section row, click the icon  . For example, if you click the icon for the `rtwdemo_sil_topmodel_initialize` task, you see the measurement probes around the call site in the SIL application.

```
66 XIL_INTERFACE_ERROR_CODE xilInitialize(uint32_T xilFcnId)
67 {
68   XIL_INTERFACE_ERROR_CODE errorCode = XIL_INTERFACE_SUCCESS;
69
70   /* initialize output storage owned by In-the-Loop */
71   /* Single In-the-Loop Component */
72   if (xilFcnId == 0) {
73     taskTimeStart_51c545e6ce8b10bf(1U);
74     rtwdemo_sil_topmodel_initialize();
75     taskTimeEnd_rt_38248ea98502ec29(1U);
76   } else {
77     errorCode = XIL_INTERFACE_UNKNOWN_FCNID;
78   }
79
80   return errorCode;
81 }
```

If you click the icon for a function, the call site is highlighted.

```
147 /* Model step function */
148 void rtwdemo_sil_topmodel_step(void)
149 {
150   /* Logic: '<Root>/Logical Operator2' incorporates:
151    *  Inport: '<Root>/count_enable'
152    *  Inport: '<Root>/counter_mode'
153    *  Logic: '<Root>/Logical Operator'
154    */
155   enableA = ((!rtU.counter_mode) && rtU.count_enable);
156
157   /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
158   CounterTypeA();
159
160   /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
```

From the Code Execution Profiling Report, you can trace the model component that produces a set of metrics. For example, in the **Section** column, if you click the `CounterTypeA` hyperlink, the Simulink Editor identifies the subsystem.



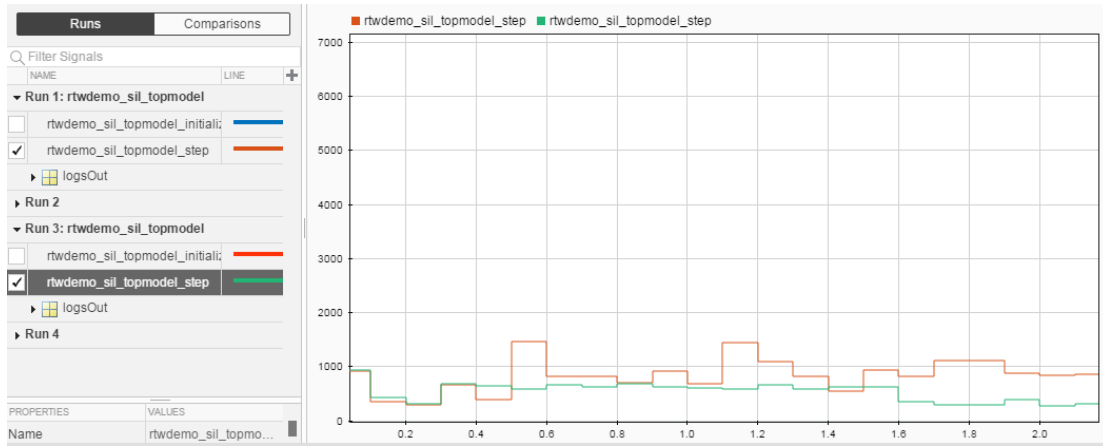
By default, the report displays time in nanoseconds (10^{-9} seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds (10^{-6} seconds), use the following command:

```
>>report(executionProfile,'Units', 'Seconds', 'ScaleFactor', '1e-06', 'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
>>executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a task or function, click the Simulation Data Inspector icon on the corresponding row. Use the Simulation Data Inspector to manage and compare plots from various simulations.



Note: To observe how code sections are invoked over the execution timeline, use the `timeline` function.

The following table describes the information provided in the code section profiles.

Column	Description
Section	Name of task, top model, subsystem, or Model block. Click the link to go to the model.

Column	Description
	With a task, the sample period and sample offset are listed next to the task name. For example, `rtwdemo_sil_topmodel_step [0.1 0]` indicates that the sample period is 0.1 seconds and the sample offset is 0.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.
Calls	Number of calls to the code section.
	Icon that you click to see the profiled code section in the Generated Code view of the Code Generation Report. The code section can be a task or a function. The specified workspace variable, for example, `executionProfile`, must be present in the base workspace.
	Icon that you click to display the profiled code section in the Command Window. Equivalent to executing the command `executionProfile.Sections(i)`. The specified workspace variable, for example, `executionProfile`, must be present in the base workspace.
	Icon that you click to display measured execution times with Simulation Data Inspector. The specified workspace variable, for example, `executionProfile`, must be present in the base workspace.

More About

- "Tips and Limitations" on page 58-21

Analyze Code Execution Data

After a SIL or PIL simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

1. Open `rtwdemo_sil_topmodel`.
2. On the **Configuration Parameters** > **Code Generation** > **Verification** pane, specify profiling options:
   - Select the **Measure task execution time** check box.
   - Specify a **Workspace variable**, for example, `myExecutionProfile`.
   - From the **Save options** drop-down list, select `All data`.
3. Run a SIL simulation.

The software generates the workspace variable `myExecutionProfile`, an `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method.

```
>> no_of_Sections = myExecutionProfile.Sections

no_of_Sections =

  1×2 ExecutionTimeTaskSection array with properties:

    Name
    Number
    ExecutionTimeInTicks
    SelfTimeInTicks
    TurnaroundTimeInTicks
    TotalExecutionTimeInTicks
    TotalSelfTimeInTicks
    TotalTurnaroundTimeInTicks
    MaximumExecutionTimeInTicks
    MaximumExecutionTimeCallNum
    MaximumSelfTimeInTicks
    MaximumSelfTimeCallNum
    MaximumTurnaroundTimeInTicks
    MaximumTurnaroundTimeCallNum
    NumCalls
    ExecutionTimeInSeconds
    Time
```

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.

```
>> FirstSectionProfile = myExecutionProfile.Sections(1)
SecondSectionProfile = myExecutionProfile.Sections(2)

FirstSectionProfile =

  ExecutionTimeTaskSection with properties:

                           Name: 'rtwdemo_sil_topmodel_initialize'
                         Number: 1
           ExecutionTimeInTicks: 1188
                SelfTimeInTicks: 1188
            TurnaroundTimeInTicks: 1188
       TotalExecutionTimeInTicks: 1188
            TotalSelfTimeInTicks: 1188
      TotalTurnaroundTimeInTicks: 1188
     MaximumExecutionTimeInTicks: 1188
     MaximumExecutionTimeCallNum: 1
          MaximumSelfTimeInTicks: 1188
          MaximumSelfTimeCallNum: 1
    MaximumTurnaroundTimeInTicks: 1188
    MaximumTurnaroundTimeCallNum: 1
                      NumCalls: 1
          ExecutionTimeInSeconds: 5.4000e-07
                           Time: 0

SecondSectionProfile =

  ExecutionTimeTaskSection with properties:

                           Name: 'rtwdemo_sil_topmodel_step [0.1 0]'
                         Number: 2
           ExecutionTimeInTicks: [1×101 uint64]
                SelfTimeInTicks: [1×101 uint64]
            TurnaroundTimeInTicks: [1×101 uint64]
       TotalExecutionTimeInTicks: 70316
            TotalSelfTimeInTicks: 70316
      TotalTurnaroundTimeInTicks: 70316
     MaximumExecutionTimeInTicks: 2448
     MaximumExecutionTimeCallNum: 2
          MaximumSelfTimeInTicks: 2448
          MaximumSelfTimeCallNum: 2
    MaximumTurnaroundTimeInTicks: 2448
    MaximumTurnaroundTimeCallNum: 2
                      NumCalls: 101
          ExecutionTimeInSeconds: [1×101 double]
                           Time: [101×1 double]
```

Use `coder.profile.ExecutionTimeSection` methods to extract profiling information for a particular code section. For example, use `Name` to obtain the name of a profiled task.

```
>> name_of_section = SecondSectionProfile.Name

name_of_section =
```

```
rtwdemo_sil_topmodel_step [0.1 0]
```

If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the `coder.profile.ExecutionTime` method `TimerTicksPerSecond` to calibrate the timer:

```
>> myExecutionProfile.TimerTicksPerSecond = 2.2e9;
>> SecondSectionProfile = myExecutionProfile.Sections(2);
```

Tips and Limitations

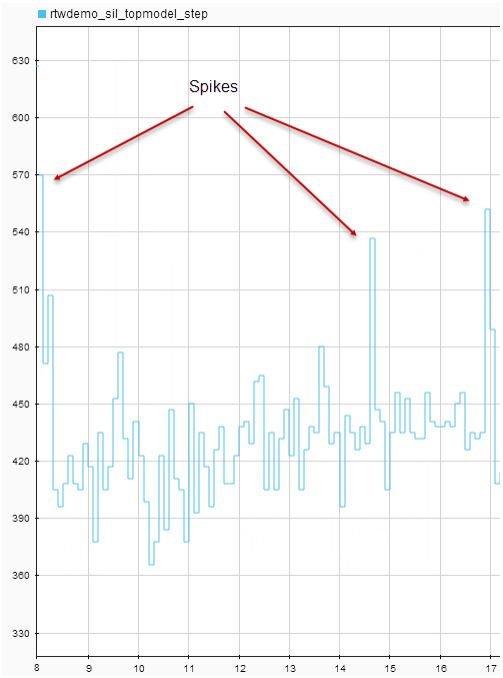
In this section...

Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.



The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than 2^{64} ticks (2^{32} ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be 2^{8}, 2^{16}, 2^{32}, or 2^{64} ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than `1/(20e6)*(2^32-1)`, that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.

Hardware-Specific Timer

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is 64 bits.
- For PIL simulation, you can specify an 8-, 16-, 32-, or 64-bit timer.

Task Context Switching Due to Preemption

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

`Warning: Analysis unsuccessful for one or more profiling data points. ...`
For example, the software might generate this warning when not all mutex take system calls (associated with rate transitions) are instrumented. In the case of Simulink Real-Time, this situation might arise if you generate code for a model reference hierarchy without enabling function profiling for all referenced models (`set_param(model, 'CodeProfilingInstrumentation', 'on')`). If a mutex take system call is not instrumented, a task context switch might occur that is not visible to the execution profiling analysis.

In other cases, although the software cannot accurately determine behavior, the software does *not* generate a warning.

Data Type Replacement Support

Data type replacement does not support the measurement of function execution times. For your model, clear one of the following check boxes:

- **Configuration Parameters > Code Generation > Verification > Measure function execution times**
- **Configuration Parameters > Code Generation > Data Type Replacement > Replace data type names in the generated code**

Subsystem Code Reuse

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see "Code Reuse For Subsystems Shared Across Models" (Simulink Coder).

Cannot Load Execution-Time Measurements from Previous Release

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

```
Format of execution profiling data is invalid. This error can occur if
you load data from a previous release. Loading data from a previous
release is not supported.
```

Code Execution Profiling for MATLAB Coder

Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

Note: SIL and PIL execution supports multiple entry-point functions. An entry-point function can call another entry-point function as a subfunction. However, the software generates execution time profiles only for functions that are called at the entry-point level. The software does not generate execution time profiles for entry-point functions that are called as subfunctions by other entry-point functions.

- "View Execution Times" on page 59-4
- "Analyze Execution Time Data" on page 59-7

Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

1. To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
2. To open your project, click  and then click `Open existing project`. Select the project.
3. On the **Generate Code** page, click **Verify Code**.
4. Select the **Enable entry point execution profiling for SIL/PIL** check box.

Or, from the Command Window, specify the `CodeExecutionProfiling` property of your `coder.EmbeddedCodeConfig` object. For example:

```
config.CodeExecutionProfiling = true;
```

More About

- "Execution Time Profiling for SIL and PIL" on page 59-2

View Execution Times

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the **Test Output** tab. For example:

```
Current plot held
### Starting SIL execution for 'kalman01'
    To terminate execution: clear kalman01_sil
    Execution profiling data is available for viewing. Open Simulation Data Inspector.
    Execution profiling report available after termination.
Current plot released
```

To observe streamed execution times while the execution runs, click the `Simulation Data Inspector` link.

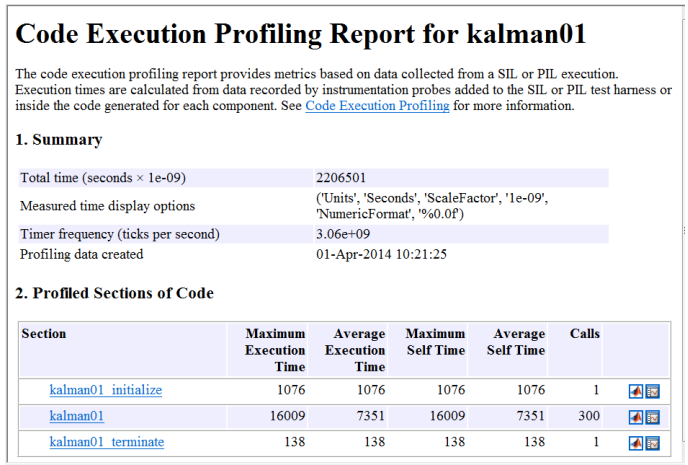
To open the code execution profiling report:

1. Click the `Stop SIL Verification` link.

   The software terminates the execution process and displays a new link.

   ```
   ### Stopping SIL execution for 'kalman01'
       Execution profiling report: report(getCoderExecutionProfile('kalman01'))
   ```

2. Click the new link.



Code Execution Profiling Report for kalman01

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

1. Summary

Total time (seconds × 1e-09)	2206501
Measured time display options	('Units', 'Seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f')
Timer frequency (ticks per second)	3.06e+09
Profiling data created	01-Apr-2014 10:21:25

2. Profiled Sections of Code

Section	Maximum Execution Time	Average Execution Time	Maximum Self Time	Average Self Time	Calls	
kalman01_initialize	1076	1076	1076	1076	1	
kalman01	16009	7351	16009	7351	300	
kalman01_terminate	138	138	138	138	1	

The first section provides a summary. The second section contains information about profiled code sections.

The report contains time measurements for:

- The *entry_point_fn*`_initialize` function, for example, `kalman01_initialize`.
- The entry-point function, for example, `kalman01`.
- The *entry_point_fn*`_terminate` function, for example, `kalman01_terminate`.

By default, the report displays time in nanoseconds (10^{-9} seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds (10^{-6} seconds), use the `report` command:

```
executionProfile=getCoderExecutionProfile('kalman01'); % Create workspace var
report(executionProfile, ...
       'Units', 'Seconds', ...
       'ScaleFactor', '1e-06', ...
       'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is established. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a code section, click the Simulation Data Inspector icon  on the corresponding row. You can use the Simulation Data Inspector to manage and compare plots from various executions.

The following table lists the information provided in the code section profiles.

Column	Description
Section	Name of function from which code is generated.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.

Column	Description
Calls	Number of calls to the code section.
	Icon that you click to display the profiled code section.
	Icon that you click to display measured execution times with Simulation Data Inspector.

- "Simulation Data Inspector in Your Workflow" (Simulink)

Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

Extract Execution Time Data for Kalman Estimator Code

1 Run SIL execution to generate execution time data

Copy MATLAB code to your working folder.

```
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator, see "C Code Generation at the Command Line" (MATLAB Coder).

Create a coder.EmbeddedCodeConfig object.

```
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

You see the following message.

```
### Starting SIL execution for 'kalman01'
    To terminate execution: clear kalman01_sil
    Execution profiling data is available for viewing. Go to Simulation Data Inspector.
    Execution profiling report available after termination.
Current plot released
```

Terminate the SIL execution process. Click the link `clear kalman01_sil`.

```
 ### Stopping SIL execution for 'kalman01'
    Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

2 Create workspace variable that holds execution time data

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```
executionProfile=getCoderExecutionProfile('kalman01');
```

3 Extract code sections

Use the `Sections` method.

```
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```
allSections =

  1x3 ExecutionTimeTaskSection array with properties:

    Name
    Number
    ExecutionTimeInTicks
    SelfTimeInTicks
    TurnaroundTimeInTicks
    TotalExecutionTimeInTicks
    TotalSelfTimeInTicks
    TotalTurnaroundTimeInTicks
    MaximumExecutionTimeInTicks
    MaximumExecutionTimeCallNum
    MaximumSelfTimeInTicks
    MaximumSelfTimeCallNum
    MaximumTurnaroundTimeInTicks
    MaximumTurnaroundTimeCallNum
    NumCalls
    ExecutionTimeInSeconds
    Time
```

4 Extract execution time data from specific code section

Specify the code section that you want to examine.

```
secondSectionProfile = executionProfile.Sections(2)
```

The software displays profile data for the code section.

```
secondSectionProfile =

  ExecutionTimeTaskSection with properties:

                          Name: 'kalman01'
                        Number: 2
          ExecutionTimeInTicks: [1x300 uint64]
               SelfTimeInTicks: [1x300 uint64]
         TurnaroundTimeInTicks: [1x300 uint64]
      TotalExecutionTimeInTicks: 6641016
           TotalSelfTimeInTicks: 6641016
     TotalTurnaroundTimeInTicks: 6641016
    MaximumExecutionTimeInTicks: 48864
    MaximumExecutionTimeCallNum: 158
         MaximumSelfTimeInTicks: 48864
         MaximumSelfTimeCallNum: 158
   MaximumTurnaroundTimeInTicks: 48864
   MaximumTurnaroundTimeCallNum: 158
                      NumCalls: 300
         ExecutionTimeInSeconds: [1x300 double]
                          Time: [300x1 double]
```

You can extract specific properties, for example, the name of a profiled function.

```
nameOfSection = secondSectionProfile.Name
```

The software displays the name.

```
nameOfSection =

kalman01
```

The following table lists the information that you can extract from each code section.

Property	Description
`Name`	Name of entry-point function
`Number`	Code section number

Property	Description
`ExecutionTimeInTicks`	Vector of execution times, measured in timer ticks. Each element contains the difference between the timer reading at the start and at the end of the code section. The data type is the same data type as the data type of the timer used on the target, which allows you to infer the maximum range of the timer measurements.
`SelfTimeInTicks`	Vector of timer tick numbers. Each element contains the number of ticks recorded for the code section, excluding the time spent in calls to child functions.
`TurnaroundTimeInTicks`	Vector of timer tick numbers. Each element contains the number of ticks recorded between the start and the finish of the code section. Unless the code is preempted, this number is the same number as the execution time.
`TotalExecutionTimeInTicks`	Total number of timer ticks recorded for the code section over the entire execution.
`TotalSelfTimeInTicks`	Total number of timer ticks recorded for the profiled code section over the entire execution. However, this number excludes the time spent in calls to child functions.
`TotalTurnaroundTimeInTicks`	Total number of timer ticks recorded between the start and the finish of the profiled code section over the entire execution. Unless the code is preempted, this number is the same as the total execution time.
`MaximumExecutionTimeInTicks`	Maximum number of timer ticks recorded for a single invocation of the code section over the execution.
`MaximumExecutionTimeCallNum`	Number of call in which `MaximumExecutionTimeInTicks` occurs.
`MaximumSelfTimeInTicks`	Maximum number of timer ticks recorded for a single code section invocation, but excluding the time spent in calls to child functions.
`MaximumSelfTimeCallNum`	Number of call in which `MaximumSelfTimeInTicks` occurs.
`MaximumTurnaroundTimeInTicks`	Maximum number of timer ticks recorded between the start and the finish of a single invocation of the profiled code section over the execution. Unless the code is preempted, this time is the same as the maximum execution time.

Property	Description
`MaximumTurnaroundTimeCallNum`	Number of call in which `MaximumTurnaroundTimeInTicks` occurs.
`NumCalls`	Total number of calls to the code section over the entire execution.
`ExecutionTimeInSeconds`	Vector of execution times, measured in seconds. Each element contains the difference between the timer reading at the start and at the end of the code section. Produced only if `TimerTicksPerSecond` is set.
`Time`	Vector of execution time measurements for the code section.

Verification

Simulation and Code Comparison in Simulink Coder

Simulation and Code Comparison

In this section...

This example shows how to verify the answers computed by code generated from the `slexAircraftExample` model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

Note To obtain a valid comparison between model output and the generated code, use the same **Solver options** and **Step size** for the simulation run and the build process.

Configure Signal Data for Logging

Configure the model for logging and recording signal data.

1. Make sure that `slexAircraftExample` is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

   ```
   clear
   ```

   The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the `slexAircraftExample` model requires.
2. In the Command Window, enter `slexAircraftExample` to open the model.
3. In the model window, choose **File > Save As**, navigate to the working folder, and save a copy of the `slexAircraftExample` model as `myAircraftExample`.
4. Set up your model to log signal data for signals: `Stick`, `alpha,rad`, and `q, rad/sec`. For each signal:

   a. Right-click the signal. From the context menu, select **Properties**.

b In the Signal Properties dialog box, select **Log signal data**.

c In the **Logging name** section, from the drop-down list, select `Custom`.

d In the text field, enter the logging name for the corresponding signal.

Signal Name	Logging Name
`Stick`	`Stick_input`
`alpha,rad`	`Alpha`
`q, rad/sec`	`Pitch_rate`

e Click **Apply** and **OK**.

For more information, see "Export Signal Data Using Signal Logging" (Simulink).

5 Select **Simulation** > **Model Configuration Parameters** to open the Configuration Parameters dialog box.

6 Select the **Solver** pane and in the **Solver options** section, specify the **Type** parameter as `Fixed-step`.

7 On the **Data Import/Export** pane:

- Specify the **Format** parameter as `Structure with time`.
- Clear the **States** parameter check box.
- Select the **Signal logging** parameter.
- Select the **Record logged workspace data in Simulation Data Inspector** parameter to enable logged signal data to send to the Simulation Data Inspector after the simulation is finished.

8 Save the model.

Proceed to "Log Simulation Data" on page 60-3.

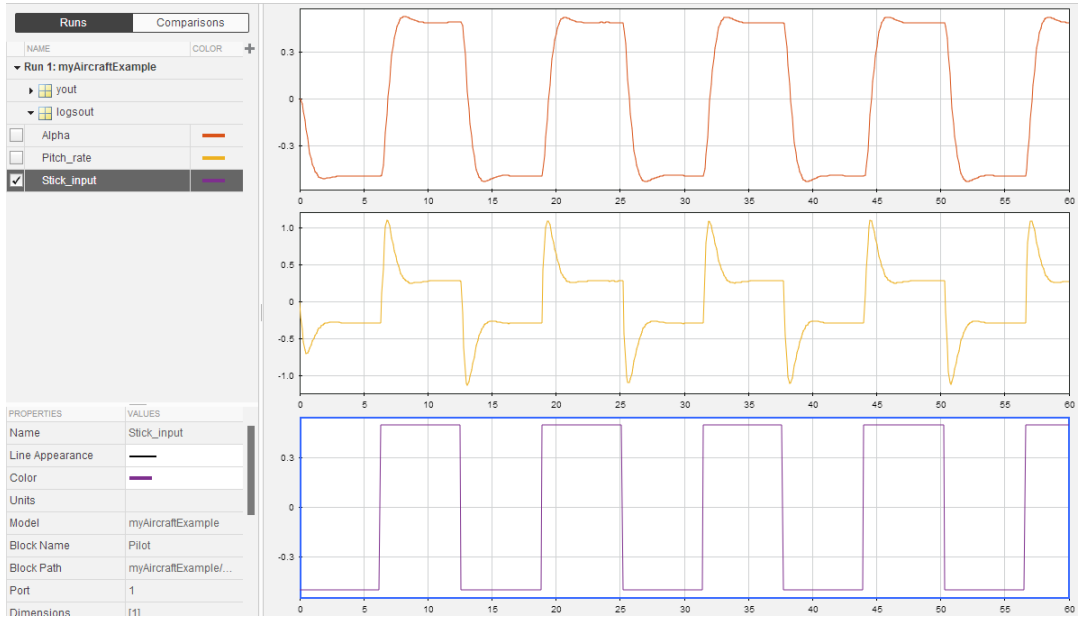
Log Simulation Data

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

1 Run the model. When the simulation is done, on the Simulink Editor toolbar, the **Simulation Data Inspector** button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

2. Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
3. Group the signals:
   a. On the **Visualize** tab, click **Group Signals**.
   b. In the Group Signals dialog box, select `Data Hierarchy` from the **Then By** list.

   c. Click **OK**.
4. Click the `logsout` expander to view the logged signals.
5. Click the **Format** tab.
6. Click the **Subplots** button and select `3x1` to show three subplots.
7. For each signal:
   a. Click the top subplot. A blue border indicates the plot selection.
   b. Select the check box next to the `Alpha` signal name. The signal data appears in the subplot.
   c. Plot the `Pitch_rate` signal in the middle subplot.
   d. Plot the `Stick_input` signal in the bottom subplot.



Proceed to “Run Executable and Load Data” on page 60-5.

Run Executable and Load Data

You must rebuild and run the `myAircraftExample` executable to obtain a valid data file because you have modified the model.

1. Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. Select the **Code Generation > Interface** pane.
3. Set the **MAT-file variable name modifier** parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
4. Click **Apply** and **OK**.
5. Save the model.
6. On the Simulink Editor toolbar, click the **Build Model** button to generate code.
7. When the build is finished, run the standalone program from the Command Window.

```
!myAircraftExample
```

The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

8 Load the data file `myAircraftExample.mat`.

```
load myAircraftExample
```

Tip: For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Proceed to "Visualize and Compare Results" on page 60-6.

Visualize and Compare Results

When you follow the example sequence that began in "Configure Signal Data for Logging" on page 60-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

1 To view the execution output for `alpha,rad`, import the data into the Simulation Data Inspector.

   a On the Simulation Data Inspector **Visualize** tab, click the **Import** button to open the Import dialog.

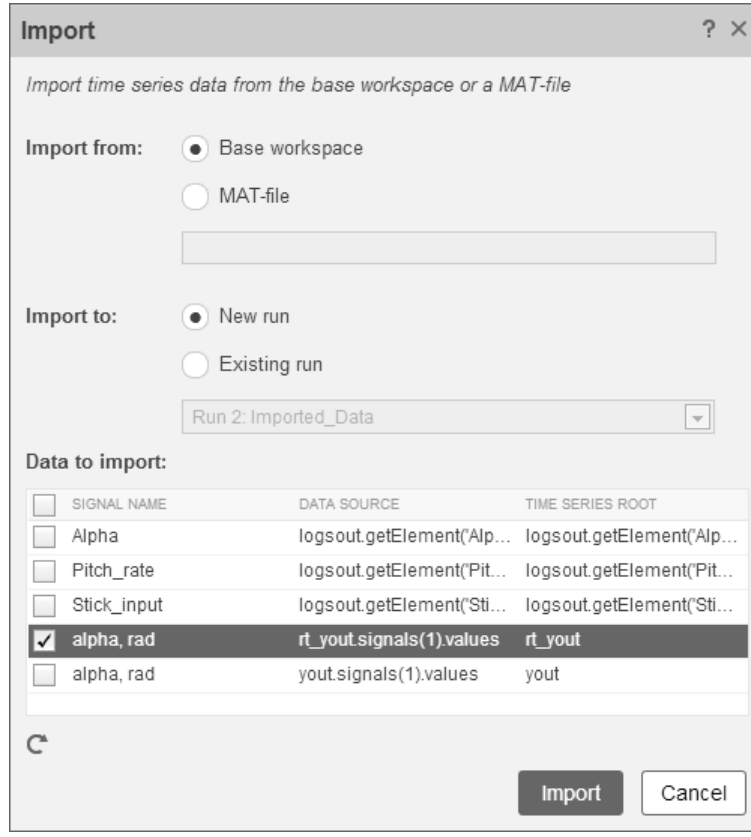
   b Specify **Import from** as **Base workspace**.

   c Specify **Import to** as **New run**.

   d To the left of **Signal Name**, click the check mark to clear the check boxes.

   e Select the check box for the `alpha,rad` data where the **Time Series Root** is `rt_yout`.

   f Click **Import**.



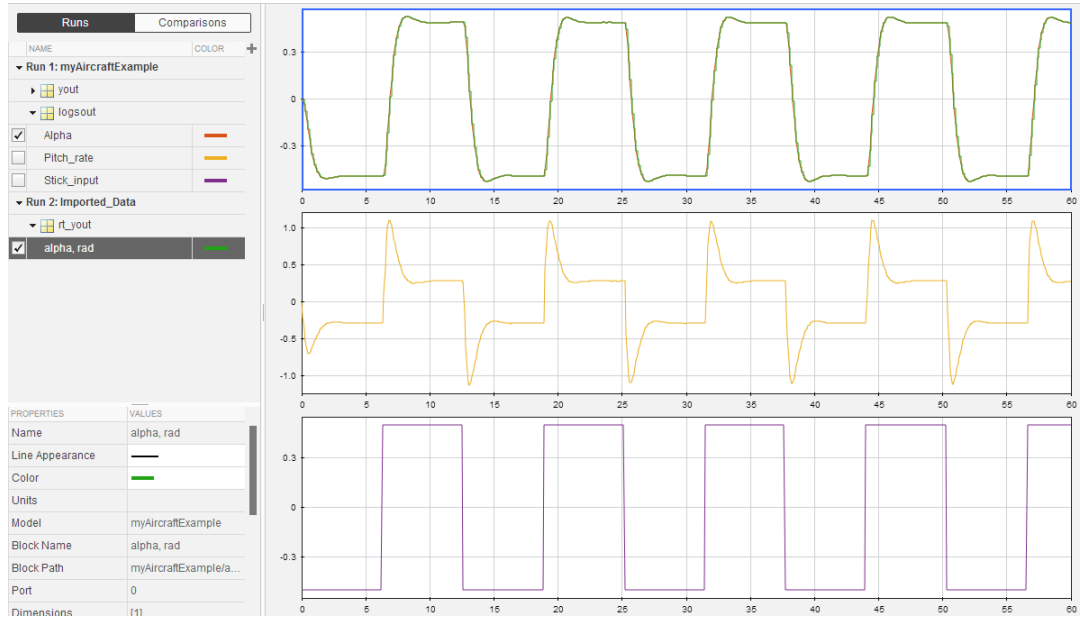
The selected data is now under **Run 2: Imported_Data**.

2 View a plot of the executed data.

a Click the `rt_yout` expander.

b Click the top subplot and select the check box next to the `alpha, rad` signal name. The signal data appears in the top subplot.

The `alpha, rad` signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.



It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as `sin(2.0)` can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

Compare States for Simulation and Code Generation

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:

```
[~,idx1]=sort({xout.signals.blockName});
xout_sorted=[xout.signals(idx1).values];
[~,idx2]=sort({rt_xout.signals.blockName});
rt_xout_sorted=[rt_xout.signals(idx2).values];
```

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

```
isequal(xout_sorted, rt_xout_sorted)
```

Code Tracing in Embedded Coder

What Is Code Tracing?

Code tracing (traceability) involves using hyperlinks to navigate between a line of generated code and its corresponding objects in a model. You can also right-click an object or objects in a model to find the lines of code to which they correspond. This two-way navigation is *bidirectional* traceability.

Code tracing provides a way to:

- Verify generated code. You can identify which model objects correspond to a line of code. You are able to keep track of code from different objects that you have or have not reviewed.
- Include comments in code generated for large-scale models. You can identify objects in generated code and avoid manually entering comments or descriptions.

The HTML code generation report that the code generator produces for a model includes resources that support code tracing:

- Code element hyperlinks (indicated with underlining) to trace through and toggle between generated source and header files.
- Tags in code comments that identify objects in a model from which lines of code are generated.
- Line number hyperlinks which link to the model component from which the line of code was generated.

Traceable Objects

Bidirectional traceability is supported for blocks and the following Stateflow objects:

- States
- Transitions
- MATLAB functions (not supported for external code called from a MATLAB function)

  Note: Traceability is not supported for external code that you call from a MATLAB function.
- Truth Table blocks and truth table functions
- Graphical functions

- Simulink functions
- State transition tables

Traceability in one direction is supported for these Stateflow objects:

- Events (code-to-model)

  Code-to-model traceability works for explicit events, but not implicit events. Clicking a hyperlink for an explicit event in the generated code highlights that item in the **Contents** pane of the Model Explorer.
- Junctions (model-to-code)

  Model-to-code traceability works for junctions with at least one outgoing transition. Right-clicking such a junction in the Stateflow Editor highlights the line of code that corresponds to the first outgoing transition for that junction.

Note: MATLAB Function blocks that you insert directly in a Simulink model are also traceable. For more information, see "Use Traceability in MATLAB Function Blocks" (Simulink).

Workflow Traceability

The basic workflow for using traceability is:

1. Open your model.
2. Define your system target file as an embedded real-time (`ert`) target.
3. Enable and configure the traceability options.
4. Generate the source code and header files for your model.
5. Do one or both of these steps:
   - Trace a line of generated code to the model.
   - Trace objects in the model to lines of code.

Related Examples

- "Trace Code to Model Objects by Using Hyperlinks" on page 61-6
- "Trace Model Objects to Generated Code" on page 61-8

- "Reload Existing Traceability Information" on page 61-28
- "Customize Traceability Reports" on page 61-29

More About

- "Traceability Tags" on page 61-5

Traceability Tags

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tags is `<system>/block_name`.

- *system* is one of the following:
  - The text `Root`
  - A unique system number assigned by the Simulink engine
- *block_name* is the name of the source block

The code generator documents the tags for a model in the comments section of the generated header file *model*`.h`. For example, the following comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```
/* Here is the system hierarchy for this model.
 *
 * <Root> : foo
 * <S1>   : foo/Outer
 * <S2>   : foo/Outer/Inner
 */
```

This code shows a tag comment adjacent to a line of code. A Gain block at the root level of a source model generates this code:

```
/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 *
  dead_gain_P.UnDeadGain1_Gain;
```

The following code shows a tag comment adjacent to a line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```
/* Gain: '<S1>/Gain' */
dead_gain_B.tempO *= (dead_gain_P.s1_Gain_Gain);
```

Trace Code to Model Objects by Using Hyperlinks

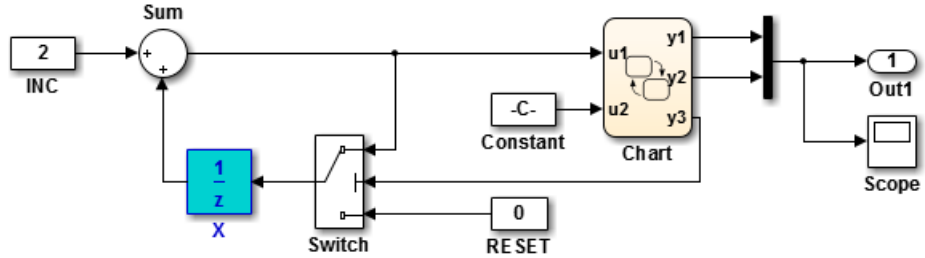
When using the Simulink Coder product, you can trace code to model objects by using the `hilite_system` command. The Embedded Coder product simplifies traceability with the use of hyperlinks in HTML code generation reports. The reports display hyperlinks in comment lines in generated code. To highlight the corresponding block or subsystem in the model diagram, click the hyperlinks.

To use hyperlinks for tracing code to model objects:

1. Open the model and make sure it is configured for an ERT target.
2. In the Configuration Parameters dialog box, on the **Code Generation** > **Report** pane, the **Create code generation report** parameter is selected by default. When selected, this parameter enables and selects **Open report automatically** and **Code-to-model**.
3. Build or generate code for the model. An HTML code generation report is displayed.
4. In the HTML report window, click hyperlinks to highlight source blocks. For example, generate an HTML report for model `rtwdemo_hyperlinks`. In the generated code for the model step function in `rtwdemo_hyperlinks.c`, click the first UnitDelay block hyperlink.

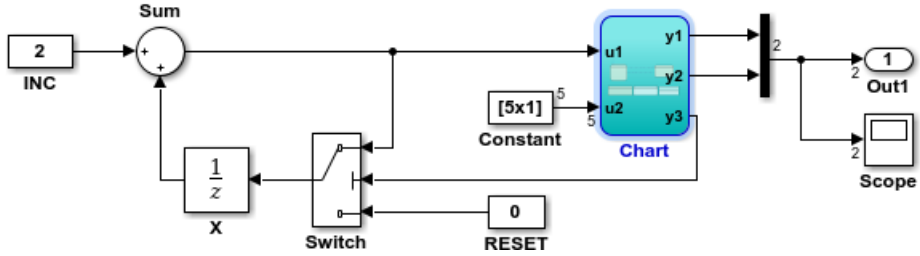
```
134  /* Model step function */
135  void rtwdemo_hyperlinks_step(void)
136  {
137    /* Chart: '<Root>/Chart' incorporates:
138     *  Constant: '<Root>/Constant'
139     *  Constant: '<Root>/INC'
140     *  Sum: '<Root>/Sum'
141     */
142    /* Gateway: Chart */
143    if (rtDWork.temporalCounter_i1 < 7U) {
144      rtDWork.temporalCounter_i1++;
145    }
```

In the model window, the corresponding UnitDelay block is highlighted.



To use line numbers for tracing code to model objects:

1. In the previous example, `rtwdemo_hyperlinks`, click the hyperlink at line number 144.
2. In the model window, the Chart subsystem is highlighted and contains the operation on line 144.



Trace Model Objects to Generated Code

1. Open the model and make sure that it is configured for an ERT target.
2. In the Configuration Parameters dialog box, the **Code Generation > Report > Create code generation report** parameter is selected by default. When selected, the parameter enables and selects the **Open report automatically** and **Code-to-model** parameters.
3. On the **All Parameters** tab, select **Model-to-code**. This parameter:
   - Enables the **Configure** button, which opens a dialog box for loading existing trace information.
   - Enables and selects parameters for customizing the content of a traceability report.
4. Build or generate code for the model. An HTML code generation report is displayed.
5. In the model window, right-click a model object. To select multiple blocks, hold **Shift** and right-click additional blocks.
6. From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. In the HTML code generation report, you see the first instance of highlighted code that is generated for the model object. In the left pane of the report, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. The following figure shows the result of tracing the Unit Delay block in model `rtwdemo_hyperlinks`.

At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Do one of the following:

- Reset the current working folder to the parent folder of the existing build folder.
- Select **Model-to-code** and rebuild the model. Rebuilding the model regenerates the build folder into the current working folder.
- Click **Configure**. In the Model-to-code navigation dialog box, reload the existing trace information.

"Model-to-code" (Simulink Coder) | "Configure" (Simulink Coder)

Trace Stateflow Objects in Generated Code

In this section...

Bidirectional Traceability for States and Transitions

See how bidirectional traceability works for states and transitions by following these steps:

1. At the command prompt, type `old_sf_car`.
2. Open the Model Configuration Parameters dialog box.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply** in the lower-right corner of the window. Traceability comments appear in generated code only for embedded real-time targets.
4. In the **Code Generation** > **Report** pane, the **Create code generation report** parameter is selected by default. This step automatically selects **Open report automatically** and **Code-to-model**.
5. On the **All Parameters** tab, select **Model-to-code**. Click **Apply**.
6. Go to the **Code Generation** > **Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.
7. Press **Ctrl+B**.

   This step generates source code and header files for the `old_sf_car` model that contains the `shift_logic` chart. After the code generation process is complete, the code generation report appears.
8. In the report, click the `old_sf_car.c` hyperlink.

9 To see the traceability comments, scroll down through the code. The following line numbers can differ from the numbers that appear in your code generation report.

```
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188   /* During 'gear_state': '<S5>:2' */
189   switch (old_sf_car_DW.is_gear_state) {
190    case old_sf_car_IN_first:
191     /* During 'first': '<S5>:6' */
192     if (*sfEvent == old_sf_car_event_UP) {
193       /* Transition: '<S5>:12' */
194       old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
195
196       /* Entry 'second': '<S5>:4' */
197       old_sf_car_B.gear = 2.0;
```

10 To navigate to the corresponding model component, click the line number hyperlinks.

11 Click the `<S5>:2` hyperlink in this traceability comment:

```
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

12 Click the `<S5>:12` hyperlink in this traceability comment:

```
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an object in the chart, select **Display** > **Remove Highlighting**.

13 You can also trace objects in the model to lines of generated code. In the chart, right-click the object `gear_state` and select **C/C++ Code** > **Navigate to C/C++ Code**.

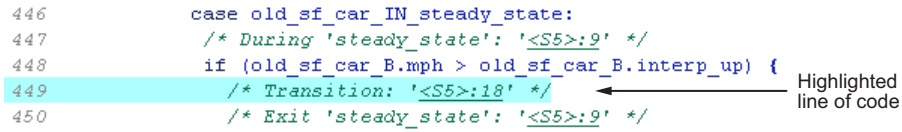
The code for that state appears highlighted in `old_sf_car.c`.

```
188   /* Function for Stateflow: '<Root>/shift_logic' */
189   static void old_sf_car_gear_state(void)
190   {
191     /* During 'gear_state': '<S5>:2' */
192     if (old_sf_car_DWork.is_active_gear_state != 0) {
193       switch (old_sf_car_DWork.is_gear_state) {
194        case old_sf_car_IN_first:
195         /* During 'first': '<S5>:6' */
```

Highlighted line of code

14 In the chart, right-click the transition with the condition `[speed > up_th]` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that transition appears highlighted in `old_sf_car.c`.



Note: For a list of the Stateflow objects in your model that are traceable, click the `Traceability Report` hyperlink in the code generation report.

Bidirectional Traceability for State Transition Tables

This example shows how to navigate bidirectionally between objects in a state transition table and the generated C/C++ and HDL code for traceability.

1 At the command prompt, type `sf_cdplayer_STT`. This model is already configured for traceability. For more information on these configurations, see "Traceability of Stateflow Objects in Generated Code" (Stateflow).

2 Press **Ctrl+B**.

This step generates source code and header files for the `sf_cdplayer_STT` model. After the code generation process is complete, the code generation report appears.

3 Click the `sf_cdplayer_STT.c` hyperlink in the report.

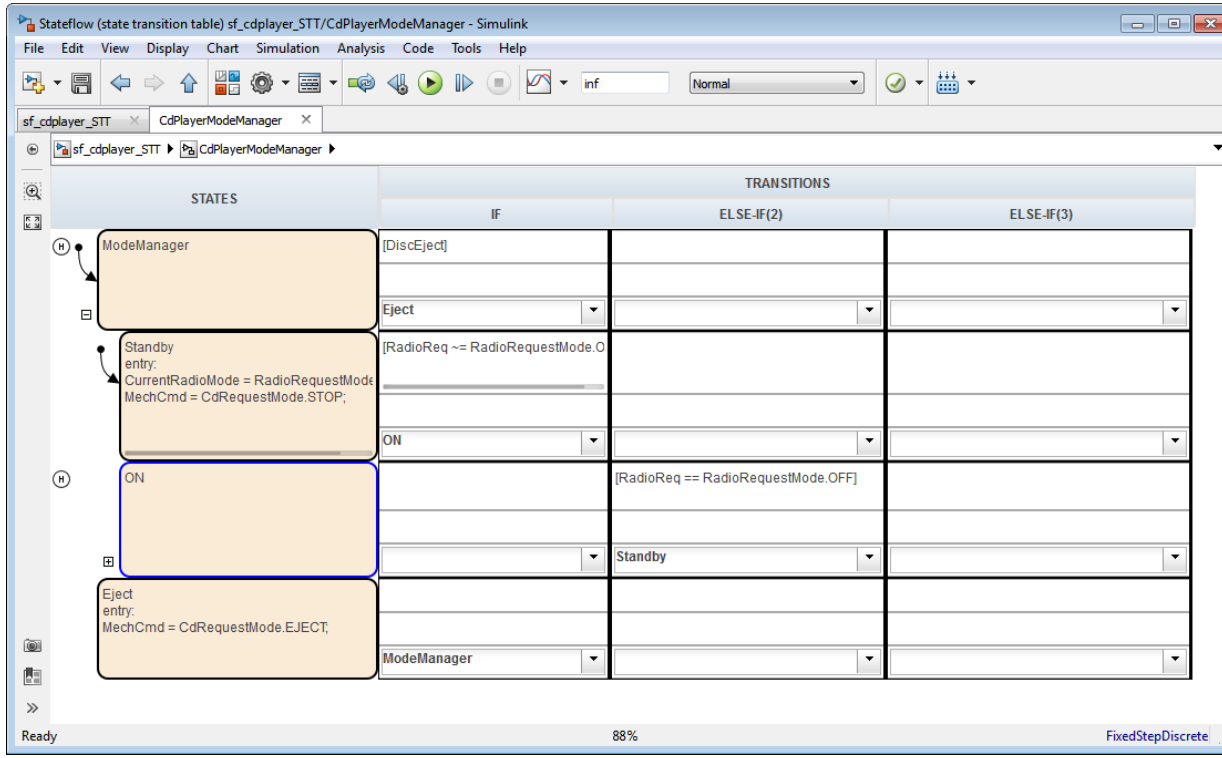
4 To see the traceability comments, scroll down through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```
60  /* Function for State Transition Table: '<Root>/CdPlayerModeManager' */
61  static void sf_cdplayer_S_enter_internal_ON(void)
62  {
63    /* Entry Internal 'ON': '<S2>:58' */
64    switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
65     case sf_cdplayer_STT_IN_AMMode:
66      sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
67      sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
68
69      /* Entry 'AMMode': '<S2>:61' */
70      sf_cdplayer_STT_B.CurrentRadioMode = AM;
71      sf_cdplayer_STT_B.MechCmd = STOP;
72      break;
73
```

5 Click the `<S2>:58` hyperlink in this traceability comment:

```
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state `'ON'` appears highlighted in the state transition table.



6 Right-click the highlighted state and select **View state object**. The state `'ON'` also appears highlighted in the underlying state transition diagram.

7 You can also trace a state or transition from the state transition table to the generated code. Right-click the state `Standby` and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state `Standby` is highlighted in the generated code.

```
234          sf_cdplayer_STT_DWork.bitsForTID1.was_ModeManager =
235            sf_cdplayer_STT_IN_Standby;
236
237          /* Entry 'Standby': '<S2>:57' */
238          sf_cdplayer_STT_B.CurrentRadioMode = OFF;
239          sf_cdplayer_STT_B.MechCmd = STOP;
240        } else if (sf_cdplayer_STT_DWork.RadioReq_prev !=
241                   sf_cdplayer_STT_DWork.RadioReq_start) {
242          /* Transition: '<S2>:75' */
243          if (sf_cdplayer_STT_P.RR_Value == CD) {
```

Bidirectional Traceability for Truth Table Blocks

See how bidirectional traceability works for a Truth Table block by following these steps:

1. At the command prompt, type `sf_climate_control`
2. Complete steps 2 through 5 in "Bidirectional Traceability for States and Transitions" on page 61-10.
3. To build the model, press **Ctrl+B**.

   The code generation report appears.
4. Click the `sf_climate_control.c` hyperlink in the report.
5. To see the traceability comments, scroll down through the code. The following line numbers can differ from the numbers that appear in your code.

```
77       /*  Turn On Humidifier */
78       /* Action '3': '<S1>:1:47' */
79       rtb_humidifier = 1;
80     } else if (eml_aVarTruthTableCondition) {
81       /* Decision 'D2': '<S1>:1:18' */
```

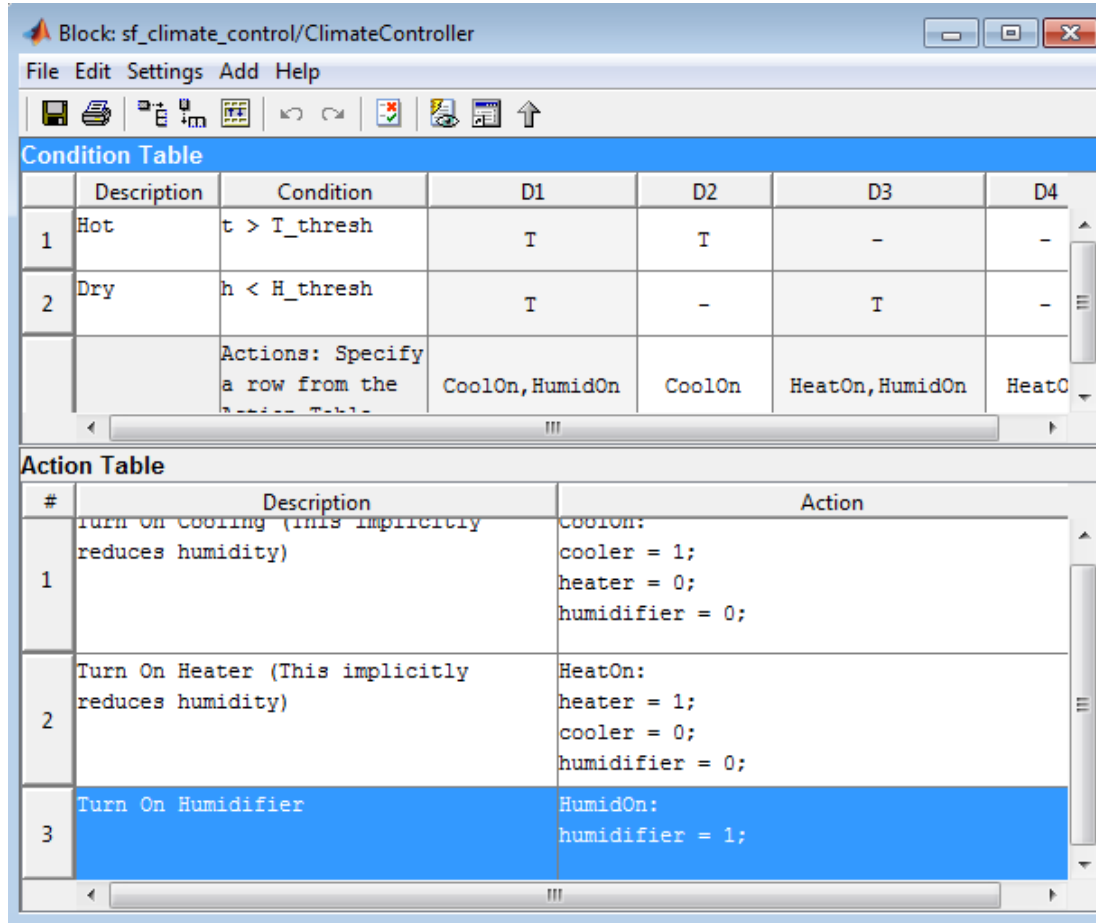
Traceability comment for a truth table action

Traceability comment for a truth table decision

6. Click the `<S1>:1:47` hyperlink in this traceability comment:

   ```
   /* Action '3': '<S1>:1:47' */
   ```

   In the Truth Table Editor, row 3 of the Action Table appears highlighted.



7 You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column `D2` and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for that decision appears highlighted in `sf_climate_control.c`.

```
77        /*  Turn On Humidifier */
78        /* Action '3': '<S1>:1:47' */
79        rtb_humidifier = 1;
80      } else if (eml_aVarTruthTableCondition) {
81        /* Decision 'D2': '<S1>:1:18' */
```

Highlighted line of code

Tip: To select **C/C++ Code** > **Navigate to C/C++ Code** for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

Bidirectional Traceability for Graphical Functions

See how bidirectional traceability works for graphical functions by following these steps:

1. At the command prompt, type `sf_clutch`.
2. Complete steps 2 through 6 in "Bidirectional Traceability for States and Transitions" on page 61-10.
3. In the Model Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver options** section, select `Fixed-step` in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable step solvers.
4. To build the model, press **Ctrl+B**.

   The code generation report appears.
5. Click the `sf_clutch.c` hyperlink in the report.
6. To see the traceability comments, scroll down through the code. The following line numbers can differ from the numbers that appear in your code generation report.

```
235           case sf_clutch_IN_Slipping:
236             /* Graphical Function 'detectLockup': '<S1>:10' */
237             /* Transition: '<S1>:28' */
238             /* Graphical Function 'getSlipTorque': '<S1>:3' */
```

Traceability comment for a graphical function

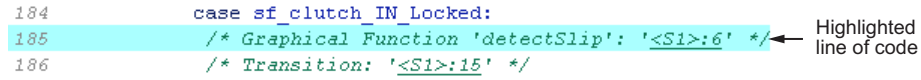
7. Click the `<S1>:3` hyperlink in this traceability comment:

   ```
   /* Graphical Function 'getSlipTorque': '<S1>:3' */
   ```

   In the chart, the graphical function `getSlipTorque` appears highlighted.

8 You can also trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function `detectSlip` and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for that graphical function appears highlighted in `sf_clutch.c`.



Code-to-Model Traceability for Events

See how code-to-model traceability works for events by following these steps:

1 At the command prompt, type `sf_security`.

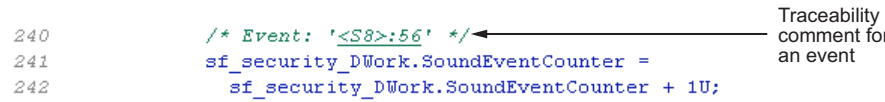
2 Complete steps 2 through 6 in "Bidirectional Traceability for States and Transitions" on page 61-10.

3 To build the model, press **Ctrl+B**.

The code generation report appears.

4 Click the `sf_security.c` hyperlink in the report.

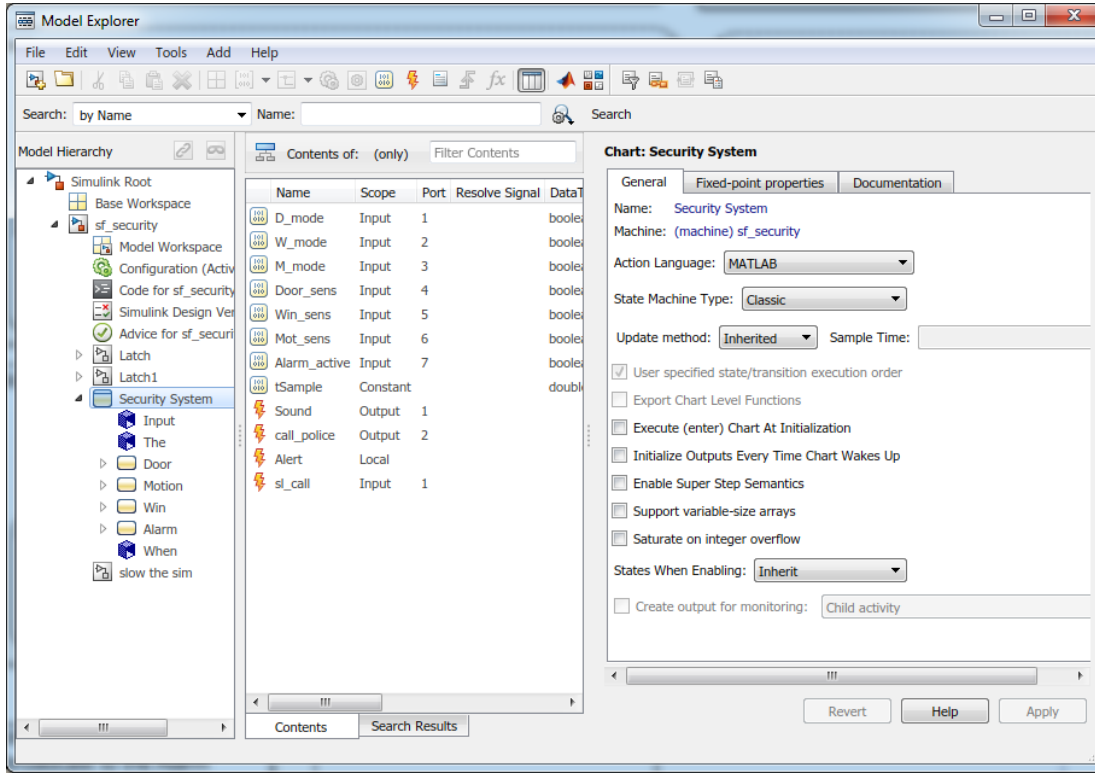
5 To see the following traceability comment, scroll down through the code. The following line numbers can differ from the numbers that appear in your code generation report.



6 Click the `<S8>:56` hyperlink in this traceability comment:

```
/* Event: '<S8>:56' */
```

In the **Contents** pane of the Model Explorer, the event `Sound` appears highlighted.



Model-to-Code Traceability for Junctions

See how model-to-code traceability works for junctions by following these steps:

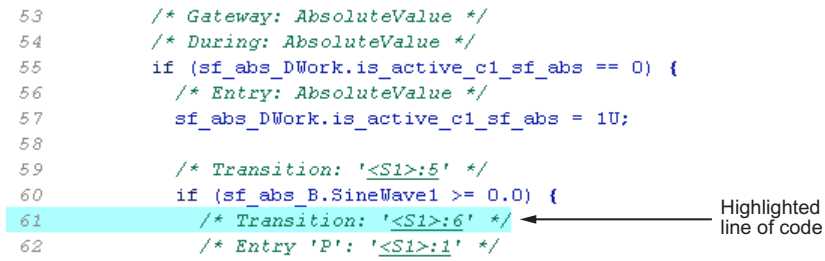
1. At the command prompt, type `sf_abs`.
2. Complete steps 2 through 6 in "Bidirectional Traceability for States and Transitions" on page 61-10.
3. In the Model Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver options** section, select `Fixed-step` in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable-step solvers.
4. To build the model, press **Ctrl+B**.

The code generation report appears.

5 Open the `AbsoluteValue` chart.

6 Right-click the left junction and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for the first outgoing transition of that junction appears highlighted in `sf_abs.c`.



Format of Traceability Comments for Stateflow Objects

The format of a traceability comment depends on the Stateflow object type.

State

Syntax

```
/* <ActionType> '<StateName>': '<ObjectHyperlink>' */
```

Example

```
/* During 'gear_state': '<S5>:2' */
```

This comment refers to the `during` action of the state `gear_state`, which has the hyperlink `<S5>:2`.

Transition

Syntax

```
/* Transition: '<ObjectHyperlink>' */
```

Example

```
/* Transition: '<S5>:12' */
```

This comment refers to a transition, which has the hyperlink `<S5>:12`.

MATLAB Function

Syntax

```
/* MATLAB Function '<Name>': '<ObjectHyperlink>' */
```

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have the following syntax:

```
/* '<ObjectHyperlink>' */
```

Examples

```
/* MATLAB Function 'test_function': '<S50>:99' */

/* '<S50>:99:20' */
```

The first comment refers to the MATLAB function named `test_function`, which has the hyperlink `<S50>:99`.

The second comment refers to line 20 of the MATLAB function in your chart.

Truth Table Block

Syntax

```
/* Truth Table Function '<Name>': '<ObjectHyperlink>' */
```

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have the following syntax:

```
/* Condition '#<Num>': '<ObjectHyperlink>' */
/* Decision 'D<Num>': '<ObjectHyperlink>' */
/* Action '<Num>': '<ObjectHyperlink>' */
```

`<Num>` is the row or column number that appears in the Truth Table Editor.

Examples

```
/* Truth Table Function 'truth_table_default': '<S10>:100' */

/* Condition '#1': '<S10>:100:8' */
/* Decision 'D1': '<S10>:100:16' */
/* Action '1': '<S10>:100:31' */
```

The first comment refers to a Truth Table block named `truth_table_default`, which has the hyperlink `<S10>:100`.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

Truth Table Function

For syntax and examples, see "Truth Table Block" on page 61-21.

Graphical Function

Syntax

```
/* Graphical Function '<Name>': '<ObjectHyperlink>' */
```

Example

```
/* Graphical Function 'hello': '<S1>:123' */
```

This comment refers to a graphical function named `hello`, which has the hyperlink `<S1>:123`.

Simulink Function

Syntax

```
/* Simulink Function '<Name>': '<ObjectHyperlink>' */
```

Example

```
/* Simulink Function 'simfcn': '<S4>:10' */
```

This comment refers to a Simulink function named `simfcn`, which has the hyperlink `<S4>:10`.

Event

Syntax

```
/* Event: '<ObjectHyperlink>' */
```

Example

```
/* Event: '<S3>:33' */
```

This comment refers to an event, which has the hyperlink `<S3>:33`.

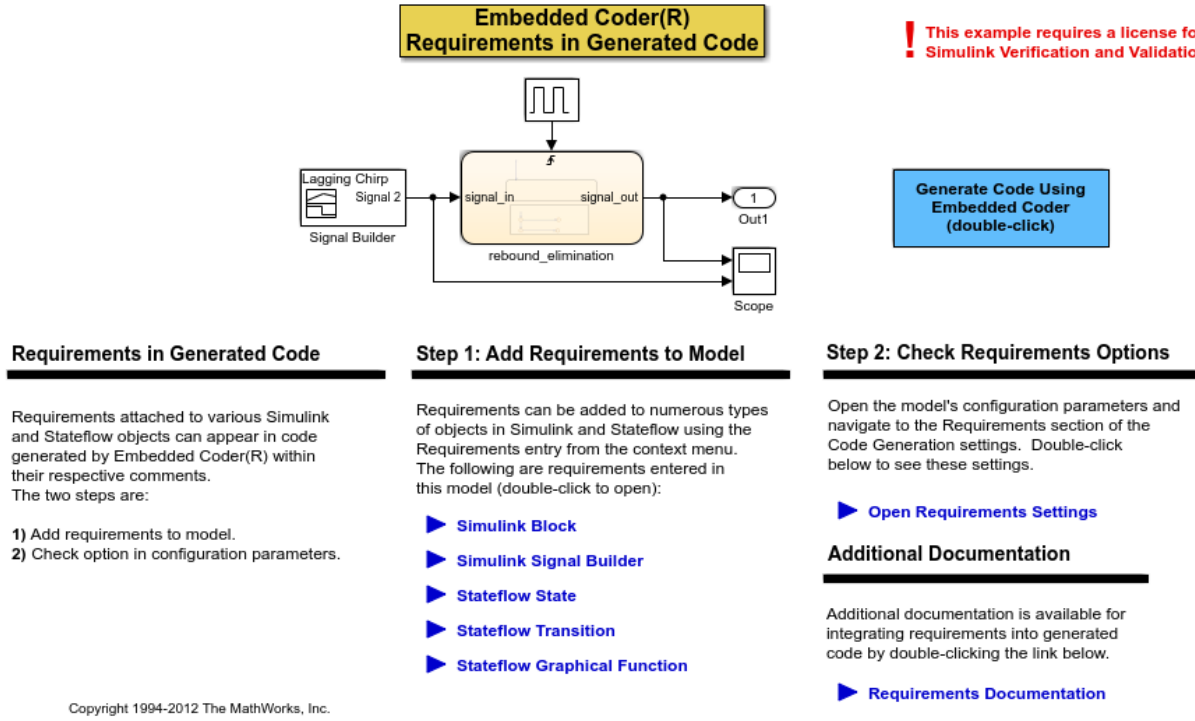
Link Generated Code to Requirements

Link generated code to model object requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

Open Model

Open the rtwdemo_requirements model. The model contains Simulink® and Stateflow® objects with associated requirements.

```
model='rtwdemo_requirements';
open_system(model);
```



View Requirements

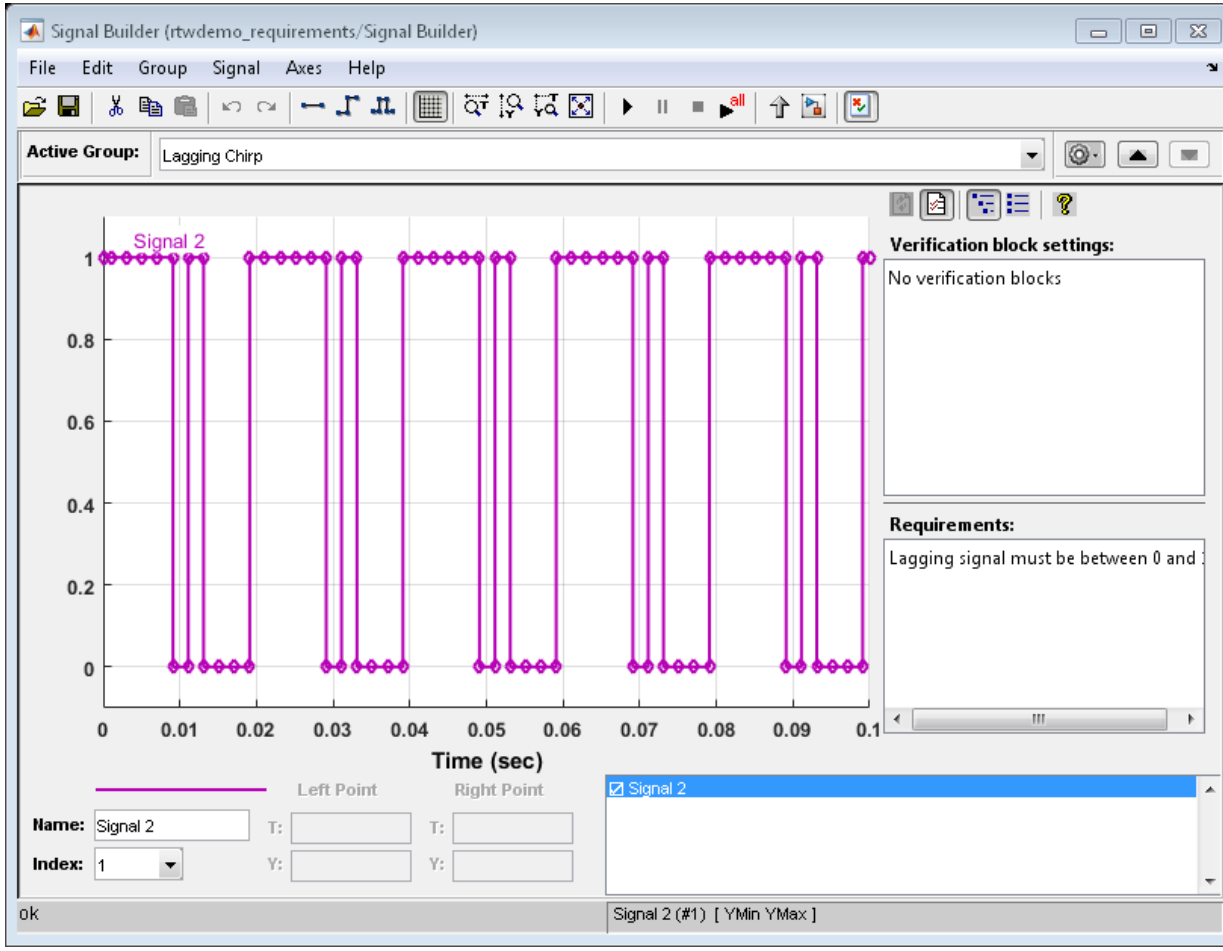
You can view requirements to model objects by using the object context menu. Right-click an object and select **Requirements Traceability**. To view the requirements, use these commands:

1. To view the requirements for the `DiscretePulseGenerator` block, open the Link Editor.

```
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the **Signal Builder** block.

```
sigbblock='rtwdemo_requirements/Signal Builder';
open_system(sigbblock)
```



3. To view the requirements for the Stateflow® state, open the Link Editor.

```
state=find(sfroot,'-isa','Stateflow.State','-and','Tag','req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Link Editor.

```
trans=find(sfroot,'-isa','Stateflow.Transition','-and','Tag','req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Link Editor.

```
func=find(sfroot,'-isa','Stateflow.Function','-and','Tag','req_function');
rmi('edit',func.id);
```

Close the open windows.

```
close_system(sigbblock);
```

Set Configuration Parameters

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

```
model = bdroot;
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Comments');
```

Generate Code

Generate code for the model.

```
rtwbuild('rtwdemo_requirements')
```

```
### Starting build procedure for model: rtwdemo_requirements
### Successful completion of build procedure for model: rtwdemo_requirements
```

In the generated code, view the comments containing the requirements.

```
rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c',...
    '/* Function for Chart:','return result;',1,0);
```

```
/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in)
{
  real_T result;

  /* Graphical Function 'rebound_fcn': '<S2>:2':
   *  1. Result Computation
   */
  /* Transition: '<S2>:4' */
  if (prev_in == curr_in) {
    /* Transition: '<S2>:5' */
    result = curr_in;
  } else {
    /* Transition: '<S2>:6' */
    /* Transition: '<S2>:7' */
```

```
    result = prev_out;
  }
```

See Also

- For requirement traceability, see Overview of the Requirements Management Interface

Close Model

```
rtwdemoclean;
close_system('rtwdemo_requirements',0);
```

Reload Existing Traceability Information

To reload existing traceability information for a model:

1. In the Configuration Parameters dialog box, on the **All Parameters** tab, under Model-to-code, click **Configure**.
2. In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Without having to reset the current working folder or rebuild the model, do the following:

1. To open the Model-to-code navigation dialog box, click **Configure**.
2. In the Model-to-code navigation dialog box, click **Browse**.
3. Browse to the build folder for your model, and select the folder. The build folder path is displayed in the **Build folder** field.
4. If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.
5. To open the context menu and trace a model object to corresponding code, right-click a model object and select **C/C++ Code** > **Navigate to C/C++ Code**.

Customize Traceability Reports

In the Configuration Parameters dialog box, the **Code Generation** section lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of the following parameters, which are on by default:

- **Eliminated / virtual blocks** (Simulink Coder) (account for blocks that are untraceable)
- **Traceable Simulink blocks** (Simulink Coder)
- **Traceable Stateflow objects** (Simulink Coder)
- **Traceable MATLAB functions** (Simulink Coder)

If you select all parameters, you get a complete mapping between model elements and the generated code.

The following figure shows the top section of the traceability report that is generated when you select all traceability content parameters for model `rtwdemo_hyperlinks`.

Traceability Report for rtwdemo_hyperlinks

Generate Traceability Matrix

Table of Contents

Eliminated / Virtual Blocks

Block Name	Comment
<Root>/Build ERT	Empty SubSystem
<Root>/Mux	Mux
<Root>/Scope	Unused code path elimination
<Root>/View Code Generation Report	Empty SubSystem

Traceable Simulink Blocks / Stateflow Objects / MATLAB Functions

Root system: rtwdemo_hyperlinks

Object Name	Code Location
<Root>/Chart	rtwdemo_hyperlinks.c:20, 43, 85, 103, 112, 143, 257 rtwdemo_hyperlinks.h:39, 40, 41, 43, 45, 46, 47, 48, 49, 52, 53
<Root>/Constant	rtwdemo_hyperlinks.c:144

Generate a Traceability Matrix

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel® format directly from the traceability report. See “Customize Traceability Reports” on page 61-29.

Go to the **Traceability Report** section of the HTML code generation report and click **Generate Traceability Matrix**.

To select an existing matrix file to update or specify a new matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and order the columns that appear in the generated matrix. For more information, see “Generating a Traceability Matrix” in either the DO Qualification Kit documentation (DO Qualification Kit) or the IEC Certification Kit documentation (IEC Certification Kit).

Traceability Limitations

These limitations apply to reports generated by Embedded Coder software.

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (').
  - An asterisk (*), that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (/).
  - The character ÿ (`char(255)`).
- If a block name contains a newline character (`\n`), in the generated code comments, the block path name hyperlink replaces the newline character with a space for readability.
- You cannot trace blocks representing these types of subsystems to generated code:
  - Virtual subsystems
  - Masked subsystems
  - Nonvirtual subsystems for which code has been optimized away

  If you cannot trace a subsystem at subsystem level, you might be able to trace individual blocks within the subsystem.
- If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability features.

Component Verification in Embedded Coder

Component Verification in the Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 64-2.

Goals of Component Verification

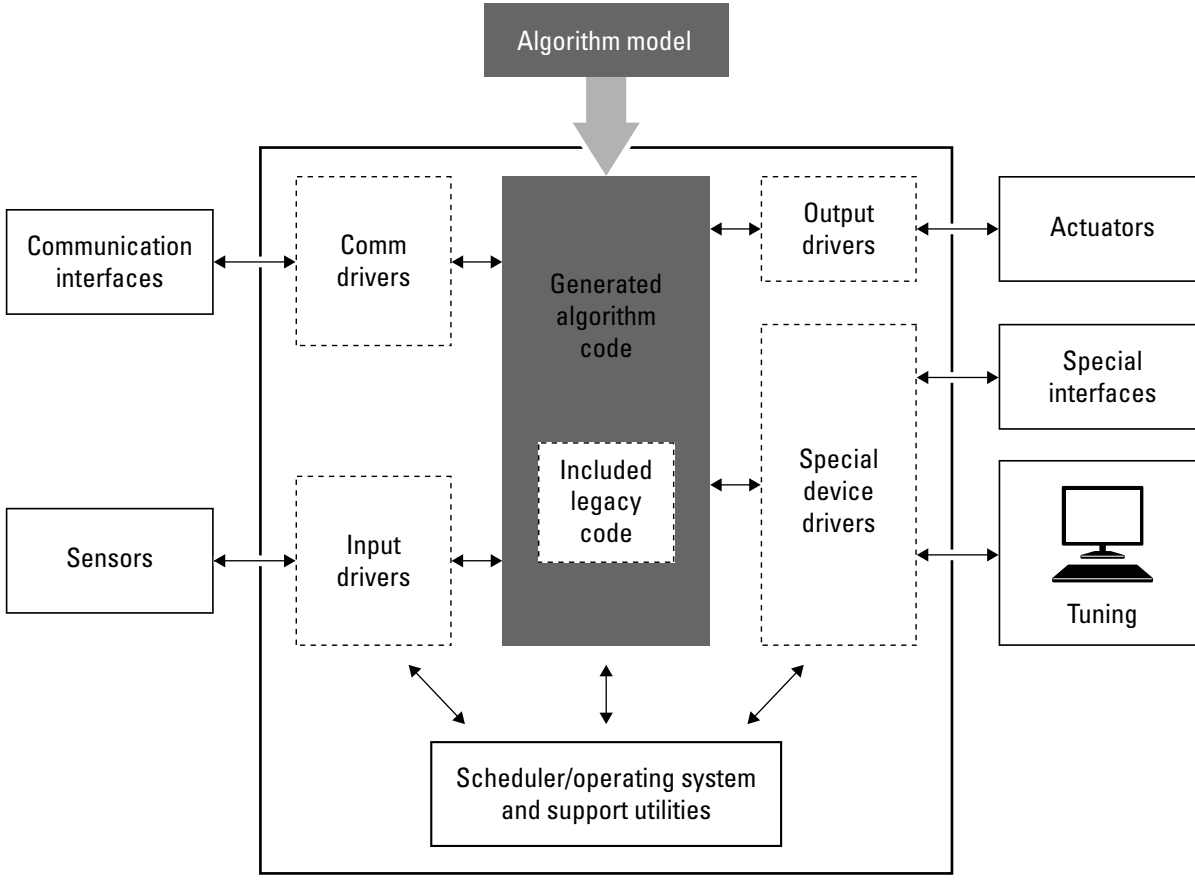
Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

Goal	Type of Code Export
Maximize code portability and configurability	ANSI C/C++
Simplify integration and maximize use of processor resources and code efficiency	Mixed code

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

Maximizing Code Portability and Configurability

To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.

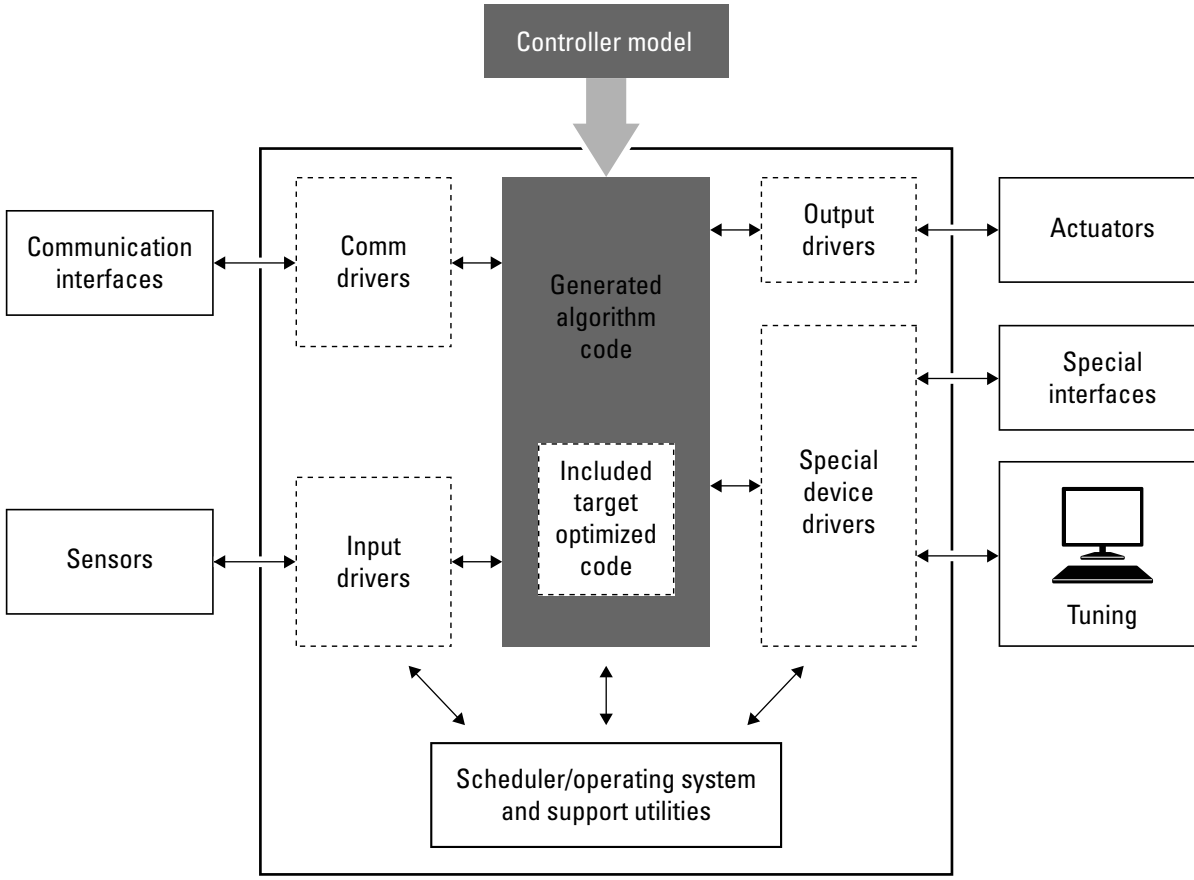


Simplifying Code Integration and Maximizing Code Efficiency

To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.



Running Component Tests

The workflow for running software component tests in the target environment is:

1. Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see "S-Functions and Code Generation" (Simulink Coder) in the Simulink Coder documentation. For more specific references that depend on your verification goals, see the following table.

For	See
ANSI C/C++ code integration	"Integrate C Functions Using Legacy Code Tool" (Simulink) in the Simulink documentation. Also, open `rtwdemos` and navigate to the **Custom Code** folder.
Mixed code integration	• "Generate Component Source Code for Export to External Code Base" on page 39-51 and example `rtwdemo_exporting_functions` • "Control Generation of Function Prototypes" on page 26-2, "Control Generation of C++ Class Interfaces" on page 26-23, and example rtwdemo_fcnprotoctrl • "What Is Code Replacement?" on page 38-2, "What Is Code Replacement Customization?" on page 51-3, and example `rtwdemo_crl_script`

2. Simulate the integrated component model.
3. Generate code for the integrated component model.
4. Connect to data interfaces for the generated C code data structures. See "Exchange Data Between Generated and External Code Using C API" (Simulink Coder) and "Export ASAP2 File for Data Measurement and Calibration" (Simulink Coder) in the Simulink Coder documentation. Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.
5. Customize and control the build process, if required. See "Customize Post-Code-Generation Build Processing" (Simulink Coder) in the Simulink Coder documentation, and example `rtwdemo_buildinfo` .

6 Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See "Relocate Code to Another Development Environment" (Simulink Coder), in the Simulink Coder documentation, and example `rtwdemo_buildinfo`.

Component Verification With a Real-Time Target Environment in Embedded Coder

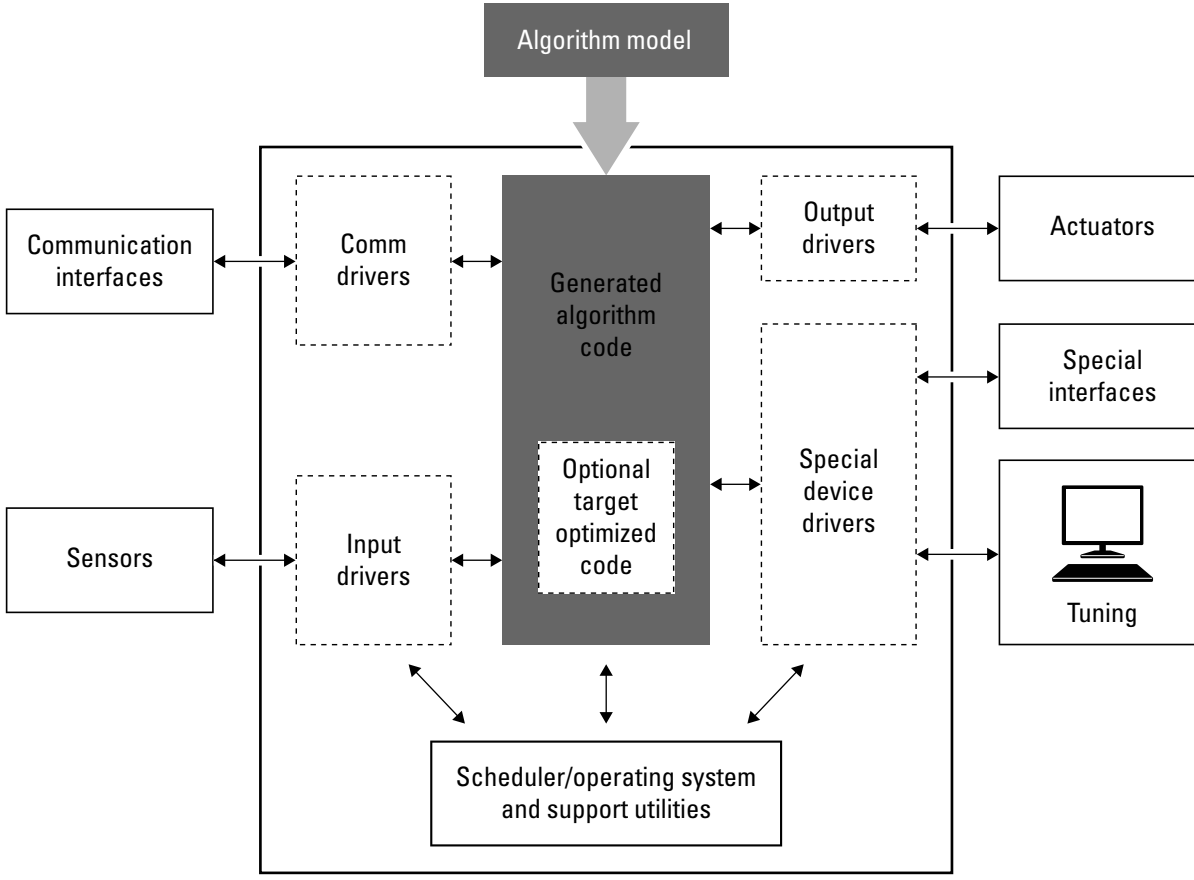
About Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.



Algorithm model
Communication interfaces
Comm drivers
Generated algorithm code
Output drivers
Actuators
Special interfaces
Optional target optimized code
Special device drivers
Sensors
Input drivers
Tuning
Scheduler/operating system and support utilities

Real-Time Software Component Testing

The workflow for testing component software as part of a complete real-time target environment is:

1. Develop a component model and generate source code for production.

   For information on building in scheduling and real-time system support, see:

   - "Time-Based Scheduling and Code Generation" (Simulink Coder) and "Modeling for Multitasking Execution" (Simulink Coder) in the Simulink Coder documentation. For an example, open `rtwdemos` and navigate to the **Multirate Support** folder.
   - "Asynchronous Events" (Simulink Coder) in the Simulink Coder documentation and example `rtwdemo_async`
   - "Deploy Generated Standalone Executable Programs To Target Hardware" on page 49-2
   - "Workflows for AUTOSAR" and example "Generate AUTOSAR-Compliant C Code and Export ARXML Descriptions".
2. Optimize generated code for a specific run-time environment, using specialized function libraries. For more information, see "What Is Code Replacement?" on page 38-2, "What Is Code Replacement Customization?" on page 51-3, and "Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®".
3. Customize post code generation build processing to accommodate third-party tools and processes, as required. See "Customize Post-Code-Generation Build Processing" (Simulink Coder) in the Simulink Coder documentation and example `rtwdemo_buildinfo`.
4. Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see "S-Functions and Code Generation" (Simulink Coder) in the Simulink Coder documentation. For more specific references depending on your verification goals, see the following table.

For...	See...
ANSI C/C++ code integration	"Integrate C Functions Using Legacy Code Tool" (Simulink) in the Simulink documentation. Also, open `rtwdemos` and navigate to the **Custom Code** folder.

For...	See...
Mixed code integration	• "Generate Component Source Code for Export to External Code Base" on page 39-51 and example `rtwdemo_exporting_functions` • "Control Generation of Function Prototypes" on page 26-2, "Control Generation of C++ Class Interfaces" on page 26-23, and example rtwdemo_fcnprotoctrl • "What Is Code Replacement?" on page 38-2, "What Is Code Replacement Customization?" on page 51-3, and example "Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®"

5 Simulate the integrated model.

6 Generate code for the integrated model.

7 Connect to data interfaces for the generated C code data structures. See "Exchange Data Between Generated and External Code Using C API" (Simulink Coder) and "Export ASAP2 File for Data Measurement and Calibration" (Simulink Coder) in the Simulink Coder documentation. Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.

8 Customize and control the build process, as required. See "Customize Post-Code-Generation Build Processing" (Simulink Coder), in the Simulink Coder documentation, and example `rtwdemo_buildinfo` .

9 Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See "Relocate Code to Another Development Environment" (Simulink Coder), in the Simulink Coder documentation, and example `rtwdemo_buildinfo`.

Numerical Equivalence Checking in Embedded Coder

SIL and PIL Simulations

In this section...

What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

Why Use SIL and PIL

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You thereby avoid leaving the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.

Situation	Use
Reuse test vectors developed for normal mode simulation to verify numerical output of generated (or legacy) code. For example, reusing test cases generated by Simulink Design Verifier™. See "What Is Test Case Generation?" (Simulink Design Verifier) in Simulink Design Verifier documentation.	SIL and PIL
Collect metrics for generated code: • Code coverage. See "Configure Code Coverage with Third-Party Tools" on page 67-10. • Execution profiling. See "Code Execution Profiling with SIL and PIL" on page 58-2 • Stack profiling. See "Perform Stack Profiling with IDE and Toolchain Targets" on page 73-22.	SIL and PIL
Achieve IEC 61508, IEC 62304, ISO 26262, or DO-178 certification. See "Embedded Coder Reference Workflow Overview" (IEC Certification Kit) in the IEC Certification Kit documentation and Testing of Outputs of Integration Process (DO Qualification Kit) in the DO Qualification Kit documentation.	SIL and PIL
Without target hardware, get a convenient alternative to PIL.	SIL

Situation	Use
With target hardware, for example, an evaluation board or instruction set simulator: • Verify behavior of target-specific code, for example, code replacement optimizations, and legacy code. See “What Is Code Replacement?” on page 38-2 and “What Is Code Replacement Customization?” on page 51-3. • Optimize the execution speed and memory footprint of your code. In this table, see the information about collecting execution profiling and stack profiling metrics. • Investigate effects of compiler settings and optimizations, for example, deviation from ANSI C overflow behavior. Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code. For information about running PIL simulations on specific targets, see “Sample Custom Targets” (Simulink Coder) in the Simulink Coder documentation.	PIL

Note: The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.

- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

Comparison of SIL and PIL Simulations

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Specify through: • Top-model simulation mode • Model block **Simulation mode** parameter	• Test behavior of generated source code on development computer. Simulation does not test code compiled for target hardware because code is compiled for the development computer (different compiler and different processor architecture than the target). • Generated production code compiled and executed on development computer as separate process, independent of MATLAB process. • Execution is host/host and nonreal time.	• Test object code that you intend to deploy in production on either real target hardware or an instruction set simulator. • On development computer, generated production code cross-compiled for target. Object code downloaded and executed on target processor or instruction set simulator. • Execution is host/target and nonreal time.

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Use SIL or PIL block created from subsystem.	• Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process. • Execution is host/host and nonreal time.	• Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator. • Execution is host/target and nonreal time.

Code Interfaces for SIL and PIL

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see "Entry-Point Functions and Scheduling" (Simulink Coder).

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a *model reference target* for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see "Build Model Reference Targets" (Simulink Coder).

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

Note: SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.

This table provides the interfaces that SIL and PIL simulations generate.

SIL/PIL Simulation	Code Interface
Top-model	SIL/PIL simulation generates the standalone code interface. If code exists, simulation calls standalone code for the model . If code does not exist, simulation generates standalone code.
Model block	If you set **Code interface** block parameter to `Top model`, SIL/PIL simulation generates standalone code interface. Simulation calls standalone code for the model if it exists. Otherwise, simulation generates standalone code by using `slbuild('model')` command. If you set **Code interface** block parameter to `Model reference`, SIL/PIL simulation generates model reference code interface. Simulation calls model reference target for Model block if it exists. Otherwise, simulation generates model reference target by using `slbuild('model', 'ModelReferenceRTWTarget')` command.
SIL or PIL block	Block uses standalone code interface.

Scheduling Considerations

Item	Information
Algebraic loops	There are algebraic loops that occur in SIL and PIL simulations but not in normal mode simulations: • **Single output/update function** in code generation optimization can introduce algebraic loops because the option introduces direct feedthrough via a combined output and update function. **Single output/update function** is not compatible with **Minimize algebraic loop occurrences** (in the Subsystem Parameters dialog box and **Configuration Parameters** > **Model Referencing** pane). **Minimize algebraic loop occurrences** allows code generation to remove algebraic loops by partitioning generated code between output and update functions to avoid direct feedthrough. • If you generate code for a virtual subsystem, code generation treats the subsystem as atomic and generates the code accordingly. The

Item	Information
	resulting code can change the execution behavior of your model, for example, by applying algebraic loops, and introduce inconsistencies to the simulation behavior. To enable consistent simulation and execution behavior for your model, declare virtual subsystems as atomic subsystems. For more information, see: • "Algebraic Loops" (Simulink) • "Algebraic Loops" (Simulink Coder) • "Code Generation of Subsystems" (Simulink Coder)
Exported functions in feedback loops	If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch (Simulink) blocks in your model. You can make context-dependent inputs become context-independent. Embedded Coder generates a warning identifying context-dependent inputs of exported function-call subsystems if you set **Configuration Parameters > Diagnostics > Connectivity > Context-dependent inputs** to one of the following: • `Enable all as warnings` • `Use local settings` • `Disable all` For more information, see: • "Code Generation of Subsystems" (Simulink Coder) • Function-Call Feedback Latch (Simulink) • "Context-dependent inputs" (Simulink)

Imported Data and Function Definitions

Item	Information
Imported data	In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with: • Signals at the root level of the component (on the I/O boundary) • Parameters • Global data stores SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with: • Internal signals (not on the I/O boundary) • Local data stores In these cases, define the storage through custom code included by the component under test or through the PIL `rtw.pil.RtIOStreamApplicationFramework` API. See also "Tunable Parameters and SIL/PIL" on page 64-63.
`GetSet` custom storage class	SIL and PIL simulations support the `GetSet` custom storage class. The SIL/PIL test harness provides C definitions of the `Get` and `Set` functions that are used during simulations. For more information, see "Access Data Through Functions with Custom Storage Class `GetSet`" on page 23-92.
AUTOSAR Runtime Environment (RTE)	You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The generated code for the AUTOSAR software component is linked with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component. **Note:** For Model block SIL/PIL, to test the AUTOSAR interface, set the **Code interface** block parameter to `Top model`.

Item	Information
	For more information, see “Verify AUTOSAR C Code with SIL and PIL”.

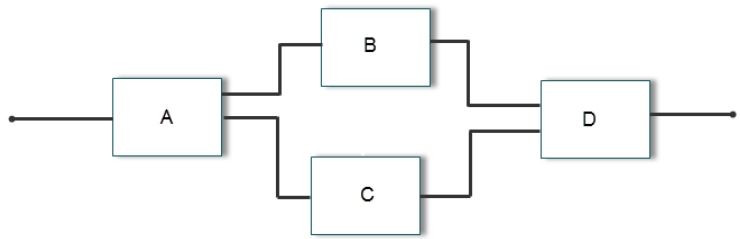
- “Check Configuration” on page 64-76

Choose a SIL or PIL Approach

In this section...

Consider a top model that consists of components `A`, `B`, `C`, and `D`:

- `A` and `B` are existing components for which code has previously been generated and tested.
- `C`, a referenced model, and `D`, a subsystem, are new components.



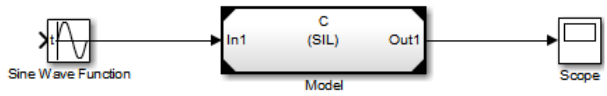
With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

- Test code from all components together. See "Test Top-Model Code" on page 64-12.
- Test new components separately (before testing code from all components). See "Test Referenced Model Code" on page 64-13 and "Test Subsystem Code" on page 64-13.

For some forms of testing, you require a test harness model. The test harness model:

- Generates test vectors or stimulus inputs that feed the block under test.
- Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.



The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block.

Test Top-Model Code

To test code generated from the top-model components together (`A`, `B`, `C`, and `D`), you can use top-model SIL/PIL or Model block SIL/PIL.

- Top-model SIL/PIL:

  1. Create test vectors or stimulus inputs in the MATLAB workspace (Simulink).
  2. Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  3. For each simulation mode, observe or capture outputs.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

- Model block SIL/PIL:

  1. Create a Model block that contains the top-model components.
  2. Insert the Model block in a simulation model, for example, your test harness model.
  3. Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Top model`.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

Test Referenced Model Code

To test code generated from the component `C` as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block `C` in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Model reference`.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

Test Subsystem Code

To test code generated from the subsystem `D`, use the SIL or PIL block approach:

1. Insert the subsystem in a simulation model, for example, your test harness model.
2. Run a normal mode simulation, capturing the outputs.
3. Create a SIL or PIL block from the subsystem.
4. In the model, replace the subsystem with the SIL or PIL block.
5. Run a simulation of the model, capturing the outputs.
6. Verify numerical equivalence by comparing normal mode subsystem outputs against SIL or PIL block outputs.

Summary

Simulation Type	Component From Which Code Is Generated	Mode Selection Method	Generated Code Interface	Test Signal Source
Top-model SIL/PIL	Top model	Menu item on Simulink Editor toolbar	Standalone	MATLAB workspace (Simulink)
Model block SIL/PIL	Model referenced by Model block	Model block parameter **Simulation mode**	Determined by Model block parameter **Code interface**: standalone or model reference.	Simulation model, for example, test harness model

Simulation Type	Component From Which Code Is Generated	Mode Selection Method	Generated Code Interface	Test Signal Source
SIL or PIL block	Subsystem	Manual block substitution	Standalone	Simulation model, for example, test harness model.

Configure and Run SIL Simulation

In this section...

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either **Simulation > Mode > Software-in-the-Loop (SIL)** or **Simulation > Mode > Processor-in-the-Loop (PIL)**. This option is available only if the model is configured for an ERT or AUTOSAR target. See "Model Configuration Parameters: Code Generation" (Simulink Coder) and "Export AUTOSAR Component XML and C Code" for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the **Data Import/Export** pane:
   - In the **Input** check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either *output logging* or *signal logging*:

    - In the **Output** check box and field, specify *output logging*.
    - In the **Signal logging** check box and field, specify *signal logging*.
  - Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation** > **Verification** > **Enable portable word sizes**.
5. If required, configure:
   - Code coverage.
   - Code execution profiling.
   - Creation of code generation report and static code metrics.
6. Start the simulation.

Note: On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(`*`model`*`)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, *`modelName`*`_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

```
Warning: The model 'modelName_wrapper' has the 'Configuration Parameters' ...
```

Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, `rtwdemo_sil_modelblock`.
2. Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
3. From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
4. From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
5. Click **OK**. The software displays the simulation mode as a block label.

   If you select `Top model`, the software displays the block label `(SIL: Top)`.
6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.

8 Start the simulation.

Note: On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1 In the Configuration Parameters dialog box, click the **All Parameters** tab.

2 From the **Create block** drop-down list, select either `SIL` or `PIL`.

3 If required, configure code execution profiling.

4 Click **OK**.

5 In your model window, right-click the subsystem that you want to simulate.

6 Select **C/C++ Code** > **Build This Subsystem**.

7 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.

8 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.

9 Run simulations with the environment or test harness model.

Note: On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.

Create block appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Configure Hardware Implementation Settings

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

Approach	Details
Portable word sizes	Switch between SIL and PIL modes without regenerating code. You use the same generated source code files for the SIL simulation on your development computer and for production deployment on the target platform. To configure a model to use portable word sizes, in **Configuration Parameters** > **All Parameters**, set: • `ProdEqTarget` to `on`. • `PortableWordSizes` to `on`.

	When you generate code for a model with portable word sizes specified, the code generator conditionalizes data type definitions in `rtwtypes.h`:
	
	`#ifdef PORTABLE_WORDSIZES /* PORTABLE_WORDSIZES defined */`
	
	…
	
	`#else /* PORTABLE_WORDSIZES not defined */`
	
	…
	
	`#endif /* PORTABLE_WORDSIZES */`
	
	If you use the template makefile approach to build code for your development computer, the template makefile that you select controls the passing of the `PORTABLE_WORDSIZES` definition to the compiler. For example, `ert_unix.tmf` has the following lines:

Approach	Details

	`ifeq ($(PORTABLE_WORDSIZES),1)`
	`CPP_REQ_DEFINES += -DPORTABLE_WORDSIZES`
	`endif`
	
	Note: The template makefile that you use to build code for your target must not contain the `PORTABLE_WORDSIZES` definition.
	
	With the toolchain approach, the software specifies `-DPORTABLE_WORDSIZES` for the compiler only for host-based builds.
	
	For information about the template makefile and toolchain approaches to building code, see "Choose and Configure Build Process" (Simulink Coder).

	Consider the case where your target uses code that your development computer cannot compile. When you switch from the PIL mode to the SIL mode and try to simulate the model, you see compilation errors. You can try to work around this problem by adding the source code files to the `SkipForSil` group in the build information object `RTW.BuildInfo`. The SIL build on the host platform does not compile source files present in the `SkipForSil` group. For information about how you add source code files to a group in the build information object, see: • addSourceFiles (Simulink Coder) in the Simulink Coder documentation • "Customize Post-Code-Generation Build Processing" (Simulink Coder) in the Simulink Coder documentation

Approach	Details
	Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions: • Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ. • Your production hardware implements rounding to `Floor` for signed integer division, and divisions in your model use rounding mode `Ceiling`, `Floor`, `Simplest`, or `Zero`. Normal and PIL simulation results match, but SIL simulation results can differ. • You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.
Test hardware	Use this approach only when you want to work around a limitation of portable word sizes. To configure a model for test hardware, in **Configuration Parameters** > **All Parameters**, set: • `PortableWordSizes` to `off`. • `ProdEqTarget` to `off`. • `TargetHWDeviceType` to `Custom Processor->MATLAB Host Processor`.
Production hardware	Use this approach only when the production hardware settings match your development computer architecture. In **Configuration Parameters** > **All Parameters**, set: • `PortableWordSizes` to `off`. • `ProdEqTarget` to `on`. • `ProdHWDeviceType` to match your development computer architecture. For example, you can select `Intel->x86-64 (Windows64)` and set `ProdLongLongMode` to `on`.

For information about test and production targets, see "Configure Run-Time Environment Options" (Simulink Coder) in the Simulink Coder documentation.

Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logsout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **All Parameters** > **Format** to `Dataset`.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

  The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logsout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- "Test Points" (Simulink)
- "Export Signal Data Using Signal Logging" (Simulink)
- "Local and Global Data Stores" (Simulink)
- "Global Data Store Example" (Simulink)
- "Log Program Execution Results" (Simulink Coder)

Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters** > **Model Referencing** > **Rebuild** to `Never`. If the Model block **Code interface** parameter is `Model reference`, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	**Configuration Parameters** > **Model Referencing** > **Rebuild** of test harness model set to `Never`.	**1** Component (algorithm) code from initial build is not regenerated. **2** Component code makefile is not called.

SIL and PIL Approach		Code Generation Behavior After Initial Build
		3 SIL/PIL application files from initial build are not regenerated. **4** SIL/PIL application makefile is called.
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1–4.

For more information, see:

- "Model Configuration Parameters: Model Referencing" (Simulink)
- "Create a Protected Model" (Simulink Coder)

Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

Note: The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see "What Is Acceleration?" (Simulink).

Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in "Configure Calls to AUTOSAR NVRAM Manager Service" shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see:

- "Modeling Functions and Callers for Code Generation" on page 4-2
- "Generate Code for Functions and Callers" on page 4-6

Configure and Run PIL Simulation

In this section...

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either **Simulation > Mode > Software-in-the-Loop (SIL)** or **Simulation > Mode > Processor-in-the-Loop (PIL)**. This option is available only if the model is configured for an ERT or AUTOSAR target. See "Model Configuration Parameters: Code Generation" (Simulink Coder) and "Export AUTOSAR Component XML and C Code" for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the **Data Import/Export** pane:
   - In the **Input** check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either *output logging* or *signal logging*:
     - In the **Output** check box and field, specify *output logging*.

    - In the **Signal logging** check box and field, specify *signal logging*.
  - Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
5. If required, configure:
   - Code coverage.
   - Code execution profiling.
   - Creation of code generation report and static code metrics.
6. Start the simulation.

Note: On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(`*`model`*`)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, *`modelName`*`_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

```
Warning: The model 'modelName_wrapper' has the 'Configuration Parameters' ...
```

Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, `rtwdemo_sil_modelblock`.
2. Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
3. From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
4. From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
5. Click **OK**. The software displays the simulation mode as a block label.

   If you select `Top model`, the software displays the block label `(SIL: Top)`.
6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.

8 Start the simulation.

Note: On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1 In the Configuration Parameters dialog box, click the **All Parameters** tab.

2 From the **Create block** drop-down list, select either `SIL` or `PIL`.

3 If required, configure code execution profiling.

4 Click **OK**.

5 In your model window, right-click the subsystem that you want to simulate.

6 Select **C/C++ Code** > **Build This Subsystem**.

7 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.

8 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.

9 Run simulations with the environment or test harness model.

Note: On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.

Create block appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logsout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **All Parameters** > **Format** to `Dataset`.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

  The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logsout` is generated but not stored in the MAT-file.

- For PIL, the target environment must support MAT-file logging.

For more information, see:

- "Test Points" (Simulink)
- "Export Signal Data Using Signal Logging" (Simulink)
- "Local and Global Data Stores" (Simulink)
- "Global Data Store Example" (Simulink)
- "Log Program Execution Results" (Simulink Coder)

Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters** > **Model Referencing** > **Rebuild** to `Never`. If the Model block **Code interface** parameter is `Model reference`, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	**Configuration Parameters** > **Model Referencing** > **Rebuild**	**1** Component (algorithm) code from initial build is not regenerated.

SIL and PIL Approach		Code Generation Behavior After Initial Build
	of test harness model set to `Never`.	**2** Component code makefile is not called. **3** SIL/PIL application files from initial build are not regenerated. **4** SIL/PIL application makefile is called.
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1–4.

For more information, see:

- "Model Configuration Parameters: Model Referencing" (Simulink)
- "Create a Protected Model" (Simulink Coder)

Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

Note: The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see "What Is Acceleration?" (Simulink).

Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in "Configure Calls to AUTOSAR NVRAM Manager Service" shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see:

- "Modeling Functions and Callers for Code Generation" on page 4-2
- "Generate Code for Functions and Callers" on page 4-6

- "Simulation Mode Override Behavior in Model Reference Hierarchy" on page 64-35

- "SIL and PIL Limitations" on page 64-61

Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The Model block itself can be a parent block containing child Model blocks at lower levels of its reference hierarchy. The simulation mode of the parent block can override the simulation mode of the child block.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes *except* rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a reference hierarchy.

Mode of Top Model or Parent Block	Mode of Parent or Child Block in Reference Hierarchy			
	Normal	Accelerator	SIL	PIL
Normal	Equivalent	Compatible	Compatible	Compatible
Accelerator	Override	Equivalent	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.
Rapid accelerator	Override	Override	Error	Error
SIL	Override	Override	Equivalent	Error
PIL	Override	Override	Error	Equivalent

The different types of behavior are:

- Equivalent — Both parent and child Model block run in the same simulation mode.
- Compatible — The software simulates the child block in the mode specified for the child block, for example, when the simulation mode of the top model is normal or accelerator.
- Error — The simulation produces an error. For example, if a top model has simulation mode rapid accelerator but contains a child block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and PIL mode of child blocks. This behavior avoids the risk of “false positives”, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of child Model blocks is tested or verified.

- Override — The simulation mode of the top model or parent Model block overrides the simulation mode of the child block. For example, if a top model or parent Model block that you configured for a SIL simulation contains a child Model block with normal or accelerator simulation mode, then the software simulates the child block in SIL mode. The override behavior:
  - Allows a Model block in the reference hierarchy to have the SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent Model block in SIL or PIL mode. You do not have to switch the simulation mode of every model component in the hierarchy.

For a model reference hierarchy that consists of multiple subhierarchies, if the top-model simulation mode is normal or accelerator, the software can run only one subhierarchy in PIL mode. For example, if your normal mode top model contains multiple Model blocks, you can specify the PIL mode for only one of the Model blocks.

Note: You can view your model hierarchy in the Model Dependency Viewer. In the Referenced Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from `printf` statements in your code.
- Error messages sent to `stderr`.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX® signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

A SIL simulation supports these debuggers;

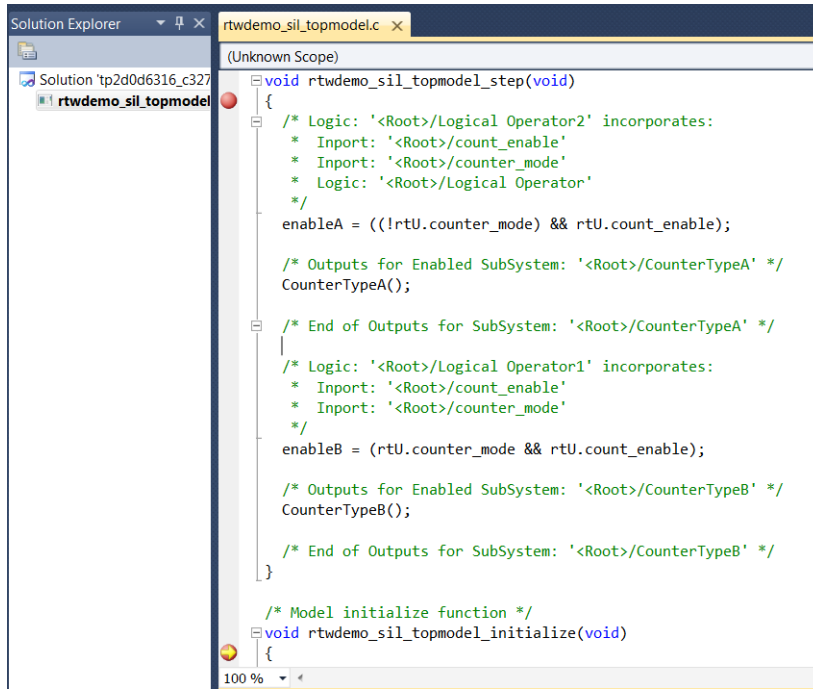
- On Windows, Microsoft Visual Studio® debugger.
- On Linux, GNU Data Display Debugger (DDD).

Note: You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++ or GNU GCC compiler. For more information, see supported compilers.

To enable your debugger for a SIL simulation, on the **Configuration Parameters** > **Code Generation** > **Verification** pane, select the **Enable source-level debugging for SIL** check box.

If your top model has Model blocks where the **Code interface** block parameter is set to `Top model`, then the **Enable source-level debugging for SIL** parameters for the top model and referenced models must have the same settings. Otherwise, the software produces an error.

When you run the SIL simulation, for example on a Windows computer, your *`model`*`.c` or *`model`*`.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *`model`*`_initialize` and *`model`*`_step` functions.



You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the `Continue` button (**F5**).

   The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

Note: In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:

```
The timeout of 1 seconds for receiving data from the rtiostream
```

```
interface has been exceeded. There are multiple possible causes
for this failure.
...
...
```

Create PIL Target Connectivity Configuration

In this section...

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

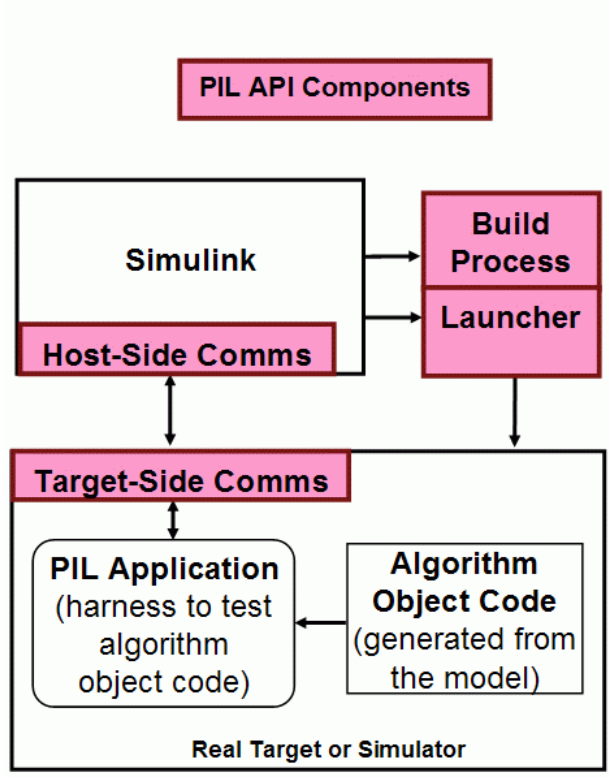
- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an `sl_customization.m` file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.



You must provide implementations of the three API components:

- Build API — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- Launcher API — Control how Simulink starts and stops the PIL executable.
- Communications API — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in "Configure Processor-In-The-Loop (PIL) for a Custom Target".

1. Create a subclass of `rtw.connectivity.Config`.

   ```
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:

   - Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

     ```
     builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
                                                targetApplicationFramework, ...
                                                exeExtension);
     ```

   - Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

     ```
     launcher = mypil.Launcher(componentArgs, builder);
     ```

3. Configure your `rtiostream` API implementation of the host-target communications on page 64-46 channel.

   - For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
   - For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

     ```
     hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
                                                                    launcher, ...
                                                                    rtiostreamLib);
     ```

4. If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See "Specify Hardware Timer" on page 64-52.

Note: Each time you modify a connectivity implementation, close and reopen the models to refresh them.

Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

1. Create or update an `sl_customization.m` file. In this file:
   - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
   - Invoke `registerTargetInfo`.
2. Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

   ```
   addpath(sl_customization_path);
   sl_refresh_customizations;
   ```

For more information, see `rtw.connectivity.ConfigRegistry`.

Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your model development and code generation, use the supplied `piltest` function. With the function, you can run a suite of tests. In the tests, the function runs various normal, SIL, and PIL simulations. The function compares results and produces errors if it detects differences between simulation modes.

Target Connectivity API Examples

For step-by-step examples, see:

- "Configure Processor-In-The-Loop (PIL) for a Custom Target"

  This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.
- "Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation"

This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

Note: If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(lFd,IPPROTO_TCP,TCP_NODELAY,(char*)&option,sizeof(option));
```

The code for your custom TCP/IP implementation can require modification.

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

Host-Target Communication for PIL

In this section...

Communications `rtiostream` API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`

- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see "Create a Target Connectivity API Implementation" on page 64-41.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see "Test an `rtiostream` Driver" on page 64-48.

Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because Simulink automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the Simulink side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

Test an `rtiostream` Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

Note: After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder *`matlabroot`*`/rtw/c/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection,param1,param2)
```

- `connection` is a character vector indicating the communication method. It can have values `'tcp'` or `'serial'`.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is `'tcp'`, then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345)`.

- If `connection` is `'serial'`, then `param1` and `param2` are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600)`.

You can run the MATLAB part of the test suite as follows:

```
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char    : 8 bit
Size of short   : 16 bit
Size of int     : 32 bit
Size of long    : 32 bit
Size of float   : 32 bit
Size of double  : 64 bit
Size of pointer : 64 bit
Byte ordering   : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ......... PASS
Test 2 (varying size data exchange): ......... PASS

### Test suite for rtiostream finished successfully ###
```

Furthermore, the following profile appears.

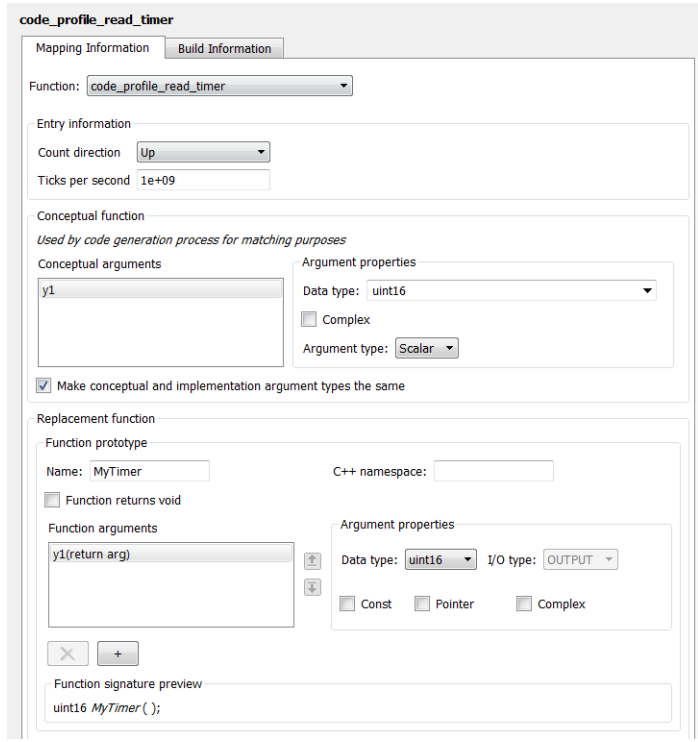
Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
2. Create a new code replacement table. Select **File** > **New table**.
3. Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry** > **Function**.
4. In the middle view, select the new unnamed function.
5. On the **Mapping Information** pane:
   a. From the **Function** drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select `Up`.
   c. In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

      The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the **Name** field, specify a replacement function name, for example, `MyTimer`.
   e. Click **Apply**.



f To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See "Specify Build Information for Replacement Code" on page 51-59.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as *`MyCrlTable.m`*, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

PIL Simulation Sequence

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

Stage		Description
1	Start	For top-model PIL, on the Simulink Editor toolbar, you select the `Processor-in-the-Loop (PIL)` mode, and then click the Run button. For Model block PIL, you set the **Simulation mode** parameter of the Model block to `Processor-in-the-loop (PIL)`, and then run a simulation of the harness model that contains the Model block. For the PIL block, you run a simulation of the harness model that contains the PIL block.
2	Validate target connectivity	The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error.
3	Generate production source code and build object code for target	The generated source code is identical to the code that is produced when you run the `slbuild` command. • For top-model PIL or Model block PIL with block parameter **Code interface** set to `Top model`, the generated code is identical to the code produced when you run `slbuild('model')`. • For Model block PIL with block parameter **Code interface** set to `Model reference`, the generated code is identical to the code produced when you run `slbuild('model', 'ModelReferenceRTWTarget')`. The model reference simulation target is also produced. The software builds object code for the target by using the template makefile or toolchain that you specify.
4	Create instances of PIL API components	The software instantiates your `rtw.connectivity.Config` class, which creates

Stage		Description
		instances of `rtw.connectivity.MakefileBuilder`, `rtw.connectivity.Launcher`, `rtw.pil.RtIOStreamApplicationFramework`, and `rtw.connectivity.RtIOStreamHostCommunicator`.
5	Generate PIL files	The generated PIL files are in the `pil` folder. At the end of the simulation, use the code generation report to view the files.
6	Build target application	The software: • Uses your instance of `rtw.connectivity.MakefileBuilder` to build the target application. • Compiles the PIL interface file, `xil_interface.c`, and other PIL files into the target executable file. On a Windows system, for example, this file is called *`modelName`*`.exe`. The object code, including the executable file, is in the `pil` folder. • If configured, produces the code generation report.
7	Start target application	The software uses `rtw.connectivity.Launcher` to start the application on the target.
8	Simulink engine interacts with PIL S-function	The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function. From the host-side, the PIL S-function communicates with the target executable code through `rtIOStream` commands. On the target side, `xil_interface` executes generated code.
9	Stop target application	The software uses `rtw.connectivity.Launcher` to stop the application on the target.

Stage		Description
10	End PIL simulation	For top-model PIL, at the end of the simulation, the software destroys the `rtw.connectivity.Config` instance. For Model block PIL and PIL block, the block creates and owns the `rtw.connectivity.Config` instance, which is not destroyed at the end of the simulation. You can rerun the simulation, which now does not require the creation of another `rtw.connectivity.Config` instance. If you want to destroy the instance, close the parent model.

Verification of Code Generation Assumptions

The settings on the **Configuration Parameters > Hardware Implementation** pane specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) simulation, the software verifies the **Hardware Implementation** pane settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Number of bits: int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

More About

- "SIL and PIL Simulations" on page 64-2

View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

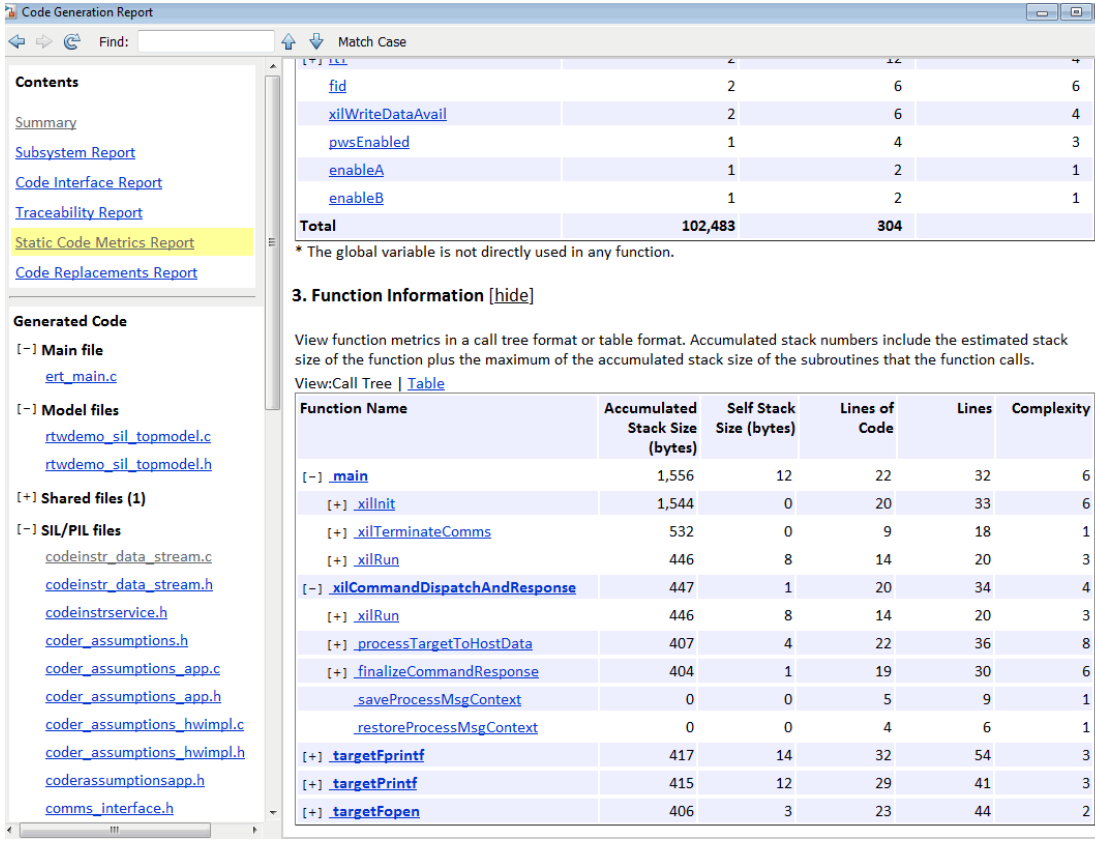
- Understand and review the SIL and PIL testing process.
- See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, on the **Configuration Parameters > Code Generation > Report** pane, select the **Create code generation report**, **Open report automatically**, and **Static code metrics** check boxes. Then click **OK**.

At the end of the simulation, in the Code Generation Report window:

- To review code metrics, in the **Contents** view, click **Static Code Metrics Report**.
- To review SIL and PIL files, in the **Generated Code** view, expand the **SIL/PIL files** node. For example:
  - To review the S-function that runs on the host, click *`modelName`*`_sbs.c` or *`modelName`*`_pbs.c`.
  - To view the SIL or PIL interface that runs on the target, click `xil_interface.c`.



Note: Do not use the SIL or PIL files in code development as these files can change over releases. Use supplied APIs for code development.

SIL and PIL Limitations

In this section...

About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations in three ways:

- Top-model SIL/PIL — Set the top-model simulation mode to `Software-in-the-Loop (SIL)` or `Processor-in-the-Loop (PIL)`.
- Model block SIL/PIL — Set the Model block parameter **Simulation mode** to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`.
- SIL/PIL block — Use SIL or PIL blocks in the model.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

General SIL and PIL Limitations

Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable *workspace* parameters but not tunable *dialog box* parameters. For information about tuning parameters, see "Block Parameter Representation in the Generated Code" on page 19-47.

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.

Parameter description	Software response		
	Top-Model SIL/PIL	Model Block SIL/PIL	SIL/PIL Block
Parameters with storage class that applies `"static"` scope or `"const"` keyword. For example, `Custom`, `Const`, or `ConstVolatile`	Warning	Warning	Warning
Parameters with multiword, fixed-point data types	Warning	Error	Warning
Parameters with data types that have different sizes on host and target	Warning	Error	Warning

For C++ class code, SIL/PIL you can tune tunable workspace parameters when **Parameter visibility** is `public`. If **Parameter visibility** is `private` or `protected`, tuning is supported only if **Parameter access** is `Method` or `Inlined method`.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is `Reusable function`.
- **All Parameters > Use dynamic memory allocation for model initialization** is not selected.

- **Optimization > Signals and Parameters > Default parameter behavior** is `Tunable`.
- The model contains parameters with storage class `Auto` or `SimulinkGlobal`.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the `rtP` model parameter structure, you see an error message like the following:

```
Parameter Dialog:InitialOutput in 'rtwdemo_sil_topmodel/CounterTypeA/count'
is part of the imported "rtP" structure in the generated code but cannot be
initialized by SIL or PIL. To avoid this error, make sure the parameter
corresponds to a tunable base workspace variable with a storage class such
as SimulinkGlobal and is supported for dynamic parameter initialization /
tuning with SIL/PIL. Alternatively, select Configuration Parameters >
Code Generation > Interface and set 'Code interface packaging' to
'Nonreusable function', or select 'Use dynamic memory allocation for model
initialization'.
```

If you select **All Parameters > Use dynamic memory allocation for model initialization**, this limitation does not apply.

For Model block SIL/PIL, if you specify the code under test to be `Top model`, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, top-model SIL/PIL and SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

SIL/PIL Does Not Check Simulink Coder Error Status

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

Missing Code Interface Description File Errors

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL

simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option **Classic call interface**, this error can occur. Therefore, do not select the option.

To Workspace Block

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

Cannot Connect SIL/PIL Outputs to Merge Block

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

Variant Condition Propagation with Variant Source and Variant Sink Blocks

Top-model SIL/PIL and SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

Unsupported Blocks

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

Multiword Fixed-Point I/O

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

Fixed-Point Data Types Wider Than 32 Bits

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit `long` and `long long`
- 64-bit execution profiling timer data type
- `int64` and `uint64` in MATLAB Coder SIL execution.

The following constraints apply:

- For 64-bit data type support, the data type must be representable as `long` or `long long` on the MATLAB host *and* the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.
- The software does not support the 40-bit `long` data type of the TI's C6000™ target.

  Through the **Configuration** > **Hardware Implementation** pane, you can enable support for the 64-bit `long long` data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit `long` data type, which SIL/PIL does not support.

Data Type Replacement

The software does not support replacement data type names that you define for the built-in data type `boolean` if these names map to the `int` or `uint` built-in data type.

Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if **All Parameters** > **Propagate sizes of variable-size signals** is `During execution`.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see "Log Internal Signals of a Component" on page 64-22.

The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
Only signals that are included in the C API are logged during SIL/PIL simulation. To observe the signals in the generated code, you can configure the signals as test points. For each signal, select the **Signal Properties > Test point** check box.	Yes	Yes
Signals feeding merge blocks are not supported for logging in normal simulation but are logged in SIL/PIL mode. The logged values during SIL/PIL are the same as the logged values for the output of the merge block.	Yes	No
Top-model normal simulation logs data at a periodic rate but top-model SIL/PIL simulation logs data at a constant rate under these circumstances: • **Default parameter behavior** is `Tunable`. • A constant sample time signal from a Model block is logged in the top model. • The logged signal is not directly connected to a root-level output port. To avoid this behavior and log at the constant rate in all simulation modes, set **Default parameter behavior** to `Inlined`.	Yes	No
Features not supported: • Signal logging in models referenced by the SIL/PIL component. • Signal logging in Simulink Function block. • Virtual signals, for example, mux. • Buses. • Custom storage classes.	Yes	Yes

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
• Continuous, asynchronous, and triggered sample times. At the top-level of export-function models, you can log signals with triggered sample times. • Logging of Stateflow states and local data. • Units.		
Variable-size, function-call, and Action signals are not supported. A normal simulation produces an error. A SIL/PIL simulation produces a warning.	Yes	No
State port signals are not supported. A normal simulation produces an error. A SIL/PIL simulation does not produce a warning.	Yes	No

Unsupported Implementation Errors

If you use a custom storage class (CSC) with a **Type** property that is `Other` or if you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

```
The following data interfaces have
implementations that are not supported by SIL or PIL.
```

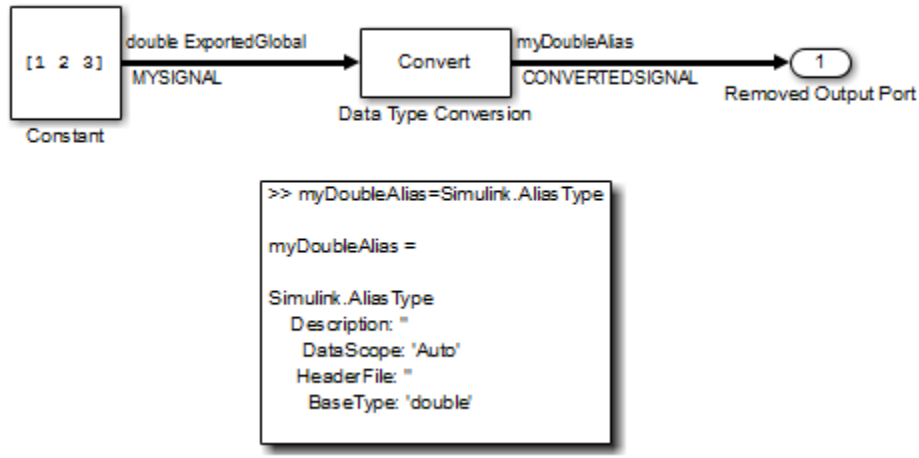
`data interfaces` can be global data stores, `inports`, `outports`, or `parameters`.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 55-17. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display Port Data Types by selecting **Display > Signals & Ports > Port Data Types** (see “Port Data Types” (Simulink)).
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display dimensions by selecting **Display > Signal & Ports > Signal Dimensions**.

Dimension changes from scalar (1) to matrix `[1x1]`, and, matrix `[1x1]` to scalar (1), can lead to this error. It is difficult to inspect the model for such changes because **Display > Signal & Ports > Signal Dimensions** does not distinguish between (1) and `[1x1]` dimensions. Both signals are displayed as scalar signals. Check your model and workspace objects carefully. Make sure that you specify scalar dimensions consistently.

The following model causes this error by changing the output port signal data type.



Hardware Implementation

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.

PIL requires that you configure the correct **Hardware Implementation** settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

Non-ASCII Characters in Folder Name

If the name of the current working folder contains non-ASCII characters, you cannot run a SIL simulation.

State Logging

SIL/PIL does not support state logging (Simulink).

Bus Elements Mapped to Imported Bit-Field Definitions

If you map Simulink bus elements to bit fields through an imported header file, a SIL or PIL simulation produces a build error. For example, if your model has an Inport block connected to a bus that is a Simulink.Bus object with these properties:

- **Name** — `myBus`
- **Bus elements** — An array of Simulink.BusElement objects with these properties.

Name	DataType	Complexity	Dimensions
bitField0	boolean	real	1
bitField1	boolean	real	1
bitField2	boolean	real	1
bitField3	boolean	real	1
bitField4	boolean	real	1
bitField5	boolean	real	1

- **Data scope** — `Imported`
- **Header file** — `busSpecification.h`. This file contains `myBus`, which defines C bit-field data types for the bus elements.

```
typedef struct myBus
{
   unsigned int bitField0 : 1;
   unsigned int bitField1 : 1;
   unsigned int bitField2 : 1;
   unsigned int bitField3 : 1;
   unsigned int bitField4 : 1;
   unsigned int bitField5 : 1;
} myBus;
```

Size Mismatch Between Simulink and Target Hardware Data Types

When a Simulink data type and the corresponding target hardware data type differ in size, a SIL or PIL simulation produces an error. This size mismatch can occur if you map a Simulink data type to the target hardware data type through definitions in an imported header file. For example, if you create a data type alias, `T_BOOL`, which is a `Simulink.AliasType` object with these properties:

- **Base type** — `boolean`.

- **Mode** — `Built in`, `boolean`.
- **Data scope** — `Imported`.
- **Header file** — `myDefinitions.h`. This file defines `T_BOOL` as an enumerated data type:

```
typedef enum _BOOL_TYPE
{
  FALSE           = 0,
  TRUE            = 1
} BOOL_TYPE;

typedef BOOL_TYPE T_BOOL;
```

  In this case, the compiler for the target hardware determines the size of `T_BOOL`, which can differ from the size of the Simulink data type, `boolean`.

Top-Model SIL/PIL Limitations

Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

- The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

  In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

  - If a signal being logged has matrix dimensions `[1x5]` but the outport connected to the signal has vector dimensions (`5`), then the data logged during a SIL or PIL simulation has vector dimensions (`5`).
  - If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions `[1x1]`, then the data logged during a SIL or PIL simulation has matrix dimensions `[1x1]`.
- Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

  During normal simulation, signals connected directly to duplicated inports are logged.

- The Signal Logging Selector / `DataLoggingOverride` override mechanism is not supported.
- Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:
  - The `SaveOutput` or `SignalLogging` configuration parameter is `on`.
  - The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the `InheritFromInputs` parameter for a Bus Creator block is set to `'on'`.
- The software inserts the suffix, `_wrapper` for *output logging*, if the save format is `Structure`, `Structure with time`, or `Dataset` and you run the `sim` command without specifying the single-output format. The software adds `_wrapper` to the block name for signals in `yout`. If the save format is `Array`, the software does not add the suffix. For example:

  ```
  >> yout.signals

  ans =
          values: [11x1 double]
      dimensions: 1
           label: 'SignalLogging'
       blockName: 'sillogging_wrapper/OutputLogging'
  ```

  To avoid this behavior, run command-line simulations with the `sim` command specifying the single-output format. See "Run Simulations Programmatically" (Simulink).

Model in Compiled State During Top-Model SIL/PIL

During a top-model SIL/PIL simulation, the software places the model in a compiled state – see `model`. This action can result in a conflict over global resources between the model and the generated SIL/PIL code. In this case, differences between normal mode and SIL/PIL simulation outputs can result.

For example, consider a model that uses UDP blocks from the DSP System Toolbox. These blocks open UDP sockets, which can lead to resource contention between the model and the generated SIL/PIL code.

Callback Support

SIL/PIL does not support the callbacks (model or block) `StartFcn` and `StopFcn`.

Note: Top-model SIL/PIL supports the callback `InitFcn`.

Incremental Build

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The `HeaderFile` property of a `Simulink.AliasType` object
- Legacy S-functions

If you make these changes, build (**Ctrl-B**) your model again before starting the next PIL simulation.

Initialize, Reset, and Terminate Function Blocks

Top-model SIL/PIL supports:

- For export-function models (Simulink), Initialize Function, Reset Function, and Terminate Function blocks.
- For models that are not export-function models, Initialize Function and Terminate Function blocks.

Model Block SIL/PIL Limitations

Top-Model Code Testing

The following limitations apply:

- The `Model Variants` block does not support the block parameter `CodeInterface`. The software behaves as if `CodeInterface` is set to `'Model reference'`. To work around this limitation, use the `Variant Subsystem` block. Through this block, you can incorporate `Model` blocks for which `CodeInterface` is set to `'Top model'`.
- Because model arguments do not apply to a top model, when the **Code interface** block parameter is set to `Top model`, the software does not support the **Model arguments** block parameter.
- Conditional execution does not apply to a top model. If a Model block is set up to execute conditionally and the **Code interface** block parameter is set to `'Top model'`, the software produces an error when you run a SIL or PIL simulation.

- For sample time independent models, you must set **Configuration Parameters > Solver > Periodic sample time constraint** to `Ensure sample time independent`.
- Simulation results from top-model code and model reference code can differ when a root-level Inport is connected to a root-level Outport by a signal that has a signal object with an initial value.

  For top-model code, the software associates the signal object with the Inport. The software can apply the initial value for the signal object to the Inport. See "Initialization Behavior Summary for Signal Objects" (Simulink).

  For model reference code, the software associates the signal object with the Outport. The software does not apply the initial value for the signal object to the Inport.

Conditionally Executed Subsystem

You see an error if:

- You place your Model block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your Model block, in either SIL or PIL simulation mode, has blocks that depend on absolute time **and** is conditionally executed.

Outputs with Constant Sample Time

If the block parameter **Code interface** is `Top model`, Model block SIL/PIL supports outputs with constant sample time.

Noninlined S-Functions

Model-block SIL/PIL simulations do not support noninlined S-functions.

SIL/PIL Block Limitations

PIL Block Mux

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.

Code Coverage

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

Subsystem with Inherited Sample Time Blocks

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:

- Before you create the SIL/PIL block, in the parent model, set **Configuration Parameters > Solver > Periodic sample time constraint** to `Ensure sample time independent`.
- Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

Related Examples

- "SIL and PIL Simulations" on page 64-2
- "Choose a SIL or PIL Approach" on page 64-11

Check Configuration

Use the cgv.Config class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

Note:

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
- Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `Simulink.ConfigSetRef.getRefConfigSet` method. For more information, see `Simulink.ConfigSetRef` in the Simulink documentation.
- If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config`. For more information, see "Callbacks for Customized Model Behavior" (Simulink).

To verify that your model is configured for SIL or PIL:

1. Construct a `cgv.Config` object that changes the configuration parameter values without saving the model. For example, to configure your model for SIL:

   ```
   c = cgv.Config('vdp', 'connectivity', 'sil');
   ```

   Tip:

- You can obtain a list of changes without changing the configuration parameter values. When you construct the object, include the `'ReportOnly', 'on'` property name and value pair.

- You can change the configuration parameter values and save the model. When you construct the object, include the `'SaveModel', 'on'` property name and value pair.

2 Determine and change the configuration parameter values that the object recommends using the `configModel` method. For example:

```
c.configModel();
```

3 Display a report of the changes that `configModel` makes. For example:

```
c.displayReport();
```

4 Review the changes.

5 To apply the changes to your model, save the model.

Related Examples

- "Verify Numerical Equivalence Between Two Modes of Execution of a Model" on page 64-79

Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

- Configure your model for SIL or PIL simulation.
- Use the cgv.Config class of the CGV API to verify the model configuration for SIL or PIL simulation.
- Configure your model for code generation. For more information, see "Configure Model for Code Generation Objectives by Using Code Generation Advisor" on page 29-2.
- Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

- Set up the tests for the first execution environment. For example, simulation.
- Use run (cgv.CGV) to run the tests for the first execution environment.
- Set up the tests for the second execution environment. For example, top-model PIL.
- Use `cgv.CGV.run` to run the tests for the second execution environment.
- Use getOutputData (cgv.CGV) to get the output data for each execution environment.
- Use getSavedSignals (cgv.CGV) to display the signal names in the output data. (optional)
- Build a list of signal names for input to other `cgv.CGV` methods. (optional)
- Use createToleranceFile (cgv.CGV) to create a file correlating tolerance information with output signal names. (optional)
- Use compare (cgv.CGV) to compare the output signals of the first and second execution environments for numerical equivalence.

Note: Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

- "Verify Numerical Equivalence Between Two Modes of Execution of a Model" on page 64-79

Verify Numerical Equivalence Between Two Modes of Execution of a Model

In this section...

The following example describes configuring, executing, and comparing the results of the rtwdemo_cgv model in normal and software-in-the-loop (SIL) simulation modes.

Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

1. Open the `rtwdemo_cgv` model.

   ```
   cgvModel = 'rtwdemo_cgv';
   load_system(cgvModel);
   ```

2. Save the model to a working directory.

   ```
   save_system(cgvModel, fullfile(pwd, cgvModel));
   close_system(cgvModel); % avoid original model shadowing saved model
   ```

3. Use the cgv.Config class to create a `cgv.Config` object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

   ```
   cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');
   ```

4. Use the configModel (cgv.Config) method to review your model configuration and to change the settings to configure your model for SIL. When `'connectivity'` is set to `'sil'`, the system target file is automatically set to `'ert.tlc'`. If you specified the parameter/value pair, (`'SaveModel', 'on'`) when you created the `cgvCfg` object, the `cgv.Config.configModel` method saves the model.

Note: CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

```
cgvCfg.configModel(); % Evaluate, change, and save your model for SIL
```

5 Display a report of the changes that `cgv.Config.configModel` makes to the model.

```
cgvCfg.displayReport(); % In this example, this reports no changes
```

Execute the Model

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

1 If you have not already done so, follow the steps described in "Configure the Model" on page 64-79.

2 Create a `cgv.CGV` object that specifies the `rtwdemo_cgv` model in normal mode simulation.

```
cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');
```

Note: When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

3 Provide the input file to the `cgvSim` object.

```
cgvSim.addInputData(1, [cgvModel '_data']);
```

4 Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.

```
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
```

5 Specify a location where the object writes all output data and metadata files for execution. This step is optional.

```
cgvSim.setOutputDir('cgv_output');
```

6 Execute the model.

```
result1 = cgvSim.run();
```

```
*** handling PostLoad file rtwdemo_cgv_init.m
Start CGV execution of model rtwdemo_cgv, ComponentType topmodel, ...
 connectivity sim, InputData rtwdemo_cgv_data.mat
End CGV execution: status completed
```

7 Get the output data associated with the input data.

```
outputDataSim = cgvSim.getOutputData(1);
```

8 For the next mode of execution, SIL, repeat steps 2–7.

```
cgvSil = cgv.CGV( cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();
```

At the MATLAB command line, the result is:

```
*** handling PostLoad file rtwdemo_cgv_init.m
Start CGV execution of model rtwdemo_cgv, ComponentType topmodel, ...
     connectivity sil, InputData rtwdemo_cgv_data.mat

### Starting build procedure for model: rtwdemo_cgv
### Successful completion of build procedure for ...
    model: rtwdemo_cgv
### Preparing to start SIL simulation ...
### Starting SIL simulation for model: rtwdemo_cgv
### Stopping SIL simulation for model: rtwdemo_cgv
End CGV execution: status completed
```

Compare All Output Signals

After setting up and running the test, compare the outputs by doing the following:

1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 64-79 and “Execute the Model” on page 64-80.

2 Test that the execution result of the model:

```
if ~result1 || ~result2
    error('Execution of model failed.');
end
```

3 Use the getOutputData (cgv.CGV) method to get the output data from the cgv.CGV objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

4 Display a list of signals by name using the getSavedSignals (cgv.CGV) method.

```
cgvSim.getSavedSignals(simData);
```

At the MATLAB command line, the result it:

```
simData.hi0.Data(:,1)
simData.hi0.Data(:,2)
simData.Vector.Data(:,1)
simData.Vector.Data(:,2)
simData.Vector.Data(:,3)
simData.Vector.Data(:,4)
simData.BusOutputs.hi0.Data(:,1)
simData.BusOutputs.hi0.Data(:,2)
simData.BusOutputs.hi1.mid0.lo0.Data(1,1,:)
simData.BusOutputs.hi1.mid0.lo0.Data(1,2,:)
simData.BusOutputs.hi1.mid0.lo0.Data(2,1,:)
simData.BusOutputs.hi1.mid0.lo0.Data(2,2,:)
simData.BusOutputs.hi1.mid0.lo1.Data
simData.BusOutputs.hi1.mid0.lo2.Data
simData.BusOutputs.hi1.mid1.Data(:,1)
simData.BusOutputs.hi1.mid1.Data(:,2)
simData.ErrorsInjected.Data
```

5 Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.

```
signalList = {'simData.ErrorsInjected.Data'};
```

6 Use the createToleranceFile (cgv.CGV) method to create a file, in this example, `'localtol'`, correlating tolerance information with output signal names.

```
toleranceList = {{'absolute', 0.5}};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
```

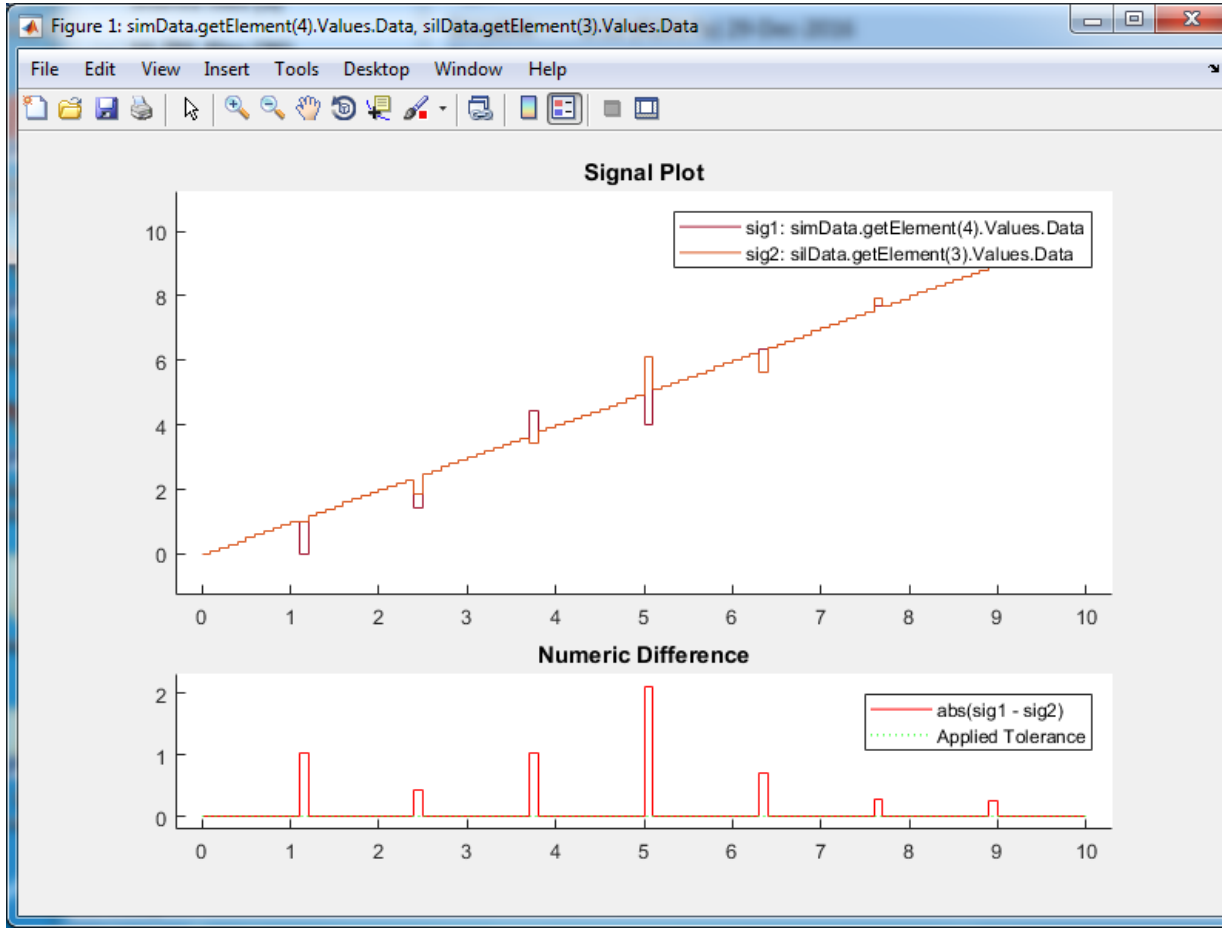
7 Compare the output data signals. By default, the compare (cgv.CGV) method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the `'Plot'` parameter is set to `'mismatch'`. Therefore, only mismatched signals produce a plot.

```
[matchNames, ~, mismatchNames, ~] = ...
    cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
    'Tolerancefile', 'localtol');
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
disp('Mismatched Signal Names:');
disp(mismatchNames);
```

At the MATLAB command line, the result is:

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
    'simData.ErrorsInjected.Data'
```

A plot results from the mismatch on signal `simData.ErrorsInjected.Data`.



The lower plot displays the numeric difference between the results.

Compare Individual Output Signals

After setting up and running the test, compare the outputs of individual signals by doing the following:

1 If you have not already done so, configure and test the model, as described in "Configure the Model" on page 64-79 and "Execute the Model" on page 64-80.

2 Use the getOutputData (cgv.CGV) method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

3 Use the getSavedSignals (cgv.CGV) method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.BusOutputs.hi1.mid0.lo1.Data', ...
'simData.BusOutputs.hi1.mid0.lo2.Data', 'simData.Vector.Data(:,3)'};
```

4 Use the specified signals as input to the compare (cgv.CGV) method to compare the signals from separate runs.

```
[matchNames, ~, mismatchNames, ~] = ...
    cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
    'signals', signalList);
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
if ~isempty(mismatchNames)
    disp( 'Mismatched Signal Names:');
    disp(mismatchNames);
end
```

At the MATLAB command line, the result is:

```
3 Signals match, 0 Signals mismatch
```

Plot Output Signals

After setting up and running the test, use the plot (cgv.CGV) method to plot output signals.

1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 64-79 and “Execute the Model” on page 64-80.

2 Use the getOutputData (cgv.CGV) method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
```

3 Use the getSavedSignals (cgv.CGV) method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.Vector.Data(:,1)'};
```

4 Use the specified signal list as input to the plot (cgv.CGV) method to compare the signals from separate runs.

```
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
     'Signals', signalList);
```

Using Code Generation Verification API

Configure and run normal, software-in-the-loop (SIL), and processor-in-the-loop (PIL) simulations, and compare results.

Note: Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

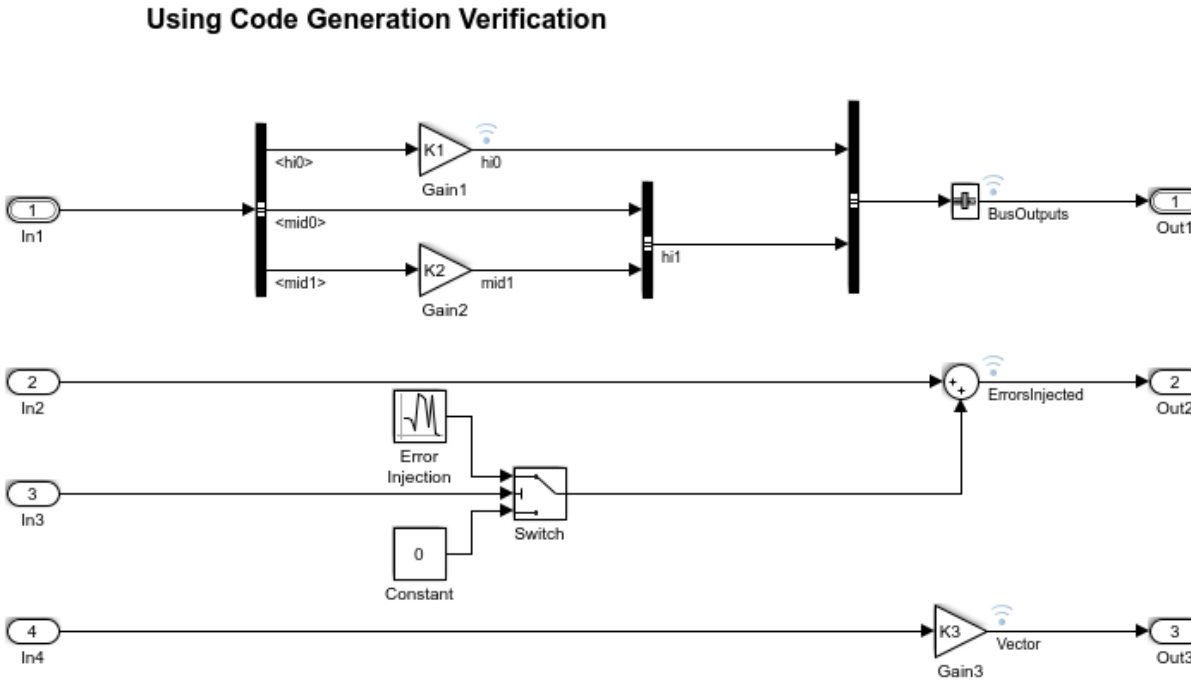
Review the Model

The rtwdemo_cgv model uses buses, scalars, and vectorized data, plus error injection to create differences between test executions.

Note: Before executing the code in this example, change to a writable folder. If you are not working in a writable folder, code generation errors occur.

To open rtwdemo_cgv, in the MATLAB® Command Window, enter the following commands.

```
baseVars = who;  % For future cleanup.
cgvModel = 'rtwdemo_cgv';
close_system(cgvModel,0);
open_system( cgvModel);
```



The model contains a hierarchical bus with three nested buses. This arrangement of buses produces complex hierarchical data at the first logged outport. At the second outport, the model injects errors in the signal at fixed intervals. These errors produce different results between two runs. The signal at the third outport is a vector of four values per sample to help show the comparison support.

Verify the Model Configuration

CGV provides a class, cgv.Config, to check whether models have a configuration that is compatible with execution in a SIL or PIL environment using an ert target. This model has already been modified using the cgv.Config class.

Execute Under CGV

Run in Normal and SIL Modes

The model executes in three modes under CGV: normal, SIL, and PIL. In each case, the CGV object captures the output data and writes it to a file. For more information, see CGV Documentation. To execute the model in normal and SIL simulation modes, enter:

```
cgvSim = cgv.CGV( cgvModel, 'Connectivity', 'Normal');
cgvSim.addInputData(1, [cgvModel '_data']);
% This next CGV function, addPostLoadFiles(), allows you to specify MATLAB(R)
% programs to execute, or mat-files to load, before execution of the model.
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
cgvSim.setOutputDir('cgv_output');
cgvSim.activateConfigSet( 'CS1_default');
result1 = cgvSim.run();

% CGV provides methods to simplify numerical equivalence checking.
% The copySetup method creates an exact duplicate of an existing CGV object without
% results data.  You can change the SimulationMode using setMode() and then
% execute again.
cgvSil = cgvSim.copySetup();
cgvSil.setMode( 'SIL');
% You can provide a baseline file to CGV for comparing the simulation
% output. In this example, the comparison results set the status to
% 'failed', because the ErrorsInjected signal differs between simulations.
cgvSil.addBaseline( 1, 'rtwdemo_cgv_results');
result2 = cgvSil.run();

% To see the name(s) of the signal(s) that did match, use getMismatches.
% Mismatched signal names are only available if a baseline was added and
% the comparison failed.
if strcmp( cgvSil.getStatus( 1), 'failed')
    disp( 'Mismatched Signal Names:');
    [signalNames, plotFiles] = cgvSil.getMismatches( 1);
    fprintf( 1, 'Signal Names: %s\n', signalNames{:} );
    fprintf( 1, 'Path to plot files: %s\n', plotFiles{:});
    assert(numel(signalNames)==1,'Expected exactly one mismatch');
end
```

```

```

Run in PIL Mode

Next, the model runs a PIL simulation, using your embedded processor. A universal embedded processor does not exist. Therefore, PIL support is provided by using the host computer where MATLAB® is running. The host processor is treated as an embedded target.

A customization file is executed that maps this model's PIL execution onto the SIL infrastructure. After the customization file is executed, CGV execution displays PIL messages for the mode. SIL messages display the connectivity target.

The configuration set for the model is already configured with: **Hardware Implementation > Test hardware > Test hardware is the same as production hardware** is checked. **Code Generation > Verification > Enable portable word sizes** is checked. These settings work in SIL and in PIL when PIL is mapped onto the SIL connectivity target.

```
copyfile( which( 'rtwdemo_cgv_sl_customization.m'), fullfile( pwd, 'sl_customization.m
```

```
sl_refresh_customizations();

cgvPil = cgvSim.copySetup();
cgvPil.setMode( 'PIL');
result3 = cgvPil.run();

Applying PostLoad file:
  B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_init.m
Starting execution:
  ComponentType: topmodel
  Connectivity: pil
  InputData:
  B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_data.mat
### Starting build procedure for model: rtwdemo_cgv
### Successful completion of build procedure for model: rtwdemo_cgv
### Preparing to start PIL simulation ...
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
### Connectivity configuration for "C:\TEMP\Bdoc17a_538369_5692\IB_CPU_21\tp32af565d\ex
### Updating code generation report with PIL files ...
### Starting application: 'rtwdemo_cgv_ert_rtw\pil\rtwdemo_cgv.exe'
End CGV execution: status completed.
```

Remove Customization

To prevent problems with other models, immediately remove the customization used to show PIL mode.

```
delete( 'sl_customization.m');
sl_refresh_customizations();
```

Check that execution did not terminate with an error

The run() function returns a Boolean value, which is true if the execution completes without model compilation or simulation error. Before accessing the data, check the result returned from each execution.

```
if ~result1 || ~result2 || ~result3
    disp('Execution of model failed.');
end

simData   = cgvSim.getOutputData(1);
silData   = cgvSil.getOutputData(1);
pilData   = cgvPil.getOutputData(1);
```

Compare Results

The executions are now complete. Compare the results. The comparison code supports a plot with filters. Plots display both the data and the difference.

CGV functions display signals names (as used in the command window) and create a file correlating tolerance information with signal names.

Show Signal Names from Normal Simulation

Display a list of signal names from the saved data.

Note: cgv.CGV.compare ignores signals that appear in only one data set. For example, the compare function ignores a logged internal signal hi0 that appears in the output of a normal simulation, but does not appear in the output of a SIL simulation.

```
cgv.CGV.getSavedSignals( simData);
```

```
simData.getElement(1).Values.Data(:,1)
simData.getElement(1).Values.Data(:,2)
simData.getElement(2).Values.Data(:,1)
simData.getElement(2).Values.Data(:,2)
simData.getElement(2).Values.Data(:,3)
simData.getElement(2).Values.Data(:,4)
simData.getElement(3).Values.hi0.Data(:,1)
simData.getElement(3).Values.hi0.Data(:,2)
simData.getElement(3).Values.hi1.mid0.lo0.Data(1,1,:)
simData.getElement(3).Values.hi1.mid0.lo0.Data(2,1,:)
simData.getElement(3).Values.hi1.mid0.lo0.Data(1,2,:)
simData.getElement(3).Values.hi1.mid0.lo0.Data(2,2,:)
simData.getElement(3).Values.hi1.mid0.lo1.Data
simData.getElement(3).Values.hi1.mid0.lo2.Data
simData.getElement(3).Values.hi1.mid1.Data(:,1)
simData.getElement(3).Values.hi1.mid1.Data(:,2)
simData.getElement(4).Values.Data
```

Create a Tolerance File

The CGV createToleranceFile function creates a file correlating tolerance information with signal names. For the options available to configure tolerances, see cgv.CGV.createToleranceFile. By default, tolerances are zero. Therefore the signals must match exactly. This example allows a delta of 0.5 on the ErrorsInjected signal.

```
signalList = {'simData.ErrorsInjected.Data' };
```

```
toleranceList = { { 'absolute', 0.5}};
cgv.CGV.createToleranceFile( 'localtol', signalList, toleranceList );
```

Compare Signals

By default, the cgv.CGV.compare function looks at signals that have a common name between both executions. In the following code, the simData.hi0.Data signals are not compared, because the signals do not appear in silData.

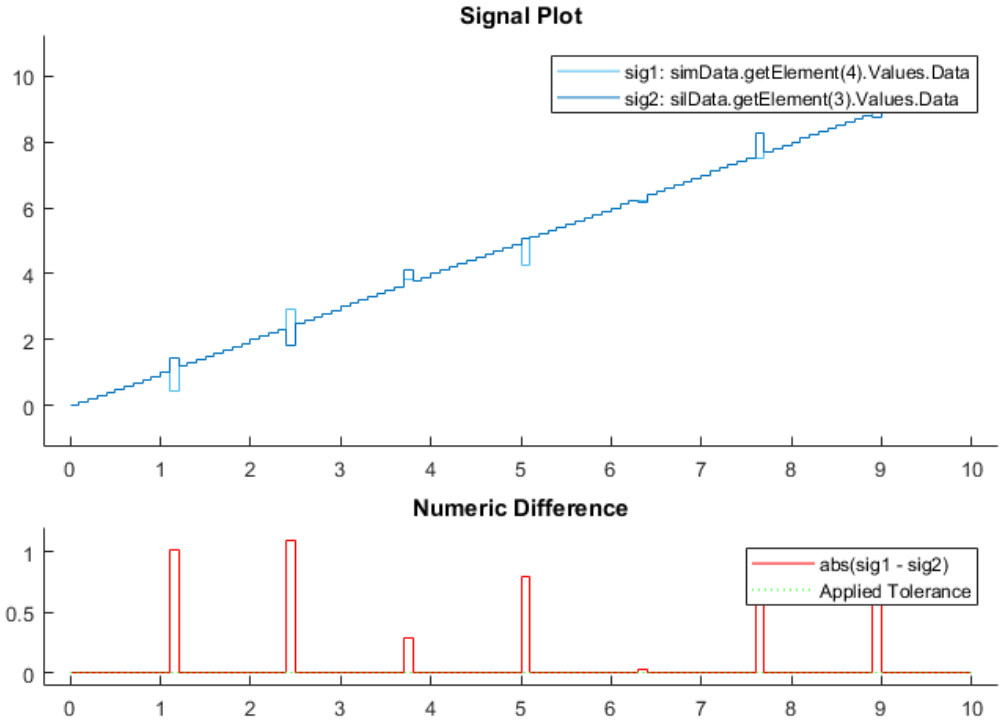
The second and fourth return parameters of the compare function are for matched figures and mismatched figures. Tildes (~) represent these parameters because this example does not use the return values.

A plot results from the mismatch on signal simData.ErrorsInjected.Data.

```
[matchNames, ~, mismatchNames, ~] = ...
    cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ...
    'Tolerancefile', 'localtol');
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
assert(length(mismatchNames) == 1,'Expected exactly one mismatch');
assert(length(matchNames) == 14, 'Expected exactly 14 matches');

disp( 'Mismatched Signal Names:');
disp(mismatchNames');
```

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
    'simData.getElement(4).Values.Data'
```



Compare Individual Signals

The cgv.CGV.compare function also compares only the specified signals. In this example, the function compares only three signals.

```
[matchNames, ~, mismatchNames, ~ ] = ...
    cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ...
    'Signals', {'simData.getElement(3).Values.hi1.mid0.lo1.Data', 'simData.getElement(3
    'simData.getElement(2).Values.Data(:,3)'});
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
assert(isempty(mismatchNames),'Expected no mismatches');
if ~isempty(mismatchNames)
    disp( 'Mismatched Signal Names:');
    disp(mismatchNames');
end
```

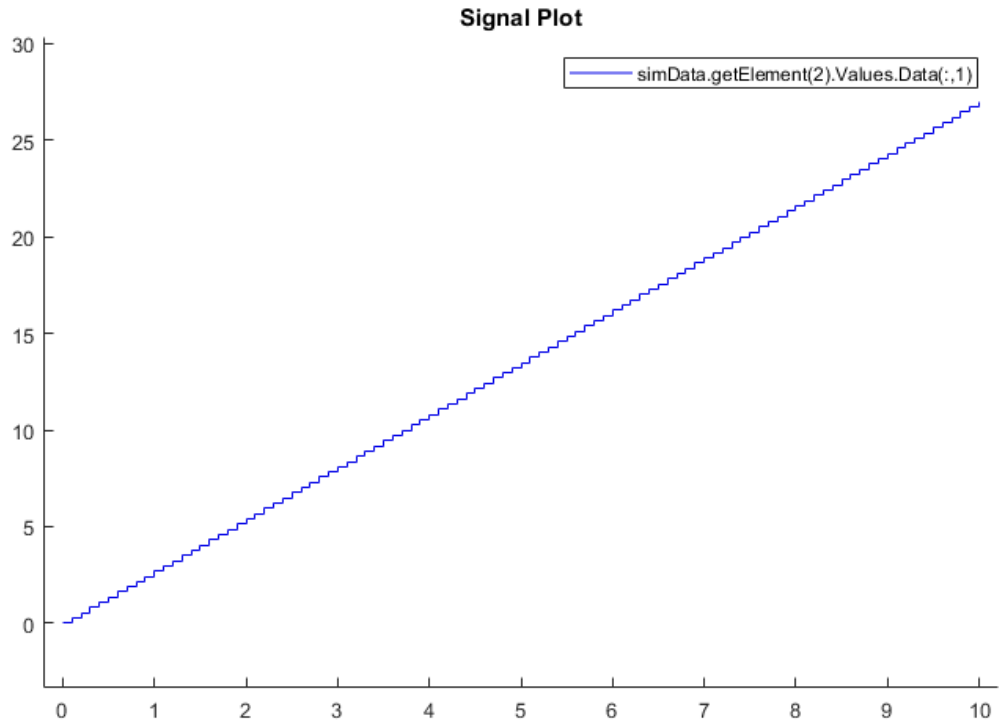
```
% Since a mismatch does not occur for these signals, a plot is not generated.

3 Signals match, 0 Signals mismatch
```

Additional Plotting Support

To create a plot of a list of signals, call cgv.CGV.plot. For example,

```
[signalNames, signalFigures] = cgv.CGV.plot( simData, ...
    'Signals', {'simData.getElement(2).Values.Data(:,1)'});
```



View Signal Data in the Simulation Data Inspector Tool

To open the Simulation Data Inspector tool, at the MATLAB® command line, enter Simulink.sdi.view. To import the signal data, in the Simulation Data Inspector tool,

select **File > Import Data**, which opens the Data Import tool. Select **Import from > Base workspace**, to view and select the signals saved in simData and silData.

Clear Your Workspace

Clear the variables from the workspace:

```
newBaseVars = who;
addedVars = setdiff( newBaseVars, baseVars);
clearCmd = ['clear ' sprintf( '%s ', addedVars{:})];
eval( clearCmd);
clear newBaseVars addedVars clearCmd
rtwdemoclean;
```

Numerical Consistency between Model and Generated Code

Numerical Consistency of Model and Generated Code Simulation Results

In this section...

Numerical Consistency

In the Model-Based Design workflow (Simulink Code Inspector), you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to `eps`.

- A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

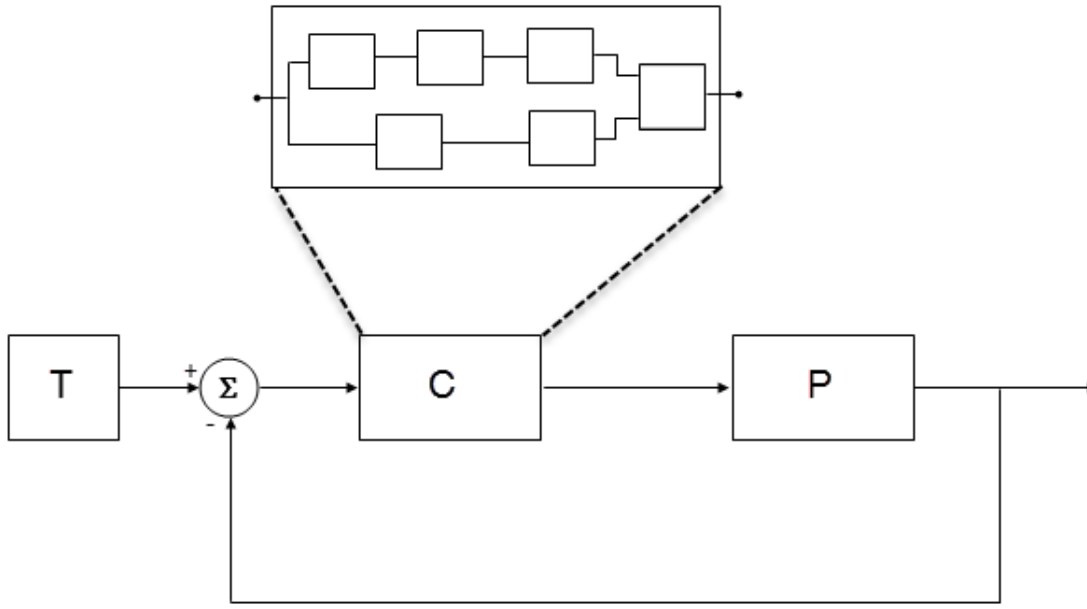
Programmatically, you can specify absolute and relative tolerance values through the `absTol` and `relTol` properties of the `Simulink.sdi.Signal` object.

Numerical Consistency in Complex Systems

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

1. Identify blocks for which block-level numerical differences exceed the error tolerance.
2. Investigate each identified block.

Consider the following plant-controller model.



- T produces reference or test signals.
- C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
- P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

1. Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
2. Specify SIL mode for C. Rerun the simulation, recording the output of C.
3. Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.

If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

1. Within C, enable signal logging for block outputs.
2. Run the model in normal mode.
3. Rerun the simulation with C in SIL mode.
4. Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See "Compare Simulation Data" (Simulink).
5. Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
6. Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

Note: If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See "Code Generation Verification Workflow with Simulink Test" (Simulink Test).

Reasons for Block-Level Numerical Differences

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.

- Algorithm sensitivity to input.
- Closed loop and open loop behavior.

Software-in-the-Loop Execution for MATLAB Coder

Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

1. Set up MATLAB Coder.
2. Fix errors detected at design time.
3. Generate MEX function.
4. Test MEX function.
5. Generate C/C++ library code.
6. Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

For more information, use the following table.

Feature	See
SIL execution	• "Software-in-the-Loop Execution with the MATLAB Coder App" on page 66-4 • "Software-in-the-Loop Execution From Command Line" on page 66-6

Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
2. To open your project, click  , and then click `Open existing project`. Select the project. For example, `kalman_filter01.prj`.
3. On the **Generate Code** page, click the **Generate** arrow  .
4. In the **Generate** dialog box:
   a. Set **Build type** to `Static Library` or `Dynamic Library`.
   b. In the **Output file name** field, use the default value. For example, `kalman01`.
   c. Specify **Language**.
   d. Clear the **Generate code only** check box.
   e. In the **Hardware Board** field, use the default value (`MATLAB Host Computer`).

   You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.
5. To generate the C or C++ code, click **Generate**.
6. Click **Verify Code**.
7. In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
8. If required, select the **Enable source-level debugging for SIL** check box.
9. To start the SIL execution, click **Run Generated Code**.

   The MATLAB Coder app:

   - Generates a standalone library, for example, `codegen\lib\kalman01`.
   - Generates SIL interface code, for example, `codegen\lib\kalman01\sil`.
   - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.

- Displays messages from the SIL execution in the **Test Output** tab.

10 Verify that the results from the SIL execution match the results from the original MATLAB functions.

11 To terminate the SIL execution process, click **Stop SIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

Note: On a Windows operating system, the Windows Firewall can potentially block the SIL execution. To allow the SIL execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

1. Create a coder.EmbeddedCodeConfig object.
2. Configure the object for SIL.
3. Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
4. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear` *`function`*`_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

SIL Execution of Code Generated for a Kalman Estimator

1 Copy MATLAB code for Kalman estimator

From *`docroot`*`\toolbox\coder\examples\kalman`, copy the following files to your working folder:

- `kalman01.m` — MATLAB function for the Kalman estimator
- `test01_ui.m` — MATLAB file to test `kalman01.m`
- `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
- `position.mat` — Input data

```
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
```

```
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see "C Code Generation at the Command Line" (MATLAB Coder).

2 Configure SIL execution

a From your working folder, create a coder.EmbeddedCodeConfig object.

```
config = coder.config('lib');
config.GenerateReport = true; % Optional, documents code in HTML report
```

b Configure the object for SIL.

```
config.VerificationMode = 'SIL';

% Check that production hardware setting is the default
% i.e. 'Generic->MATLAB Host Computer'
disp(config.HardwareImplementation.ProdHWDeviceType);
```

c If required, enable the Microsoft Visual Studio debugger for SIL execution:

```
config.SILDebugging = true;
```

3 Generate code and run SIL execution

a Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

b Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

Verify that the output of this run matches the output from the original `kalman01.m` function.

Note: On a Windows operating system, the Windows Firewall can potentially block the SIL execution. To allow the SIL execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

4 Debug code during SIL execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

a Remove all breakpoints.

b Click the `Continue` button (**F5**).

The SIL execution runs to completion.

5 Terminate SIL execution

Terminate the SIL execution process.

```
clear kalman01_sil;
```

You can also use the command `clear mex`, which clears MEX functions from memory.

Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from `printf` statements in your code.
- If you enable run-time error detection, messages sent to `stderr`.
- Some low-level system messages.

Note: During a SIL execution, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

A SIL execution supports the following debuggers:

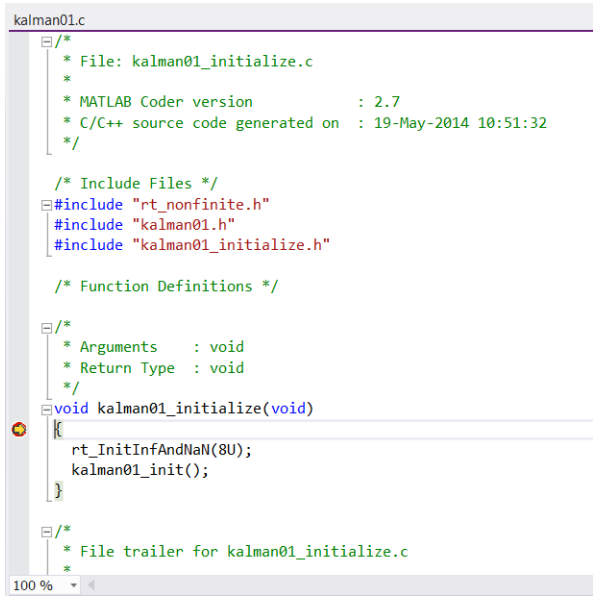
- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

Note: You can perform SIL debugging only if your Microsoft Visual C++ or GNU GCC compiler is supported by the MATLAB product family. For more information, see supported compilers.

To run a SIL execution with debugging enabled:

1. On the **Generate Code** page, click **Verify Code**.
2. Select the **Enable source-level debugging for SIL** check box.
3. Click **Run Generated Code**.

On a Windows computer, your *`user_fn`*`.c` or *`user_fn`*`.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *`user_fn`*`_initialize` and *`user_fn`* functions.



You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the `Continue` button (**F5**).

   The SIL execution runs to completion.
3. To terminate the SIL execution process, on the **Test Output** tab, click the link that follows `To terminate execution`, for example, `clear kalman01_sil`.

   The Microsoft Visual Studio IDE closes automatically.

Note: If you select **Debug** > **Stop Debugging**, the SIL execution times out with the following error message:

```
Communications error: failed to send data to the target. There might be
multiple reasons for this failure.

...
...
```

Create PIL Target Connectivity Configuration

In this section...

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

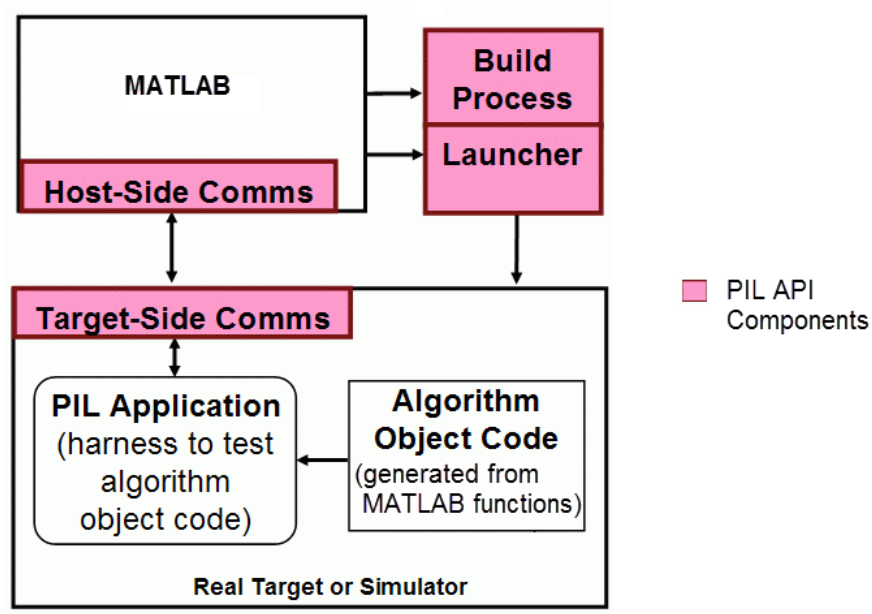
- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.



You must provide implementations of the three API components:

- Build API — Specify a toolchain approach for building generated code.
- Launcher API — Control how MATLAB starts and stops the PIL executable.
- Communications API — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in "Processor-in-the-Loop Execution From Command Line" on page 66-27.

1 Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

2 In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
                targetApplicationFramework, ...
                exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

3 Configure your `rtiostream` API implementation of the host-target communications on page 66-16 channel.

- For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
                        componentArgs, ...
                        launcher, ...
                        rtiostreamLib);
```

4 If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See "Specify Hardware Timer" on page 66-22.

Register Target Connectivity Configuration

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

1 Create or update an `rtwTargetInfo.m` file. In this file:

- Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.
- Invoke `registerTargetInfo`.

2 Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your algorithm development and code generation, use the `piltest` function. With the function, you can run a suite of tests. The function:

- Runs the MATLAB function and performs PIL executions.
- Compares results and produces errors if it detects differences.

For an example, see "PIL Execution of Code Generated for a Kalman Estimator" on page 66-27.

Host-Target Communication for PIL

In this section...

Communications `rtiostream` API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`

- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see "Create a Target Connectivity API Implementation" on page 66-13.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see "Test an `rtiostream` Driver" on page 66-18.

Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator` . This approach works well for connection-oriented TCP/IP `rtiostream` implementations because MATLAB automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the MATLAB side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

Test an `rtiostream` Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

Note: After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder *`matlabroot`*`/rtw/c/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection,param1,param2)
```

- `connection` is a character vector indicating the communication method. It can have values `'tcp'` or `'serial'`.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is `'tcp'`, then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345)`.

- If `connection` is `'serial'`, then `param1` and `param2` are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600)`.

You can run the MATLAB part of the test suite as follows:

```
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char    : 8 bit
Size of short   : 16 bit
Size of int     : 32 bit
Size of long    : 32 bit
Size of float   : 32 bit
Size of double  : 64 bit
Size of pointer : 64 bit
Byte ordering   : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ......... PASS
Test 2 (varying size data exchange): ......... PASS

### Test suite for rtiostream finished successfully ###
```

Furthermore, the following profile appears.

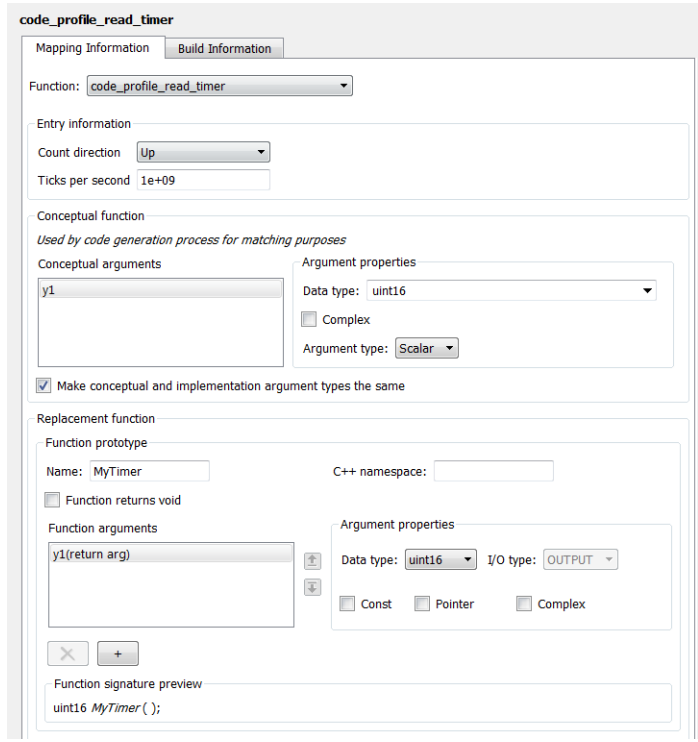
Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
2. Create a new code replacement table. Select **File** > **New table**.
3. Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry** > **Function**.
4. In the middle view, select the new unnamed function.
5. On the **Mapping Information** pane:
   a. From the **Function** drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select `Up`.
   c. In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

      The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the **Name** field, specify a replacement function name, for example, `MyTimer`.
   e. Click **Apply**.



f To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See "Specify Build Information for Replacement Code" on page 51-59.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as *`MyCrlTable.m`*, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

Processor-in-the-Loop Execution with the MATLAB Coder App

Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In "Processor-in-the-Loop Execution From Command Line" on page 66-27, steps 1 and 2 of the example PIL Execution of Code Generated for a Kalman Estimator show how you can set up and register a connectivity configuration for PIL execution on your development computer.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
2. To open your project, click  , and then click `Open existing project`. Select the project. For example, `kalman_filter.prj`.
3. On the **Generate Code** page, click the **Generate** arrow  .
4. In the **Generate** dialog box:
   a. Set **Build type** to `Static Library` or `Dynamic Library`.
   b. In the **Output file name** field, use the default value. For example, `kalman01`.
   c. Clear the **Generate code only** check box.
   d. From the **Hardware Board** drop-down list, select `None - Select device below`.
   e. In the **Device** fields, specify vendor and type. These settings must match the target hardware settings in the `rtwTargetInfo.m` file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:
      - For a Windows 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`. In addition, set **Enable long long** to `Yes`.
      - For a Linux 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Linux 64)`.
      - For a Mac OS X system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Mac OS X)`.

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

5. To generate the C or C++ code, click **Generate**.
6. Click **Verify Code**.
7. In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
8. To start the PIL execution, click **Run Generated Code**.

   The MATLAB Coder app:

   - Generates a standalone library, for example, `codegen\lib\kalman01`.
   - Generates PIL interface code, for example, `codegen\lib\kalman01\pil`.
   - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
   - Displays messages from the PIL execution in the **Test Output** tab.
9. Verify that the results from the PIL execution match the results from the original MATLAB functions.
10. To terminate the PIL execution process, click **Stop PIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

1. Create, register, and verify your target connectivity configuration.
2. Create a coder.EmbeddedCodeConfig object.
3. Configure the object for PIL.
4. Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
5. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear` *`function`*`_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

PIL Execution of Code Generated for a Kalman Estimator

1 Create a target connectivity API implementation

a. In your current working folder, make a local copy of the connectivity classes.

```
src_dir = ...
    fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
    rmdir('+mypil','s')
end
mkdir +mypil
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');
```

b. Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'),'+w');
```

c. Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
    './+mypil/ConnectivityConfig.m',...
    'coder.mypil',...
    'mypil');
```

d Check that you now have a folder `+mypil` in the current folder, which includes three files, `Launcher.m`, `TargetApplicationFramework.m`, and `ConnectivityConfig.m`.

```
dir './+mypil'
```

e Review the code that starts the PIL application. The `mypil.Launcher` class configures a tool for starting the PIL executable. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. For example, consider the `setArgString` method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

f The class `mypil.ConnectivityConfig` configures target connectivity.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. For example:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`.

g Review the target-side communication drivers.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'rtw','c','src','rtiostream',...
    'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and`rtIOStreamRecv`.

These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `mypil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```
edit(which('mypil.TargetApplicationFramework'))
```
The file specifies additional files to include in the build.

2 Register a target connectivity configuration

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`
- A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see "Custom Toolchain Registration" (MATLAB Coder).

a Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```
function rtwTargetInfo(tr)
% Register PIL connectivity config: mypil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
% Associate the connectivity configuration with the connectivity
```

```
% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain =  rtw.connectivity.Utils.getHostToolchainNames;

% Through the HardwareBoard and TargetHWDeviceType properties,
% define compatible code for the target connectivity configuration
config.HardwareBoard = {};  % Any hardware board
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...
                             'Generic->Custom' ...
                             'Intel->x86-64 (Windows64)', ...
                             'Intel->x86-64 (Mac OS X)', ...
                             'Intel->x86-64 (Linux 64)'};
```

b Refresh the MATLAB Coder library registration information.

```
RTW.TargetRegistry.getInstance('reset');
```

3 Verify target connectivity configuration

Use the supplied `piltest` function to verify your target connectivity configuration.

a Create a `coder.EmbeddedCodeConfig` object for verifying the target connectivity configuration.

```
configVerify = coder.config('lib');
```

b Specify the manufacturer and test hardware type. For example, PIL execution on a 64-bit Windows development computer requires:

```
configVerify.HardwareImplementation.TargetHWDeviceType =...
   'Intel->x86-64 (Windows64)';
configVerify.HardwareImplementation.ProdLongLongMode = true;
```

c Run `piltest`.

```
piltest(configVerify, 'ConfigParam', {'ProdLongLongMode'} )
```

4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

```
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');
```

```
copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see "C Code Generation at the Command Line" (MATLAB Coder).

5 Configure the PIL execution

a Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
```

b Configure the object for PIL.

```
config.VerificationMode = 'PIL';
```

c Specify production hardware, which must match one of the test hardware settings in `rtwTargetInfo.m`. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:

```
config.HardwareImplementation.ProdHWDeviceType =...
   'Intel->x86-64 (Windows64)';
config.HardwareImplementation.ProdLongLongMode = true;
```

For a Linux 64-bit system, set `ProdHWDeviceType` to `'Intel->x86-64 (Linux 64)'`.

For a Mac OS X system, set `ProdHWDeviceType` to `'Intel->x86-64 (Mac OS X)'`.

6 Generate code and run PIL execution

a Generate library code for the `kalman01` MATLAB function and the PIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\pil` — PIL interface code for `kalman01`.

b Run the MATLAB test file `test01_ui` with `kalman01_pil`. `kalman01_pil` is the PIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_pil.' mexext]);
```

Verify that the output of this run matches the output from the original `kalman01.m` function.

7 Terminate PIL execution

Terminate the PIL execution process.

```
clear kalman01_pil;
```

More About

- "Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution" on page 66-2

Verification of Code Generation Assumptions

The settings on the **More Settings > Hardware** tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the **Hardware** tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Sizes > int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

SIL/PIL Execution Support and Limitations

Feature		Supported
Output types	Static library	Yes
	Dynamic library	Yes
	Executable	No
Languages	C	Yes
	C++	Yes
Interface types	Inputs	Yes
	Outputs	Yes
	Constant inputs	Yes
	Global data	Yes. SIL and PIL execution supports four types of storage classes on page 77-2 for MATLAB Coder global variables. The synchronization (MATLAB Coder) of global data between MATLAB and the SIL or PIL application depends on the type of storage class that you specify: • `ExportedGlobal` (default) — The synchronization of global data between MATLAB and a SIL or PIL application is identical to the synchronization between MATLAB and a MEX function. • `ExportedDefine` — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses the values of the global variables in MATLAB at the time of code generation. • `ImportedExtern` and `ImportedExternPointer` — There is no synchronization of

Feature		Supported
		global data between MATLAB and the SIL or PIL application. The application uses initial values of global variables, which you specify in the external code. If the global variables are not initialized in the external code, the SIL or PIL execution results are undefined.
	Constant global data	Yes
	Reentrant code	Yes
	Multiple entry points	Yes
Data types	Basic types	Yes
	Enumerated types	Yes
	Structures	Yes
	Complex data	Yes
	Fixed-point data	Yes
	Multiword fixed-point data	SIL only
	`char` arrays	Yes
	Empty values	Yes
	Cell arrays	Yes
Size	Scalars	Yes
	Fixed-size arrays	Yes
	Static variable-size arrays	Yes
	Dynamic variable-size size arrays	Yes

Code Coverage in Embedded Coder

Simulink Code Coverage Metrics

In this section...

If you have a Simulink Verification and Validation license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

Statement Coverage for Code Coverage

Statement coverage determines the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

Statement coverage = (Number of executed statements / Total number of statements) *100

Statement Coverage Example

This code snippet contains five statements. To achieve 100% statement coverage, you need at least three test cases. Specifically, tests with positive *x* values, negative *x* values, and *x* values of zero.

```
if (x > 0)
  printf( "x is positive" );
else if (x < 0)
  printf( "x is negative" );
else
  printf( "x is 0" );
```

Condition Coverage for Code Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or ||). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

Condition coverage = (Number of executed condition outcomes / Total number of condition outcomes) *100

Condition Coverage Example

In this expression:

```
y = x<=5 && x!=7;
```

there are these conditions:

```
x<=5
x!=7
```

Decision Coverage for Code Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators && or ||. Conditions within branching constructs (if/else, while, do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

Note: The decision coverage definition for DO-178C compliance differs from the Simulink Verification and Validation definition. For decision coverage compliance with DO-178C, select the `Condition Decision` structural coverage level for Boolean expressions not containing && or || operators.

Decision coverage = (Number of executed decision outcomes / Total number of decision outcomes) *100

Decision Coverage Example

This code snippet contains three decisions:

```
y = x<=5 && x!=7;    // decision #1

if( x > 0 )     // decision #2
  printf( "decision #2 is true" );
else if( x < 0 && y )    // decision #3
  printf( "decision #3 is true" );
else
  printf( "decisions #2 and #3 are false" );
```

Modified Condition/Decision Coverage (MCDC) for Code Coverage

Modified condition/decision coverage (MCDC) is the extent to which the conditions within decisions are independently exercised during code execution.

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

MCDC coverage = (Number of conditions evaluated to all possible outcomes affecting the outcome of the decision / Total number of conditions within the decisions) *100

Modified Condition/Decision Coverage Example

For this decision:

```
X || ( Y && Z )
```

the following set of test cases delivers 100% MCDC coverage.

	X	Y	Z
Test case #1	0	0	1
Test case #2	0	1	0
Test case #3	0	1	1
Test case #4	1	0	1

Cyclomatic Complexity for Code Coverage

Cyclomatic complexity is a measure of the structural complexity of code that uses the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

$$c = \sum_{1}^{N} (o_n - 1)$$

N is the number of decisions in the code. o_n is the number of outcomes for the n^{th} decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

Coverage Example

For this code snippet:

```
void evalNum( int x ){

 if (x > 0)
   printf( "x is positive" );
 else if (x < 0)
   printf( "x is negative" );
 else
  printf( "x is 0" );
}
```

the cyclomatic complexity is 3.

Relational Boundary for Code Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in "Relational Boundary Coverage" (Simulink Verification and Validation). Fixed-point values in your model are integers during code coverage.

Related Examples

- "Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode" on page 67-6

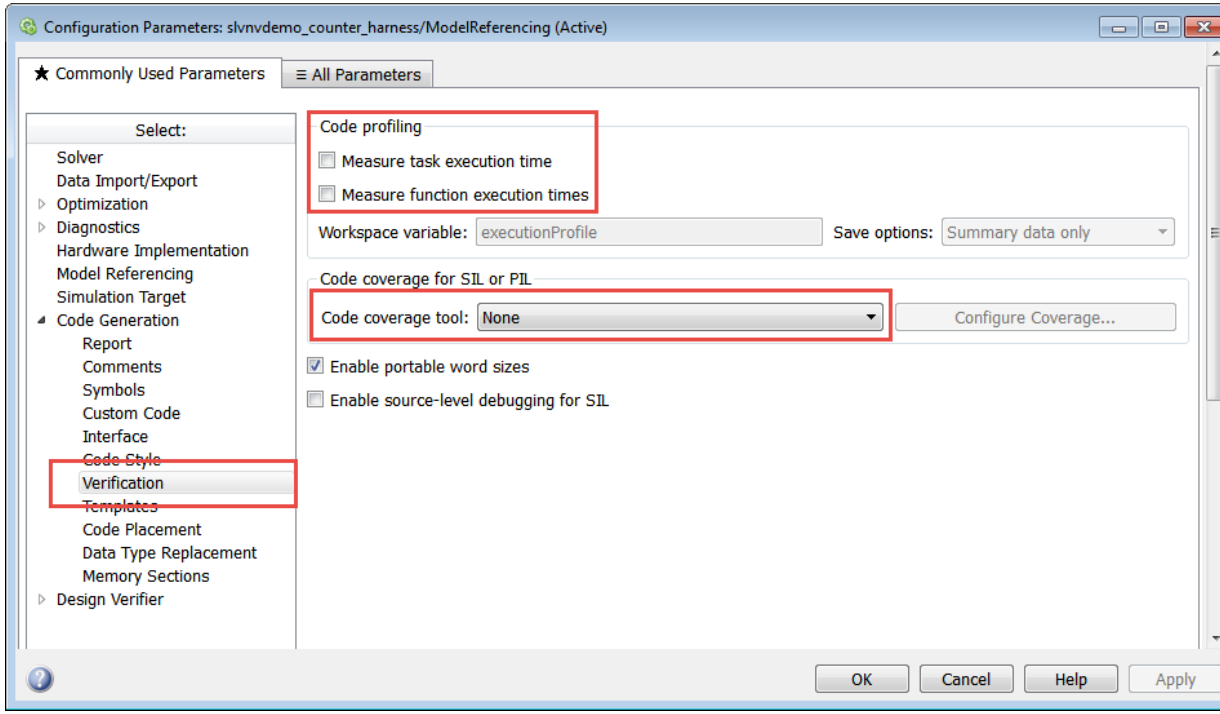
Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode

In this section...

Requirements to Enable SIL or PIL Code Coverage for a Model

If you have both an Embedded Coder license and a Simulink Verification and Validation license, you can measure coverage for code generated from models in software-in-the-loop (SIL) mode or processor-in-the-loop (PIL) mode. The following configurations must apply for the parameters in **Code Generation > Verification**:

- Under **Code profiling**, clear **Measure function execution times**.
- Under **Code coverage for SIL or PIL**, the selected **Code coverage tool** must be `None`.



Conditions for Simulink Verification and Validation Code Coverage Measurement

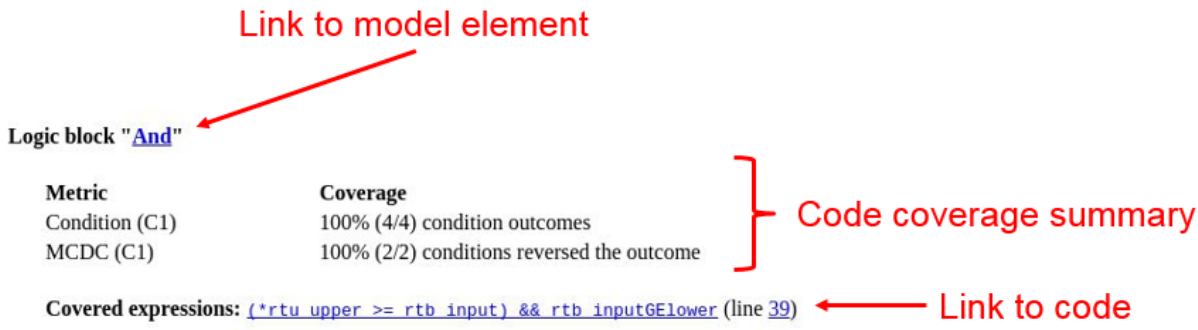
There are two workflows for measuring code coverage:

- The top model is in SIL mode or PIL mode. Measures code coverage for the top model depending on `RecordCoverage`. Also measures code coverage for referenced models, depending on `CovModelRefEnable`.
- The top model is in Normal mode and contains at least one reference model in SIL or PIL mode. Measures code coverage for the referenced model if `CovModelRefEnable` is `'on'`, `'all'`, or `'filtered'` and `RecordCoverage` is `'off'`.

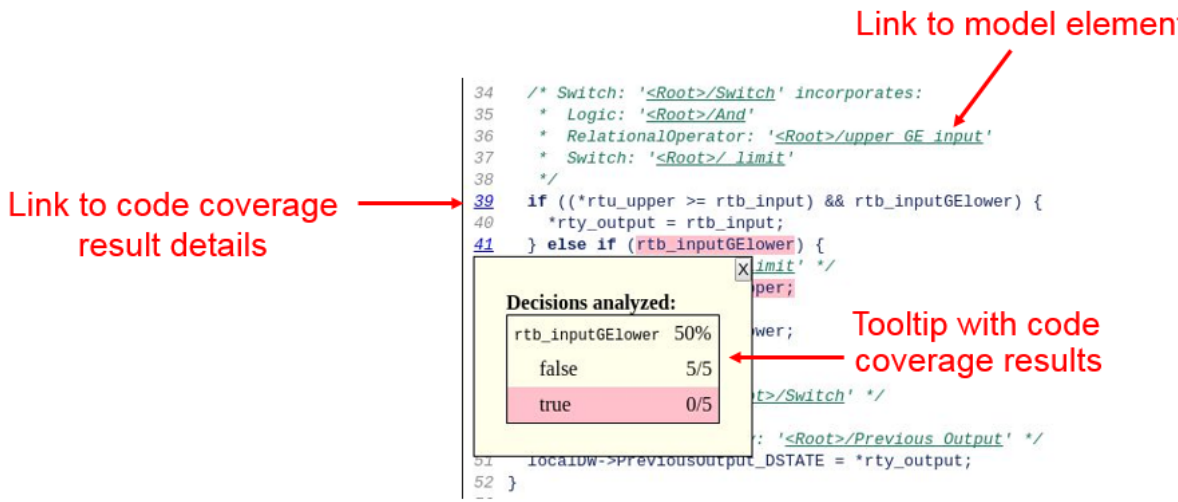
Reviewing the Coverage Results for Models in SIL or PIL Mode

In the code coverage report, each hyperlink opens a report with more details on the coverage analysis for the model. The code coverage results in these reports are similar to

the coverage results for C/C++ code in S-function blocks, as described in "View Coverage Results for C/C++ Code in S-Function Blocks" (Simulink Verification and Validation). You can navigate from code coverage results to the associated model blocks by using the links within the detailed code coverage reports.



Each detailed code coverage report also contains syntax highlighted code with coverage information.



Limitations

Coverage for models in SIL and PIL mode has these limitations:

- The model must meet the requirements listed in "Requirements to Enable SIL or PIL Code Coverage for a Model" on page 67-6.
- Code coverage results must not include external C/C++ files in read-only folders.

Related Examples

- "Software-in-the-Loop Code Coverage" (Simulink Verification and Validation)

Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- LDRA Testbed from LDRA Software Technology. For information about installing and using this tool, go to www.ldra.com.

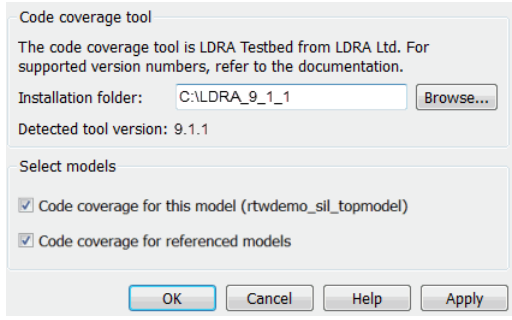
  The software supports LDRA Testbed code coverage for SIL and PIL.

- BullseyeCoverage from Bullseye Testing Technology. For information about installing and using this tool, go to www.bullseye.com.

  The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation:

1. Select **Simulation** > **Model Configuration Parameters** > **Code Generation** > **Verification**.
2. From the **Code coverage tool** drop-down list, select a tool, for example, `BullseyeCoverage` or `LDRA Testbed`.
3. Click **Configure Coverage** to open the Code Coverage Settings dialog box.
4. In the **Installation folder** field, specify the location where your coverage tool is installed. If you click **Browse**, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.



By default, the software selects the following check boxes:

- **Code coverage for this model** — Generate coverage data for the current (top) model.
- **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks where the **Code interface** block parameter is set to `Top model`, then the top model and referenced models must have the same settings for these parameters. Otherwise, the software produces an error.

5 Click **OK**. You return to the **Verification** pane.

6 To view cumulative code coverage results within a code generation report, in the **Configuration Parameters** > **Code Generation** > **Report** pane, select the following check boxes:

- **Create code generation report**
- **Launch report automatically**

7 Click **OK**. You return to the model window.

With LDRA Testbed:

- The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  - Run a simulation with a new model using the existing code generation folder.
  - Run a simulation that results in additional source code files being instrumented.
- If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

View Code Coverage Information at the End of SIL or PIL Simulations

In this section...

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

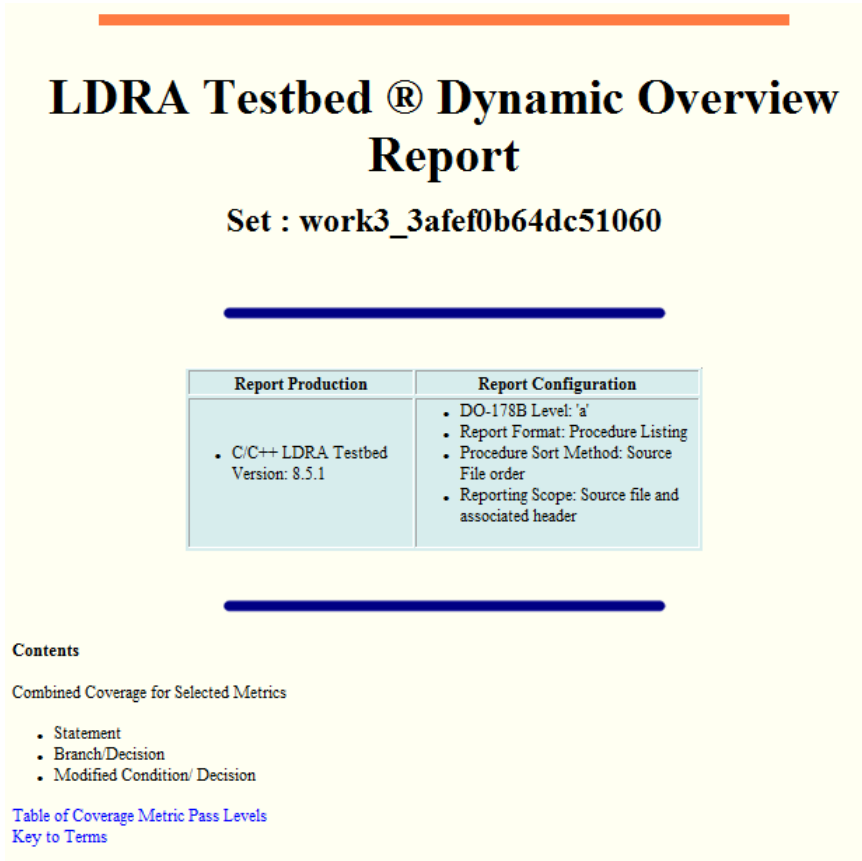
View LDRA Testbed Results

If you specified the LDRA Testbed, you see three links in the Command Window:

```
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Starting analysis of coverage data
### Use the following links to view code coverage results:
    LDRA Testbed GUI
    LDRA Testbed Code Coverage Overview Report
    HTML code generation report with code coverage annotations
### Completed code coverage analysis
>>
```

To go to the LDRA Testbed GUI, click the `LDRA Testbed GUI` link.

To open the LDRA Testbed Report with your Web browser, click the `LDRA Testbed Code Coverage Overview Report` link.



LDRA Testbed ® Dynamic Overview Report

Set : work3_3afef0b64dc51060

Report Production	Report Configuration
• C/C++ LDRA Testbed Version: 8.5.1	• DO-178B Level: 'a' • Report Format: Procedure Listing • Procedure Sort Method: Source File order • Reporting Scope: Source file and associated header

Contents

Combined Coverage for Selected Metrics

- Statement
- Branch/Decision
- Modified Condition/ Decision

Table of Coverage Metric Pass Levels
Key to Terms

For information about using this report, refer to the LDRA Testbed documentation.

LDRA Testbed analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The `LDRA Testbed Code Coverage Overview Report` link identifies the location of the LDRA Testbed analysis results, which is determined by:

- The LDRA Testbed configuration.
- The name of the LDRA Testbed set associated with the current code generation folder.

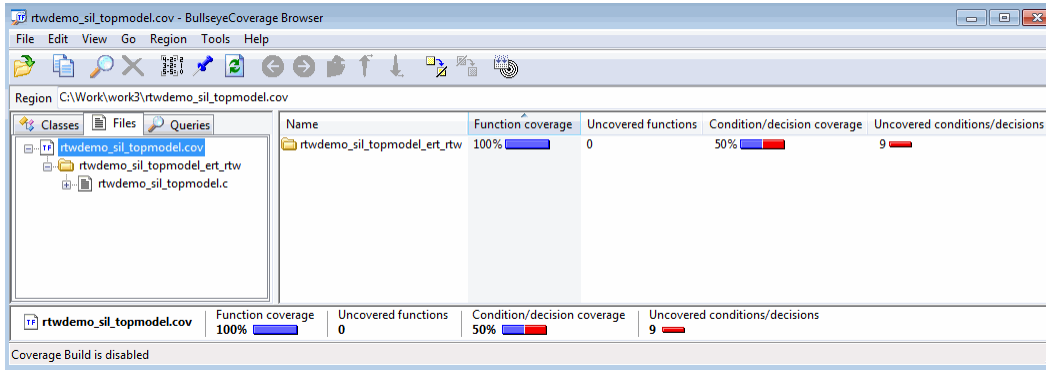
To view summary data and code annotations with coverage information in the code generation report, click the `HTML code generation report with code coverage annotations` link.

View BullseyeCoverage Results

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

```
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Processing code coverage data
### Use the following links to view code coverage results:
    BullseyeCoverage browser (coverage for last run)
    HTML code generation report (cumulative coverage)
### Completed code coverage analysis
>>
```

To view the coverage report using the BullseyeCoverage Browser, click the `BullseyeCoverage browser (coverage for last run)` link.



The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to www.bullseye.com.

To view summary data and code annotations with coverage information in the code generation report, click the `HTML code generation report (cumulative coverage)` link.

- “Code Coverage Summary and Annotations” on page 67-18

Configure Code Coverage Programmatically

You can configure code coverage for your model using command-line APIs. A typical workflow with BullseyeCoverage is:

1. Using `get_param`, retrieve the object containing coverage settings for the current model, for example, `gcs`.

   ```
   >> covSettings = get_param(gcs, 'CodeCoverageSettings')

   covSettings =

     CodeCoverageSettings with properties:

             TopModelCoverage: 'on'
       ReferencedModelCoverage: 'off'
                  CoverageTool: 'BullseyeCoverage'
   ```

   The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is `'on'`, then no code coverage data is generated during a SIL simulation.

   If LDRA Testbed is the specified code coverage tool, then the property `CoverageTool` is `'LDRA Testbed'`.

   When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

2. Check the class of `covSettings`.

   ```
   >> class(covSettings)

   ans =

   coder.coverage.CodeCoverageSettings
   ```

3. Turn on coverage for referenced models.

   ```
   >> covSettings.ReferencedModelCoverage='on';
   ```

4. Using `set_param`, apply the new coverage settings to the model.

   ```
    >>set_param(gcs,'CodeCoverageSettings', covSettings);
   ```

5. Assuming you have installed the BullseyeCoverage tool, specify the installation path.

   ```
   >>coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
   ```

For LDRA Testbed, use `coder.coverage.LDRA.setPath('C:\...)`.

6 Check that the path is saved as a preference.

```
>> coder.coverage.BullseyeCoverage.getPath
```

For LDRA Testbed, use `coder.coverage.LDRA.getPath`.

Code Coverage Summary and Annotations

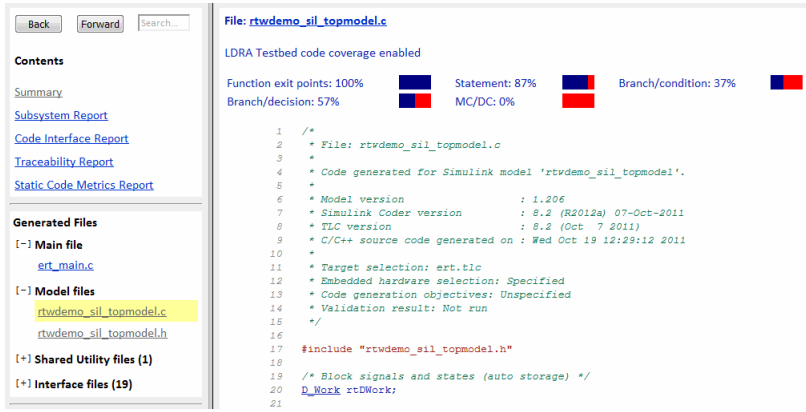
In this section...

If you specify a code coverage tool for a SIL or PIL simulation, the software produces a code generation report that provides summary data and code annotations with coverage information. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution.

The code generation report also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

LDRA Testbed Coverage

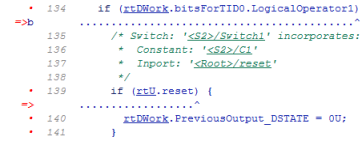
The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.



The software provides LDRA Testbed annotations in the code generation report to help you to review code coverage.

Note: Do not use the code generation report alone to verify that you have achieved your coverage goals. You must refer to the LDRA Testbed Report.

This example shows three kinds of annotations. On lines 134, 139, 140, and 141, the annotation • indicates that statement coverage for each of these lines of code is not complete.



Placing the cursor over the annotation =>b produces a tooltip.

This tooltip indicates that only one branch destination is covered. The code within the curly brackets, which starts at column 45 of line 134, is not executed. As the `if` statement on line 139 lies within this code, the corresponding annotation => states that the branch is not covered.

The following table describes the LDRA Testbed code annotations that you might see in a code generation report produced by a SIL and PIL simulations.

Code feature	Annotation symbol	What happened during simulation
Function	Fcn	Function *name* returned through this exit point.
	=>	Function *name* never returned through this exit point.
Branch/condition	=>	Condition not encountered.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.

Code feature	Annotation symbol	What happened during simulation
	tf	Condition evaluated both true and false.
Branch/decision	=>	Branch never encountered.
	=>b	Branch to at least one destination covered and branch to at least one other destination not covered.
	b	Branch fully exercised.
Modified Condition/ Decision Coverage (MC/DC)	=>mc	Condition did not independently affect outcome of decision.
	mc	Condition independently affected outcome of decision.
Statement		Statements associated with line covered.
		Not all statements associated with line covered.
Code that is reformatted by LDRA Testbed and does not match the original source code. For example, source code with `#include` statements to include other files, and source code with `#define` statements for macros. For detailed coverage information, refer to the LDRA Testbed report.	=>Σ	Zero coverage — probes within source code line or files included by source code line not exercised.
	=>Σ	Coverage probes within source code line or any included file partially exercised.
	Σ	Coverage probes within source code line or included files fully exercised.

BullseyeCoverage Information

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from

simulations with other top models that share referenced models with your current top model.

The software provides BullseyeCoverage annotations in the code generation report to help you to review code coverage.

This example shows two kinds of annotations. At line 41, TF indicates that the `if` decision had both true and false outcomes during the simulation. At line 52, =>F indicates that the `if` decision was false only during the simulation.

```
TF      41    if (rtU.reset) {
        42      rtDWork.PreviousOutput_DSTATE = 20U;
        43    }
        44
        45    /* Switch: '<Root>/Switch' incorporates:
        46     *  Constant: '<Root>/C1'
        47     *  Constant: '<Root>/C5'
        48     *  Inport: '<Root>/ ticks_to_count'
        49     *  RelationalOperator: '<Root>/upper GE input'
        50     *  Sum: '<Root>/Add'
        51     */
 =>F    52    if ((uint8_T)((uint32_T)rtU.ticks_to_count + (uint32
        53                  rtDWork.PreviousOutput_DSTATE) == 40)
```

The following table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.

Code feature	Annotation symbol	What happened during simulation
Decision	=>	Decision not executed.
	TF	Decision evaluated both true and false.

Code feature	Annotation symbol	What happened during simulation
	=>T	Decision evaluated true only.
	=>F	Decision evaluated false only.
Function	=>	Function not called.
	Fcn	Function called.
Switch label	=>	Switch command not used.
	Sw	Switch command used.
Constant	k	Decision or condition was constant, which did not allow any variation in coverage.
Condition	=>	Condition not encountered.
	tf	Condition evaluated both true and false.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
Try	=>	Try block never completed.
	Try	Try block covered.
Catch	=>	Catch block not covered.
	Cat	Catch block covered.

Code Coverage Tool Support

Embedded Coder code coverage provides the following support for the BullseyeCoverage and LDRA Testbed tools.

	BullseyeCoverage		LDRA Testbed	
Operating system	**Version supported**	**Compiler supported**	**Version supported**	**Compiler supported**
Windows	8.9.37	Microsoft Visual C++ (MSVC)	9.4.6	• Microsoft Visual C++ (MSVC) • LCC • MinGW
Linux	8.9.37	`gcc`	9.4.6	`gcc`
Mac	Not supported		Not supported	

Related Examples

- “Configure Code Coverage with Third-Party Tools” on page 67-10
- “Select and Configure C or C++ Compiler or IDE” (Simulink Coder)

Tips and Limitations

Right-Click Subsystem Build Unsupported for Code Coverage

The software does not support right-click builds for subsystems if a code coverage tool is specified.

BullseyeCoverage License Wait

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, select **Configuration Parameters > All Parameters > Verbose build**.

Current Working Folder Cannot be UNC Path

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

Characters in `matlabroot` and File Path

If `matlabroot` or the path to your generated files contains a space or the `.` (period) character, code coverage might fail.

Header Files with Identical Names

Consider a model that is configured for LDRA Testbed code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

Code Coverage for Source Files in Shared Utility Folders

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the

software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

BullseyeCoverage Behavior with Inline Macros

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <=
(ll)) ? (ll) : (sig)) )
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

1. Open the BullseyeCoverage Browser.
2. Select **Tools** > **Options** to open the Options dialog box.
3. On the **Build** tab, select the **Instrument macro expansions** check box.
4. Click **OK**.
5. Rerun your simulation.

Alternatively, you can add the text `-macro` to the `BullseyeCoverage` configuration file. For more information, go to www.bullseye.com/help.

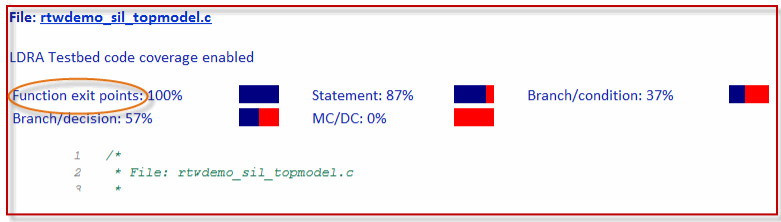
SIL and PIL Simulations with Open LDRA Testbed

If you enable code coverage with the LDRA Testbed tool, you must verify that the LDRA Testbed GUI is not open when you run your SIL or PIL simulation. If the set name in the LDRA Testbed GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

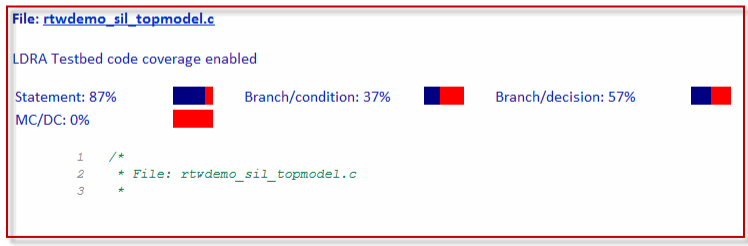
Minor SIL and PIL Differences for LDRA Testbed

The target connectivity API supports code coverage with LDRA Testbed for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.



SIL



PIL

PIL Zero Coverage LDRA Testbed Annotations

For a PIL simulation with LDRA Testbed code coverage specified, there might be some source files where the recorded coverage is zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.

You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

```
0 out of N coverage probes were exercised (detailed breakdown unavailable)
```

PIL Support for BullseyeCoverage

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide `fopen` and `fread` access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

Modify Legacy Code

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see "Limitation" (Simulink Coder).

IDE Link Does Not Support LDRA Testbed

When you generate code for IDE Link, you cannot use LDRA Testbed for SIL or PIL code coverage. Specifically, this limitation applies when you use the following settings together:

- **Configuration Parameters** > **Code Generation** > **System target file**: `idelink_ert.tlc`
- **Configuration Parameters** > **Code Generation** > **Verification** > **Code coverage tool**: `LDRA Testbed`.

Embedded IDEs and Embedded Targets

Getting Started with Embedded Targets in Embedded Coder

Embedded Coder Supported Hardware

As of this release, Embedded Coder supports the following hardware.

Support Package	Vendor	Earliest Release Available	Last Release Available
Altera SoC	Altera®	R2014b	Current

Run-Time Data Interface Extensions in Simulink Coder

Customize Generated ASAP2 File

In this section...

About ASAP2 File Customization

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

ASAP2 File Structure on the MATLAB Path

The ASAP2 related files are organized within the folders identified below:

- TLC files for generating ASAP2 file

  The *`matlabroot`*`/rtw/c/tlc/mw` (open) folder contains TLC files that generate ASAP2 files, `asamlib.tlc`, `asap2lib.tlc`, `asap2main.tlc`, and `asap2grouplib.tlc`. These files are included by the selected **System target file**. (See “Targets Supporting ASAP2” on page 44-3.)

- ASAP2 target files

  The *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2` (open) folder contains the ASAP2 system target file and other control files.

- Customizable TLC files

  The *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user` (open) folder contains files that you can modify to customize the content of your ASAP2 files.

- ASAP2 templates

The *matlabroot*/toolbox/rtw/targets/asap2/asap2/user/templates (open) folder contains templates that define each type of CHARACTERISTIC in the ASAP2 file.

Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the *matlabroot*/toolbox/rtw/targets/asap2/asap2/user (open) folder. This section refers to this folder as the asap2/user folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

1. Make a copy of the asap2/user folder before making modifications.
2. Remove the old asap2/user folder from the MATLAB path, or add the new asap2/user folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, asap2setup.tlc, in the new folder.

   asap2setup.tlc specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify asap2setup.tlc to control the folders and folders included in the TLC path.
3. Modify the static parts of the ASAP2 file. These include

   - Project and header symbols, which are specified in asap2setup.tlc
   - Static sections of the file, such as file header and tail, A2ML, MOD_COMMON, and so on These are specified in asap2userlib.tlc.
   - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include

     RECORD_LAYOUT: modify parts of the ASAP2 template files.

`CHARACTERISTIC`: modify parts of the ASAP2 template files. For more information on modifying the appearance of `CHARACTERISTIC` records, see "ASAP2 Templates" on page 69-4.

- `MEASUREMENT`: These are specified in `asap2userlib.tlc`.
- `COMPU_METHOD`: These are specified in `asap2userlib.tlc`.

ASAP2 Templates

The appearance of `CHARACTERISTIC` records in the ASAP2 file is controlled using a different template for each type of `CHARACTERISTIC`. The `asap2/user` folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

1. Create a template definition file. See "Create Template Definition Files" on page 69-4.
2. Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, `asap2setup.tlc`.

Create Template Definition Files

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from `asap2lookup1d.tlc`, the template definition file for the `Lookup1D` template. This template corresponds to the `Lookup1D` parameter group.

Note When creating a new template, use the corresponding parameter group name in place of `Lookup1D` in the code shown.

Template Registration Function

The input argument is the name of the parameter group associated with this template:

```
%<LibASAP2RegisterTemplate("Lookup1D")>
```

RECORD_LAYOUT Name Definition Function

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```
%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
  %switch dtId
  %case tSS_UINT8
    %return "Lookup1D_UBYTE"
  ...
  %endswitch
%endfunction
```

Function to Write RECORD_LAYOUT Definitions

This function writes `RECORD_LAYOUT` definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

```
%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
  /begin RECORD_LAYOUT
%<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
    ...
  /end   RECORD_LAYOUT
%endfunction
```

Function to Write the CHARACTERISTIC

This function writes the `CHARACTERISTIC` associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a `Lookup1D` parameter group that has two members. The references to the associated `x` and `y` data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, `LibASAP2GetSymbol` returns the symbol (name) for the specified data record:

```
%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup)
Output
```

```
  %assign xParam = paramGroup.Member[0].Reference
  %assign yParam = paramGroup.Member[1].Reference
  %assign dtId = LibASAP2GetDataTypeId(xParam)
    /begin CHARACTERISTIC
     /* Name */              %<LibASAP2GetSymbol(xParam)>
     /* Long identifier */   "%<LibASAP2GetLongID(xParam)>"
     ...
    /end CHARACTERISTIC
%endfunction
```

Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is

```
cmName = getCompuMethodName(dataTypeName, cmUnits)
```

where *`dataTypeName`* is the name of the data type associated with the computation method, *`cmUnits`* is the units as specified in the `Unit` property of a `Simulink.Parameter` or `Simulink.Signal` object (for example, `rpm` or `m/s`), and *`cmName`* returns the constructed computation method name.

The default constructed name returned by the function has the format

```
<localPrefix><datatype>_<cmUnits>
```

where

- `<local_Prefix>` is a local prefix, `CM_`, defined in *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<datatype>` and `<cmUnits>` are the arguments you specified to the `getCompuMethodName` function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with <ASAP2CompuMethodName_Prefix>, a model prefix defined in *matlabroot*/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc.

For example, if you call the getCompuMethodName function with the *dataTypeName* argument 'int16' and the *cmUnits* argument 'm/s', and generate an ASAP2 file for a model named myModel, the computation method name would appear in the generated file as follows:

```
/begin COMPU_METHOD
   /* Name of CompuMethod */ myModel_CM_int16_m_s
   /* Units */ "m/s"
   ...
/end COMPU_METHOD
```

Suppress Computation Methods for FIX_AXIS

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the Conversion Method parameter must be set to the value NO_COMPU_METHOD. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option ASAP2GenNoCompuMethod. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value NO_COMPU_METHOD. For example:

```
/begin CHARACTERISTIC
/* Name            */
lu1d_fix_axisTable_data
...
/begin AXIS_DESCR
    ...
    /* Conversion Method    */
NO_COMPU_METHOD
    ...
/end CHARACTERISTIC
```

The ASAP2GenNoCompuMethod option is defined in *matlabroot*/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc.

Create a Transport Layer for External Communication

In this section...

About Creating a Transport Layer for External Communication

This section helps you to connect your custom target by using external mode using your own low-level communications layer. The topics include:

- An overview of the design and operation of external mode
- A description of external mode source files
- Guidelines for modifying the external mode source files and building an executable to handle the tasks of the default `ext_comm` MEX-file

This section assumes that you are familiar with the execution of Simulink Coder programs, and with the basic operation of external mode.

Design of External Mode

External mode communication between the Simulink engine and a target system is based on a client/server architecture. The client (the Simulink engine) transmits messages requesting the server (target) to accept parameter changes or to upload signal data. The server responds by executing the request.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

This design makes it possible for different targets to use different transport layers. The GRT, ERT, and RSim targets support host/target communication by using TCP/IP and

RS-232 (serial) communication. The Simulink Desktop Real-Time target supports shared memory communication. The Wind River Systems Tornado® target supports TCP/IP only.

The Simulink Coder product provides full source code for both the client and server-side external mode modules, as used by the GRT, ERT, Rapid Simulation, and Tornado targets, and the Simulink Desktop Real-Time and Simulink Real-Time products. The main client-side module is `ext_comm.c`. The main server-side module is `ext_svr.c`.

These two modules call the specified transport layer through the following source files.

Built-In Transport Layer Implementations

Protocol	Client or Server?	Source Files
TCP/IP	Client (host)	• *matlabroot*`/toolbox/coder/simulinkcoder_core/ext_mode/host/common/rtiostream_interface.c` • *matlabroot*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`
	Server (target)	• *matlabroot*`/rtw/c/src/ext_mode/common/rtiostream_interface.c` • *matlabroot*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`
Serial	Client (host)	• *matlabroot*`/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_transport.c` • *matlabroot*`/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`
	Server (target)	• *matlabroot*`/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c` • *matlabroot*`/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`

For serial communication, the modules `ext_serial_transport.c` and `rtiostream_serial.c` implement the client-side transport functions and the modules `ext_svr_serial_transport.c` and `rtiostream_serial.c` implement the corresponding server-side functions. For TCP/IP communication, the modules `rtiostream_interface.c` and `rtiostream_tcpip.c` implement both client-side and server-side functions. You can edit copies of these files (but do not modify the originals).

You can support external mode using your own low-level communications layer by creating similar files using the following templates:

- Client (host) side: *matlabroot*/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c (TCP/IP) or *matlabroot*/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c (serial)
- Server (target) side: *matlabroot*/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c (TCP/IP) or *matlabroot*/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c (serial)

The file `rtiostream_interface.c` is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see "Communications `rtiostream` API" on page 64-46. Implement your `rtiostream` communications channel by using the documented interface to avoid having to make changes to the file `rtiostream_interface.c` or other external mode related files.

Note Do not modify working source files. Use the templates provided in the `/custom` or `/rtiostream` folder as starting points, guided by the comments within them.

You need only provide code that implements low-level communications. You need not be concerned with issues such as data conversions between host and target, or with the formatting of messages. The Simulink Coder software handles these functions.

On the client (Simulink engine) side, communications are handled by `ext_comm` (for TCP/IP) and `ext_serial_win32_comm` (for serial) MEX-files.

On the server (target) side, external mode modules are linked into the target executable. This takes place automatically if the **External mode** code generation option is selected at code generation time, based on the **External mode transport** option selected in the target code generation options dialog box. These modules, called from the main program and the model execution engine, are independent of the generated model code.

The general procedure for implementing your own client-side low-level transport protocol is as follows:

1. Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
2. Generate a MEX-file executable for your custom transport.

3 Register your new transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box.

For more details, see "Create a Custom Client (Host) Transport Protocol" on page 69-17.

The general procedure for implementing your own server-side low-level transport protocol is as follows:

1 Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls. Typically this involves writing or integrating device drivers for your target hardware.

2 Modify template makefiles to support the new transport.

For more details, see "Create a Custom Server (Target) Transport Protocol" on page 69-21.

External Mode Communications Overview

This section gives a high-level overview of how a Simulink Coder generated program communicates with Simulink external mode. This description is based on the TCP/IP version of external mode that ships with the Simulink Coder product.

For communication to take place,

- The server (target) program must have been built with the conditional `EXT_MODE` defined. `EXT_MODE` is defined in the *`model`*`.mk` file if the **External mode** code generation option was selected at code generation time.
- Both the server program and the Simulink software must be executing. This does not mean that the model code in the server system must be executing. The server can be waiting for the Simulink engine to issue a command to start model execution.

The client and server communicate by using bidirectional sockets carrying packets. Packets consist either of *messages* (commands, parameter downloads, and responses) or *data* (signal uploads).

If the target program was invoked with the `-w` command-line option, the program enters a wait state until it receives a message from the host. Otherwise, the program begins execution of the model. While the target program is in a wait state, the Simulink engine can download parameters to the target and configure data uploading.

When the user chooses the **Connect to Target** option from the **Simulation** menu, the host initiates a handshake by sending an `EXT_CONNECT message`. The server responds with information about itself. This information includes

- Checksums. The host uses model checksums to determine that the target code is an exact representation of the current Simulink model.
- Data format information. The host uses this information when formatting data to be downloaded, or interpreting data that has been uploaded.

At this point, host and server are connected. The server is either executing the model or in the wait state. (In the latter case, the user can begin model execution by selecting **Start Real-Time Code** from the **Simulation** menu.)

During model execution, the message server runs as a background task. This task receives and processes messages such as parameter downloads.

Data uploading comprises both foreground execution and background servicing of the signal packets. As the target computes model outputs, it also copies signal values into data upload buffers. This occurs as part of the task associated with each task identifier (`tid`). Therefore, data collection occurs in the foreground. Transmission of the collected data, however, occurs as a background task. The background task sends the data in the collection buffers to the Simulink engine by using data packets.

The host initiates most exchanges as messages. The target usually sends a response confirming that it has received and processed the message. Examples of messages and commands are:

- Connection message / connection response
- Start target simulation / start response
- Parameter download / parameter download response
- Arm trigger for data uploading / arm trigger response
- Terminate target simulation / target shutdown response

Model execution terminates when the model reaches its final time, when the host sends a terminate command, or when a Stop Simulation block terminates execution. On termination, the server informs the host that model execution has stopped, and shuts down its socket. The host also shuts down its socket, and exits external mode.

External Mode Source Files

- “Client (Host) MEX-file Interface Source Files” on page 69-13

- "Server (Target) Source Files" on page 69-14
- "Other Files in the Server Folder" on page 69-16

Client (Host) MEX-file Interface Source Files

The source files for the MEX-file interface component are located in the folder *matlabroot*`/toolbox/coder/simulinkcoder_core/ext_mode/host` (open), except as noted:

- `common/ext_comm.c`

  This file is the core of external mode communication. It acts as a relay station between the target and the Simulink engine. `ext_comm.c` communicates to the Simulink engine by using a shared data structure, `ExternalSim`. It communicates to the target by using calls to the transport layer.

  Tasks carried out by `ext_comm.c` include establishment of a connection with the target, downloading of parameters, and termination of the connection with the target.

- `common/rtiostream_interface.c`

  This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see "Communications `rtiostream` API" on page 64-46. Implement your `rtiostream` communications channel using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- *matlabroot*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`

  This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- *matlabroot*`/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`

  This file implements required serial transport layer functions. The version of `rtiostream_serial.c` shipped with the Simulink Coder software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- `serial/ext_serial_transport.c`

This file implements required serial transport layer functions. `ext_serial_transport.c` includes `ext_serial_utils.c`, which is located in *`matlabroot`*`/rtw/c/src/ext_mode/serial` (open) and contains functions common to client and server sides.

- `common/ext_main.c`

  This file is a MEX-file wrapper for external mode. `ext_main.c` interfaces to the Simulink engine by using the standard `mexFunction` call. (See the `mexFunction` reference page and "MATLAB API for Other Languages" (MATLAB) for more information.) `ext_main.c` contains a function dispatcher, `esGetAction`, that sends requests from the Simulink engine to `ext_comm.c`.

- `common/ext_convert.c` and `ext_convert.h`

  This file contains functions used for converting data from host to target formats (and vice versa). Functions include byte-swapping (big to little- endian), conversion from non-IEEE floats to IEEE doubles, and other conversions. These functions are called both by `ext_comm.c` and directly by the Simulink engine (by using function pointers).

  Note You do not need to customize `ext_convert` to implement a custom transport layer. However, you might want to customize `ext_convert` for the intended target. For example, if the target represents the `float` data type in Texas Instruments format, `ext_convert` must be modified to perform a Texas Instruments to IEEE conversion.

- `common/extsim.h`

  This file defines the `ExternalSim` data structure and access macros. This structure is used for communication between the Simulink engine and `ext_comm.c`.

- `common/extutil.h`

  This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_transport.h`

  This file defines functions that must be implemented by the transport layer.

Server (Target) Source Files

These files are linked into the *`model`*`.exe` executable. They are located within *`matlabroot`*`/rtw/c/src/ext_mode` (open) except as noted.

- `common/ext_svr.c`

  `ext_svr.c` is analogous to `ext_comm.c` on the host, but generally is responsible for more tasks. It acts as a relay station between the host and the generated code. Like `ext_comm.c`, `ext_svr.c` carries out tasks such as establishing and terminating connection with the host. `ext_svr.c` also contains the background task functions that either write downloaded parameters to the target model, or extract data from the target data buffers and send it back to the host.

- `common/rtiostream_interface.c`

  This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see "Communications `rtiostream` API" on page 64-46. Implement your `rtiostream` communications channel by using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`

  This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`

  This file implements required serial transport layer functions. The version of rtiostream_serial.c shipped with the software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- *`matlabroot`*`/rtw/c/src/rtiostream.h`

  This file defines the `rtIOStream*` functions implemented in `rtiostream_tcpip.c`.

- `serial/ext_svr_serial_transport.c`

  This file implements required serial transport layer functions. `ext_svr_serial_transport.c` includes `serial/ext_serial_utils.c`, which contains functions common to client and server sides.

- `common/updown.c`

  `updown.c` handles the details of interacting with the target model. During parameter downloads, `updown.c` does the work of installing the new parameters into the

model's parameter vector. For data uploading, `updown.c` contains the functions that extract data from the model's `blockio` vector and write the data to the upload buffers. `updown.c` provides services both to `ext_svr.c` and to the model code (for example, `grt_main.c`). It contains code that is called by using the background tasks of `ext_svr.c` as well as code that is called as part of the higher priority model execution.

- *`matlabroot`*`/rtw/c/src/dt_info.h` (included by generated model build file *`model`*`.h`)

  These files contain data type transition information that allows access to multi-data type structures across different computer architectures. This information is used in data conversions between host and target formats.

- `common/updown_util.h`

  This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_svr_transport.h`

  This file defines the `Ext*` functions that must be implemented by the server (target) transport layer.

Other Files in the Server Folder

- `common/ext_share.h`

  Contains message code definitions and other definitions required by both the host and target modules.

- `serial/ext_serial_utils.c`

  Contains functions and data structures for communication, MEX link, and generated code required by both the host and target modules of the transport layer for serial protocols.

- The serial transport implementation includes the additional files
  - `serial/ext_serial_pkt.c` and `ext_serial_pkt.h`
  - `serial/ext_serial_port.h`

Implement a Custom Transport Layer

- “Requirements for Custom Transport Layers” on page 69-17

Requirements for Custom Transport Layers

- By default, `ext_svr.c` and `updown.c` use `malloc` to allocate buffers in target memory for messages, data collection, and other purposes, although there is also an option to preallocate static memory. If your target uses another memory allocation scheme, you must modify these modules.
- The target is assumed to support both `int32_T` and `uint32_T` data types.

Create a Custom Client (Host) Transport Protocol

To implement the client (host) side of your low-level transport protocol,

1. Edit the template file *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.

   a. Copy and rename the file to `rtiostream_`*`name`*`.c` (replacing *`name`* with a name meaningful to you).

   b. Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication primitives. These functions are called from other external mode modules via `rtiostream_interface.c`. For more information, see "Communications `rtiostream` API" on page 64-46.

   c. Build your `rtiostream` implementation into a shared library that exports the `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamRecv` and `rtIOStreamSend` functions.

2. Build the customized MEX-file executable using the MATLAB `mex` function. See "MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files" on page 69-18 for examples of `mex` invocations.

   Do not replace the existing `ext_comm` MEX-file if you want to preserve its existing function. Instead, use the `-output` option to name the resulting

executable (for example, `mex -output ext_myrtiostream_comm ...` builds `ext_myrtiostream_comm.`*`mexext`*, on Windows platforms).

3 Register your new client transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box. For details, see "Register a Custom Client (Host) Transport Protocol" on page 69-20.

Sample commands for rebuilding external mode MEX-files are listed in "MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files" on page 69-18.

MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files

The following table lists the commands for building the standard `ext_comm` and `ext_serial_win32` modules on PC and UNIX platforms.

Platform	Commands

Windows, TCP/IP	`>> cd (matlabroot)`
	`>> mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\rtiostream_interface.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ...`
	`-Irtw\c\src -Irtw\c\src\rtiostream\utils ...`
	`-Irtw\c\src\ext_mode\common ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ...`
	`-lmwrtiostreamutils -lsl_services ...`
	`-DEXTMODE_TCPIP_TRANSPORT ...`
	`-DSL_EXT_DLL -output toolbox\coder\simulinkcoder_core\ext_comm`
	
	Note: The `rtiostream_interface.c` function defines RTIOSTREAM_SHARED_LIB as `libmwrtiostreamtcpip` and dynamically loads the MathWorks TCP/IP `rtiostream` shared library. Modify this file if you need to load a different `rtiostream` shared library.

Linux, TCP/IP	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_SO`. • Change `-lsl_services` to `-lmwsl_services`. • Replace back slashes with forward slashes.
Mac, TCP/IP	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_DYLIB`.

Platform	Commands
	• Change `-lsl_services` to `-lmwsl_services`. • Replace back slashes with forward slashes.

Windows, serial	`>> cd (matlabroot)`
	`>> mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_transport.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_pkt.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\rtiostream_serial_interface.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ...`
	`-Irtw\c\src -Irtw\c\src\rtiostream\utils ...`
	`-Irtw\c\src\ext_mode\common ...`
	`-Irtw\c\src\ext_mode\serial ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ...`
	`-lmwrtiostreamutils -lsl_services ...`
	`-DEXTMODE_SERIAL_TRANSPORT -DSL_EXT_DLL ...`
	`-output toolbox\coder\simulinkcoder_core\ext_serial_win32_comm`
	
	Note: The `rtiostream_interface.c` function defines RTIOSTREAM_SHARED_LIB as `libmwrtiostreamserial` and dynamically loads the MathWorks serial `rtiostream` shared library. Modify this file if you need to load a different `rtiostream` shared library.

Linux, serial	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_SO`. • Change `-lsl_services` to `-lmwsl_services`. • Replace back slashes with forward slashes.
Mac, serial	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_DYLIB`. • Change `-lsl_services` to `-lmwsl_services`. • Replace back slashes with forward slashes.

Note: `mex` requires a compiler supported by the MATLAB API. See the `mex` reference page and "MATLAB API for Other Languages" (MATLAB) for more information about the `mex` function.

Register a Custom Client (Host) Transport Protocol

To register a custom client transport protocol with the Simulink software, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
% -- end of sl_customization
```

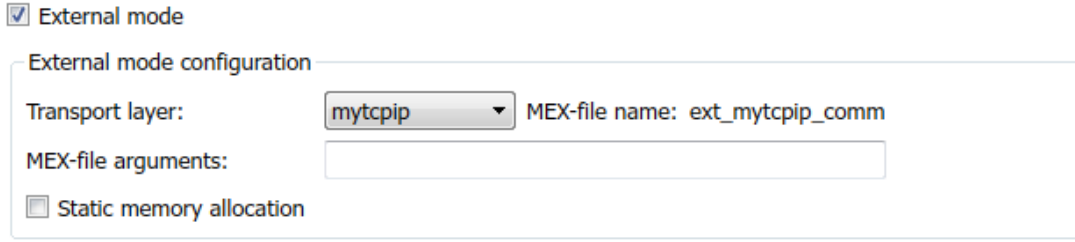
where

- *`stf`*`.tlc` is the name of the system target file for which the transport will be registered (for example, `'grt.tlc'`)
- *`transport`* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, `'mytcpip'`)
- *`mexfile`* is the name of the transport's associated external interface MEX-file (for example, `'ext_mytcpip_comm'`)

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('grt.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
  cm.ExtModeTransports.add('ert.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
% -- end of sl_customization
```

If you place the `sl_customization.m` file containing the transport registration information on the MATLAB path, your custom client transport protocol will be registered with each subsequent Simulink session. The name of the transport will appear in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box. When you select the transport for your model, the name of the associated external interface MEX-file will appear in the noneditable **MEX-file name** field, as shown in the following figure.



Create a Custom Server (Target) Transport Protocol

The `rtIOStream*` function prototypes in *`matlabroot`*`/rtw/c/src/rtiostream.h` define the calling interface for both the server (target) and client (host) side transport layer functions.

- The TCP/IP implementations are in *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`.
- The serial implementations are in *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`.

Note: The `Ext*` function prototypes in *`matlabroot`*`/rtw/c/src/ext_mode/common/ext_svr_transport.h` are implemented in *`matlabroot`*`/rtw/c/src/ext_mode/common/rtiostream_interface.c` or *`matlabroot`*`/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c`. In most cases you will not need to modify `rtiostream_interface.c` or `rtiostream_serial_interface.c` for your custom TCP/IP or serial transport layer.

To implement the server (target) side of your low-level TCP/IP or serial transport protocol:

1. Edit the template *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` or *`matlabroot`*`/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` to replace low-level communication calls with your own communication calls.

   a. Copy and rename the file to `rtiostream_`*`name`*`.c` (replacing *`name`* with a name meaningful to you).

   b. Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication drivers.

      You must implement the functions defined in `rtiostream.h`, and your implementations must conform to the prototypes defined in that file. Refer to the original `rtiostream_tcpip.c` or `rtiostream_serial.c` for guidance.

2. Incorporate the external mode source files for your transport layer into the model build process, according to your target type:

- If your target uses toolchain controls to configure a build, use a build process mechanism such as a post code generation command or a `before_make` hook function to make the transport files available to the build process. (For more information on the build process mechanisms, see "Customize Post-Code-Generation Build Processing" (Simulink Coder), "Customize Build Process with STF_make_rtw_hook File" (Simulink Coder), and "Customize Build Process with sl_customization.m" (Simulink Coder).) For example:

  - Add the file created in the previous step to the build information:

    ```
    path/rtiostream_name.c
    ```

  - For TCP/IP, add the following file to the build information:

    ```
    matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c
    ```

  - For serial, add the following files to the build information:

    ```
    matlabroot/rtw/c/src/ext_mode/serial/ext_serial_pkt.c
    matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c
    matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c
    ```

- If your target uses template makefile controls to configure a build, modify template makefiles to support the new transport. Be sure to include the file created in the previous step, `rtiostream_name.c`. If you are writing your own template makefile, make sure that the `EXT_MODE` code generation option is defined. The generated makefile will then link `rtiostream_name.c`, `rtiostream_interface.c` or `rtiostream_serial_interface.c`, and other server code into your executable.

Note: For external mode, check that `rtIOStreamRecv` is not a blocking implementation. Otherwise, it might cause the external mode server to block until the host sends data through the `comm` layer.

Serial Receive Buffer Smaller than 64 Bytes

For serial communication, if the serial receive buffer of your target is smaller than 64 bytes:

1 Update the following macro with the actual target buffer size:

```
#define TARGET_SERIAL_RECEIVE_BUFFER_SIZE 64
```

Implement the change in the following files:

```
matlabroot/rtw/c/src/ext_mode/serial/ext_serial_utils.c
matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_utils.c
```

2. Run the command to rebuild the `ext_serial_win32` MEX-file. See "MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files" on page 69-18.

Build Process Integration in Simulink Coder

Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether or not to compile and link an executable program. This decision is governed by the following:

- **Generate code only** option

  When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option

  When you clear this option, the code generator does not produce a makefile for the model. You must specify post code generation processing, including compilation and linking, as a user-defined command, as explained in "Customize Post-Code-Generation Build Processing" on page 70-14.

- Makefile-only target

  The Microsoft Visual C++ Project Makefile versions of the `grt` and Embedded Coder target configurations generate a Visual C++ project makefile (*`model`*`.mak`). To build an executable, you must open *`model`*`.mak` in the Visual C++ IDE and compile and link the model code.

- `HOST` template makefile variable

  The template makefile variable `HOST` identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: `PC`, `UNIX`, or `ANY`.

  By default, `HOST` is set to `UNIX` in template makefiles designed for use with The Open Group UNIX platforms (such as `grt_unix.tmf`), and to `PC` in the template makefiles designed for use with development systems for the PC (such as `grt_vc.tmf`).

  If the Simulink software is running on the same type of system as that specified by the `HOST` variable, then the executable is built. Otherwise,

  - If `HOST = ANY`, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one the Simulink software is running on.
  - Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

```
### Make will not be invoked - template makefile is for a different host
```

- `TGT_FCN_LIB` template makefile variable

  The template makefile variable `TGT_FCN_LIB` specifies compiler command line options. The line in the makefile is `TGT_FCN_LIB = |>TGT_FCN_LIB<|`. Use this token in a makefile conditional statement to specify a standard math library as a compiler option. Possible `|>TGT_FCN_LIB<|` token values are:

Value	Generates Calls To
Name of custom CRL	ISO®/IEC 9899:1990 C (`ANSI_C`) standard math library
`ISO_C`	ISO/IEC 9899:1999 C standard math library
`ISO_C++`	ISO/IEC 14882:2003 C++ standard math library
`GNU`	GNU extensions to the ISO/IEC 9899:1999 C standard math library

Cross-Compile Code Generated on Microsoft Windows

If you need to generate code with the code generator on a Microsoft Windows system but compile the generated code on a different supported platform, you can do so by modifying your TMF and model configuration parameters. For example, you would need to do this if you develop applications with the MATLAB and Simulink products on a Windows system, but you run your generated code on a Linux system.

To set up a cross-compilation development environment, do the following (here a Linux system is the destination platform):

1. On your Windows system, copy the UNIX TMF for your target to a local folder. This will be your working folder for initiating code generation. For example, you might copy the file *matlabroot*`/rtw/c/grt/grt_unix.tmf` to `D:/work/my_grt_unix.tmf`.
2. Make the following changes to your copy of the TMF:
   - Add the following line near the `SYS_TARGET_FILE =` line:

     ```
     MAKEFILE_FILESEP = /
     ```
   - Search for the line `'ifeq ($(OPT_OPTS),$(DEFAULT_OPT_OPTS))'` and, for each occurrence, remove the conditional logic and retain only the `'else'` code. That is, remove everything from the `'if'` to the `'else'`, inclusive, as well as the closing `'endif'`. Only the lines from the `'else'` portion should remain. This forces the run-time libraries to build for a Linux system.
3. Open your model and make the following changes in the **Code Generation** pane of the Configuration Parameters dialog:
   - Specify the name of your new TMF in the "Template makefile" (Simulink Coder) text box (for example, `my_grt_unix.tmf`).
   - Select **Generate code only** and click **Apply**.
4. Generate the code.
5. If the build folder (folder from which the model was built) is not already Linux accessible, copy it to a Linux accessible path. For example, if your build folder for the generated code was `D:\work\mymodel_grt_rtw`, copy that entire folder tree to a path such as `/home/user/mymodel_grt_rtw`.
6. If the MATLAB folder tree on the Windows system is Linux accessible, skip this step. Otherwise, copy the include and source folders to a Linux accessible drive partition, for example, `/home/user/myinstall`. These folders appear in the makefile after

`MATLAB_INCLUDES =` and `ADD_INCLUDES =` and can be found by searching for `$(MATLAB_ROOT)`. Paths that contain `$(MATLAB_ROOT)` must be copied. Here is an example list (your list will vary depending on your model):

```
$(MATLAB_ROOT)/rtw/c/grt
$(MATLAB_ROOT)/extern/include
$(MATLAB_ROOT)/simulink/include
$(MATLAB_ROOT)/rtw/c/src
$(MATLAB_ROOT)/rtw/c/tools
```

Additionally, paths containing `$(MATLAB_ROOT)` in the build rules (lines with `%.o :`) must be copied. For example, based on the build rule

```
%.o : $(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip/%.c
```

the following folder should be copied:

```
$(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip
```

Note: The path hierarchy relative to the MATLAB root must be maintained. For example, `c:\MATLAB\rtw\c\tools\*` would be copied to `/home/user/mlroot/rtw/c/tools/*`.

For some blocksets, it is easiest to copy a higher-level folder that includes the subfolders listed in the makefile. For example, the DSP System Toolbox product requires the following folders to be copied:

```
$(MATLAB_ROOT)/toolbox/dspblks
$(MATLAB_ROOT)/toolbox/rtw/dspblks
```

---

7 Make the following changes to the generated makefile:

- Set both `MATLAB_ROOT` and `ALT_MATLAB_ROOT` equal to the Linux accessible path to *`matlabroot`* (for example, `home/user/myinstall`).
- Set `COMPUTER` to the computer value for your platform, such as `GLNX86`. Enter `help computer` in the MATLAB Command Window for a list of computer values.
- In the `ADD_INCLUDES` list, change the build folder (designating the location of the generated code on the Windows system) and parent folders to Linux accessible include folders. For example, change `D:\work\mymodel_grt_rtw\` to `/home/user/mymodel_grt_rtw`.

  Additionally, if *`matlabroot`* is a UNC path, such as `\\my-server\myapps\matlab`, replace the hard-coded MATLAB root with `$(MATLAB_ROOT)`.

8 From a Linux shell, compile the code you generated on the Windows system. You can do this by running the generated *`model`*`.bat` file or by typing the make command line as it appears in the `.bat` file.

Note: If errors occur during makefile execution, you may need to run the `dos2unix` utility on the makefile (for example, `dos2unix mymodel.mk`).

Related Examples

- Use packNGo to Relocate Code to Another Development Environment (Simulink Coder)

Control Library Location and Naming During Build

Use the `TargetPreCompLibLocation` and `TargetLibSuffix` configuration parameters to control values in generated makefiles during model builds when you use the toolchain approach or the template makefile approach.

In this section...

Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```
function mytarget_select_callback_handler(varargin)
    hDig=varargin{1};
    hSrc=varargin{2};
    slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation',...
    'c:\mytarget\precomplibs');
    slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix',...
    '_target.library');
```

The TMF has corresponding expansion tokens:

```
    |>EXPAND_LIBRARY_LOCATION<|
    |>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model,'TargetPreCompLibLocation',...
```

```
'c:\mytarget\precomplibs');
```

Note: If your model contains referenced models, you can use the make option `USE_MDLREF_LIBPATHS` to control whether libraries used by the referenced models are copied to the parent model's build folder. For more information, see "Control the Location of Model Reference Libraries" on page 70-10.

Using TargetLibSuffix with the Toolchain Approach

With `TargetLibSuffix`, you specify a suffix followed by an extension. For example: *`suffix.extension`*

However, when you use the toolchain approach, only the suffix provided by `TargetLibSuffix` is honored. The extension that the `TargetLibSuffix` provides is not honored because the toolchain approach provides a different extension.

For example, with the target makefile approach, the final binary name is composed of the *`modelname`*, the *`suffix`*, and the *`extension`* provided by `TargetLibSuffix`:

```
modelname+suffix.extension_from_TargetLibSuffix
```

With the toolchain approach, the final binary name is composed of the *`modelname`*, the *`suffix`*, and the *`extension`* provided by the toolchain approach:

```
model+suffix.extension_from_toolchain_approach
```

The extension that the toolchain approach uses comes from the file extension of the static library that the build tool creates. To get this information:

Create the toolchain object. For example, enter:

```
tc = ToolchainInfo used in the model
```

Get the build tool name. For example, enter:

```
tool = tc.getBuildTool('C Compiler');
```
or
```
tool = tc.getBuildTool('C++ Compiler');
```
Get the extension. For example, enter:

```
extension_from_ToolchainInfo = tool.getFileExtension('Static Library')
```

Note: Note: If you do not set the `TargetLibSuffix` parameter, template makefile and toolchain approaches behave identically. See "Customize Library File Suffix and File Type" (Simulink Coder).

Specify the Location of Precompiled Libraries

Use the `TargetPreCompLibLocation` configuration parameter to:

- Override the precompiled library location specified in the `rtwmakecfg.m` file (see "Use rtwmakecfg.m API to Customize Generated Makefiles" on page 70-26 for details)
- Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

However, for some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Libraries supported by the target should be compiled and placed in the target-specific location so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```
set_param(model,'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `'rtwlib'`, the template makefile build approach expands the token from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\
```

```
_target.library
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.

Control the Location of Model Reference Libraries

On platforms other than the Apple Macintosh platform, when building a model that uses referenced models, the default build process includes:

- Copy libraries that the referenced models uses to the parent model's build folder.
- Assign the file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

For example, if a model includes a referenced model `sub`, the build process assigns the library name `sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process copies the library file to the parent model's build folder. This definition is then used in the final link line, which links the library into the final product (usually an executable). This technique minimizes the length of the link line.

On the Macintosh platform, and optionally on other platforms, the build process includes:

- No copying of libraries that the referenced models uses to the parent model's build folder.
- Assign the relative paths and file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

When using this technique, the build process assigns a relative path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

To change to the nondefault behavior on platforms other than the Macintosh platform, select the **Configuration Parameters** > **Code Generation** > **Make command** field. Enter:

```
make_rtw USE_MDLREF_LIBPATHS=1
```

If you specify other Make command arguments, such as `OPTS="-g"`, the order in which you specify the multiple arguments does not matter.

To return to the default behavior, set USE_MDLREF_LIBPATHS to 0, or remove it.

Control the Suffix Applied to Library File Names

Use the TargetLibSuffix configuration parameter to control the suffix applied to library names (for example, _target.lib or _target.a). The specified suffix scheme must include a period (.). You can apply TargetLibSuffix to the following libraries:

- Libraries on which a target depends, as specified in the rtwmakecfg.m API. You can use TargetLibSuffix to change the suffix of both precompiled and non-precompiled libraries configured from the rtwmakecfg API. For details, see "Use rtwmakecfg.m API to Customize Generated Makefiles" on page 70-26.

  In this case, a target can set the parameter in its select callback. For example:

  ```
  slConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix',...
  '_target.library');
  ```

  Alternatively, you can use a call to the set_param function. For example:

  ```
  set_param(model,'TargetLibSuffix','_target.library');
  ```

  During the TMF-to-makefile conversion, the build process replaces the token |>EXPAND_LIBRARY_SUFFIX<| with the specified suffix. For example, if the library name specified in the rtwmakecfg.m file is 'rtwlib', the TMF expands from:

  ```
  LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\
  |>EXPAND_LIBRARY_SUFFIX<|
  ```

  to:

  ```
  LIBS += c:\mytarget\precomplibs\rtwlib_target.library
  ```

  By default, TargetLibSuffix is set to an empty character vector. In this case, the build process replaces the token |>EXPAND_LIBRARY_SUFFIX<| with an empty character vector.

- Shared utility library and the model libraries created with model reference. For these cases, associated makefile variables do not require the |>EXPAND_LIBRARY_SUFFIX<| token. Instead, the build process includes TargetLibSuffix implicitly. For example, for a top model named topmodel with referenced models named refmodel1 and refmodel2, the top model's TMF is expanded from:

  ```
  SHARED_LIB          = |>SHARED_LIB<|
  ```

```
MODELLIB           = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
```

to:

```
SHARED_LIB         = \
..\slprj\ert\_sharedutils\rtwshared_target.library
MODELLIB           = topmodellib_target.library
MODELREF_LINK_LIBS = \
refmodel1_rtwlib_target.library refmodel2_rtwlib_target.library
```

By default, the `TargetLibSuffix` parameter is an empty character vector. In this case, the build process chooses a default suffix for these three tokens using a file extension of `.lib` on Windows hosts and `.a` on UNIX hosts. (For model reference libraries, the default suffix additionally includes `_rtwlib`.) For example, on a Windows host, the expanded makefile values are:

```
SHARED_LIB         = ..\slprj\ert\_sharedutils\rtwshared.lib
MODELLIB           = topmodellib.lib
MODELREF_LINK_LIBS = refmodel1_rtwlib.lib refmodel2_rtwlib.lib
```

Recompile Precompiled Libraries

You can recompile precompiled libraries included as part of the code generator, such as `rtwlib` or `dsplib`, by using a supplied MATLAB function, `rtw_precompile_libs`. You might consider doing this if you need to customize compiler settings for various platforms or environments. For details on using `rtw_precompile_libs`, see "Precompile S-Function Libraries" on page 39-47.

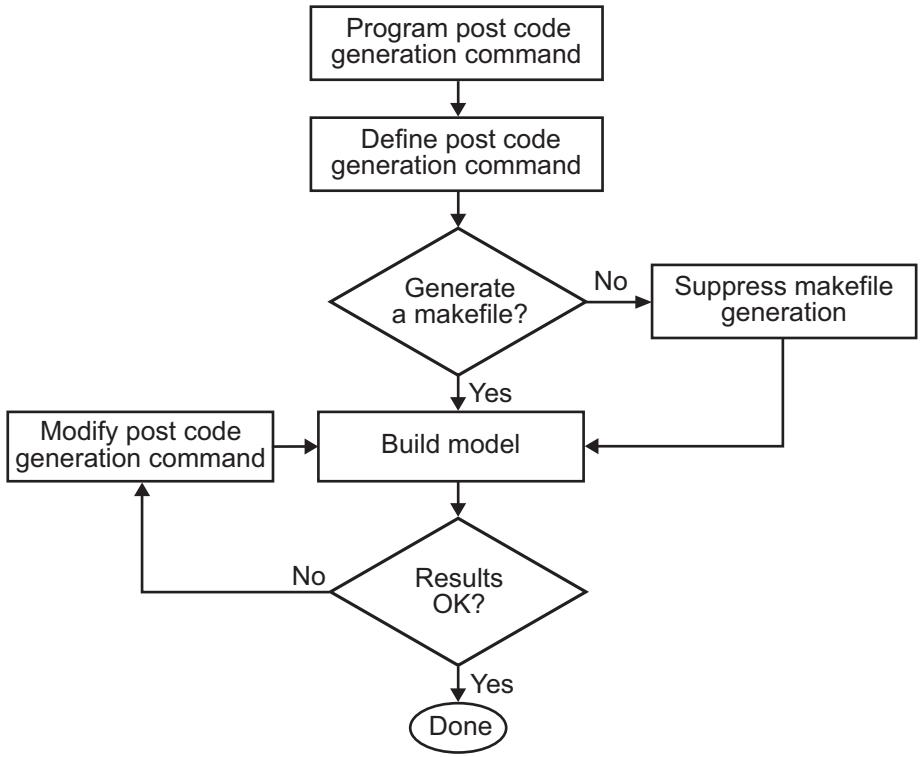
Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You might use such customizations for target development or the integration of third-party tools into your application development environment.

In this section...

Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.



1. Program the post code generation command.
2. Define the post code generation command.
3. Suppress makefile generation, if applicable.
4. Build the model.
5. Modify the command and rebuild the model until the build results are acceptable.

Build Information Object

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options
- Preprocessor identifier definitions
- Linker options

- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see "Build Process Customization" (Simulink Coder). "Program a Post Code Generation Command" on page 70-16 explains how to use the functions to control post code generation build processing.

Program a Post Code Generation Command

For certain applications, you might want to control aspects of the build process after the code generation. For example, you might do this if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the model's build information object. You can program the command as a script or function.

If You Program the Command as a...	Then the...
Script	Script can gain access to the model name and the build information directly
Function	Function can pass the model name and the build information as arguments

If your post code generation command calls user-defined functions, make sure the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in "Build Process Customization" (Simulink Coder), to customize the model's post code generation build processing.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```
function analyzegencode(buildInfo)
% Get the names and paths of source and include files
% generated for the model and then analyze them.

% buildInfo - build information for my model.

% Define cell array to hold data.
MyBuildInfo={};

% Get source file information.
MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);

% Get include (header) file information.
MyBuildInfo.incfiles=getIncludeFiles(buildInfo, true, true);
MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);

% Analyze generated code.
.
.
.
```

Define a Post Code Generation Command

After you program a post code generation command, you need to inform the build process that the command exists and to add it to the model's build processing. You do this by defining the command with the `PostCodeGenCommand` model configuration parameter. When you define a post code generation command, the build process evaluates the command after generating and writing the model's code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

Note: When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the model's name and build information to the function, specify identifiers `modelName` and `buildInfo` as arguments.

Script

```
set_param(model, 'PostCodeGenCommand',...
'pcgScriptName');
```

Function

```
set_param(model, 'PostCodeGenCommand',...
 'pcgFunctionName(modelName)');
```

Multiple Functions

```
pcgFunctions=...
'pcgFunction1Name(modelName);...
pcgFunction2Name(buildInfo)';
set_param(model, 'PostCodeGenCommand',...
 pcgFunctions);
```

The following call to `set_param` defines `PostCodGenCommand` to evaluate the function `analyzegencode`.

```
set_param(model, 'PostCodeGenCommand',...
'analyzegencode(buildInfo)');
```

Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment

This example shows how to use the Build Information API and the **Post Code Generation Command** parameter, `PostCodeGenCommand`.

The `PostCodeGenCommand` parameter value is `rtwdemo_buildinfo_data`. This value directs the build process to invoke the function after code generation.

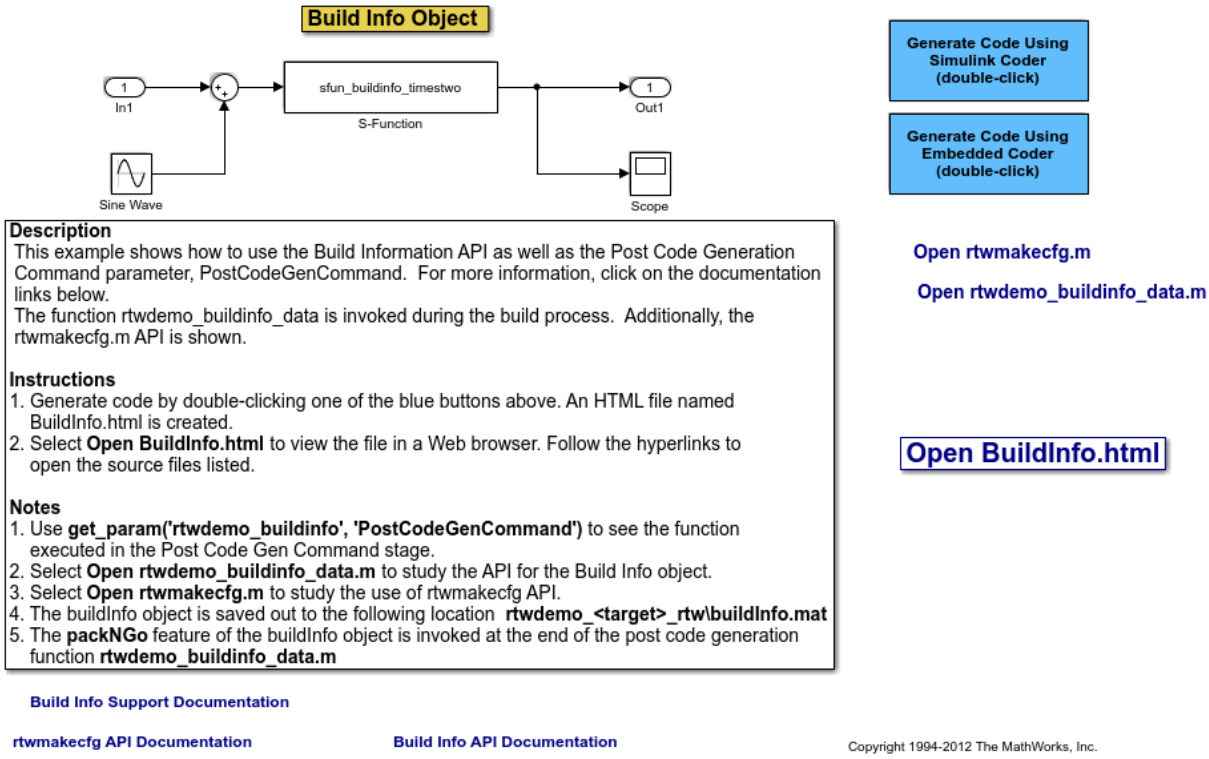
The example also demonstrates how to use the `rtwmakecfg.m` API.

For more information, click on the documentation links in the model.

Open Example Model

Open the example model `rtwdemo_buildinfo`.

```
open_system('rtwdemo_buildinfo');
```



Generate Code from Model

Double-click on the **Generate Code Using Simulink Coder** button to generate code for the GRT target.

Or, if Embedded Coder is installed, double-click on the **Generate Code Using Embedded Coder** button to generate code for the ERT target.

The build process generates a `BuildInfo.html` file to document the build information object.

Examine the Build Process Customizations and Output

Use the links in the model to examine the build process customizations and the post code generation query of the build information object.

To view the `BuildInfo.html` file in a Web browser, click on **Open BuildInfo.html**.

The example uses the `PostCodeGenCommand` parameter of the model to generate the html file from the build information object. The file provides hyperlinks to open the source files (generated code) from the model. To view the `PostCodeGenCommand` parameter value, type:

```
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

This value indicates a function to execute in the **Post Code Gen Command** stage.

```
rtwdemo_buildinfo_data(buildInfo);
```

To study how the example uses the `rtwmakecfg` API, click on **Open rtwmakecfg.m** or type:

```
edit rtwmakecfg.m;
```

To study the API for the `buildInfo.mat` object, click on **Open rtwdemo_buildinfo_data.m** or type:

```
edit rtwdemo_buildinfo_data.m;
```

The `buildInfo.mat` object is available at:

```
rtwdemo_<target>_rtw\buildInfo.mat
```

At the end of the `rtwdemo_buildinfo_data.m` post code generation function, the function invokes `packNGo` to package the source and objects identified in the `buildInfo` object for relocation.

Further Study Topics

- “Build Process Customization” (Simulink Coder)
- “Customize Post-Code-Generation Build Processing” (Simulink Coder)
- “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder)
- “Relocate Code to Another Development Environment” (Simulink Coder)

Suppress Makefile Generation

The code generator provides the ability to suppress makefile generation during the build process. For example, you might do this to integrate tools into the build process that are not driven by makefiles.

To instruct the code generator to not produce a makefile, do one of the following:

- Clear the **Generate makefile** option on the **Code Generation** pane of the Configuration Parameters dialog box.
- Set the value of the configuration parameter `GenerateMakefile` to `off`.

When you suppress makefile generation,

- You cannot explicitly specify a make command or template makefile.
- You must specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 70-16 and “Define a Post Code Generation Command” on page 70-17.

Configure Generated Code with TLC

In this section...

About Configuring Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the **Code Generation** pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

Note: You should not customize TLC files in the folder *`matlabroot`*`/rtw/c/tlc` even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

Assigning Target Language Compiler Variables

The `%assign` statement lets you assign a value to a TLC variable, as in

```
%assign MaxStackSize = 4096
```

This is also known as creating a *parameter name/parameter value pair*.

For a description of the `%assign` statement see "Target Language Compiler Directives" (Simulink Coder). You should write your `%assign` statements in the `Configure RTW code generation settings` section of the system target file.

The following table lists the code generation variables you can set with the `%assign` statement.

Target Language Compiler Optional Variables

Variable	Description
`MaxStackSize=`*`N`*	When the **Enable local block outputs** check box is selected, the total allocation size of local variables that

Variable	Description
	are declared by block outputs in the model cannot exceed `MaxStackSize` (in bytes). `MaxStackSize` can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for `MaxStackSize` is `rtInf`, that is, unlimited stack size. **Note:** Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the `MaxStackSize` calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.
`MaxStackVariableSize=`*`N`*	When the **Enable local block outputs** check box is selected, this limits the size of a local block output variable declared in the code to `N` bytes, where `N>0`. A variable whose size exceeds `MaxStackVariableSize` is allocated in global, rather than local, memory. The default is 4096.
`WarnNonSaturatedBlocks=`*`value`*	Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (unchecked) in their dialog. These are the options: • `0` — Warning is not displayed. • `1` — Displays one warning for the model during code generation • `2` — Displays one warning that contains a list of offending blocks

Set Target Language Compiler Options

You can specify TLC command line options for code generation using the model parameter `TLCOptions` in a `set_param` function call. For information about these options, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).

Use makecfg to Customize Generated Makefiles for S-Functions

With the toolchain and template makefile approach for building code, you can customize generated makefiles for S-functions. Through the customization, you can specify additional items for the S-function build process:

- Source files and folders
- Include files and folders
- Library names
- Preprocessor macro definitions
- Compiler flags
- Link objects

1. To customize the generated makefile:
   - For all S-functions in the build folder (Simulink Coder), create a `makecfg.m` file.
   - For a specific S-function in the build folder, create a *`specificSFunction`*`_makecfg.m` file.
2. In the file that you create, use `RTW.BuildInfo (Simulink Coder)` functions to specify additional items for the S-function build process. For example, you can use:
   - `addCompileFlags` to specify compiler options.
   - `addDefines` to specify preprocessor macro definitions.
3. Save the created file in the build folder.

After code generation, in the build folder, the code generator searches for `makecfg.m` and *`specificSFunction`*`_makecfg.m` files. If the files are present in the build folder, the code generator uses these files to customize the generated makefile, *`model`*`.mk`.

For example, consider a build folder that contains `signalConvert.mexa64` (S-function binary file) and `signalConvert.tlc` (inlined S-function implementation) after the TLC phase (Simulink Coder) of the build process. The S-function requires an additional source code file, `filterV1.c`, which is located in `anotherFolder`. You can create a file, `signalConvert_makecfg.m`, that uses `RTW.BuildInfo` functions to specify `filterV1.c` for the build process.

```
function signalConvert_makecfg(objBuildInfo)
```

```
absolute = fullfile('$(START_DIR)', 'anotherFolder');

addIncludePaths(objBuildInfo, absolute);
addSourcePaths(objBuildInfo, absolute);
addSourceFiles(objBuildInfo,'filterV1.c');
```

Use rtwmakecfg.m API to Customize Generated Makefiles

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

About the rtwmakecfg Function

Using an `rtwmakecfg` function, you add this information to the makefile during the build operation for S-functions. The `rtwmakecfg` function is particularly useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

1. Create the MATLAB language `rtwmakecfg` function in the `rtwmakecfg.m` file. The code generator associates this file with your S-function based on its folder location. “Create the rtwmakecfg Function” on page 70-26 describes the requirements for the `rtwmakecfg` function and the data it returns.
2. If you are using the template makefile approach, modify your target's TMF such that it supports macro expansion for the information that the `rtwmakecfg` function returns. “Modify the Template Makefile for rtwmakecfg” on page 70-29 describes the required modifications. If you are using the toolchain approach, the information that the rtwmakecfg function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an `rtwmakecfg.m` file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the `rtwmakecfg` function.

Create the rtwmakecfg Function

Create the `rtwmakecfg.m` file containing the `rtwmakecfg` function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such as

`.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

Field	Description
`makeInfo.includePath`	A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.
`makeInfo.sourcePath`	A cell array that specifies additional source folder names, organized as a row vector. You must include the folder names of files entered into the **S-function modules** field on the S-Function Block Parameters dialog box or into the block's `SFunctionModules` parameter if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.
`makeInfo.sources`	A cell array that specifies additional source file names (C or C ++), organized as a row vector. Do not include the name of the S-function or any files entered into the **S-function modules** field on the S-Function Block Parameters dialog box or into the block's `SFunctionModules` parameter. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the `sourcePath` field.
`makeInfo.linkLibsObjs`	A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to incorporate source files from languages other than C and C++. This is possible if you first create a C compatible object file or library outside of the build process.
`makeInfo.precompile`	A Boolean flag that indicates whether the libraries specified in the `rtwmakecfg.m` file exist in a specified location (`precompile==1`) or if you must create the libraries in the build folder during the build process (`precompile==0`).

Field	Description
`makeInfo.library`	A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.

The `makeInfo.library` field consists of the following elements.

Element	Description
`makeInfo.library(n).Name`	A character array that specifies the name of the library (without an extension).
`makeInfo.library(n).Location`	A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of `makeInfo.precompile` in the preceding table. A target can use the `TargetPreCompLibLocation` parameter to override this value. See "Specify the Location of Precompiled Libraries" (Simulink Coder).
`makeInfo.library(n).Modules`	A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.

Note: The `makeInfo.library` field must fully specify each library and how to build it. The modules list in the `makeInfo.library(n).Modules` element cannot be empty. If you need to specify a link-only library, use the `makeInfo.linkLibsObjs` field instead.

Example:

```
disp(['Running rtwmakecfg from folder: ',pwd]);
   makeInfo.includePath = { fullfile(pwd, 'somedir2') };
   makeInfo.sourcePath = {fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3')};
   makeInfo.sources  = { 'src1.c', 'src2.cpp'};
   makeInfo.linkLibsObjs = { fullfile(pwd, 'somedir3', 'src3.object'),...
                             fullfile(pwd, 'somedir4', 'mylib.library')};
   makeInfo.precompile = 1;
   makeInfo.library(1).Name     = 'myprecompiledlib';
   makeInfo.library(1).Location = fullfile(pwd,'somdir2','lib');
   makeInfo.library(1).Modules  = {'srcfile1' 'srcfile2' 'srcfile3' };
```

Note: If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to "Enable Build Process for Folder Names with Spaces" (Simulink Coder).

Modify the Template Makefile for rtwmakecfg

To expand the information that an `rtwmakecfg` function generates, modify the following sections of your target's TMF:

- `Include Path`
- `C Flags` and/or `Additional Libraries`
- `Rules`

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in *`matlabroot`*`/rtw/c/grt` (open) or *`matlabroot`*`/rtw/c/ert` (open).

Add Folder Names to the Makefile Include Path

The following TMF code example adds folder names to the include path in the generated makefile:

```
ADD_INCLUDES = \
|>START_EXPAND_INCLUDES<|   -I|>EXPAND_DIR_NAME<| \
|>END_EXPAND_INCLUDES<|
```

Additionally, the `ADD_INCLUDES` macro must be added to the `INCLUDES` line.

```
INCLUDES = -I. -I.. $(MATLAB_INCLUDES) $(ADD_INCLUDES) $(USER_INCLUDES)
```

Add Library Names to the Makefile

The following TMF code example adds library names to the generated makefile.

```
LIBS =
|>START_PRECOMP_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_EXPAND_LIBRARIES<|
```

For more information, see "Control Library Location and Naming During Build" on page 70-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```
|>START_EXPAND_RULES<|
$(BLD)/%.o: |>EXPAND_DIR_NAME<|/%.c $(SRC)/$(MAKEFILE) rtw_proj.tmw
    @$(BLANK)
    @echo ### "|>EXPAND_DIR_NAME<|\$*.c"
    $(CC) $(CFLAGS) $(APP_CFLAGS) -o $(BLD)$(DIRCHAR)$*.o \
    |>EXPAND_DIR_NAME<|$(DIRCHAR)$*.c > $(BLD)$(DIRCHAR)$*.lst
|>END_EXPAND_RULES<|

|>START_EXPAND_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<|    |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
    @$(BLANK)
    @echo ### Creating $@
    $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_EXPAND_LIBRARIES<|

|>START_PRECOMP_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<|    |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
    @$(BLANK)
    @echo ### Creating $@
    $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_PRECOMP_LIBRARIES<|
```

Customize Build Process with STF_make_rtw_hook File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

In this section...

The STF_make_rtw_hook File

You can modify hook methods in a file generically referred to as *STF*`_make_rtw_hook.m`, where *STF* is the name of a system target file, such as `ert` or `mytarget`. This file implements a function, *STF*`_make_rtw_hook`, that dispatches to a specific action, depending on the `hookMethod` argument passed in.

The build process calls *STF*`_make_rtw_hook`, passing in the`hookMethod` argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an *STF*`_make_rtw_hook.m` for each reference model as required. The build process calls each *STF*`_make_rtw_hook` for reference models, processing these files recursively (in dependency order).

Conventions for Using the STF_make_rtw_hook File

For the build process to call the *STF*`_make_rtw_hook`, check that the following conditions are met:

- The *STF*`_make_rtw_hook.m` file is on the MATLAB path.

- The file name is the name of your system target file (`STF`), appended to the text `_make_rtw_hook.m`. For example, if you generate code with a custom system target file `mytarget.tlc`, name your hook file `mytarget_make_rtw_hook.m`, and name the hook function implemented within the file `mytarget_make_rtw_hook`.
- The hook function implemented in the file uses the function prototype described in "STF_make_rtw_hook.m Function Prototype and Arguments" on page 70-32.

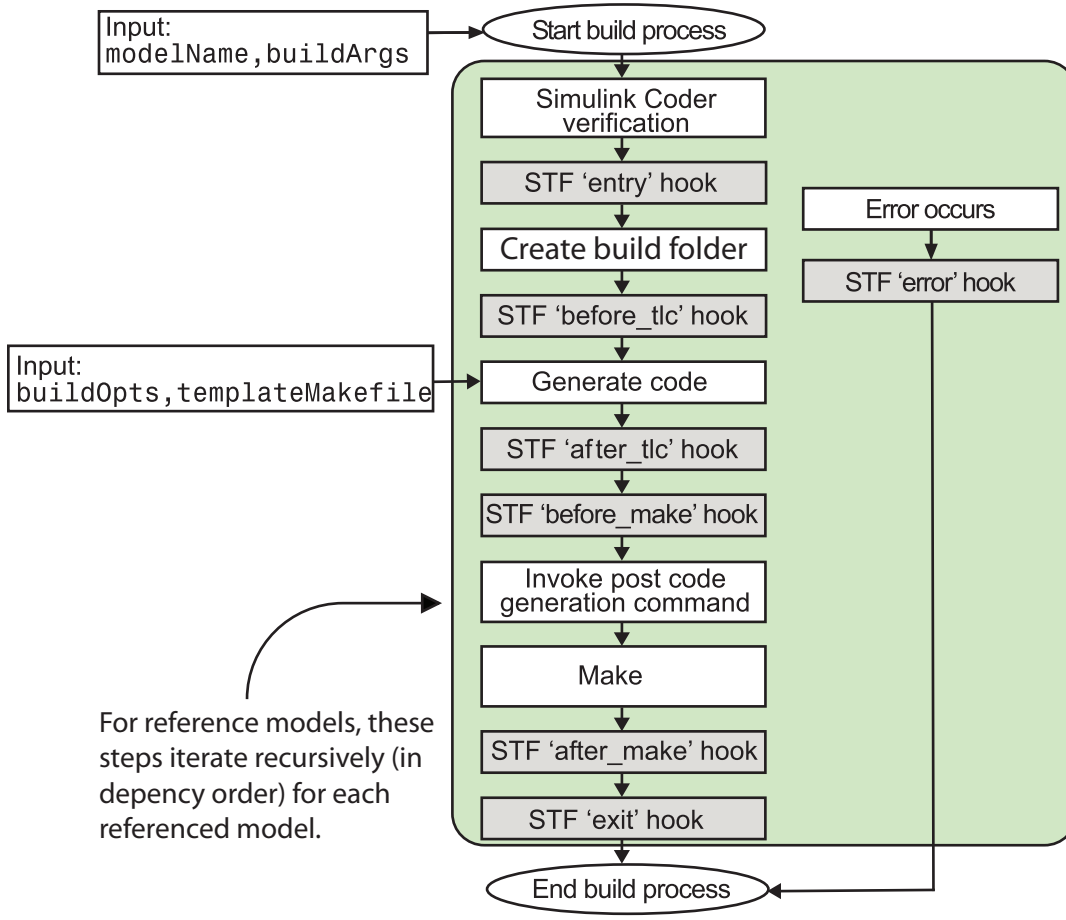
STF_make_rtw_hook.m Function Prototype and Arguments

The function prototype for *`STF`*`_make_rtw_hook` is:

```
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile,
buildOpts, buildArgs, buildInfo)
```

The arguments are defined as:

- `hookMethod`: Character vector specifying the stage of build process from which the *`STF`*`_make_rtw_hook` function is called. The following flowchart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. The *`STF`*`_make_rtw_hook` function dispatches to the relevant code with a `switch` statement.



- `modelName`: Character vector specifying the name of the model. Valid at all stages of the build process.
- `rtwRoot`: Reserved.
- `templateMakefile`: Name of template makefile.
- `buildOpts`: A MATLAB structure containing the fields described in the following list. Valid for the `'before_make'`, `'after_make'`, and `'exit'` stages only. The `buildOpts` fields include:
  - `modules`: Character vector specifying a list of additional files to compile.

  - `codeFormat`: Character vector specifying the value of the `CodeFormat` TLC variable for the target. (ERT-based targets must use the `'Embedded-C'` value for the `CodeFormat` TLC variable and use the corresponding `'ert.tlc'` value in the `rtwgensettings.DerivedFrom` field.)
  - `noninlinedSFcns`: Cell array specifying a list of noninlined S-functions in the model.
  - `compilerEnvVal`: Character vector specifying the compiler environment variable value (for example, `C:\Applications\Microsoft Visual`).
- `buildArgs`: Character vector containing the argument to `make_rtw`. When you invoke the build process, `buildArgs` is copied from the argument following `"make_rtw"` in the **Configuration Parameters**+**Code Generation**+**Make command** field.

  For example, the following make arguments from the **Make command** field

  ```
  make_rtw VAR1=0 VAR2=4
  ```

  generate the following:

  ```
  % make -f untitled.mk VAR1=0 VAR2=4
  ```

  The `buildArgs` argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the `make_rtw` call. To provide custom definitions (for example, `VAR1=0 VAR2=4`) on the compiler command line that apply for both TMF approach and toolchain approach builds, use the **Configuration Parameters** > **Code Generation** > **Custom Code** > **Defines** field.
- `buildInfo`: The MATLAB structure that contains the model build information fields. Valid for the `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'` stages only. For information about these fields and functions to access them, see “Build Process Customization” (Simulink Coder).

Applications for STF_make_rtw_hook.m

Here are some examples of how you might apply the *STF*_make_rtw_hook.m hook methods.

In general, you can use the 'entry' hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the 'entry' hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, 'before_tlc', 'after_tlc', 'before_make', 'after_make', 'exit', and 'error' are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you could use the *STF*_make_rtw_hook.m file at a stage after 'entry' to obtain the path to the build folder. At the 'exit' stage, you could then locate generated code files within the build folder and check them into your version control system. You might use 'error' to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

Note: The build process temporarily changes the MATLAB working folder to the build folder for stages 'before_make', 'after_make', 'exit', and 'error'. Your *STF*_make_rtw_hook.m file must not make incorrect assumptions about the location of the build folder. At a point after the 'entry' stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable buildDirPath.

```
buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');
```

Control Code Regeneration Using STF_make_rtw_hook.m

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on the criteria, see “Control Regeneration of Top Model Code” on page 40-48.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including *STF*`_make_rtw_hook` functions and the post code generation command. The following mechanisms allow you to perform actions related to code regeneration in the *STF*`_make_rtw_hook` functions:

- To force code regeneration, use the following function call from the `'entry'` hook:

  ```
  rtw.targetNeedsCodeGen('set', true);
  ```

- In hooks from `'before_tlc'` through `'exit'`, the `buildOpts` structure passed to the hook has a Boolean field `codeWasUpToDate`. The field is set to `true` if model code was up to date and code was not regenerated, or `false` if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

  ```
  ...
  case 'before_tlc'
      if buildOpts.codeWasUpToDate
          %Perform hook actions for up to date model
      else
          %Perform hook actions for full code generation
      end
  ...
  ```

Use STF_make_rtw_hook.m for Your Build Procedure

To create a custom *STF*`_make_rtw_hook` hook file for your build procedure, copy and edit the example `ert_make_rtw_hook.m` file, which is located in the folder*`matlabroot`*`/toolbox/coder/embeddedcoder` (open), as follows:

1. Copy `ert_make_rtw_hook.m` to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in "Conventions for Using the STF_make_rtw_hook File" on page 70-31. For example, to use it with the GRT target `grt.tlc`, rename it to `grt_make_rtw_hook.m`.
2. Rename the `ert_make_rtw_hook` function within the file to match the file name.
3. Implement the hooks that you require by adding code to case statements within the `switch hookMethod` statement.

Customize Build Process with sl_customization.m

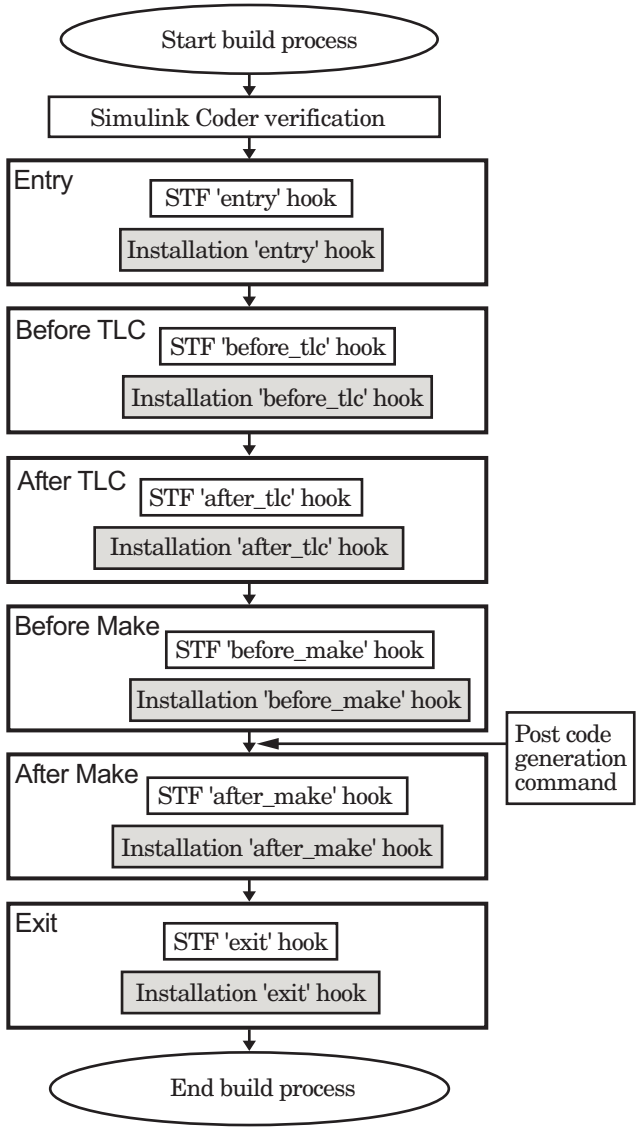
The Simulink customization file `sl_customization.m` is a mechanism that allows you to use MATLAB to customize the build process interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see "Registering Customizations" (Simulink).

In this section...

The sl_customization.m File

The `sl_customization.m` file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through `sl_customization.m` complement System Target File (STF) hooks (described in "Customize Build Process with STF_make_rtw_hook File" on page 70-31) and post-code generation commands (described in "Customize Post-Code-Generation Build Processing" on page 70-14).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.



Start build process
Simulink Coder verification
Entry
STF 'entry' hook
Installation 'entry' hook
Before TLC
STF 'before_tlc' hook
Installation 'before_tlc' hook
After TLC
STF 'after_tlc' hook
Installation 'after_tlc' hook
Before Make
STF 'before_make' hook
Installation 'before_make' hook
Post code generation command
After Make
STF 'after_make' hook
Installation 'after_make' hook
Exit
STF 'exit' hook
Installation 'exit' hook
End build process

Register Build Process Hook Functions Using sl_customization.m

To register installation-level hook functions that will be invoked during the build process, you create a MATLAB function called `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

  Registers the MATLAB hook script or function specified by `hook` for the build process stage represented by `hookType`. The valid values for `hookType` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'`.

Your instance of the `sl_customization` function should use this method to register installation-specific hook functions.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, you must restart the Simulink session or enter the following command in the Command Window to enable the changes:

```
sl_refresh_customizations
```

Variables Available for sl_customization.m Hook Functions

The following variables are available for `sl_customization.m` hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code (valid only for the `'after_make'` stage)

A hook script can directly access the valid variables. A hook function can pass the valid variables as arguments to the function. For example:

```
hObj.addUserHook('after_make', 'afterMakeFunction(modelName,dependencyObject);');
```

Example Build Process Customization Using sl_customization.m

The `sl_customization.m` file shown in Example 1: sl_customization.m for Build Process Customizations uses the `addUserHook` method to specify installation-specific build process hooks to be invoked at the `'entry'` and `'after_tlc'` stages of the build process. For the hook function source code, see Example 2: CustomRTWEntryHook.m and Example 3: CustomRTWPostProcessHook.m.

Example 1: sl_customization.m for Build Process Customizations

```
function sl_customization(cm)
% Register user customizations

% Get default (factory) customizations
hObj = cm.RTWBuildCustomizer;

% Register build process hooks
hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName);');
hObj.addUserHook('after_tlc', 'CustomRTWPostProcessHook(modelName);');

end
```

Example 2: CustomRTWEntryHook.m

```
function [str, status] = CustomRTWEntryHook(modelName)
str =sprintf('Custom entry hook for model ''%s.''',modelName);
disp(str)
status =1;
```

Example 3: CustomRTWPostProcessHook.m

```
function [str, status] = CustomRTWPostProcessHook(modelName)
str =sprintf('Custom post process hook for model ''%s.''',modelName);
disp(str)
status =1;
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages will appear in the displayed output for builds. For example, if you open the ERT-based model `rtwdemo_udt`, open the **Code Generation** pane of the Configuration Parameters dialog box, and press **Ctrl+B** to initiate a build, the following messages are displayed:

```
>> rtwdemo_udt

### Starting build procedure for model: rtwdemo_udt
Custom entry hook for model 'rtwdemo_udt.'
Custom post process hook for model 'rtwdemo_udt.'
```

```
### Successful completion of build procedure for model: rtwdemo_udt
>>
```

Replace STF_rtw_info_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF*`_rtw_info_hook.m`). The *STF*`_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The *STF*`_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your *STF*`_rtw_info_hook` file.

For backward compatibility, existing *STF*`_rtw_info_hook` files are available. However, you should convert your target and models to use of the **Hardware Implementation** pane. See “Configure Production and Test Hardware” (Simulink Coder).

Customize Build to Use Shared Utility Code

The shared utility folders (`slprj/`*`target`*`/_sharedutils`) typically store generated utility code that is common to a top model and the models it references. You can also force the build process to use a shared utilities folder for a standalone model. See "Specify Generated Code Interfaces" (Simulink Coder) for details.

If you want your target to support compilation of code generated in the shared utilities folder, you must modify your template makefile (TMF). The shared utilities folder is required to support model reference builds. See "Support Model Referencing" on page 71-83 to learn about additional updates for supporting model reference builds.

The exact syntax of the changes can vary due to differences in the `make` utility and compiler/archive tools used by your target. The examples below are based on the Free Software Foundation's GNU make utility. You can find the following updated TMF examples for GNU and Microsoft Visual C++ make utilities in the GRT and ERT target folders:

- GRT: *`matlabroot`*`/rtw/c/grt` (open)
  - `grt_lcc.tmf`
  - `grt_vc.tmf`
  - `grt_unix.tmf`
- ERT: *`matlabroot`*`/rtw/c/ert` (open)
  - `ert_lcc.tmf`
  - `ert_vc.tmf`
  - `ert_unix.tmf`

Use the GRT or ERT examples as a guide to the location, within the TMF, of the changes and additions described below.

Note The ERT-based TMFs contain extra code to handle generation of ERT S-functions and model reference simulation targets. Your target does not need to handle these cases.

Modify Template Makefiles to Support Shared Utilities

Make the following changes to your TMF to support the shared utilities folder:

1. Add the following make variables and tokens to be expanded when the makefile is generated:

```
SHARED_SRC      = |>SHARED_SRC<|
SHARED_SRC_DIR  = |>SHARED_SRC_DIR<|
SHARED_BIN_DIR  = |>SHARED_BIN_DIR<|
SHARED_LIB      = |>SHARED_LIB<|
```

   SHARED_SRC specifies the shared utilities folder location and the source files in it. A typical expansion in a makefile is

```
SHARED_SRC      = ../slprj/ert/_sharedutils/*.c
```

   SHARED_LIB specifies the library file built from the shared source files, as in the following expansion.

```
SHARED_LIB      = ../slprj/ert/_sharedutils/rtwshared.lib
```

   SHARED_SRC_DIR and SHARED_BIN_DIR allow specification of separate folders for shared source files and the library compiled from the source files. In the current release, TMFs use the same path, as in the following expansions.

```
SHARED_SRC_DIR  = ../slprj/ert/_sharedutils
SHARED_BIN_DIR  = ../slprj/ert/_sharedutils
```

2. Set the SHARED_INCLUDES variable according to whether shared utilities are in use. Then append it to the overall INCLUDES variable.

```
SHARED_INCLUDES =
ifneq ($(SHARED_SRC_DIR),)
SHARED_INCLUDES = -I$(SHARED_SRC_DIR)
endif

INCLUDES = -I. $(MATLAB_INCLUDES) $(ADD_INCLUDES) \
           $(USER_INCLUDES) $(SHARED_INCLUDES)
```

3. Update the SHARED_SRC variable to list shared files explicitly.

```
SHARED_SRC := $(wildcard $(SHARED_SRC))
```

4. Create a SHARED_OBJS variable based on SHARED_SRC.

```
SHARED_OBJS = $(addsuffix .o, $(basename $(SHARED_SRC)))
```

5. Create an OPTS (options) variable for compilation of shared utilities.

```
SHARED_OUTPUT_OPTS = -o $@
```

6. Provide a rule to compile the shared utility source files.

```
$(SHARED_OBJS) : $(SHARED_BIN_DIR)/%.o : $(SHARED_SRC_DIR)/%.c
 $(CC) -c $(CFLAGS) $(SHARED_OUTPUT_OPTS) $<
```

7 Provide a rule to create a library of the shared utilities. The following example is based on The Open Group UNIX platforms.

```
$(SHARED_LIB) : $(SHARED_OBJS)
   @echo "### Creating $@ "
   ar r $@ $(SHARED_OBJS)
   @echo "### Created  $@ "
```

8 Add `SHARED_LIB` to the rule that creates the final executable.

```
$(PROGRAM) : $(OBJS) $(LIBS) $(SHARED_LIB)
$(LD) $(LDFLAGS) -o $@ $(LINK_OBJS) $(LIBS) $(SHARED_LIB)\
    $(SYSLIBS)
@echo "### Created executable: $(MODEL)"
```

9 Remove explicit reference to `rt_nonfinite.c` or `rt_nonfinite.cpp` from your TMF. For example, change

```
ADD_SRCS = $(RTWLOG) rt_nonfinite.c
```

to

```
ADD_SRCS = $(RTWLOG)
```

Custom Target Development in Simulink Coder

About Embedded Target Development

Target files bundled with the code generator are suitable for many different applications and development environments. Third-party targets provide additional versatility. In addition, you have the option of implementing a custom target.

To implement a target based on the ARM Cortex®-A or ARM Cortex-M processor, install the corresponding support package and see the Target SDK: Embedded Coder Support Package for ARM Cortex-A Processors, "Develop a Target" (Embedded Coder Support Package for ARM Cortex-A Processors) or Embedded Coder Support Package for ARM Cortex-M Processors, "Develop a Target" (Embedded Coder Support Package for ARM Cortex-M Processors). Otherwise, use these functions and topics.

Custom Targets

You might want to implement a custom target for one of the following reasons:

- To enable end users to generate executable production code for a specific CPU or development board, using a specific development environment (compiler/linker/debugger).
- To support I/O devices on the target hardware by incorporating custom device driver blocks into your models.
- To configure the build process for a special compiler (such as a cross-compiler for an embedded microcontroller or DSP board) or development/debugging environment.

The code generator provides a point of departure for the creation of custom embedded targets, for the basic purposes above. This manual covers the tasks and techniques you need to implement a custom embedded target.

Types of Targets

The following sections describe several types of targets intended for different use cases

About Target Types

There is a progression of capabilities from baseline or rapid prototyping targets to production targets. Initially, you might want to implement a rapid prototyping target. Later, you can enhance the target to be more full-featured. For example, you might want to add support for software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation at some point for verifying your embedded target. The target types are not mutually exclusive. An embedded target can support more than one of these use cases, or additional uses not outlined here.

The discussion of target types is followed by "Recommended Features for Embedded Targets" on page 71-4, which contains a suggested list of features and general guidelines for embedded target development.

Rapid Prototyping Targets

A *rapid prototyping target* or baseline target offers a starting point for targeting a production processor. A rapid prototyping target integrates coded generator software with one or more popular cross-development environments (compiler/linker/debugger tool chains). A rapid prototyping target provides a starting point from which you can customize the target for application needs.

Target files provided for this type of target should be readable, easy to understand, and fully commented and documented. Specific attention should be paid to the interface to the intended cross-development environment. This interface should be implemented using the preferred approach for that particular development system. For example, some development environments use traditional make utilities, while others are based on project-file builds that can be automated under control of the code generator.

When you use a rapid prototyping target, you need to include your own device driver and legacy code and modify linker memory maps to suit your needs. You should be familiar with the targeted development system.

Production Targets

A *production target* supports embedded application development for a production processor. It includes the capability to create program executables that interact immediately with the external world. In general, ease of use is more important than simplicity or readability of generated code files, because it is assumed that you do not want or need to modify the files.

Desirable features for a production target include:

- Significant I/O driver support, provided out of the box
- Easy downloading of generated standalone executable programs with third-party debuggers
- User-controlled placement of an executable in FLASH or RAM memory
- Support for code visibility and tuning on target hardware

Verifying Targets With SIL and PIL Simulation

You can use software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation to verify generated code and validate the target compiler/processor environment.

You can use SIL and PIL simulation modes to verify automatically generated code by comparing the results with a normal mode simulation. With SIL, you can easily verify the behavior of production-intent source code on your host computer; however, it is generally not possible to verify exactly the same code that will subsequently be compiled for your target hardware because the code must be compiled for your host platform (i.e. a different compiler and different processor architecture than the target). With PIL simulation, you can verify exactly the same code that you intend to deploy in production, and you can run the code either on real target hardware or on an instruction set simulator.

For examples describing how to run processor-in-the-loop testing to verify a custom target, see “Sample Custom Targets” on page 71-9.

For more information on SIL and PIL simulation, see “SIL and PIL Simulations” on page 64-2.

HIL Simulation

A specialized use case is the generation of executables intended for use in *hardware-in-the-loop* (HIL) simulations. In a HIL simulation, parts of a pure simulation are gradually replaced with hardware components as components are refined and fabricated. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

Recommended Features for Embedded Targets

- "Deployment and Hardware Issues" on page 71-7

Basic Target Features

- You can base targets on the generic real-time (GRT) target or the Embedded Real-Time (ERT) target that is included in the Embedded Coder product.

  If your target is based on the ERT target, it should use `'Embedded-C'` value for the `CodeFormat` TLC variable, and it should inherit the options defined in the ERT target's system target file with the following lines in the TLC file:

  ```
  %% Assign code format
  %assign CodeFormat = "Embedded-C"
  %%-----------------------------
  /%
    BEGIN_RTW_OPTIONS
    rtwgensettings.DerivedFrom = 'ert.tlc';
    END_RTW_OPTIONS
  %/
  %%-----------------------------
  ```

  By following these recommendations, your target has the production code generation capabilities of the ERT target.

  See "Customize System Target Files" on page 71-29 for further details on the inheritance mechanism, setting the `CodeFormat`, and other details.

- The most fundamental requirement for an embedded target is that it generate a real-time executable from a model or subsystem. Typically, an embedded target generates a timer interrupt-based, bareboard executable (although targets can be developed for an operating system environment as well).

  Your target should support code generator concepts of single-tasking and multitasking solver modes for model execution. Tasking support is available with the ERT target, but you should thoroughly understand how it works before implementing an ERT-based target.

  For information on timer interrupt-based execution, see "Absolute and Elapsed Time Computation" (Simulink Coder) and "Asynchronous Events" (Simulink Coder).

- You should generate the target executable's main program module, rather than using a static main module (such as the static `rt_main.c` or `rt_cppclass_main.cpp` module provided with the software). A generated `main.c` or `.cpp` can be made much more readable and more efficient, since it omits preprocessor checks and other extra code.

For information on generated and static main program modules, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 49-2.

- Follow the guidelines in “Folder and File Naming Conventions” on page 71-11.

Integration with Target Development Environments

- Most cross-development systems run under a Microsoft Windows PC host. Your target should support the Windows operating system as the host environment.

  Some cross-development systems support one or more versions of The Open Group UNIX platforms, allowing for UNIX host support as well.
- Your embedded target must support at least one embedded development environment. The interface to a development environment can take one of several forms. The toolchain approach and template makefile approach generate standard makefiles to work with your development environment. For general information about these build approaches, see “Choose and Configure Build Process” (Simulink Coder). For detailed information about the structure of template makefiles, see “Customize Template Makefiles” on page 71-62.

  Another approach with IDE-based tools is to create a Microsoft Visual Studio Solution from your target for integration within a Visual Studio project.

  It is important to consider the license requirements and restrictions of the development environment vendor. You may need to modify files provided by the vendor and ship them as part of the embedded target.

  See “Interface to Development Tools” on page 71-104 for further information.

Observing Execution of Target Code

- Your target should support a mechanism you can use to observe the target code as it runs in real time (outside of a debugger).

  You can use the `rtiostream` API to implement a communication channel to enable exchange of data between different processes. For an example of creating a communication channel for target connectivity, see “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation”. This `rtiostream` communication channel is required to enable processor-in-the-loop (PIL) on a new target. See “Communications `rtiostream` API” on page 64-46.

One industry-standard approach is to use the CAN bus, with an ASAP2 file and CAN Calibration Protocol (CCP). There are several host-based graphical front-end tools available that connect to a CCP-enabled target and provide data viewing and parameter tuning. Supporting these tools requires implementation of CAN hardware drivers and CCP protocol for the target, as well as ASAP2 file generation. Your target can leverage the ASAP2 support provided with the code generator.

Another option is to support Simulink external mode over a serial interface (RS-232). See the "What You Can Do with a Host/Target Communication Channel" (Simulink Coder) for information on using the external mode API.

Deployment and Hardware Issues

- Device driver support is an important issue in the design of an embedded target. Device drivers are Simulink blocks that support either hardware I/O capabilities of the target CPU, or I/O features of the development board.

  If you are developing a rapid prototyping target, consider providing minimal driver support, on the assumption that end users develop their own drivers. If you are developing a production target, you should provide full driver support.

  See "Device Drivers" (Simulink Coder).

- Automatic download of generated code to the target hardware makes a target easier to use. Typically a debugger utility is used; if the chosen debugger supports command script files, this can be straightforward to implement. "STF_make_rtw_hook.m" on page 71-21 describes a mechanism to execute code from the build process. You can use this mechanism to make `system()` calls to invoke utilities such as a debugger. You can invoke other simple downloading utilities in a similar fashion.

  If your development system supports COM automation, you can control the download process by that mechanism. Using COM automation is discussed in "Interface to Development Tools" on page 71-104.

- Executables that are mapped to RAM memory are typical. You can provide optional support for FLASH or RAM placement of the executable by using your target's code generation options. To support this capability, you might need multiple linker command files, multiple debugger scripts, and possibly multiple makefiles or project files. Also include the ability to automatically switch between these files, depending on the RAM/FLASH option value.

- Select a popular, widely available evaluation or prototype board for your target processor. Consider enclosed and ruggedized versions of the target board. Also consider board level support for the various on-chip I/O capabilities of the target CPU, and the availability of development systems that support the selected board.

Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

1. Start by downloading the embedded targets development guide `zip` file from this web page:

   Is there an example guide on developing an embedded target...?

   The `zip` file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

   Read the example guide along with this document to understand the tasks for developing embedded targets.

2. For more detailed example files for specific processors, see:

   - Is there an example Freescale S12X target... using the Cosmic Compiler?
   - Is there an example Freescale S12X target... using the CodeWarrior Compiler?

   These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

   The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured

and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

3 You can watch videos showing overviews of both the example kits at the following links:

- `www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html`
- `www.mathworks.com/videos/programming-arm9-using-the-hitex-str9-comstick-68812.html`

For another example target for the ARM9 (STR9) processor, see Is there an example ARM9 (STR9) target... using the GNU ARM Compiler and Hitex STR9-comStick?.

If you have questions on specific targets, please email mytarget@mathworks.com.

The example kits and this document describe Embedded Coder features such as customized `ert` system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information to develop custom targets, configure folder usage, and use custom targets in the build process.

In this section...

Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use *only* lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do *not* place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the `matlabroot` folder). If you place your folder under `matlabroot` you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to the your MATLAB path. They also provide high-level descriptions of the files.

In this document, `mytarget` is a placeholder name that represents folders and files that use the target's name. The names `dev_tool1`, `dev_tool2`, and so on represent

subfolders containing files associated with development environments or tools. This document describes an example structure where the folder `mytarget` contains subfolders for `mytarget`, `blocks`, `dev_tool1`, `dev_tool2`. The top level folder `mytarget` is the *target root folder*.

Components of a Custom Target

Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in "Folder and File Naming Conventions" on page 71-11.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file (STF) to control the code generation process.
  - File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
  - Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an `info.xml` file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories.

Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
- User-written blocks (S-functions)
- Parameters of the model that are visible, and can be interfaced to, external code

Execution Support Files

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

Execution Support Files

You Provide...	The Code Generator Provides...
Customized main program	Generic main program
Timer interrupt handler to run model	Execution engine and integration solver (called by timer interrupt handler)
Other interrupt handlers	Example interrupt handlers (Asynchronous Interrupt blocks)
Device drivers	Example device drivers
Data logging, parameter tuning, signal monitoring, and external mode support	Data logging, parameter tuning, signal monitoring, and external mode APIs

User-Written Execution Support Files

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

- A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

  If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.

- The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

  If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

  Your main program typically is based on a generated or static main program. For details on the structure of the execution support files, code execution, and guidelines for customizing main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 49-2.

- *Device drivers*. Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.

- *Other interrupt handlers*. If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.

- *Data logging, parameter tuning, signal monitoring, and external mode support*. It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Data Exchange Interfaces” (Simulink Coder) for details.

Control Files

The code generation and build process is directed by a number of TLC and MATLAB files collectively called *control files*. This section introduces and summarizes the main control files.

Top-Level Control File (make_rtw)

The build process is initiated when you press **Ctrl+B**. At this point, the build process parses the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is `make_rtw`, and the default top-level control file for the build process is `make_rtw.m`.

Note: `make_rtw` is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how `make_rtw` works. (The details for target developers are described in "Target Development and the Build Process" on page 71-23.) You should not invoke `make_rtw` directly from MATLAB code, and you should not customize `make_rtw.m`.

The `make_rtw.m` file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. `make_rtw` does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the STF to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

System Target File (STF)

The Target Language Compiler (TLC) generates target-specific C or C++ code from an partial description of your Simulink block diagram (*`model`*`.rtw`). The Target Language Compiler reads *`model`*`.rtw` and executes a program consisting of several target files (`.tlc` files.) The STF, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized STF to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (*`matlabroot`*`/rtw/c/ert/ert.tlc`).

The detailed structure of the STF is described in "Customize System Target Files" on page 71-29.

Note: The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See "Customize System Target Files" on page 71-29.

Template Makefile (TMF)

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (`.mk` file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in *`matlabroot`*`/rtw/c/ert` (open). The standard TMFs are described in "Template Makefiles and Make Options" (Simulink Coder).

The detailed structure of the TMF is described in "Customize Template Makefiles" on page 71-62.

Note: The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See "Customize System Target Files" on page 71-29.

Hook Files

The build process allows you to supply optional *hook files* that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. "Folder and File Naming Conventions" on page 71-11 describes these requirements.

Key Folders Under Target Root (mytarget)

Target Root Folder (mytarget)

This folder contains the key subfolders for the target (see "Folder and File Naming Conventions" on page 71-11). You can also locate miscellaneous files (such as a `readme` file) in the target root folder. The following sections describe required and optional subfolders and their contents.

Target Folder (mytarget/mytarget)

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). "Key Files in Target Folder (mytarget/mytarget)" on page 71-19 summarizes the files that should be stored in `mytarget/mytarget`, and provides pointers to detailed information about these files.

Note `mytarget/mytarget` should be on the MATLAB path.

Target Block Folder (mytarget/blocks)

If your target includes device drivers or other blocks, locate the block implementation files in this folder. `mytarget/blocks` contains

- Compiled block MEX-files
- Source code for the blocks
- TLC inlining files for the blocks
- Library models for the blocks (if you provide your blocks in one or more libraries)

Note `mytarget/blocks` should be on the MATLAB path.

You can also store example models and supporting files in `mytarget/blocks`. Alternatively, you can create a `mytarget/mytargetdemos` folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment , you can create the files described below and store them in `mytarget/blocks`.

mytarget/blocks/slblocks.m

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

Example slblocks.m File

```
function blkStruct = slblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target\n for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'')';

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name    = 'Embedded Target for MYTARGET';
Browser(1).IsFlat  = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

mytarget/blocks/demos.xml

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

Example demos.xml File

```
<?xml version="1.0" encoding="utf-8"?>
<demos>
   <name>Embedded Target for MYTARGET</name>
   <type>simulink</type>
   <icon>$toolbox/matlab/icons/boardicon.gif</icon>
   <description source = "file">mytarget_overview.html</description>

   <demosection>
      <label>Multirate model</label>
      <demoitem>
         <label>MYTARGET demo</label>
         <file>mytarget_overview.html</file>
         <callback>mytarget_model</callback>
```

```
    </demoitem>
  </demosection>

</demos>
```

Development Tools Folder (mytarget/dev_tool1, mytarget/dev_tool2)

These folders contain files associated with specific development environments or tools (`dev_tool1`, `dev_tool2`, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the build process. `mytarget/dev_tool1` includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

Target Source Code Folder (mytarget/src)

This folder is optional. If the complexity of your target requires it, you can use `mytarget/src` to store common source code and configuration code (such as boot and startup code).

Key Files in Target Folder (mytarget/mytarget)

Introduction

The target folder `mytarget/mytarget` contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

mytarget.tlc

`mytarget.tlc` is the system target file (STF). Functions of the STF include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your STF on `ert.tlc`, the STF provided by Embedded Coder software.

"Customize System Target Files" on page 71-29 gives detailed information on the structure of the STF, and also gives instructions on how to customize an STF to

- Display your target in the System Target File Browser
- Add your own target options to the Configuration Parameters dialog box
- Tailor the code generation and build process to the requirements of your target

mytarget.tmf

`mytarget.tmf` is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see "Customize Template Makefiles" on page 71-62.

If your target development environment requires automation of a modern integrated development environment (IDE) rather than use of a traditional make utility, see "Interface to Development Tools" on page 71-104.

mytarget_genfiles.tlc

This file is optional. `mytarget_genfiles.tlc` is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See "Using mytarget_genfiles.tlc" on page 71-45 for details.

mytarget_main.c

A main program module is required for your target. To provide a main module, you can either

- Modify the `rt_main.c` or `rt_cppclass_main.cpp` module provided by the software

- Generate `mytarget_main.c` or `.cpp` during the build process

For a description of the operation of main programs, see "Deploy Generated Standalone Executable Programs To Target Hardware" on page 49-2. The section also contains guidelines for generating and modifying a main program module.

STF_make_rtw_hook.m

STF`_make_rtw_hook.m` is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. *STF*`_make_rtw_hook.m` implements a function that dispatches to a specific action depending on the `method` argument that is passed into it.

"Customize Build Process with STF_make_rtw_hook File" (Simulink Coder) describes the operation of the *STF*`_make_rtw_hook.m` hook file in detail.

STF_rtw_info_hook.m (obsolete)

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF*`_rtw_info_hook.m`). The *STF*`_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The *STF*`_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your *STF*`_rtw_info_hook` file.

For backward compatibility, existing *STF*`_rtw_info_hook` files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See "Configure Run-Time Environment Options" (Simulink Coder).

info.xml

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see "Display Custom Documentation" (MATLAB).

mytarget_overview.html

By convention, this file serves as home page for the target examples.

The <description> field in demos.xml should point to mytarget_overview.html (see “mytarget/blocks/demos.xml” on page 71-18).

Example mytarget_overview.html File

```
<html>
<head><title>Embedded Target for MYTARGET</title></head><body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target
for MYTARGET Example Model</p>

<p>This example provides a simple model that allows you to generate an executable
for a supported target board. You can then download and run the executable and
set breakpoints to study and monitor the execution behavior.</p>

</body>
</html>
```

Additional Files for Externally Developed Targets

Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within mytarget/mytarget, for the convenience of your users. The following sections describe the required materials and where to place them.

mytarget/mytarget/mytarget_setup.m

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function savepath in your mytarget_setup.m script. This function saves the added paths, so users need to run mytarget_setup.m only once.

The following code is an example mytarget_setup.m file.

```
function mytarget_setup()
curpath = pwd;
tgtpath = curpath(1:end-length('\mytarget'));
```

```
addpath(fullfile(tgtpath, 'mytarget'));
addpath(fullfile(tgtpath, 'dev_tool1'));
addpath(fullfile(tgtpath, 'blocks'));
addpath(fullfile(tgtpath, 'mytargetdemos'));
savepath;
disp('MYTARGET Target Path Setup Complete.');
```

mytarget/mytarget/doc

You should put the documentation related to your target in the folder `mytarget/mytarget/doc`.

Target Development and the Build Process

About the Build Process

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in "Code Generation" (Simulink Coder) and "Build Process" (Simulink Coder).

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with "Additional Information Passing Techniques" on page 71-26, describing assorted tips and tricks for passing information during the build process.

Build Process Phases and Information Passing

It is important to understand where (and when) the build process obtains required information. Sources of information include

- The *`model`*`.rtw` file, which provides information about the generating model. The information in *`model`*`.rtw` is available to target TLC files.

- The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the `rtwoptions` data structure. Use the **Configuration Parameters** > **Code Generation** > **Custom Code** > **Additional build information** > **Defines** field to define makefile tokens .
- The selected toolchain (for toolchain approach builds) or selected template makefile `.tmf` (for template makefile approach builds); these generate the model-specific makefile.
- Environment variables on the host computer. Environment variables provide additional information about installed development tools.
- Other target-specific files such as target-related TLC files, linker command files, or project files.

It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (`slbuild.m` or `rtwbuild.m`) to sequence through the build process for a target
- Conversion of the model into the TLC input file (*`model`*`.rtw`)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with `make` or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as and IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 71-19 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

Additional Information Passing Techniques

This section describes a number of useful techniques for passing information among different phases of the build process.

tlcvariable Field in rtwoptions Structure

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the `tlcvariable` field of the option's entry in the `rtwoptions` structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.

See “System Target File Structure” on page 71-30 for further information.

makevariable Field in rtwoptions Structure

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtwoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when make is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See “System Target File Structure” on page 71-30 for further information.

Accessing Host Environment Variables

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```
getenv ('MSDEVDIR')

ans =

D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```
%assign eVar = FEVAL("getenv","<varname>")
```

Supplying Development Environment Information to Your Template Makefile

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the make process to run these tools, the TMF must

be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as make variables. This allows the TMF to be tailored to specific needs.

Using MATLAB Application Data

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. If you are unfamiliar with this technique for creating graphical user interfaces, see "Store Data as Application Data" (MATLAB).

The following code examples illustrates the use of application data to pass information to TLC.

This file, `tlc2appdata.m`, stores the `data` passed in as application data under the name passed in (`appDataName`).

```
function k = tlc2appdata(appDataName,data)
  disp([mfilename,': ',appDataName,' ', data]);
  setappdata(0,appDataName,data);
  k = 0;  % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the `FEVAL` directive to invoke `tlc2appdata.m` to store arbitrary application data, under the name `z80`.

```
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata",myApp,myData)
```

To test this technique:

1. Create the `tlc2appdata.m` file as shown. Check that `tlc2appdata.m` is stored in a folder on the MATLAB path.
2. Create the TLC file as shown. Save it as `test.tlc`.
3. Enter the following command at the MATLAB prompt to execute the TLC file:

   ```
   tlc test.tlc
   ```

4 Get the application data at the MATLAB prompt:

```
k = getappdata(0,'z80')
```

The function returns the value 314159.

5 Enter the following command.

```
who
```

Note that application data is not stored in the MATLAB workspace. Also observe that the z80 data is not visible. Using application data in this way has the advantage that it does not clutter the MATLAB workspace. Also, it helps prevent you from accidently deleting your data, since it is not stored directly in the your workspace.

A real-world use of application data might be to collect information from the *`model`*`.rtw` file and store it for use later in the build process.

Adding Block-Specific Information to the Makefile

The `rtwmakecfg` mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in "Use rtwmakecfg.m API to Customize Generated Makefiles" (Simulink Coder).

More About

- "About Embedded Target Development" (Simulink Coder)

Customize System Target Files

This section provides information on the structure of the STF, guidelines for customizing an STF, and a basic tutorial that helps you get a skeletal STF up and running.

In this section...

Control Code Generation With the System Target File

The system target file (STF) exerts overall control of the code generation stage of the build process. The STF also lets you control the presentation of your target to the end user. The STF provides

- Definitions of variables that are fundamental to the build process, such as the value for the `CodeFormat` TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the STF is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying an STF, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” (Simulink Coder) and “Scripts vs. Functions” (MATLAB) describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the STFs provided with the code generator. Most of these files are stored in the target-specific folders under *`matlabroot`*`/`

`rtw/c` (open). Additional STFs are stored under *`matlabroot`*`/toolbox/rtw/targets` (open).

System Target File Naming and Location Conventions

An STF must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for STFs and related target files given in "Folder and File Naming Conventions" on page 71-11.

System Target File Structure

Overview

This section is a guide to the structure and contents of an STF. The following listing shows the general structure of an STF. Note that this is not a complete code listing of an STF. The listing consists of excerpts from each of the sections that make up an STF.

```
%%----------------------------
%% Header Comments Section
%%----------------------------
%% SYSTLC: Example Real-Time Target
%%    TMF: my_target.tmf MAKE: make_rtw EXTMODE: ext_comm
%% Inital comments contain directives for STF Browser.
%% Documentation, date, copyright, and other info may follow.
          ...
%selectfile NULL_FILE
         ...
%%----------------------------
%% TLC Configuration Variables Section
%%----------------------------
%% Assign code format, language, target type.
%%
%assign CodeFormat = "Embedded-C"
```

```
%assign TargetType = "RT"
%assign Language   = "C"
%%
%%-----------------------------
%% TLC Program Entry Point
%%-----------------------------
%% Call entry point function.
%include "codegenentry.tlc"
%%
%%-----------------------------
%% (OPTIONAL) Generate Files for Build Process
%%-----------------------------
%include "mytarget_genfiles.tlc"
%%-----------------------------
%% RTW_OPTIONS Section
%%-----------------------------
/%
  BEGIN_RTW_OPTIONS
  %% Define rtwoptions structure array. This array defines target-specific
  %% code generation variables, and controls how they are displayed.
  rtwoptions(1).prompt = 'example code generation options';
        ...
  rtwoptions(6).prompt = 'Show eliminated blocks';
  rtwoptions(6).type = 'Checkbox';
         ...
  %---------------------------------------%
  % Configure RTW code generation settings %
  %---------------------------------------%
         ...
  %%---------------------------
  %% rtwgensettings Structure
  %%---------------------------
  %% Define suffix text for naming build folder here.
  rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
  %% Callback compatibility declaration
  rtwgensettings.Version = '1';

  %% (OPTIONAL) target inheritance declaration
  rtwgensettings.DerivedFrom = 'ert.tlc';
  %% (OPTIONAL) other rtwGenSettings fields...
         ...
  END_RTW_OPTIONS
%/
%%-----------------------------
%% targetComponentClass - MATHWORKS INTERNAL USE ONLY
%% REMOVE NEXT SECTION FROM USER_DEFINED CUSTOM TARGETS
%%-----------------------------
/%
  BEGIN_CONFIGSET_TARGET_COMPONENT
  targetComponentClass = 'Simulink.ERTTargetCC';
  END_CONFIGSET_TARGET_COMPONENT
%/
```

If you are creating a custom target based on an existing STF, you must remove the `targetComponentClass` section (bounded by the directives

BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT). This section is reserved for the use of targets developed internally by MathWorks.

Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required information to the System Target File Browser and to the build process. Note that you must place the browser comments at the head of the file, before other comments or TLC statements.

The presence of the comments enables the code generator to detect STFs. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- SYSTLC: The descriptor that appears in the browser.
- TMF: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the "Template makefile" (Simulink Coder) field of the **Code Generation** pane of the Configuration Parameters dialog box.
- MAKE: `make` command to use during build process. When the target is selected, this command is displayed in the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box.
- EXTMODE: Name of external mode interface file (if any) associated with your target. If your target does not support external mode, use `no_ext_comm`.

The following header comments are from *`matlabroot`*`/rtw/c/ert/ert.tlc`.

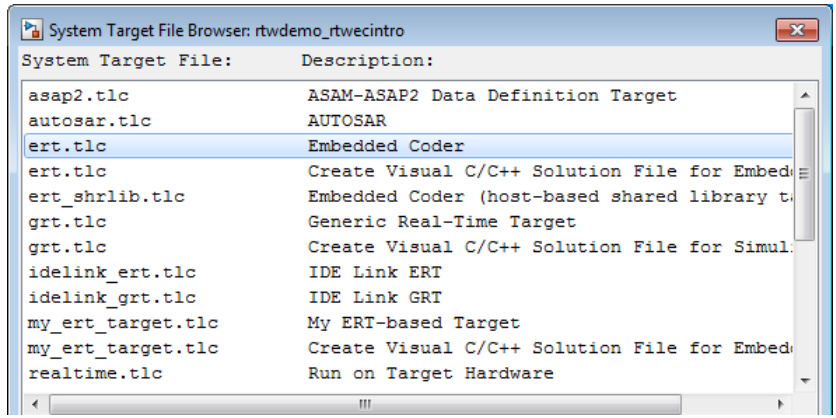
```
%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw \
%%    EXTMODE: ext_comm
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder\
%%    TMF: RTW.MSVCBuild MAKE: make_rtw EXTMODE: ext_comm
.
.
.
```

Note:

- Limitation: Each comment can only contain a maximum of two lines, as shown in the preceding example.
- If you do not specify the TMF or EXTMODE fields in the system target file, the file is still valid. To change the values for the parameters **Template makefile**

(`TemplateMakefile`) and **External mode** (`ExtMode`), you can instead use the callback function specified by `rtwgensettings.SelectCallback`.

Note that you can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates and builds a Microsoft Visual C++ Solution (`.sln`) file. The figure below shows how these configurations appear in the System Target File Browser.



See “Create a Custom Target Configuration” on page 71-48 for an example of customized header comments.

TLC Configuration Variables

This section of the STF assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (`ert.tlc`). It is especially important that your STF use the `'Embedded-C'` value for the `CodeFormat` TLC variable and uses the corresponding `rtwgensettings.DerivedFrom = 'ert.tlc'` in the `RTW_OPTIONS` section of the TLC file. Verify that values are assigned to the following variables:

- `CodeFormat`: The `CodeFormat` TLC variable selects generated code features. The `'Embedded-C'` value for this variable is used by the ERT target. Your ERT-based

target should specify `'Embedded-C'` as the value for `CodeFormat`. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

For information on other values for the `CodeFormat` TLC variable, see "Compare System Target File Support" (Simulink Coder).

- `Language`: The only valid value is `C`, which enables support for `C` or `C++` code generation as specified by the configuration parameter `TargetLang`.
- `TargetType`: The code generator defines the preprocessor symbols `RT` and `NRT` to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The `TargetType` variable determines whether `RT` or `NRT` is defined.

  Most targets are intended to generate real-time code. They assign `TargetType` as follows.

  ```
  %assign TargetType = "RT"
  ```

  Some targets, such as the model reference simulation target, accelerated simulation target, RSim target, and S-function target, generate code for use in nonreal time only. Such targets assign `TargetType` as follows.

  ```
  %assign TargetType = "NRT"
  ```

TLC Program Entry Point and Related %includes

The code generation process normally begins with `codegenentry.tlc`. The STF invokes `codegenentry.tlc` as follows.

```
%include "codegenentry.tlc"
```

Note `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your STF. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- "Using mytarget_genfiles.tlc" on page 71-45 for an example of custom TLC code for execution after the main code generation entry point.
- "Target Development and the Build Process" on page 71-23 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See "TLC Files" (Simulink Coder) for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.
- `commonsetup.tlc`: sets up global variables.
- `commonentry.tlc`: starts the process of generating code.

RTW_OPTIONS Section

The `RTW_OPTIONS` section is bounded by the directives:

```
/%
  BEGIN_RTW_OPTIONS
.
.
.
  END_RTW_OPTIONS
%/
```

The first part of the `RTW_OPTIONS` section defines an array of `rtwoptions` structures. This structure is discussed in "Using rtwoptions to Display Custom Target Options" on page 71-38.

The second part of the `RTW_OPTIONS` section defines `rtwgensettings`, a structure defining the build folder name and other settings for the code generation process. See "rtwgensettings Structure" on page 71-35 for information about `rtwgensettings`.

rtwgensettings Structure

The final part of the STF defines the `rtwgensettings` structure. This structure stores information that is written to the *`model`*`.rtw` file and used by the build process. The `rtwgensettings` fields of most interest to target developers are

- `rtwgensettings.Version`: Use this property to enable `rtwoptions` callbacks and to use the Callback API in `rtwgensettings.SelectCallback`.

  Note: To use callbacks, you *must* set:

  ```
  rtwgensettings.Version = '1';
  ```

  Add the statement above to the **Configure RTW code generation settings** section of the system target file.
- `rtwgensettings.DerivedFrom`: This structure field defines the system target file from which options are to be inherited. See "Inheriting Target Options" on page 71-44.
- `rtwgensettings.SelectCallback`: This structure field specifies a `SelectCallback` function. You must set `rtwgensettings.Version = '1';` or your callback will be ignored. `SelectCallback` is associated with the target rather than with any of its individual options. The `SelectCallback` function is triggered when the user selects a target with the System Target File browser.

  The `SelectCallback` function is useful for setting up (or disabling) configuration parameters specific to the target.

  The following code installs a `SelectCallback` function:

  ```
  rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `SelectCallback` function `(hDlg, hSrc)` are handles to private data used by the callback API functions.

  Note If you have developed a custom target and you want it to be compatible with model referencing, you must implement a `SelectCallback` function to declare model reference compatibility. See "Support Model Referencing" on page 71-83.
- `rtwgensettings.ActivateCallback`: this property specifies an `ActivateCallback` function. The `ActivateCallback` function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

  The following code installs an `ActivateCallback` function:

  ```
  rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
  ```

The arguments to the `ActivateCallback` function `(hDlg,hSrc)` are handles to private data used by the callback API functions.

- `rtwgensettings.PostApplyCallback`: this property specifies a `PostApplyCallback` function. The `PostApplyCallback` function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration Parameters dialog box. The `PostApplyCallback` function is called after the changes have been applied to the configuration set.

  The following code installs an `PostApplyCallback` function:

  ```
  rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `PostApplyCallback` function `(hDlg, hSrc)` are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: Most targets define a folder name suffix that identifies build folders created by the target. The build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name to form the name of the build folder. For example, if you define `rtwgensettings.BuildDirSuffix` as follows

  ```
  rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
  ```

  the build folders are named *`model`*`_mytarget_rtw`.

Additional Code Generation Options

"Configure Generated Code with TLC" (Simulink Coder) describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```
set_param(modelName,'TLCOptions','-aVariable=val');
```

(For more information, see "Specify TLC for Code Generation" (Simulink Coder).)

However, the preferred approach is to assign these variables in the STF using statements of the form:

```
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the STF after the comment **Configure RTW code generation settings**.

Model Reference Considerations

See “Support Model Referencing” on page 71-83 for important information on STF and other modifications you may need to make to support the code generator model referencing features.

Define and Display Custom Target Options

Using rtwoptions to Display Custom Target Options

You control the options to display in the **Code Generation** pane of the Configuration Parameters dialog box by customizing the `rtwoptions` structure in your system target file.

The fields of the `rtwoptions` structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the `rtwoptions` structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the `rtwoptions` structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (grayed-out) state. If an option is enabled, the user can change the option value.

You can also use the `rtwoptions` structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 71-42 for details.

The elements of the `rtwoptions` structure array are organized into groups. Each group of items begins with a header element of type `Category`. The default field of a `Category` header must contain a count of the remaining elements in the category.

The `Category` header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table rtwoptions Structure Fields Summary summarizes the fields of the `rtwoptions` structure.

Example rtwoptions Structure

The following `rtwoptions` structure is excerpted from an example system target file, *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The code defines an `rtwoptions` structure array. The default field of the first (header) element is set to `4`, indicating the number of elements that follow the header.

```
  rtwoptions(1).prompt        = 'userPreferred target options (I)';
  rtwoptions(1).type          = 'Category';
  rtwoptions(1).enable        = 'on';
  rtwoptions(1).default       = 4;   % number of items under this category
                                     % excluding this one.
  rtwoptions(1).popupstrings  = '';  % At the first item, user has to
  rtwoptions(1).tlcvariable   = '';  % initialize all supported fields
  rtwoptions(1).tooltip       = '';
  rtwoptions(1).callback      = '';
  rtwoptions(1).makevariable  = '';

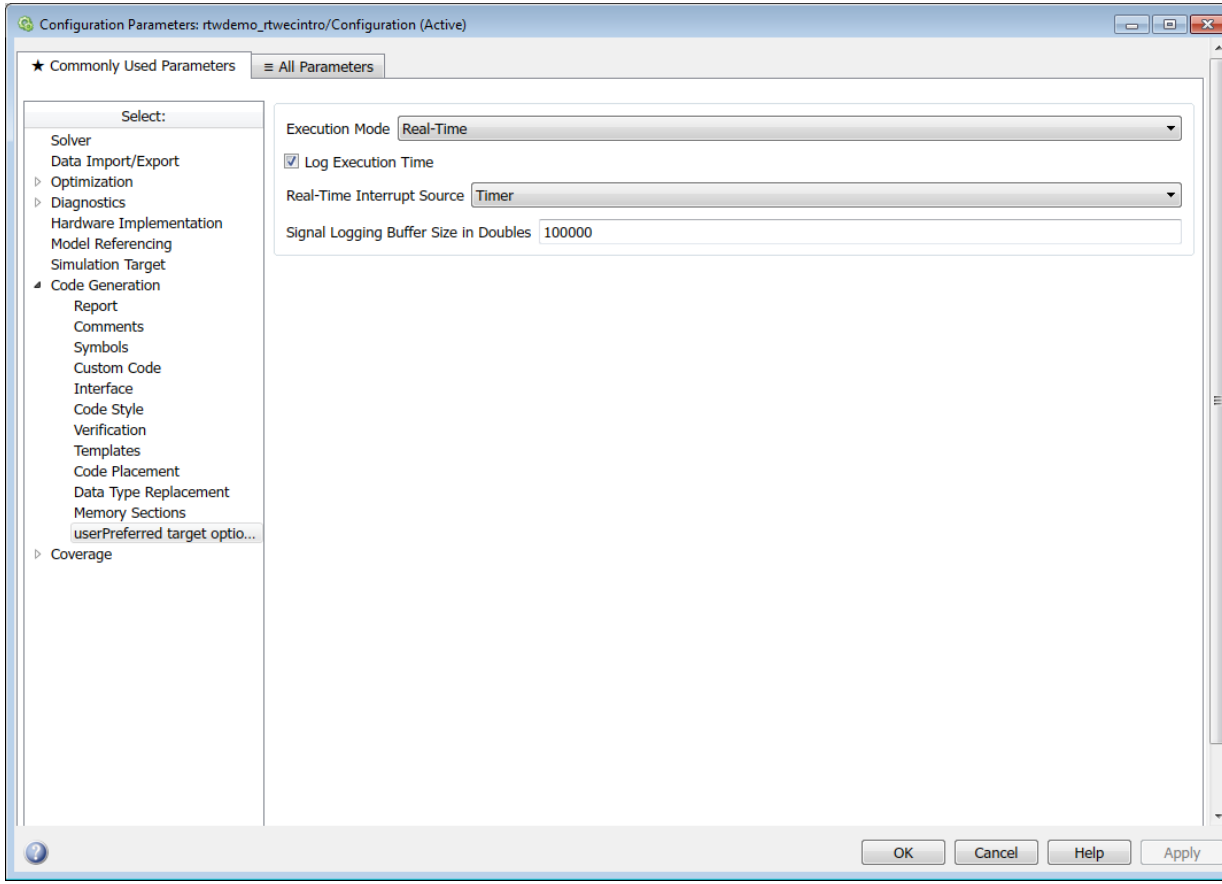
  rtwoptions(2).prompt        = 'Execution Mode';
  rtwoptions(2).type          = 'Popup';
  rtwoptions(2).default       = 'Real-Time';
  rtwoptions(2).popupstrings  = 'Real-Time|UserDefined';
  rtwoptions(2).tlcvariable   = 'tlcvariable1';
  rtwoptions(2).tooltip       = ['See this text as tooltip'];

  rtwoptions(3).prompt        = 'Log Execution Time';
  rtwoptions(3).type          = 'Checkbox';
  rtwoptions(3).default       = 'on';
  rtwoptions(3).tlcvariable   = 'RL32LogTETModifier';
  rtwoptions(3).tooltip       = ['']; % no tooltip

  rtwoptions(4).prompt        = 'Real-Time Interrupt Source';
  rtwoptions(4).type          = 'Popup';
  rtwoptions(4).default       = 'Timer';
  rtwoptions(4).popupstrings  = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
  rtwoptions(4).tlcvariable   = 'tlcvariable3';
  rtwoptions(4).callback      = 'usertargetcallback(hDlg, hSrc, ''tlcvariable3'')';
  rtwoptions(4).tooltip       = [''];
  rtwoptions(4).tooltip       = ['See TLC file for how to use reserved '...
    ' keyword ''hDlg'', and ''hSrc''.'];
...
  rtwoptions(5).prompt        = 'Signal Logging Buffer Size in Doubles';
  rtwoptions(5).type          = 'Edit';
```

```
rtwoptions(5).default       = '100000';
rtwoptions(5).tlcvariable   = 'tlcvariable2';
rtwoptions(5).tooltip       = [''];
```

The first element adds a **userPreferred target options (I)** pane under **Code Generation** in the Configuration Parameters dialog box. The pane displays the options defined in `rtwoptions(2)`, `rtwoptions(3)`, `rtwoptions(4)`, and `rtwoptions(5)`.



If you want to define a large number of options, you can define multiple `Category` groups within a single system target file.

Note the `rtwoptions` structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your `rtwoptions` structure

definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about `usertarget.tlc` and the example callback files provided with it, see "Example System Target File With Customized rtwoptions" on page 71-43. For more examples of target-specific `rtwoptions` definitions, see the *`target`*`.tlc` files under *`matlabroot`*`/rtw/c` (open).

rtwoptions Structure Fields Summary lists the fields of the `rtwoptions` structure.

rtwoptions Structure Fields Summary

Field Name	Description
`callback`	For examples of callback usage, see "Example System Target File With Customized rtwoptions" on page 71-43.
`closecallback` `(obsolete)`	Do not use `closecallback`. Use `rtwgensettings.PostApplyCallback` instead (see "rtwgensettings Structure" on page 71-35). `closecallback` is ignored. For examples of callback usage, see "Example System Target File With Customized rtwoptions" on page 71-43.
`default`	Default value of the option (empty if the `type` is `Pushbutton`).
`enable`	Must be `'on'` or `'off'`. If `'on'`, the option is displayed as an enabled item; otherwise, as a disabled item.
`makevariable`	Template makefile token (if any) associated with the option. The `makevariable` is expanded during processing of the template makefile. See "Template Makefile Tokens" on page 71-62.
`modelReferenceParameter-Check`	Specifies whether the option must have the same value in a referenced model and its parent model. If this field is unspecified or has the value `'on'` the option values must be same. If the field is specified and has the value `'off'` the option values can differ. See "Controlling Configuration Option Value Agreement" on page 71-88.
`NonUI`	Element that is not displayed, but is used to invoke a close or open callback. See "NonUI Elements" on page 71-42.
`opencallback`	Do not use `opencallback`.

Field Name	Description
`(obsolete)`	Use `rtwgensettings.SelectCallback` instead (see "rtwgensettings Structure" on page 71-35). For examples of callback usage, see "Example System Target File With Customized rtwoptions" on page 71-43.
`popupstrings`	If `type` is `Popup`, `popupstrings` defines the items in the menu. Items are delimited by the `"|"` (vertical bar) character. The following example defines the items of the **MAT-file variable name modifier** menu used by the GRT target. `'rt_|_rt|none'`
`prompt`	Label for the option.
`tlcvariable`	Name of TLC variable associated with the option.
`tooltip`	Help text displayed when mouse is over the item.
`type`	Type of element: `Checkbox`, `Edit`, `NonUI`, `Popup`, `Pushbutton`, or `Category`.

NonUI Elements

Elements of the `rtwoptions` array that have type `NonUI` exist solely to invoke callbacks. A `NonUI` element is not displayed in the Configuration Parameters dialog box. You can use a `NonUI` element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, "Example System Target File With Customized rtwoptions" on page 71-43 for an example.

Note: The default value of a `NonUI` element determines the set of values allowed for that element.

- If the default value is `'0'` or `'1'`, the element stores a Boolean value.
- If the default value contains an integer other than `'0'` or `'1'`, the element stores a value of type `int32`.
- If the default value does not contain an integer, the element is evaluated as a character vector.

Example System Target File With Customized rtwoptions

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the `rtwoptions` structure to display and process custom options on the **Code Generation** pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

`matlabroot``/toolbox/rtw/rtwdemos/rtwoptions_demo`

The example target files include:

- `usertarget.tlc`: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.
- `usertargetcallback.m`: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, `usertarget.tlc`: illustrates the use of `rtwoptions` to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, `usertargetcallback.m`. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

1. Make *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwoptions_demo` (open) your working folder.
2. Open a model of your choice.
3. Open the Configuration Parameters dialog box and select the **Code Generation** pane.
4. Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
5. Observe that the **Code Generation** pane contains a custom sub-tab: **userPreferred target options (I)**.

6 As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB Command Window. These messages are printed from code in the STF, or from callbacks invoked from the STF.

Inheriting Target Options

`ert.tlc` provides a basic set of Embedded Coder code generation options. If your target is based on `ert.tlc`, your STF should normally inherit the options defined in ERT.

Use the `rtwgensettings.DerivedFrom` field in the `rtwgensettings` structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the `rtwgensettings.DerivedFrom` field value as in the following example:

```
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where `stf` is the name of the system target file from which options are to be inherited. For example:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from `stf.tlc` automatically. If `stf.tlc` is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

Handling Unsupported Options

If your target does not support all of the options inherited from `ert.tlc`, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the **Code Generation** pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the `rtwoptions` structure in the STF. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and simply assign the TLC variable `CombineOutputUpdateFcns` to `on`. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are *not* to be combined. Less efficient code is generated as a result.

Tips and Techniques for Customizing Your STF

Introduction

The following sections include information on techniques for customizing your STF, including

- How to invoke custom TLC code from your STF
- Approaches to supporting multiple development environments

Required and Recommended %includes

If you need to implement target-specific code generation features, we recommend that your STF include the TLC file `mytarget_genfiles.tlc`.

Once your STF has set up the required TLC environment, you must include `codegenentry.tlc` to start the standard code generation process.

`mytarget_genfiles.tlc` provides a mechanism for executing custom TLC code after the main code generation entry point. See "Using mytarget_genfiles.tlc" on page 71-45.

Using mytarget_genfiles.tlc

`mytarget_genfiles.tlc` (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process, or after the executable is created. This is done with the *STF*_make_rtw_hook.m mechanism, as described in "Customize Build Process with STF_make_rtw_hook File" (Simulink Coder).

The following TLC code shows an example mytarget_genfiles.tlc file.

```
%selectfile NULL_FILE

%assign ModelName = CompiledModel.Name

%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"

%if RTWVerbose
   %selectfile STDOUT
   ### Creating %<model_script_file>
   %selectfile NULL_FILE
%endif

%include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
%<CreateDebuggerScript()>
%closefile bld_file
```

Handling Aliases for Target Option Values

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (ProdHWDeviceType) and the code replacement library (CodeReplacementLibrary).

RTW.isHWDeviceTypeEq

To test if two target device type values represent the same hardware device, invoke the following function:

```
result = RTW.isHWDeviceTypeEq(type1,type2)
```

where *type1* and *type2* are character vectors containing target device type values or aliases.

The RTW.isHWDeviceTypeEq function returns true if *type1* and *type2* are character vectors representing the same hardware device. For example, the following call returns true:

```
RTW.isHWDeviceTypeEq('Specified','Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters "Device vendor" (Simulink) and "Device type" (Simulink).

RTW.resolveHWDeviceType

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveHWDeviceType(type)
```

where *`type`* is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return `'Generic->Custom'`:

```
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters "Device vendor" (Simulink) and "Device type" (Simulink).

RTW.isTflEq

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```
result = RTW.isTflEq(name1,name2)
```

where *`name1`* and *`name2`* are character vectors containing CRL values or aliases.

The `RTW.isTflEq` function returns true if *`name1`* and *`name2`* are character vectors representing the same code replacement library. For example, the following call returns true:

```
RTW.isTflEq('GNU','GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see "Code replacement library" (Simulink Coder).

RTW.resolveTflName

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveTflName(name)
```

where *name* is a character vector containing a CRL value or alias.

The `RTW.resolveTflName` function returns the value of the referenced code replacement library. For example, the following calls both return `'GNU C99 extensions'`:

```
RTW.resolveTflName('GNU')
RTW.resolveTflName('GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see "Code replacement library" (Simulink Coder).

Supporting Multiple Development Environments

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple STFs. Each STF invokes a template makefile for the development environment. This amounts to providing two separate targets.

Create a Custom Target Configuration

Introduction

This tutorial can supplement the example target guides described in "Sample Custom Targets" on page 71-9. For an introduction and example files, try the example targets first.

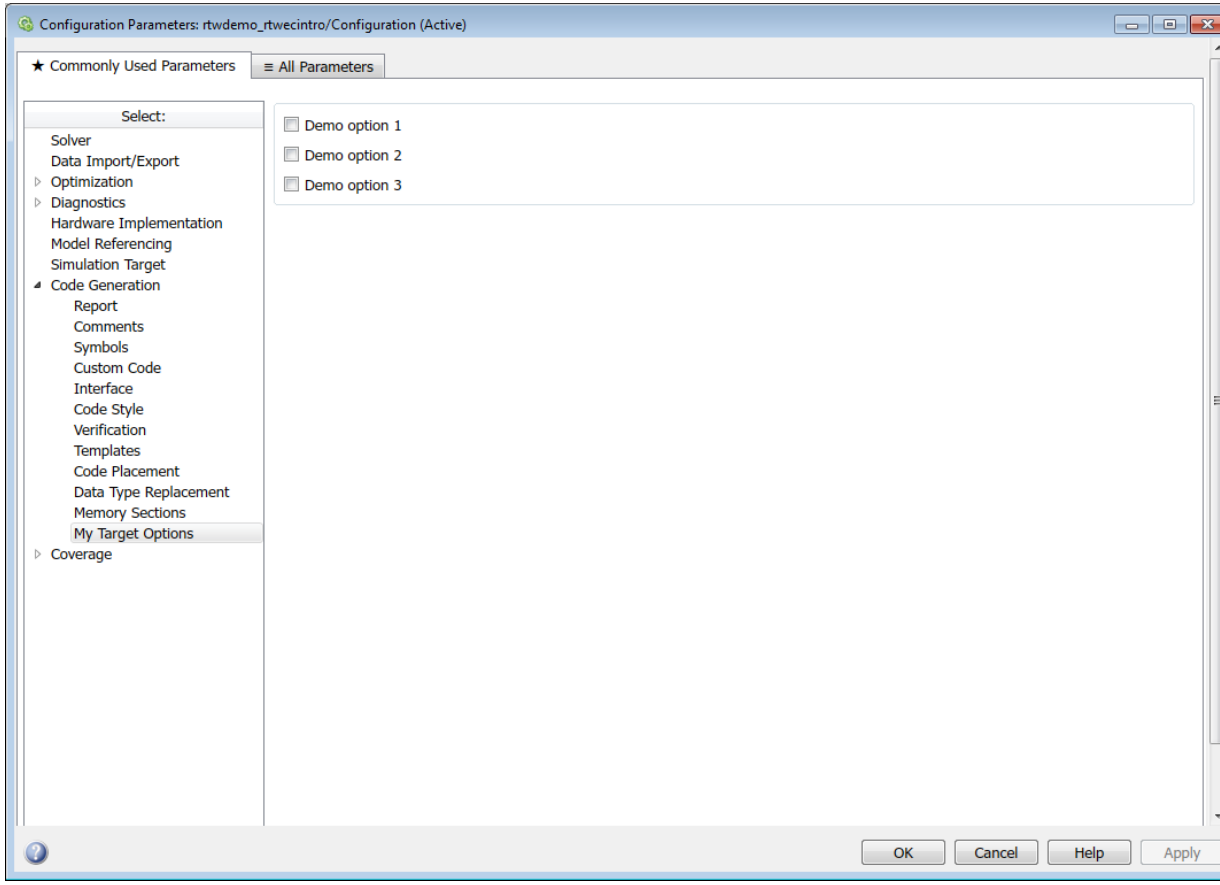
This tutorial guided you through the process of creating an ERT-based target, `my_ert_target`. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard STF and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

my_ert_target Overview

In the following sections, you create a skeletal target, `my_ert_target`. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see Target-Specific Options for my_ert_target).



Target-Specific Options for my_ert_target

`my_ert_target` supports a toolchain-based build, generating code and executables that run on the host system. `my_ert_target` uses the `lcc` compiler on a Microsoft Windows platform. The chosen compiler is readily available and is distributed with the code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up `lcc` temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the `lcc` link.

Note On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

`my_ert_target` can also support template makefile-based builds. For more information about using this target with the template makefile approach, see "Create ERT-Based TMF" on page 71-58.

You can test `my_ert_target` with a model that is compatible with the ERT target (see "Select a System Target File" on page 30-2). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with `targetmodel`, a very simple fixed-step model (see "Create Test Model and S-Function" on page 71-58). The S-Function block in `targetmodel` uses the source code from the `timestwo` example, and generates fully inlined code. See "S-Function Examples" (Simulink) and "Inline S-Functions with TLC" (Simulink Coder) for further discussion of the `timestwo` example S-function.

Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see "Folder and File Naming Conventions" on page 71-11). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder `c:/work`. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the *`matlabroot`* folder).

To create the folders and make them accessible:

1. Create a target root folder, `my_ert_target`. From the MATLAB Command Window on a Windows platform, enter:

   ```
   cd c:/work
   mkdir my_ert_target
   ```

2. Within the target root folder, create a subfolder to store your target files.

   ```
   mkdir my_ert_target/my_ert_target
   ```

3. Add these folders to your MATLAB path.

   ```
   addpath c:/work/my_ert_target
   addpath c:/work/my_ert_target/my_ert_target
   ```

4. Create a folder, `my_targetmodel`, to store the test model, S-function, and generated code.

```
mkdir my_targetmodel
```

Create ERT-Based, Toolchain Compliant STF

Create an STF for your target by copying and modifying the standard STF for the ERT target. Then, validate the STF by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

Editing the STF

To edit the STF, use these steps:

1. Change your working folder to the folder you created in "Creating Target Folders" on page 71-51.

   ```
   cd c:/work/my_ert_target/my_ert_target
   ```

2. Place a copy of *`matlabroot`*`/rtw/c/ert/ert.tlc` in `c:/work/my_ert_target/my_ert_target` and rename it to `my_ert_target.tlc`. The file `ert.tlc` is the STF for the ERT target.

3. Open `my_ert_target.tlc` in a text editor of your choice.

4. Customize the STF, replacing the header comment lines with directives that make your STF visible in the System Target File Browser and define the associated TMF, `make` command, and external mode interface file (if any). For more information about these directives, see "Header Comments" on page 71-32 .

   Replace the header comments in `my_ert_target.tlc` with the following header comments.

   ```
   %% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw \
   %%    EXTMODE: no_ext_comm
   ```

5. The file `my_ert_target.tlc` inherits the standard ERT options, using the mechanism described in "Inheriting Target Options" on page 71-44. Therefore, the existing `rtwoptions` structure definition is superfluous. Edit the RTW_OPTIONS section such that it includes only the following code.

   ```
   /%
     BEGIN_RTW_OPTIONS

     %----------------------------------------%
     % Configure RTW code generation settings %
     %----------------------------------------%

     rtwgensettings.BuildDirSuffix = '_ert_rtw';
   ```

```
  END_RTW_OPTIONS
%/
```

6 Delete the code after the end of the `RTW_OPTIONS` section, which is delimited by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT`. This code is for use only by internal MathWorks developers.

7 Modify the build folder suffix in the `rtwgenSettings` structure in accordance with the conventions described in "rtwgensettings Structure" on page 71-35.

To set the suffix to a character vector for the `_my_ert_target` custom target, change the line

```
rtwgensettings.BuildDirSuffix = '_ert_rtw'
```

to

```
rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw'
```

8 Modify the `rtwgenSettings` structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in "rtwgensettings Structure" on page 71-35. Add the following code to the `rtwgenSettings` definition:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
```

9 Add an `rtwoptions` structure that defines a target-specific options category with three check boxes just after the `BEGIN_RTW_OPTIONS` directive. The following code shows the complete `RTW_OPTIONS` section, including the previous `rtwgenSettings` changes.

```
/%
  BEGIN_RTW_OPTIONS

  rtwoptions(1).prompt         = 'My Target Options';
  rtwoptions(1).type           = 'Category';
  rtwoptions(1).enable         = 'on';
  rtwoptions(1).default        = 3;   % number of items under this category
                                      % excluding this one.
  rtwoptions(1).popupstrings  = '';
  rtwoptions(1).tlcvariable   = '';
  rtwoptions(1).tooltip       = '';
  rtwoptions(1).callback      = '';
  rtwoptions(1).makevariable  = '';

  rtwoptions(2).prompt         = 'Demo option 1';
  rtwoptions(2).type           = 'Checkbox';
  rtwoptions(2).default        = 'off';
  rtwoptions(2).tlcvariable    = 'DummyOpt1';
  rtwoptions(2).makevariable   = '';
```

```
    rtwoptions(2).tooltip        = ['Demo option1 (non-functional)'];
    rtwoptions(2).callback       = '';

    rtwoptions(3).prompt         = 'Demo option 2';
    rtwoptions(3).type           = 'Checkbox';
    rtwoptions(3).default        = 'off';
    rtwoptions(3).tlcvariable    = 'DummyOpt2';
    rtwoptions(3).makevariable   = '';
    rtwoptions(3).tooltip        = ['Demo option2 (non-functional)'];
    rtwoptions(3).callback       = '';

    rtwoptions(4).prompt         = 'Demo option 3';
    rtwoptions(4).type           = 'Checkbox';
    rtwoptions(4).default        = 'off';
    rtwoptions(4).tlcvariable    = 'DummyOpt3';
    rtwoptions(4).makevariable   = '';
    rtwoptions(4).tooltip        = ['Demo option3 (non-functional)'];
    rtwoptions(4).callback       = '';

    %---------------------------------------%
    % Configure RTW code generation settings %
    %---------------------------------------%

    rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw';
    rtwgensettings.DerivedFrom = 'ert.tlc';
    rtwgensettings.Version = '1';
    rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
    %SelectCallback provides toolchain approach support, but requires custom function
    %Omit this SelectCallback if using the template makefile approach

    END_RTW_OPTIONS
  %/
```

10 Save your changes to `my_ert_target.tlc` and close the file.

Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the `SelectCallback` near the end of the custom STF. This function sets properties for toolchain compliance.

```
function enableToolchainCompliant(hSrc, hDlg)
  hCS = hSrc.getConfigSet();

  % The following parameters enable toolchain compliance.
  slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
  hCS.setProp('GenerateMakefile','on');

  % The following parameters are not required for toolchain compliance.
  % But, it is recommended practice to set these default values and
  % disable the parameters (as shown).
  hCS.setProp('RTWCompilerOptimization','off');
  hCS.setProp('MakeCommand','make_rtw');
  hCS.setPropEnabled('RTWCompilerOptimization',false);
```

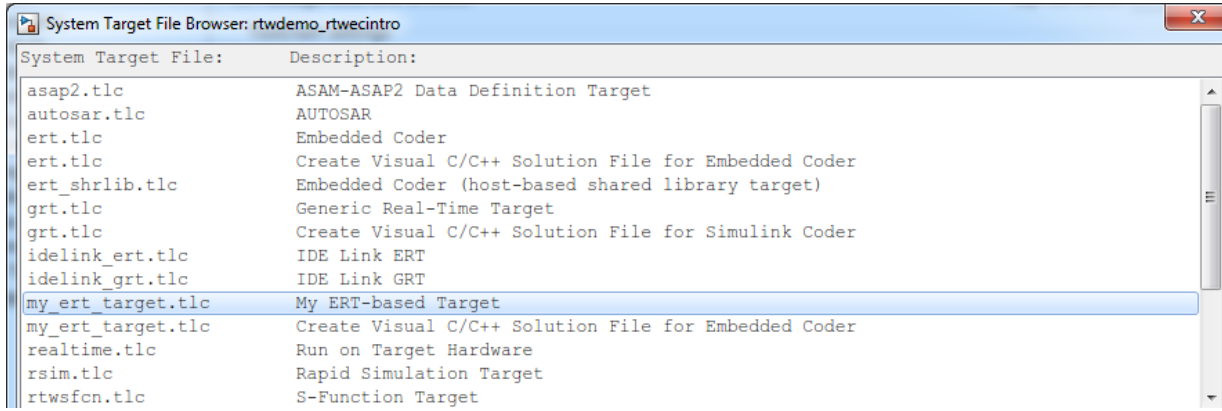
```
  hCS.setPropEnabled('MakeCommand',false);
end
```

Note: If you are using the template makefile approach, omit calling the function enabling toolchain-compliance from your STF file. Instead, use the information in "Create ERT-Based TMF" on page 71-58.

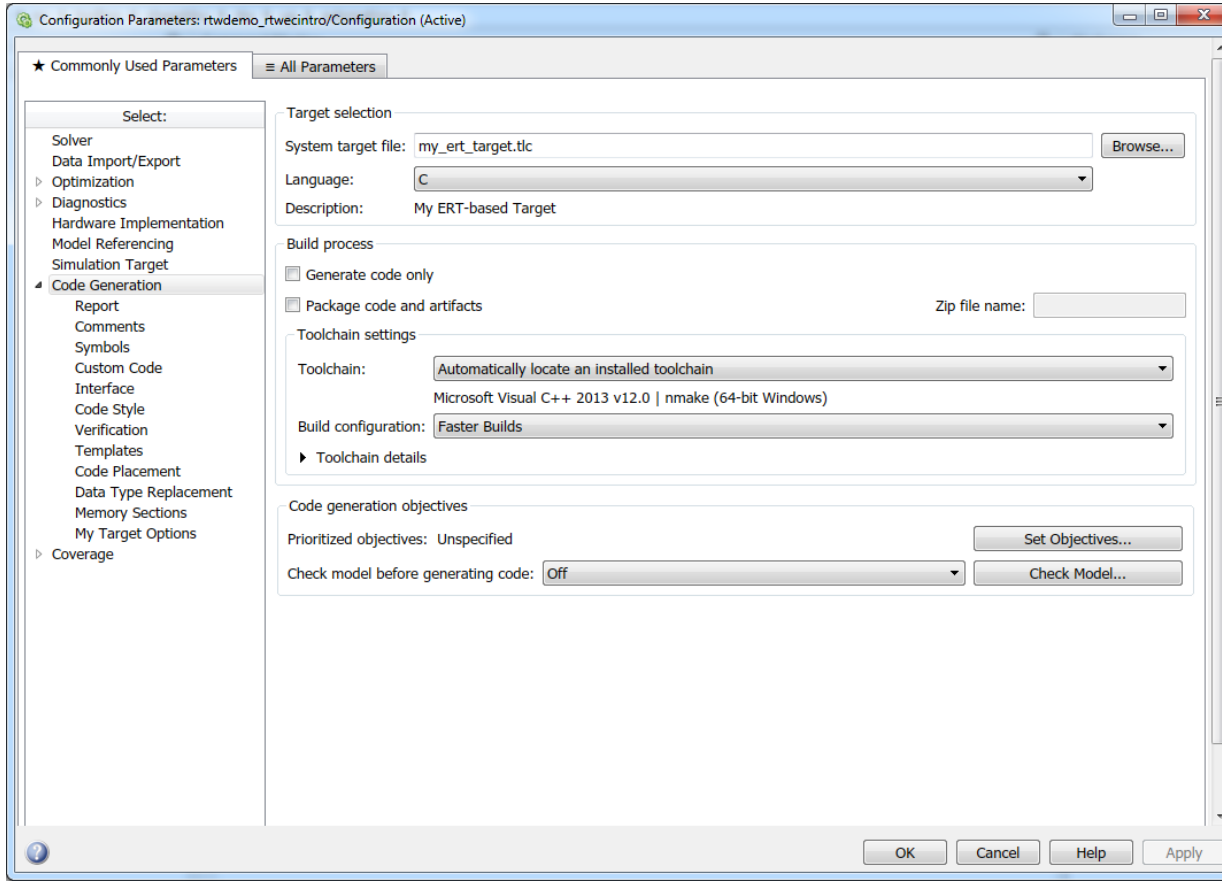
Viewing the STF

At this point, you can verify that the target inherits and displays ERT options as follows:

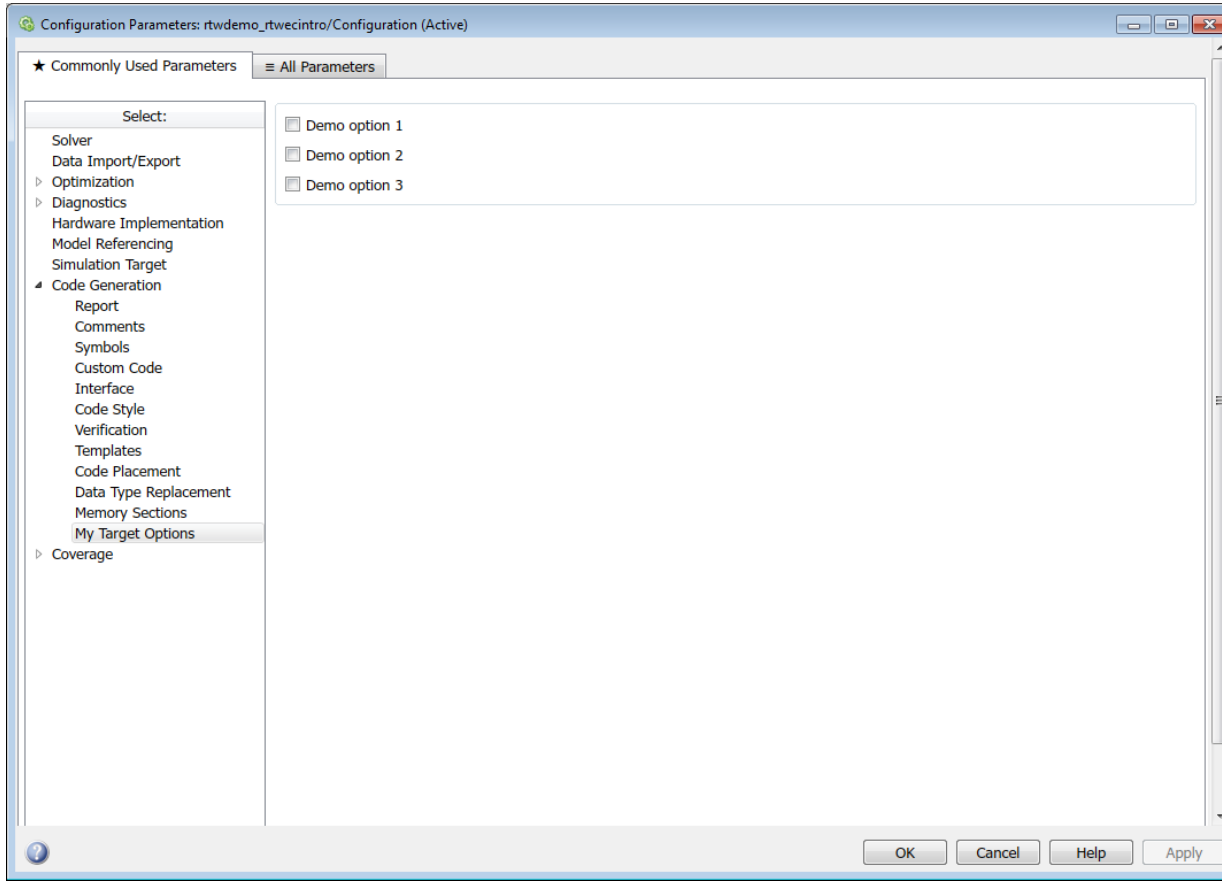
1. Create a new model.
2. Open the Model Explorer or the Configuration Parameters dialog box.
3. Select the **Code Generation** pane.
4. Click **Browse** to open the System Target File browser.
5. In the file browser, scroll through the list of targets to find the new target, `my_ert_target.tlc`. (This step assumes that your MATLAB path contains `c:/work/my_ert_target/my_ert_target`, as previously set in "Creating Target Folders" on page 71-51.)
6. Select `My ERT-based Target` and click **OK.**



7. The **Code Generation** pane now shows that the model is configured for the `my_ert_target.tlc` target. The **System target file**, **Language**, **Toolchain**, and **Build configuration** fields should appear:



8 Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.



9 Select the **Code Generation** pane and reopen the System Target File Browser.

10 Select the Embedded Coder target (`ert.tlc`). The target displays the standard ERT options.

11 Close the model. You do not need to save it.

The STF for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, `my_ert_target_lcc.tmf`, in the STF header comments prevents you from invoking

the build process for your target until the TMF file is in place. First, you must create a `my_ert_target_lcc.tmf` file.

Create ERT-Based TMF

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the templated makefile approach, follow the steps applying to TMF and omit calling the function enabling toolchain-compliance from your STF file, which is described in "Create ERT-Based, Toolchain Compliant STF" on page 71-52.

Create a TMF for your target by copying and modifying the standard ERT TMF for the LCC compiler:

1. Make sure that your working folder is still set to the target file folder you created previously in "Creating Target Folders" on page 71-51.

   ```
   c:/work/my_ert_target/my_ert_target
   ```

2. Place a copy of *`matlabroot`*`/rtw/c/ert/ert_lcc.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc.tmf` is the ERT compiler-specific template makefile for the LCC compiler.
3. Open `my_ert_target_lcc.tmf` in a text editor.
4. Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the `make` file. Change the line

   ```
   SYS_TARGET_FILE = any
   ```

   to

   ```
   SYS_TARGET_FILE = my_ert_target.tlc
   ```

5. Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

1. Set your working folder to `c:/work/my_targetmodel`.

```
cd c:/work/my_targetmodel
```

For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build folder within the working folder. When inlined code is generated for the `timestwo` S-function, the build process looks for the TLC implementation of the S-function in the working folder.

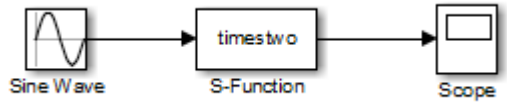
2. Copy the following C and TLC files for the `timestwo` S-function to your working folder:

   - *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`
   - *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`

3. Build the `timestwo` MEX-file in `c:/work/my_targetmodel`.

   ```
   mex timestwo.c
   ```

4. Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as `targetmodel`.



5. Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name `timestwo`. Click **OK**. The block is now bound to the `timestwo` MEX-file.
6. Open Model Explorer or the Configuration Parameters dialog box and select the **Solver** pane.
7. Set the solver **Type** to `fixed-step` and click **Apply**.
8. Save the model.
9. Open the scope and run a simulation. Verify that the `timestwo` S-function multiplies its input by 2.0.

Keep the `targetmodel` model open for use in the next section, in which you generate code using the test model.

Verify Target Operation

In this section you configure `targetmodel` for the `my_ert_target` custom target, and use the target to generate code and build an executable:

1. Open the Configuration Parameters dialog box and select the **Code Generation** pane.
2. Click **Browse** to open the System Target File Browser.
3. In the Browser, select `My ERT-based Target` and click **OK**.
4. The Configuration Parameters dialog box now displays the **Code Generation** pane for `my_ert_target`.
5. Select the **Code Generation** > **Report** pane and select the **Create code generation report** option.
6. Click **Apply** and save the model. The model is configured for `my_ert_target`.
7. Build the model. If the build succeeds, the MATLAB Command Window displays the message below.

   ```
   ### Created executable: ../targetmodel.exe
   ### Successful completion of build procedure for model:
   targetmodel
   ```

   Your working folder contains the `targetmodel.exe` file and the build folder, `targetmodel_my_ert_target_rtw`, which contains generated code and other files. The working folder also contains an `slprj` folder, used internally by the build process.

   The code generator also creates and displays a code generation report.
8. To view the generated model code, go to the code generation report window. In the **Contents** pane, click the `targetmodel.c` link.
9. In `targetmodel.c`, locate the model step function, `targetmodel_step`. Observe the following code.

   ```
   /* S-Function Block: <Root>/S-Function */
   /* Multiply input by two */
   targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
   ```

   The presence of this code confirms that the `my_ert_target` custom target has generated an inlined output computation for the S-Function block in the model.

Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the `make` command works and how it processes makefiles. You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the make utility you use.

In this section...
"Template Makefiles and Tokens" on page 71-62
"Invoke the make Utility" on page 71-68
"Structure of the Template Makefile" on page 71-69
"Customize and Create Template Makefiles" on page 71-73

Template Makefiles and Tokens

TMFs are made up of statements containing tokens. The build process expands tokens and creates a makefile, *`model`*`.mk`. TMFs are designed to generate makefiles for specific compilers on specific platforms. The generated *`model`*`.mk` file is tailored to compile and link code generated from your model, using commands specific to your development system.

Creation of model.mk

Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating *`model`*`.mk`. The `make_rtw` command processes the TMF specified on the **Code Generation** pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by make_rtw lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
- To provide the macro definitions for compiling the files, for example, `-DINTEGER_CODE=1`.

Template Makefile Tokens Expanded by make_rtw

Token	Expansion
General purpose	
`|>ADDITIONAL_LDFLAGS<|`	Linker flags automatically added by blocks.
`|>ALT_MATLAB_BIN<|`	Alternate full pathname for the MATLAB executable; value is different than value for `MATLAB_BIN` token when the full pathname contains spaces.
`|>ALT_MATLAB_ROOT<|`	Alternate full pathname for the MATLAB installation; value is different than value for `MATLAB_ROOT` token when the full pathname contains spaces.
`|>BUILDARGS<|`	Options passed to `make_rtw`. This token is provided so that the contents of your *`model`*`.mk` file changes when you change the build arguments, thus forcing an update of modules when your build options change.
`|>COMBINE_OUTPUT_UPDATE_FCNS<|`	True (1) when **Single output/update function** is selected, otherwise False (0). Used for the macro definition `-DONESTEPFCN=1`.
`|>COMPUTER<|`	Computer type. See the MATLAB `computer` command.
`|>EXPAND_LIBRARY_LOCATION<|`	Location of precompiled library file. The `TargetPreCompLibLocation` configuration parameter can override this setting. For examples, see "Control Library Location and Naming During Build" (Simulink Coder).
`|>EXPAND_LIBRARY_NAME<|`	Library name. For examples, see "Control Library Location and Naming During Build" (Simulink Coder) and "Modify the Template Makefile for rtwmakecfg" (Simulink Coder).

Token	Expansion
`|>EXPAND_LIBRARY_SUFFIX<|`	Library suffix. The `TargetLibSuffix` configuration parameter can override this setting. For examples, see "Control Library Location and Naming During Build" (Simulink Coder).
`|>EXT_MODE<|`	True (1) to enable generation of external mode support code, otherwise False (0).
`|>EXTMODE_TRANSPORT<|`	Index of transport mechanism (for example, `tcpip`, `serial`) for external mode.
`|>EXTMODE_STATIC<|`	True (1) if static memory allocation is selected for external mode. False (0) if dynamic memory allocation is selected.
`|>EXTMODE_STATIC_SIZE<|`	Size of static memory allocation buffer (if any) for external mode.
`|>GENERATE_ERT_S_FUNCTION<|`	True (1) when **Create SIL block** is selected, otherwise False (0). Used for control of the makefile target of the build.
`|>INCLUDE_MDL_TERMINATE_FCN<|`	True (1) when **Terminate function required** is selected, otherwise False (0). Used for the macro definition `-DTERMFCN==1`.
`|>INTEGER_CODE<|`	True (1) when **Support floating-point numbers** is not selected, otherwise False (0). `INTEGER_CODE` is a required macro definition when compiling the source code and is used when selecting precompiled libraries to link against.
`|>MAKEFILE_NAME<|`	*`model`*`.mk` — The name of the makefile that was created from the TMF.
`|>MAT_FILE<|`	True (1) when **MAT-file logging** is selected, otherwise False (0). `MAT_FILE` is a required macro definition when compiling the source code and also is used to include logging code in the build process.
`|>MATLAB_BIN<|`	Location of the MATLAB executable.
`|>MATLAB_ROOT<|`	Path to where MATLAB is installed.

Token	Expansion
`|>MEM_ALLOC<|`	Either `RT_MALLOC` or `RT_STATIC`. Indicates how memory is to be allocated.
`|>MEXEXT<|`	MEX-file extension. See the MATLAB `mexext` command.
`|>MODEL_MODULES<|`	Additional generated source modules. For example, you can split a large model into two files, *`model`*`.c` and *`model`*`1.c`. In this case, this token expands to *`model`*`1.c`.
`|>MODEL_MODULES_OBJ<|`	Object filenames (`.obj`) corresponding to additional generated source modules.
`|>MODEL_NAME<|`	Name of the Simulink block diagram currently being built.
`|>MULTITASKING<|`	True (1) if solver mode is multitasking, otherwise False (0).
`|>NCSTATES<|`	Number of continuous states.
`|>NUMST<|`	Number of sample times in the model.
`|>PORTABLE_WORDSIZES<|`	True (1) when **Enable portable word sizes** is selected, otherwise False (0).
`|>RELEASE_VERSION<|`	The MATLAB release version.
`|>S_FUNCTIONS<|`	List of noninlined S-function sources.
`|>S_FUNCTIONS_LIB<|`	List of S-function libraries available for linking.
`|>S_FUNCTIONS_OBJ<|`	Object (`.obj`) file list corresponding to noninlined S-function sources.
`|>SOLVER<|`	Solver source filename, for example, `ode3.c`.
`|>SOLVER_OBJ<|`	Solver object (`.obj`) filename, for example, `ode3.obj`.
`|>TARGET_LANG_EXT<|`	`c` when the **Language** selection is C, `cpp` when the **Language** selection is C++. Used in the makefile to control the extension on generated source files.
`|>TGT_FCN_LIB<|`	Specifies compiler command line options. The line in the makefile is `TGT_FCN_LIB = |>TGT_FCN_LIB<|`. Use this token in a makefile conditional statement to

<table>
<tr><th>Token</th><th>Expansion</th></tr>

<tr><td><code>|>START_EXPAND_RULES<|</code>
<code>|>EXPAND_DIR_NAME<|</code>
<code>|>END_EXPAND_RULES<|</code></td><td>Makefile rules.</td></tr>
<tr><td><code>|>START_PRECOMP_LIBRARIES<|</code></td><td>List of precompiled library names.</td></tr>
</table>

Token	Expansion
`|>EXPAND_LIBRARY_NAME<|` `|>END_PRECOMP_LIBRARIES<|`	
Model reference support **Note:** For examples of the tokens in this section, see "Providing Model Referencing Support in the TMF" on page 71-85.	
`|>MASTER_ANCHOR_DIR<|`	For parallel builds, current work folder (`pwd`) at the time the build started.
`|>MODELLIB<|`	Name of the library file generated for the current model.
`|>MODELREFS<|`	List of models referenced by the top model.
`|>MODELREF_LINK_LIBS<|`	List of referenced model libraries against which the top model links.
`|>MODELREF_LINK_RSPFILE_NAME<|`	Name of a response file against which the top model links. This token is valid only for build environments that support linker response files. For an example of its use, see *`matlabroot`*`/rtw/c/grt/grt_vc.tmf`.
`|>MODELREF_TARGET_TYPE<|`	Type of target being built. Possible values are • `NONE`: Standalone model or top model referencing other models • `RTW`: Model reference target build • `SIM`: Model reference simulation target build
`|>RELATIVE_PATH_TO_ANCHOR<|`	Relative path, from the location of the generated makefile, to the MATLAB working folder.
`|>START_DIR<|`	Current work folder (`pwd`) at the time the build started. This token is required for parallel builds.

`|`
`>START_MDLREFINC_EXPAND_INCLUDES<`
`|>MODELREF_INC_PATH<|`
`|>END_MDLREFINC_EXPAND_INCLUDES<|`
	List of include paths for models referenced by the top model.

`|>SHARED_BIN_DIR<|`	Folder for the library file built from the shared source files.

Token	Expansion
`|>SHARED_LIB<|`	Library file built from the shared source files, including the path to the library folder.
`|>SHARED_SRC<|`	Shared source files specification, including the path to the shared utilities folder.
`|>SHARED_SRC_DIR<|`	Folder for shared source files.

These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

```
NUMST = |>NUMST<|
```

expands to the following in *`model`*`.mk`.

```
NUMST = 2
```

In addition to the above, `make_rtw` expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the `rtwoptions` section of the system target file. Structures in the `rtwoptions` structure array that contain the field `makevariable` are expanded.

The following example is extracted from *`matlabroot`*`/rtw/c/grt/grt.tlc`. The section starting with `BEGIN_RTW_OPTIONS` contains MATLAB code that sets up `rtwoptions`. The following directive causes the `|>EXT_MODE<|` token to be expanded to `1` (on) or `0` (off), depending on how you set the external mode options.

```
rtwoptions(2).makevariable = 'EXT_MODE'
```

Invoke the make Utility

- “make Command” on page 71-68
- “make Utility Versions” on page 71-69

make Command

After creating *`model`*`.mk` from your TMF, the build process invokes a `make` command. To invoke `make`, the build process issues this command.

```
makecommand -f model.mk
```

makecommand is defined by the MAKECMD macro in your target's TMF (see "Structure of the Template Makefile" on page 71-69). You can specify additional options to make in the **Make command** field of the **Code Generation** pane. (See the sections "Specify a Make Command" (Simulink Coder) and "Template Makefiles and Make Options" (Simulink Coder).)

For example, specifying OPT_OPTS=-O2 in the **Make command** field causes make_rtw to generate the following make command.

```
makecommand -f model.mk OPT_OPTS=-O2
```

A comment at the top of the TMF specifies the available make command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

make Utility Versions

The make utility lets you control nearly every aspect of building your real-time program. There are several different versions of make available. The code generator provides the Free Software Foundation GNU make for both UNIX[11] and PC platforms in platform-specific subfolders under

```
matlabroot/bin
```

It is possible to use other versions of make with the code generator, although GNU Make is recommended. To be compatible with the code generator, verify that your version of make supports the following command format.

```
makecommand -f model.mk
```

Structure of the Template Makefile

A TMF has multiple sections, including the following:

- Abstract — Describes what the makefile targets. Here is a representative abstract from the GRT TMFs in *matlabroot*/rtw/c/grt (open):

```
# File    : grt_lcc.tmf
#
# Abstract:
#       Template makefile for building a PC-based stand-alone generic real-time
#       version of Simulink model using generated C code and LCC compiler
#       Version 2.4.
#
```

11. UNIX is a registered trademark of The Open Group in the United States and other countries.

```
#       This makefile attempts to conform to the guidelines specified in the
#       IEEE Std 1003.2-1992 (POSIX) standard. It is designed to be used
#       with GNU Make (gmake) which is located in matlabroot/bin/win32.
#
#       Note that this template is automatically customized by the build
#       procedure to create "<model>.mk"
#
#       The following defines can be used to modify the behavior of the
#       build:
#         OPT_OPTS       - Optimization options. Default is none. To enable
#                          debugging specify as OPT_OPTS=-g4.
#         OPTS           - User specific compile options.
#         USER_SRCS      - Additional user sources, such as files needed by
#                          S-functions.
#         USER_INCLUDES  - Additional include paths
#                          (i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
#                          (For Lcc, have a '/'as file seperator before the
#                          file name instead of a '\' .
#                          i.e.,  d:\work\proj1/myfile.c - reqd for 'gmake')
#
#       This template makefile is designed to be used with a system target
#       file that contains 'rtwgensettings.BuildDirSuffix'. See grt.tlc.
```

- `Macros read by make_rtw` section — Defines macros that tell `make_rtw` how to process the TMF. Here is a representative `Macros read by make_rtw` section from the GRT TMFs in *`matlabroot`*`/rtw/c/grt` (open):

```
#----------------------- Macros read by make_rtw ------------------------------
#
# The following macros are read by the build procedure:
#
#  MAKECMD         - The command that invokes the make utility
#  HOST            - The platform (for example, PC) for which this TMF is written
#  SHELL           - An operating system shell command (for example, cmd) for the platform
#  BUILD           - The flag that indicates whether to invoke make from the build procedure
#  SYS_TARGET_FILE - Name of system target file.

MAKECMD         = "%MATLAB%\bin\win32\gmake"
HOST            = PC
SHELL           = cmd
BUILD           = yes
SYS_TARGET_FILE = grt.tlc
BUILD_SUCCESS   = *** Created
COMPILER_TOOL_CHAIN = lcc

MAKEFILE_FILESEP = /
```

  The macros in this section might include:

  - `MAKECMD` — Specifies the command used to invoke the make utility. For example, if `MAKECMD = mymake`, then the `make` command invoked is

    ```
    mymake -f model.mk
    ```

- HOST — Specifies the platform targeted by this TMF. This can be PC, UNIX, *computer_name* (see the MATLAB computer command), or ANY.
- SHELL — Specifies an operating system shell command for the platform. For Windows, this can be cmd.
- BUILD — Instructs make_rtw whether or not it should invoke make from the build procedure. Specify yes or no.
- SYS_TARGET_FILE — Specifies the name of the system target file or the value any. This is used for consistency checking by make_rtw to verify the system target file specified in the **Target selection** panel of the **Code Generation** pane of the Configuration Parameters dialog box. If you specify any, you can use the TMF with any system target file.
- BUILD_SUCCESS — Optional macro that specifies the build success message to be displayed for make completion on the PC. For example,

  ```
  BUILD_SUCCESS = ### Successful creation of
  ```

  The BUILD_SUCCESS macro, if used, replaces the standard build success message found in the TMFs distributed with the bundled code generator targets (such as GRT):

  ```
  @echo ### Created executable $(MODEL).exe
  ```

  Your TMF must include either the standard build success message, or use the BUILD_SUCCESS macro. For an example of the use of BUILD_SUCCESS, see *matlabroot*/rtw/c/grt/grt_lcc.tmf or the code example above this list of macros.
- BUILD_ERROR — Optional macro that specifies the build error message to be displayed when an error is encountered during the make procedure. For example,

  ```
  BUILD_ERROR = ['Error while building ', modelName]
  ```
- VERBOSE_BUILD_OFF_TREATMENT = PRINT_OUTPUT_ALWAYS — Optional macro to include if you want the makefile output to be displayed regardless of the setting of the **Verbose build** option in the **Code Generation** > **Debug** pane.
- COMPILER_TOOL_CHAIN — For builds on Windows systems, specifies which compiler setup file — located in *matlabroot*/toolbox/rtw/rtw (open) — to use:
  - lcc selects setup_for_lcc.m
  - vc selects setup_for_visual.m

- `vcx64` selects `setup_for_visual_x64.m`
- `default` selects `setup_for_default.m`

For builds on UNIX systems, specify `unix`. Other values are flagged as unknown and `make_rtw` uses `setup_for_default.m`.

Note: Do not omit `COMPILER_TOOL_CHAIN` or leave it unspecified in your TMF. If your compiler is not the host compiler, specify `COMPILER_TOOL_CHAIN = default`.

- `DOWNLOAD` — An optional macro that you can specify as yes or no. If specified as yes (and `BUILD=yes`), then `make` is invoked a second time with the download target.

  ```
  make -f model.mk download
  ```

- `DOWNLOAD_SUCCESS` — An optional macro that you can use to specify the download success message to be used when looking for a completed download. For example,

  ```
  DOWNLOAD_SUCCESS = ### Downloaded
  ```

- `DOWNLOAD_ERROR` — An optional macro that you can use to specify the download error message to be displayed when an error is encountered during the download. For example,

  ```
  DOWNLOAD_ERROR = ['Error while downloading ', modelName]
  ```

- `Tokens expanded by make_rtw` section — Defines the tokens that `make_rtw` expands. Here is a brief excerpt from a representative `Tokens expanded by make_rtw` section from the GRT TMFs in *`matlabroot`*`/rtw/c/grt` (open):

```
#---------------------- Tokens expanded by make_rtw ----------------------------
#
# The following tokens, when wrapped with "|>" and "<|" are expanded by the
# build procedure.
#
#  MODEL_NAME          - Name of the Simulink block diagram
#  MODEL_MODULES       - Any additional generated source modules
#  MAKEFILE_NAME       - Name of makefile created from template makefile <model>.mk
#  MATLAB_ROOT         - Path to where MATLAB is installed.
...

MODEL                = |>MODEL_NAME<|
MODULES              = |>MODEL_MODULES<|
MAKEFILE             = |>MAKEFILE_NAME<|
```

```
MATLAB_ROOT          = |>MATLAB_ROOT<|
...
```

For more information about TMF tokens, see Template Makefile Tokens Expanded by make_rtw.

- Subsequent sections vary based on compiler, host, and target. Some common sections include `Model and reference models`, `External mode`, `Tool Specifications` or `Tool Definitions`, `Include Path`, `C Flags`, `Additional Libraries`, and `Source Files`.
- `Rules` section — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The `Rules` section might be followed by related sections such as `Dependencies`.

Customize and Create Template Makefiles

Introduction

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read "Folder and File Naming Conventions" on page 71-11 to understand the folder structure and MATLAB path requirements for custom targets.

Setting Up a Template Makefile

To customize or create a new TMF, you should copy an existing GRT or ERT TMF from one of the following locations:

```
matlabroot/rtw/c/grt (open)
matlabroot/rtw/c/ert (open)
```

Place the copy in the same folder as the associated system target file (STF). Usually, this is the `mytarget/mytarget` folder within the target folder structure. Then, rename your TMF (for example, `mytarget.tmf`) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the STF file header (see "System Target File Structure" on page 71-30). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the TMF directive of the STF file header.

```
TMF: mytarget.tmf
```

Using Macros and Pattern Matching Expressions in a Template Makefile

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in the *`model`*`.mk` file.

The make utility processes the *`model`*`.mk` makefile and generates a set of commands based upon dependency rules defined in *`model`*`.mk`. After `make` generates the set of commands for building or rebuilding `test`, `make` executes them.

For example, to build a program called `test`, `make` must link the object files. However, if the object files don't exist or are out of date, `make` must compile the source code. Thus there is a dependency between source and object files.

Each version of `make` differs slightly in its features and how rules are defined. For example, consider a program called `test` that gets created from two sources, `file1.c` and `file2.c`. Using most versions of `make`, the dependency rules would be

```
test: file1.o file2.o
        cc -o test file1.o file2.o

file1.o: file1.c
        cc -c file1.c

file2.o: file2.c
        cc -c file2.c
```

In this example, a UNIX[12] environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule

12. UNIX is a registered trademark of The Open Group in the United States and other countries.

```
test: file1.o file2.o
```

`make` sees that to build `test`, it needs to build `file1.o` and `file2.o`. To build `file1.o`, `make` processes the rule

```
file1.o: file1.c
```

If `file1.o` doesn't exist, or if `file1.o` is older than `file1.c`, `make` compiles `file1.c`.

The format of TMFs follows the above example. Our TMFs use additional features of `make` such as macros and file-pattern-matching expressions. In most versions of `make`, a macro is defined with

```
MACRO_NAME = value
```

References to macros are made with `$(MACRO_NAME)`. When `make` sees this form of expression, it substitutes *`value`* for `$(MACRO_NAME)`.

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU[13] Make, you could replace the two "`file1.o: file1.c`" and "`file2.o: file2.c`" rules with the single rule

```
%.o : %.c
        cc -c $<
```

Note that `$<` in the previous example is a special macro that equates to the dependency file (that is, `file1.c` or `file2.c`). Thus, using macros and the "`%`" pattern matching character, the previous example can be reduced to

```
SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)

test: $(OBJS)
        cc -o $@ $(OBJS)

%.o : %.c
        cc -c $<
```

Note that the `$@` macro above is another special macro that equates to the name of the current dependency target, in this case `test`.

This example generates the list of objects (`OBJS`) from the list of sources (`SRCS`) by using the text substitution feature for macro expansion. It replaces the source file extension

13. GNU is a registered trademark of the Free Software Foundation.

(for example, `.c`) with the object file extension (`.o`). This example also generalized the build rule for the program, `test`, to use the special `"$@"` macro.

Customizing Generated Makefiles with rtwmakecfg

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an `rtwmakecfg.m` file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

To add information pertaining to an S-function to the makefile,

1. Create the function `rtwmakecfg` in file `rtwmakecfg.m`. The code generator associates this file with your S-function based on its folder location.
2. Modify your target's TMF such that it supports macro expansion for the information returned by `rtwmakecfg` functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an `rtwmakecfg.m` file in the folder that contains the S-function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder).

Supporting Continuous Time in Custom Targets

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

Template Makefile Modifications

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```
NUMST = |>NUMST<|
NCSTATES = |>NCSTATES<|
```

In addition, add NCSTATES to the CPP_REQ_DEFINES macro, as in the following example:

```
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
-DMAT_FILE=$(MAT_FILE)
-DINTEGER_CODE=$(INTEGER_CODE) \
-DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \
-DHAVESTDIO
-DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \
```

Modifications to Main Program Module

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. NUMST (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on NUMST directly.

When the model has continuous time and the flag TID01EQ is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and TID01EQ is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take TID01EQ into account, as follows:

1. Before NUMST is referenced in the file, add the following code:

   ```
   #if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
   #define DISC_NUMST (NUMST - 1)
   #else
   #define DISC_NUMST NUMST
   #endif
   ```

2. Replace instances of NUMST in the file by DISC_NUMST.

Model Reference Considerations

See “Support Model Referencing” on page 71-83 for important information on TMF modifications you may need to make to support the code generator model referencing features.

Note: If you are using a TMF without the variables SHARED_SRC or MODELREFS, the file might have been used with a previous release of Simulink software. If you want your

TMF to support model referencing, add either variable `SHARED_SRC` or `MODELREFS` to the make file.

- "Custom Target Optional Features" (Simulink Coder)
- "Support Toolchain Approach with Custom Target" (Simulink Coder)

Custom Target Optional Features

This section describes how to configure a custom embedded target to support these optional features.

To ...	Use Target Configuration Parameters ...	For more information, see ...
Indicate a custom target is toolchain-compliant	`UseToolchainInfoCompliaGenerateMakefile`	"Support Toolchain Approach with Custom Target" (Simulink Coder)
Build a model that includes referenced models and uses a custom target	`ModelReferenceCompliant` `ParMdlRefBuildCompliant` (parallel build support)	"Support Model Referencing" (Simulink Coder)
Control the compiler optimization level building generated code for a custom target	`CompOptLevelCompliant`	"Support Compiler Optimization Level Control" (Simulink Coder)
Control C function prototypes of initialize and step functions that are generated for a model that uses a custom target	`ModelStepFunctionProtot Compliant` (ERT only)	"Support C Function Prototype Control" (Simulink Coder)
Control C++ class interfaces that are generated for a model that uses a custom target	`CPPClassGenCompliant` (ERT only)	"Support C++ Class Interface Control" (Simulink Coder)
Enable concurrent execution of multiple tasks on a multicore platform for a model that uses a custom target	`ConcurrentExecutionComp`	"Support Concurrent Execution of Multiple Tasks" (Simulink Coder)

The required configuration changes are modifications to your system target file (STF), and in some cases also modifications to your template makefile (TMF) or your custom static main program.

The API for STF callbacks provides a function `SelectCallback` for use in STFs. `SelectCallback` is associated with the target rather than with its individual options. If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file (STF) must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.
- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can present either the build controls for the toolchain approach or the template makefile approach. The model parameters that contribute to determining which build controls appear include these parameters.

Model Parameter	Value	Notes
`UseToolchainInfoCompliant`	`on`	For toolchain approach, set this parameter to `'on'`. For TMF approach, set this parameter to `'off'`.
`GenerateMakefile`	`on`	For toolchain approach, set this parameter to `'on'`.

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a `SelectCallback` function in the custom target file to set the properties. The `SelectCallback` function call in the RTW_OPTION section of the TLC file can take the form:

```
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```
function enableToolchainCompliant(hSrc, hDlg)
  hCS = hSrc.getConfigSet();

  % The following parameters enable toolchain compliance.
  slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
  hCS.setProp('GenerateMakefile','on');

  % The following parameters are not required for toolchain compliance.
  % But, it is recommended practice to set these default values and
  % disable the parameters (as shown).
  hCS.setProp('RTWCompilerOptimization','off');
  hCS.setProp('MakeCommand','make_rtw');
  hCS.setPropEnabled('RTWCompilerOptimization',false);
```

```
  hCS.setPropEnabled('MakeCommand',false);
end
```

When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 71-48.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Support Model Referencing

This section describes how to configure a custom embedded target to support model referencing. Without the described modifications, you will not be able to use the custom target when building a model that includes referenced models. If you do not intend to use referenced models with your target, you can skip this section. If you later find that you need to use referenced models, you can upgrade your target then.

In this section...

About Model Referencing with a Custom Target

The requirements for supporting model referencing are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare model reference compliance, as described in "Declaring Model Referencing Compliance" on page 71-84.
- The template makefile (TMF) must define some entities that support model referencing, as described in "Providing Model Referencing Support in the TMF" on page 71-85.
- The TMF must support using the Shared Utilities folder, as described in "Supporting the Shared Utilities Folder" on page 71-88.

Optionally, you can provide additional capabilities that support model referencing:

- You can configure a target to support parallel builds for large model reference hierarchies (see "Reduce Build Time for Referenced Models" (Simulink Coder)). To do

this, you must modify the STF and TMF for parallel builds as described in "Declaring Model Referencing Compliance" on page 71-84 and "Providing Model Referencing Support in the TMF" on page 71-85.

- If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers, as described in "Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)" on page 71-92.
- You can modify hook files to handle referenced models differently than top models to prevent resource conflicts, as described in "Preventing Resource Conflicts (Optional)" on page 71-94.

See "Overview of Model Referencing" (Simulink) for information about model referencing in Simulink models, and "Generate Code for Referenced Models" (Simulink Coder) for information about model referencing in generated code.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Declaring Model Referencing Compliance

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in "Reduce Build Time for Referenced Models" (Simulink Coder).

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ParMdlRefBuildCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ParMdlRefBuildCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

Providing Model Referencing Support in the TMF

Do the following to configure the template makefile (TMF) to support model referencing:

1 Add the following make variables and tokens to be expanded when the makefile is generated:

```
MODELREFS                  = |>MODELREFS<|
MODELLIB                   = |>MODELLIB<|
MODELREF_LINK_LIBS         = |>MODELREF_LINK_LIBS<|
MODELREF_LINK_RSPFILE      = |>MODELREF_LINK_RSPFILE_NAME<|
MODELREF_INC_PATH         = |>START_MDLREFINC_EXPAND_INCLUDES<|\
    -I|>MODELREF_INC_PATH<| |>END_MDLREFINC_EXPAND_INCLUDES<|
RELATIVE_PATH_TO_ANCHOR    = |>RELATIVE_PATH_TO_ANCHOR<|
MODELREF_TARGET_TYPE       = |>MODELREF_TARGET_TYPE<|
```

The following code excerpt shows how makefile tokens are expanded for a referenced model.

```
MODELREFS                =
MODELLIB                 = engine3200cc_rtwlib.a
MODELREF_LINK_LIBS       =
MODELREF_LINK_RSPFILE    =
MODELREF_INC_PATH        =
RELATIVE_PATH_TO_ANCHOR  = ../../..
MODELREF_TARGET_TYPE     = RTW
```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```
MODELREFS                = engine3200cc transmission
MODELLIB                 = archlib.a
MODELREF_LINK_LIBS       = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_LINK_RSPFILE    =
MODELREF_INC_PATH      = -I../slprj/ert/engine3200cc -I../slprj/ert/transmission
RELATIVE_PATH_TO_ANCHOR  = ..
MODELREF_TARGET_TYPE     = NONE
```

Token	Expands to
`MODELREFS` for the top model	List of referenced model names.

Token	Expands to
MODELLIB	Name of the library generated for the model.
MODELREF_LINK_LIBS token for the top model	List of referenced model libraries that the top model links against.
MODELREF_LINK_RSPFILE token for the top model	Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see *matlabroot*/rtw/c/grt/grt_vc.tmf.
MODELREF_INC_PATH token for the top model	Include path to the referenced models.
RELATIVE_PATH_TO_ANCHOR	Relative path, from the location of the generated makefile, to the MATLAB working folder.
MODELREF_TARGET_TYPE	Signifies the type of target being built. Possible values are • NONE: Standalone model or top model referencing other models • RTW: Model reference target build • SIM: Model reference simulation target build

If you are configuring your target to support parallel builds, as discussed in "Reduce Build Time for Referenced Models" (Simulink Coder), you must also add the following token definitions to your TMF:

```
START_DIR = |>START_DIR<|
MASTER_ANCHOR_DIR = |>MASTER_ANCHOR_DIR<|
```

Token	Expands to
START_DIR	Current work folder (pwd) at the time the build started.
MASTER_ANCHOR_DIR	Current work folder (pwd) at the time the build started.

2. Add `RELATIVE_PATH_TO_ANCHOR` and `MODELREF_INC_PATH` include paths to the overall `INCLUDES` variable.

```
INCLUDES = -I. -I$(RELATIVE_PATH_TO_ANCHOR) $(MATLAB_INCLUDES) $(ADD_INCLUDES) \
    $(USER_INCLUDES) $(MODELREF_INC_PATH) $(SHARED_INCLUDES)
```

3. Change the `SRCS` variable in your TMF so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```
SRCS  = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

to

```
SRCS = $(MODULES) $(S_FUNCTIONS)
```

4. Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

```
PROGRAM    = ../$(MODEL)
```

and replace it with

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
  # Top model for RTW
  PRODUCT            = $(RELATIVE_PATH_TO_ANCHOR)/$(MODEL)
  BIN_SETTING        = $(LD) $(LDFLAGS) -o $(PRODUCT) $(SYSLIBS)
  BUILD_PRODUCT_TYPE = "executable"
  # ERT based targets
  SRCS               += $(MODEL).c ert_main.c $(EXT_SRC)
  # GRT based targets
  # SRCS             += $(MODEL).c grt_main.c rt_sim.c $(EXT_SRC) $(SOLVER)

else
  # sub-model for RTW
  PRODUCT            = $(MODELLIB)
  BUILD_PRODUCT_TYPE = "library"
endif
```

5. Create rules for the final target of the makefile (replace existing final target rules). For example:

```
ifeq ($(MODELREF_TARGET_TYPE),NONE)
  # Top model for RTW
  $(PRODUCT) : $(OBJS) $(SHARED_LIB) $(LIBS) $(MODELREF_LINK_LIBS)
               $(BIN_SETTING) $(LINK_OBJS) $(MODELREF_LINK_LIBS)
               $(SHARED_LIB) $(LIBS)
               @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
else
  # sub-model for RTW
  $(PRODUCT) : $(OBJS) $(SHARED_LIB) $(LIBS)
               @rm -f $(MODELLIB)
               $(ar) ruvs $(MODELLIB) $(LINK_OBJS)
```

```
                @echo "### Created $(MODELLIB)"
                @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
endif
```

6 Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (pwd).

```
%.o : $(RELATIVE_PATH_TO_ANCHOR)/%.c
 $(CC) -c $(CFLAGS) $<
```

Note: If you are using a TMF without the variables SHARED_SRC or MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable SHARED_SRC or MODELREFS to the make file.

Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in any referenced model and its parent model. To relax this requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to `'off'`. For example:

```
rtwoptions(2).prompt         = 'My Custom Parameter';
rtwoptions(2).type           = 'Checkbox';
rtwoptions(2).default        = 'on';
rtwoptions(2).modelReferenceParameterCheck  = 'on';
rtwoptions(2).tlcvariable    = 'mytlcvariable';
...
```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 71-29 for information about TLC-based system target files, and rtwoptions Structure Fields Summary for a list of `rtwoptions` fields.

Supporting the Shared Utilities Folder

Overview

The makefile used by the build process must support compiling and creating libraries, and so on, from the locations in which the code is generated. Therefore, you need to update your makefile and the model reference build process to support the shared utilities location. The **Shared code placement** options have the following requirements:

- `Auto`
  - Standalone model build — Build files go to the build folder; makefile is not updated.
  - Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.
- `Shared location`
  - Standalone model build — Use shared utilities folder; makefile requires shared location support.
  - Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.

The shared utilities folder (`slprj/`*`target`*`/_sharedutils`) typically stores generated utility code that is common between a top model and the models it references. You can also force the build process to use a shared utilities folder for a standalone model. See "Manage Build Process Folders" (Simulink Coder) for details.

If you want your target to support compilation of code generated in the shared utilities folder, several updates to your template makefile (TMF) are required. Support for Model Reference builds requires the shared utilities folder. See the preceding sections to learn about additional updates for supporting Model Reference builds.

The exact syntax of the changes can vary due to differences in the make utility and compiler/archiver tools used by your target. The examples below are based on the GNU[14] make utility. You can find the following updated TMF examples for GNU and Microsoft Visual C++ make utilities in the GRT and ERT target folders:

- GRT: *`matlabroot`*`/rtw/c/grt` (open)
  - `grt_lcc.tmf`
  - `grt_vc.tmf`

14. GNU is a registered trademark of the Free Software Foundation.

  - `grt_unix.tmf`
- ERT: *`matlabroot`*`/rtw/c/ert` (open)
  - `ert_lcc.tmf`
  - `ert_vc.tmf`
  - `ert_unix.tmf`

Use the GRT or ERT examples as a guide to the location, within the TMF, of the changes and additions described below.

Note The ERT-based TMFs contain extra code to handle generation of ERT S-functions and Model Reference simulation targets. Your target does not need to handle these cases.

Implementing Shared Utilities Folder Support

Make the following changes to your TMF to support the shared utilities folder:

1. Add the following make variables and tokens to be expanded when the makefile is generated:

   ```
   SHARED_SRC      = |>SHARED_SRC<|
   SHARED_SRC_DIR  = |>SHARED_SRC_DIR<|
   SHARED_BIN_DIR  = |>SHARED_BIN_DIR<|
   SHARED_LIB      = |>SHARED_LIB<|
   ```

   `SHARED_SRC` specifies the shared utilities folder location and the source files in it. A typical expansion in a makefile is

   ```
   SHARED_SRC      = ../slprj/ert/_sharedutils/*.c
   ```

   `SHARED_LIB` specifies the library file built from the shared source files, as in the following expansion.

   ```
   SHARED_LIB      = ../slprj/ert/_sharedutils/rtwshared.lib
   ```

   `SHARED_SRC_DIR` and `SHARED_BIN_DIR` allow specification of separate folders for shared source files and the library compiled from the source files. In the current release, the TMFs use the same path, as in the following expansions.

   ```
   SHARED_SRC_DIR  = ../slprj/ert/_sharedutils
   ```

```
SHARED_BIN_DIR  = ../slprj/ert/_sharedutils
```

2 Set the SHARED_INCLUDES variable according to whether shared utilities are in use. Then append it to the overall INCLUDES variable.

```
SHARED_INCLUDES =
ifneq ($(SHARED_SRC_DIR),)
SHARED_INCLUDES = -I$(SHARED_SRC_DIR)
endif

INCLUDES = -I. $(MATLAB_INCLUDES) $(ADD_INCLUDES) \
           $(USER_INCLUDES) $(SHARED_INCLUDES)
```

3 Update the SHARED_SRC variable to list shared files explicitly.

```
SHARED_SRC := $(wildcard $(SHARED_SRC))
```

4 Create a SHARED_OBJS variable based on SHARED_SRC.

```
SHARED_OBJS = $(addsuffix .o, $(basename $(SHARED_SRC)))
```

5 Create an OPTS (options) variable for compilation of shared utilities.

```
SHARED_OUTPUT_OPTS = -o $@
```

6 Provide a rule to compile the shared utility source files.

```
$(SHARED_OBJS) : $(SHARED_BIN_DIR)/%.o : $(SHARED_SRC_DIR)/%.c
 $(CC) -c $(CFLAGS) $(SHARED_OUTPUT_OPTS) $<
```

7 Provide a rule to create a library of the shared utilities. The following example is based on UNIX[15].

```
$(SHARED_LIB) : $(SHARED_OBJS)
   @echo "### Creating $@ "
   ar r $@ $(SHARED_OBJS)
   @echo "### Created  $@ "
```

Note: Depending on your make utility, you may be able to combine Steps 6 and 7 into one rule. For example, gmake (used with ert_unix.tmf) uses:

```
$(SHARED_LIB) : $(SHARED_SRC)
    @echo "### Creating $@ "
    cd $(SHARED_BIN_DIR); $(CC) -c $(CFLAGS) $(GCC_WALL_FLAG_MAX) $(notdir $?)
    ar ruvs $@ $(SHARED_OBJS)
    @echo "### $@ Created "
```

15. UNIX is a registered trademark of The Open Group in the United States and other countries.

See this and other examples in the files `ert_vc.tmf`, `ert_lcc.tmf`, and `ert_unix.tmf` located at *`matlabroot`*`/rtw/c/ert` (open).

8 Add `SHARED_LIB` to the rule that creates the final executable.

```
$(PROGRAM) : $(OBJS) $(LIBS) $(SHARED_LIB)
 $(LD) $(LDFLAGS) -o $@ $(LINK_OBJS) $(LIBS)
$(SHARED_LIB) $(SYSLIBS)
 @echo "### Created executable: $(MODEL)"
```

9 Remove explicit references to `rt_nonfinite.c` from your TMF. For example, change

```
ADD_SRCS = $(RTWLOG) rt_nonfinite.c
```

to

```
ADD_SRCS = $(RTWLOG)
```

Note If your target interfaces to a development environment that is not makefile based, you must make equivalent changes to provide information to your target compilation environment.

Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)

If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers. This addresses the possibility that parallel workers might have different configurations, some of which might not be compatible with a specific target build. For example, the required compiler might not be installed on a worker system.

The code generator provides a programming interface that you can use to automatically check the configuration of parallel workers. If parallel workers are not set up as expected, take action, such as reverting to sequential builds or throwing an error.

To set up automatic verification of workers, you must define a parallel configuration check function named *`STF`*`_par_cfg_chk`, where *`STF`* designates your system target file name. For example, the parallel configuration check function for `ert.tlc` is `ert_par_cfg_chk`.

The general syntax for the function is:

```
function varargout = STF_par_cfg_chk(action,varargin)
```

The number of output and input arguments vary according to the *`action`* specified, and according to the types of information you choose to coordinate between the client and the workers. The function should support the following general sequence of parallel configuration setup calls, differentiated by the first argument passed in:

Call Syntax	Called on:	Action
`cfg = STF_par_cfg_chk ('getPreferredCfg');`	Client	Return a structure representing the preferred configuration for MATLAB Distributed Computing Server workers.
`[tf, cfg] = STF_par_cfg_chk ('getWorkerCfg', cfg);`	Workers	Each worker is passed the MATLAB Distributed Computing Server client's preferred configuration. Return true if the worker can support the preferred configuration; otherwise return false along with a structure representing a configuration the worker can support. Information returned by each worker is added to a cell array of configurations.
`[tf, cfg] = STF_par_cfg_chk ('getCommonCfg', cfgs);`	Client	The client is passed the cell array of worker configurations. If a usable common configuration exists, return true, and return the common configuration to set for all systems. If a common configuration cannot be established, return false or take some action, such as reverting to sequential builds or throwing an error.
`tf = STF_par_cfg_chk ('setCommonCfg', cfg);`	Workers and client	Each system is passed the common configuration to use. Set up the common configuration and, if successful, return true. If errors or issues occur, return false or take some action, such as reverting to sequential builds or throwing an error.
`STF_par_cfg_chk ('clearCfg');`	Workers and client	Clean up after completion of the parallel build.

The parallel configuration check functions for MathWorks provided targets are implemented as wrapper functions that call a function named `parallelMdlRefHostConfigCheckFcn`. For example, see the ERT parallel configuration check function in the file *`matlabroot`*`/toolbox/rtw/rtw/`

`ert_par_cfg_chk.m`, and the function it calls in the file *`matlabroot`*`/toolbox/simulink/simulink/+Simulink/parallelMdlRefHostConfigCheckFcn.m`. The `parallelMdlRefHostConfigCheckFcn` function tries to establish a common compiler across the MATLAB Distributed Computing Server client and workers.

For more information about parallel builds, see "Reduce Build Time for Referenced Models" (Simulink Coder).

Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your *`STF`*`_make_rtw_hook.m file`:

```
% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName,`ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, `NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
  % code that is specific to the top model
else
  % code that is specific to the referenced model
end
```

You may need to do a similar check in your TLC code.

```
%if !IsModelReferenceTarget()
  %% code that is specific to the top model
%else
  %% code that is specific to the referenced model
%endif
```

Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you will not be able to use the **Compiler optimization level** parameter on the **All Parameters** tab of the Configuration Parameters dialog box to control the compiler optimization level for building generated code. (For more information about compiler optimization level control, see "Compiler optimization level" (Simulink Coder).)

In this section...

About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare compiler optimization level control compliance, as described in "Declaring Compiler Optimization Level Control Compliance" on page 71-95.
- The target makefile must honor the setting for **Compiler optimization level**, as described in "Providing Compiler Optimization Level Control Support in the Target Makefile" on page 71-96.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the `CompOptLevelCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `CompOptLevelCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CompOptLevelCompliant` target configuration parameter is set to `on`, the **Compiler optimization level** parameter is displayed in the **Code Generation** pane of the Configuration Parameters dialog box for your model.

Providing Compiler Optimization Level Control Support in the Target Makefile

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for **Compiler optimization level**. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

Support C Function Prototype Control

This section describes how to configure a custom embedded target to support C function prototype control. Without the described modifications, you will not be able to use the **Configure Model Functions** button on the **Interface** pane of the Configuration Parameters dialog box to control the function prototypes of initialize and step functions that are generated for your model. For more information about C function prototype control, see "Control Generation of Function Prototypes" on page 26-2.

In this section...

About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C function prototype control compliance, as described in "Declaring C Function Prototype Control Compliance" on page 71-97.
- If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in "Providing C Function Prototype Control Support in the Custom Static Main Program" on page 71-98.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the `ModelStepFunctionPrototypeControlCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered

whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelStepFunctionPrototypeControlCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to `on`, you can use the **Configure Model Functions** button on the **Interface** pane of the Configuration Parameters dialog box to control the function prototypes of initialize and step functions that are generated for your model.

Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

1. Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.
2. Generate your main program using **Generate an example main program** on the **Templates** pane of the Configuration Parameters dialog box. The generated main program declares model data and calls the function prototype controlled initialize and step function.

Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use `C++ class` code interface packaging and the **Configure C++ Class Interface** button on the **Interface** pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code. For more information about C++ class interface control, see "Control Generation of C++ Class Interfaces" on page 26-23.

In this section...

About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C++ class interface control compliance, as described in "Declaring C++ Class Interface Control Compliance" on page 71-100.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the `CPPClassGenCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `CPPClassGenCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the `C++ class` code interface packaging and the **Configure C++ Class Interface** button on the **Interface** pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code.

Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting `C++ class` code interface packaging for your model turns on the model option **Generate an example main program**. With this option on, code generation generates an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

- “Sample Custom Targets” (Simulink Coder)
- “Customize System Target Files” (Simulink Coder)

Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option `ConcurrentExecutionCompliant`. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If `ConcurrentExecutionCompliant` is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (*`mytarget`*`.tlc`):

  ```
  rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
  ''ConcurrentExecutionCompliant'',''on'');';
  rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
  ''ConcurrentExecutionCompliant'',''on'');';
  ```

- Implement a callback function that sets the `ConcurrentExecutionCompliant` option, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

  ```
  rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

  Your callback function should set the `ConcurrentExecutionCompliant` option as follows:

  ```
  slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
  slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
  ```

  For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ConcurrentExecutionCompliant` target configuration option is set to `'on'`, you can select the custom target and configure your multicore target model for concurrent execution.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

- “Customize System Target Files” (Simulink Coder)

Interface to Development Tools

Unless you are developing a target purely for code generation purposes, you will want your embedded target to support a complete build process. A full post-code generation build process includes

- Compilation of generated code
- Linking of compiled code and runtime libraries into an executable program module (or some intermediate representation of the executable code, such as S-Rec format)
- Downloading the executable to target hardware with a debugger or other utility
- Initiating execution of the downloaded program

Supporting a complete build process is inherently a complex task, because it involves interfacing to cross-development tools and utilities that are external to the code generator.

If your development tools can be controlled with traditional makefiles and a make utility such as `gmake`, it may be relatively simple for you to adapt existing target files (such as the `ert.tlc` and `ert.tmf` files provided by the Embedded Coder software) to your requirements. This approach is discussed in "Template Makefile Approach" on page 71-105.

In this section...

About Interfacing to Development Tools

Automating your build process through a modern integrated development environment (IDE) presents a different set of challenges. Each IDE has its own way of representing the set of source files and libraries for a project and for specifying build arguments. Interfacing to an IDE may require generation of specialized file formats required by the IDE (for example, project files) and, and also may require the use of inter-application communication (IAC) techniques to run the IDE. One such approach to build automation is discussed in "Interface to an Integrated Development Environment" on page 71-105.

Template Makefile Approach

A template makefile provides information about your model and your development system. The build process uses this information to create a makefile (`.mk` file) to build an executable program. The code generator provides a number of template makefiles suitable for development computer compilers, such as LCC (`ert_lcc.tmf`) and Microsoft Visual C++ (`ert_vc.tmf`).

Adapting one of the existing template makefiles to your cross-compiler's make utility may require little more than copying and renaming the template makefile in accordance with the conventions of your project.

If you need to make more extensive modifications, you need to understand template makefiles in detail. For a detailed description of the structure of template makefiles and of the tokens used in template makefiles, see "Customize Template Makefiles" on page 71-62.

The following topics supplement the basic template makefile information:

- "Supporting Multiple Development Environments" on page 71-48
- "Supplying Development Environment Information to Your Template Makefile" on page 71-26

Interface to an Integrated Development Environment

This section describes techniques that have been used to integrate embedded targets with integrated development environment (IDEs), including

- How to generate a header file containing directives to define variables (and their values) required by a non-makefile based build.
- Some problems and solutions specific to interfacing embedded targets with the Freescale Semiconductor CodeWarrior IDE. The examples provided should help you to deal with similar interfacing problems with your particular IDE.

- "Generating a CPP_REQ_DEFINES Header File" on page 71-105
- "Interfacing to the Freescale CodeWarrior IDE" on page 71-107

Generating a CPP_REQ_DEFINES Header File

In template makefiles, the token `CPP_REQ_DEFINES` is expanded and replaced with a list of parameter settings entered with various dialog boxes. This variable often contains

information such as MODEL (name of generating model), NUMST (number of sample times in the model), MT (model is multitasking or not), and numerous other parameters (see "Template Makefiles and Tokens" on page 71-62).

The makefile mechanism handles the CPP_REQ_DEFINES token automatically. If your target requires use of a project file, rather than the traditional makefile approach, you can generate a header file containing directives to define these variables and provide their values.

The following TLC file, gen_rtw_req_defines.tlc, provides an example. The code generates a C header file, cpp_req_defines.h. The information required to generate each #define directive is derived either from information in the *model*.rtw file (e.g., CompiledModel.NumSynchronousSampleTimes), or from make variables from the rtwoptions structure (for example, PurelyIntegerCode).

```
%% File: gen_rtw_req_defines_h.tlc
%openfile CPP_DEFINES = "cpp_req_defines.h"
#ifndef _CPP_REQ_DEFINES_
#define _CPP_REQ_DEFINES_
#define MODEL %<CompiledModel.Name>
#define ERT  1
#define NUMST %<CompiledModel.NumSynchronousSampleTimes>
#define TID01EQ %<CompiledModel.FixedStepOpts.TID01EQ>
%%
%if CompiledModel.FixedStepOpts.SolverMode == "MultiTasking"
#define MT  1
#define MULTITASKING  1
%else
#define MT  0
#define MULTITASKING  0
%endif
%%
#define MAT_FILE  0
#define INTEGER_CODE %<PurelyIntegerCode>
#define ONESTEPFCN %<CombineOutputUpdateFcns>
#define TERMFCN %<IncludeMdlTerminateFcn>
%%
#define MULTI_INSTANCE_CODE  0
#define HAVESTDIO  0
#endif
%closefile CPP_DEFINES
```

Interfacing to the Freescale CodeWarrior IDE

Interfacing an embedded target's build process to the CodeWarrior IDE requires that two problems must be dealt with:

- The build process must generate a CodeWarrior compatible project file. This problem, and a solution, is discussed in "XML Project Import" on page 71-107. The solution described is applicable to ASCII project file formats.
- During code generation, the target must automate a CodeWarrior session that opens a project file and builds an executable. This task is described in "Build Process Automation" on page 71-112. The solution described is applicable to IDEs that can be controlled with Microsoft Component Object Model (COM) automation.

XML Project Import

This section illustrates how to use the Target Language Compiler (TLC) to generate an eXtensible Markup Language (XML) file, suitable for import into the CodeWarrior IDE, that contains information about the source code generated by an embedded target.

The choice of XML format is dictated by the fact that the CodeWarrior IDE supports project export and import with XML files. As of this writing, native CodeWarrior project files are in a proprietary binary format.

Note that if your target needs to support some other compiler's project file format, you can apply the techniques shown here to other ASCII file formats (see "Generating a CPP_REQ_DEFINES Header File" on page 71-105).

To illustrate the basic concept, consider a hypothetical XML file exported from a CodeWarrior stationery project. The following is a partial listing:

```
<target>
   <settings>
    ...
   <\settings>
   <file><name>foo.c<\name>
   <\file>
   ...
   <file><name>foobar.c<\name>
   <\file>
   <fileref><name>foo.c<\name>
   <\fileref>
   ...
   <fileref><name>foobar.c<\name>
```

```
   <\fileref>
<\target>
```

Insert this XML code into an `%openfile/%closefile` block within a TLC file, `test.tlc`, as shown below.

```
%% test.tlc
%% This code will generate a file model_project.xml,
%% where model is the generating model name specified in
%% the CompiledModel.Name field of the model.rtw file.
%openfile XMLFileContents = %<CompiledModel.Name>_project.xml
<target>
   <settings>
    ...
   <\settings>
   <file><name>%<CompiledModel.Name>.c<\name>
   <\file>
   ...
   <file><name>foobar.c<\name>
   <\file>
   <fileref><name>%<CompiledModel.Name>.c<\name>
   <\fileref>
   ...
   <fileref><name>foobar.c<\name>
   <\fileref>
<\target>
%closefile XMLFileContents
%selectfile NULL_FILE
```

Note the use of the TLC token `CompiledModel.Name`. The token is resolved and the resulting filename is included in the output stream. You can specify other information, such as paths and libraries, in the output stream by specifying other tokens defined in *`model`*`.rtw`. For example, `System.Name` may be defined as `<Root>/Subsystem1`.

Now suppose that `test.tlc` is invoked during a target's build process, where the generating model is `mymodel`. This should be done after the `codegenentry` statement. For example, `test.tlc` could be included directly in the system target file:

```
%include "codegenentry.tlc"
%include "test.tlc"
```

Alternatively, the `%include "test.tlc"` directive could be inserted into the `mytarget_genfiles.tlc` hook file, if present.

TLC tokens such as

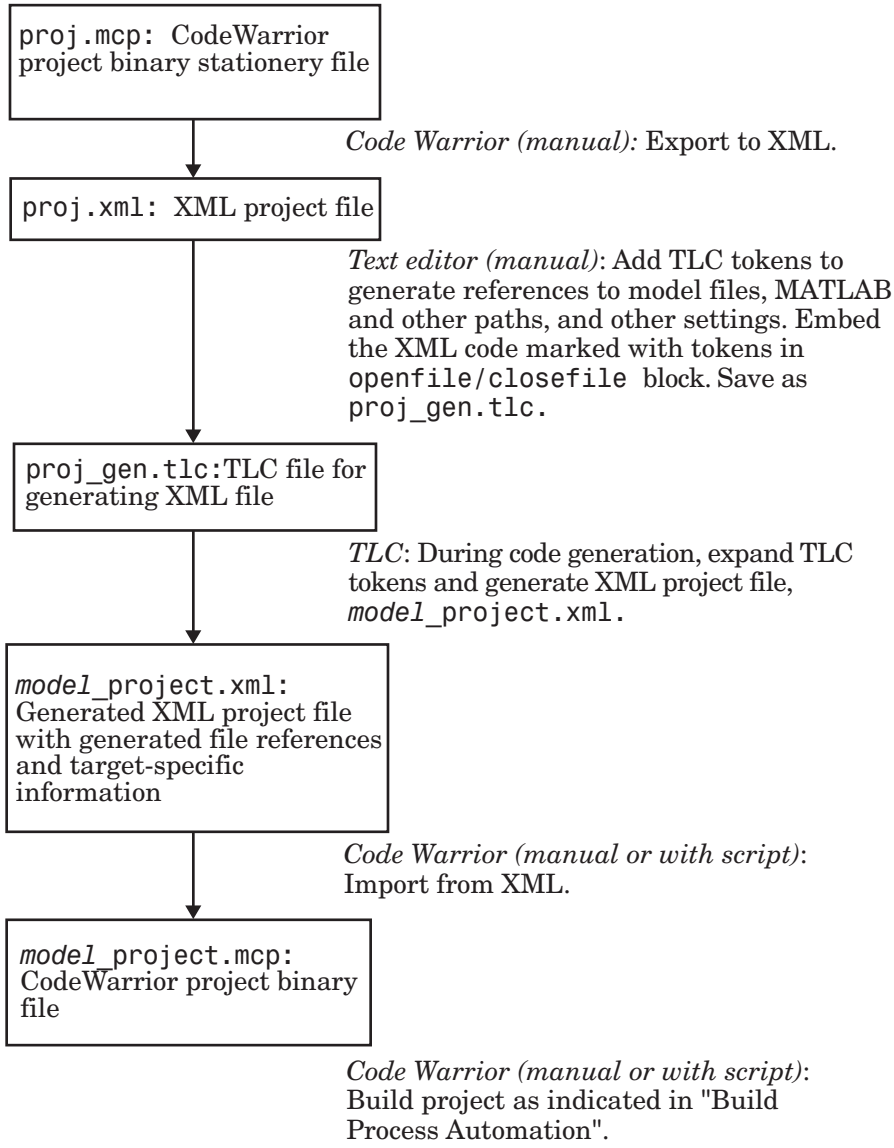
```
<file><name>%<CompiledModel.Name>.c<\name>
```

are expanded, with the `CompiledModel` record in the `mymodel.rtw` file, as in

```
<file><name>mymodel.c<\name>
```

`test.tlc` generates an XML file, file *`model`*`_project.xml`, from a model. *`model`*`_project.xml` contains references to generated code files. *`model`*`_project.xml` can be imported into the CodeWarrior IDE as a project.

The following flowchart summarizes this process.



Note This process has drawbacks. First, manually editing an XML file exported from a CodeWarrior stationery project can be a laborious task, involving modification of a few

dozen lines embedded within several thousand lines of XML code. Second, if you make changes to the CodeWarrior project after importing the generated XML file, the XML file must be exported and manually edited once again.

Build Process Automation

An application that supports COM automation can control other applications that include a COM interface. Using MATLAB COM automation functions, a MATLAB file can command a COM-compatible development system to execute tasks required by the build process.

The MATLAB COM automation functions described in this section are documented in "Call COM Objects" (MATLAB).

For information about automation commands supported by the CodeWarrior IDE, see your CodeWarrior documentation.

COM automation is used by some embedded targets to automate the CodeWarrior IDE to execute tasks such as:

- Opening a new CodeWarrior session
- Configure a project
- Loading a CodeWarrior project file
- Removing object code from the project
- Building or rebuilding the project
- Debug an application

COM technology automates certain repetitive tasks and allows the user to interact directly with the external application. For example, when the end user of the embedded targets capability initiates a build, the target quickly invokes CodeWarrior actions and leaves a project built and ready to run with the IDE.

Example COM Automation Functions

The functions below use the MATLAB `actxserver` command to invoke COM functions for controlling the CodeWarrior IDE from a MATLAB file:

- `CreateCWComObject`: Create a COM connection to the CodeWarrior IDE.
- `OpenCW`: Open the CodeWarrior IDE without opening a project.

- `OpenMCP`: Open the CodeWarrior project file (`.mcp` file) specified by the input argument.
- `BuildCW`: Open the specified `.mcp` file, remove object code, and build project.

These functions are examples; they do not constitute a full implementation of a COM automation interface. If your target creates the project file during code generation, the top-level `BuildCW` function should be called after the code generation process is completed. Normally `BuildCW` would be called from the `exit` method of your *`STF`*`_make_rtw_hook.m` file (see "STF_make_rtw_hook.m" on page 71-21).

In the code examples, the variable `in_qualifiedMCP` is assumed to store a fully qualified path to a CodeWarrior project file (for example, path, filename, and extension). For example:

```
in_qualifiedMCP = 'd:\work\myproject.mcp';
```

In actual practice, your code is responsible for determining the conventions used for the project filename and location. One simple convention would be to default to a project file *`model`*`.mcp`, located in your target's build folder.

```
%=============================================================================
% Function: CreateCWComObject
% Abstract: Creates the COM connection to CodeWarrior
%
function ICodeWarriorApp = CreateCWComObject
  vprint([mfilename ': creating CW com object']);
  try
    ICodeWarriorApp = actxserver('CodeWarrior.CodeWarriorApp');
  catch
    error(['Error creating COM connection to ' ComObj ...
       '. Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
  end
  return;

  % Argument checking. This method requires valid project file.
  if ~exist(in_qualifiedMCP)
      error([mfilename ': Missing or empty project file argument']);
  end
  if isempty(in_qualifiedMCP)
      error([mfilename ': Missing or empty project file argument']);
  end
  ICodeWarriorApp = CreateCWComObject;
  vprint([mfilename ': Importing']);
  try
    ICodeWarriorProject = ...
      invoke(ICodeWarriorApp.Application,...
      'OpenProject', in_qualifiedMCP,...
      1,0,0);
  catch
    error(['Error using COM connection to import project. ' ...
       ' Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
  end

%=========================================================================
% Function: BuildCW
% Abstract: Opens CodeWarrior.
%           Opens the specified CodeWarrior project.
%           Deletes objects.
%           Builds.
%
function ICodeWarriorApp = BuildCW(in_qualifiedMCP)
    % ICodeWarriorApp = BuildCW;
    ICodeWarriorApp = CreateCWComObject;
    CloseAll;
    OpenMCP(in_qualifiedMCP);
    try
      invoke(ICodeWarriorApp.DefaultProject,'RemoveObjectCode', 0, 1);
    catch
      error(['Error using COM connection to remove objects of current project. ' ...
       'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
    end
    try
      invoke(ICodeWarriorApp.DefaultProject,'BuildAndWaitToComplete');
    catch
      error(['Error using COM connection to build current project. ' ...
       'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
    end
```

Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder) and “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).

More About

- “About Embedded Target Development” (Simulink Coder)
- “Sample Custom Targets” (Simulink Coder)
- “Customize System Target Files” (Simulink Coder)

Project and Build Configurations for Embedded Targets in Embedded Coder

Model Setup

In this section...

Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (`embeddedtargetslib`) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

Block Name/Category	Library	Description
Scope	Simulink, DSP System Toolbox software	Provides oscilloscope view of your output. Do not use the **Save data to workspace** option on the **Data history** pane in the Scope Parameters dialog.
To Workspace	Simulink	Return data to your MATLAB workspace.
From Workspace	Simulink	Send data to your model from your MATLAB workspace.
Spectrum Scope	DSP System Toolbox	Compute and display the short-time FFT of a signal. It has internal buffering that can slow your process without adding value.

Block Name/Category	Library	Description
To File	Simulink	Send data to a file on your host machine.
From File	Simulink	Get data from a file on your host machine.
Triggered to Workspace	DSP System Toolbox	Send data to your MATLAB workspace.
Signal To Workspace	DSP System Toolbox	Send a signal to your MATLAB workspace.
Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
Triggered Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
To Wave device	DSP System Toolbox	Send data to a `.wav` device.
From Wave device	DSP System Toolbox	Get data from a `.wav` device.

Configure Target Hardware Resources

This topic contains the following subtopics:

About Supported IDEs

This "Configure Target Hardware Resources" on page 72-3 section applies to the following IDEs:

- Analog Devices VisualDSP++®
- Wind River Diab/GCC (makefile generation only)

Configure Parameters Under the Target Hardware Resources Tab

Configure the parameters under the Target Hardware Resources tab of your Simulink model for a specific tool chain and target hardware. Doing so updates other parameters in the Configuration Parameters dialog to the default values for the software build tool chain and target hardware you are using.

Note: The Target Preferences (Removed) block has been removed from the Simulink block libraries for the Embedded Coder and Simulink Coder products.

Parameters in the Target Preferences block have been moved to the Target Hardware Resources tab.

To configure your Simulink model for a specific tool chain and target hardware:

1. In a Simulink model, open the model Configuration Parameters by:
   - Clicking the gear icon,

   - Pressing **Ctrl+E** on your keyboard
   - Selecting the **Simulation** > **Model Configuration Parameters** menu items
2. In the Configuration Parameters dialog, click **Code Generation**, and then click "+" next to Code Generation. This action displays the sub-panes under Code Generation.
3. On the Code Generation pane, change **System target file** to `idelink_ert.tlc` or `idelink_grt.tlc`.

   The dialog displays a **Coder Target** pane under the Code Generation pane.
4. Select the **Coder Target** pane.
5. Select the **Target Hardware Resources** tab.
6. Set the following parameters to match the tool chain and target hardware you are using:
   - **IDE/Tool Chain**
   - **Board**
   - **Processor**
7. Review the other parameters under the **Target Hardware Resources** tab.
8. Click **Apply**, and save the changes to your model.

Configuration Parameters

- "What are Configuration Parameters?" on page 72-5

What are Configuration Parameters?

To see the model Configuration Parameters, open the **Configuration Parameters** dialog. You can do this in the model editor by selecting **Simulation** > **Model Configuration Parameters**, or by pressing **Ctrl+E** on your keyboard.

The **Configuration Parameters** dialog specifies the values for a model's active *configuration set*. These parameters determine the type of solver used, the import and export settings, and other values that determine how the model runs.

Setting Model Configuration Parameters

To set the Configuration Parameters to the right values for you to generate code from your model, see "Configure Parameters Under the Target Hardware Resources Tab" on page 72-3. This action initializes the model Configuration Parameters to the right default values for you to generate code. You can then use the Configuration Parameters dialog to make further modifications to the values. You can generate buildable code using these default values.

The following subsections provide a quick overview of the panes and parameters with which you are most likely to interact.

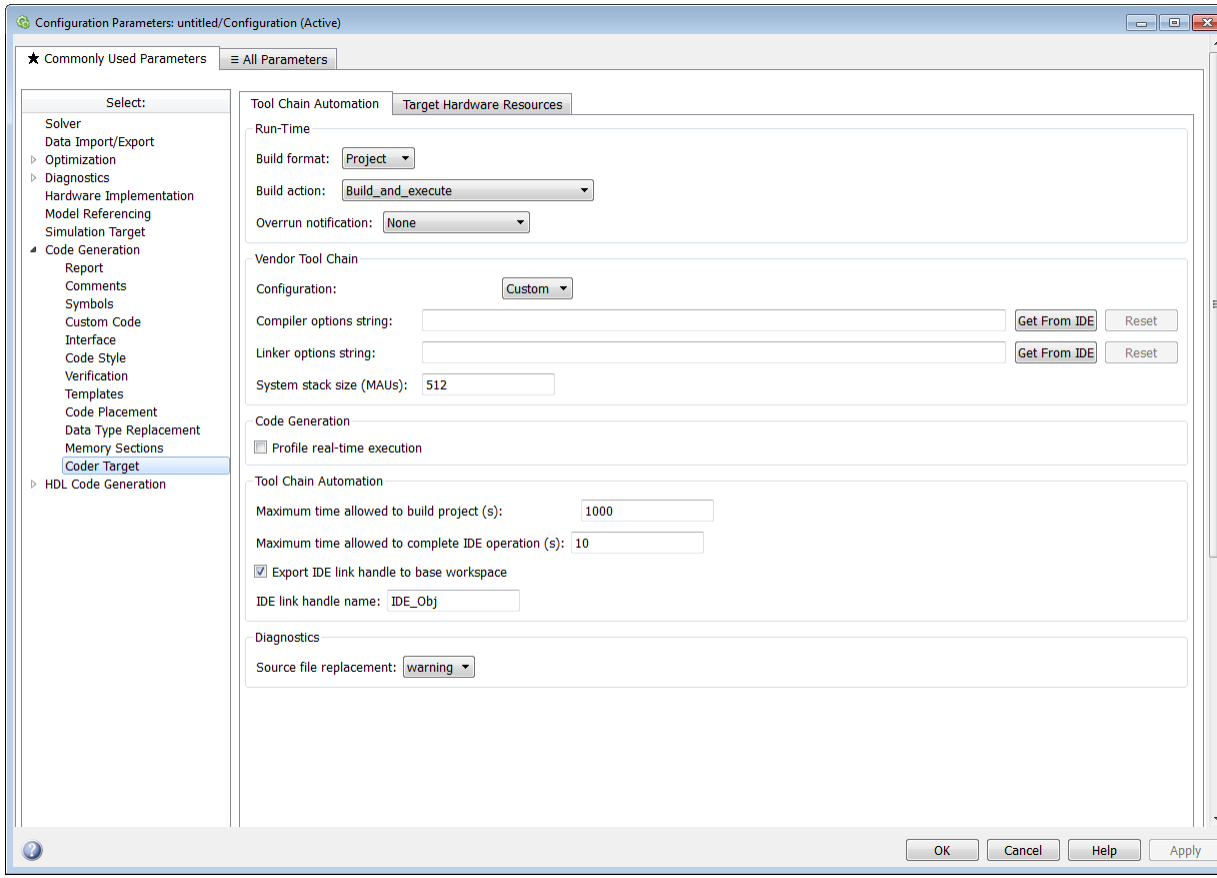
Code Generation Pane

When you set **System target file** to `idelink_ert.tlc` or `idelink_grt.tlc`, the dialog adds an **Coder Target** pane to the list of panes under **Code Generation**.

Leave **Language** set to `C`. The `idelink_ert.tlc` and `idelink_grt.tlc` system target files do not support `C++` code generation.

For more information, see "Model Configuration Parameters: Code Generation" (Simulink Coder).

Coder Target Pane Parameters



The Coder Target entry provides options in these areas:

- **Run-Time** — Set options for run-time operations, like the build action
- **Vendor Tool Chain** — Set compiler, linker, and system stack size options
- **Code Generation** — Configure your code generation requirements
- **Link Automation** — Export an IDE link handle object, such as `IDE_Obj`, to your MATLAB workspace
- **Diagnostics** — Determine how the code generation process responds when you use source code replacement in the **Custom Code** pane.

For more information, see Code Generation Pane: Coder Target.

Build format

Select `Project` to create an IDE project, or select `Makefile` to create a makefile build script.

Build action

Your selection for **Build action** determines what happens when you press **Ctrl+B**. Your selection tells Simulink Coder software when to stop the code generation and build process.

To run your model on the processor, select `Build_and_execute`. This selection is the default build action.

The actions are cumulative—each action performs an additional step relative to the preceding action on the list.

If you set **Build format** to `Project`, select one of the following options:

- `Create_project` — Directs Simulink Coder software to start the IDE and populate a new project with the files from the build process. This option offers a convenient way to build projects in the IDE.
- `Archive_library` — Directs Simulink Coder software to create an archive library for this model. Use this option when you plan to use the model in a model reference application. Model reference requires that you archive your the IDE projects for models that you use in model referencing.
- `Build` — Builds the executable file, but does not download the file to the target hardware.
- `Build_and_execute` — Directs Simulink Coder software to build, download, and run your generated code as an executable on your target hardware.
- `Create_processor_in_the_loop_project` — Directs code generation process to create PIL algorithm object code as part of the project build. This option requires an Embedded Coder license.

If you set **Build format** to `Makefile`, select one of the following options:

- `Create_makefile` — Creates a makefile.
- `Archive_library` — Creates a makefile and the generated output will be an archive library.

- `Build` — Creates a makefile and an executable.
- `Build_and_execute` — Creates a makefile and an executable. Then it evaluates the execute instruction in the current configuration.

Overrun notification

To enable the overrun indicator, choose one of three ways for the target to respond to an overrun condition in your model:

- `None` — Ignore overruns encountered while running the model.
- `Print_message` — When the target encounters an overrun condition, it prints a message to the standard output device, `stdout`.
- `Call_custom_function` — Respond to overrun conditions by calling the custom function you identify in **Function name**.

Function name

When you select `Call_custom_function` from the **Overrun notification** list, you enable this option. Enter the name of the function the target should use to notify you that an overrun condition occurred. The function must exist in your code on the target hardware.

Configuration

The **Configuration** parameter defines sets of build options that apply to the files generated from your model.

The `Release` and `Debug` option apply build settings that are defined by your compiler. For more information, refer to your compiler documentation.

`Custom` has the same default values as `Release`, but:

- Leaves **Compiler options string** empty.

Compiler options string

To determine the degree of optimization provided by the optimizing compiler, enter the optimization level to apply to files in your project. For details about the compiler options, refer to your IDE documentation. When you create new projects, the code generator does not set optimization flags.

With Texas Instruments Code Composer Studio™ 3.3 and Analog Devices VisualDSP++, the user interface displays **Get From IDE** and **Reset** buttons next to this parameter.

If you have an active project open in the IDE, you can click **Get From IDE** to import the compiler option setting from the current project in the IDE. To reset the compiler option to the default value, click **Reset**.

Linker options string

To specify the options provided by the linker during link time, you enter the linker options as text. For details about the linker options, refer to your IDE documentation. When you create new projects, the code generator does not set linker options.

With Texas Instruments Code Composer Studio 3.3 and Analog Devices VisualDSP++, the user interface displays **Get From IDE** and **Reset** buttons next to this parameter. If you have an active project open in the IDE, you can click **Get From IDE** to import the linker options text from the current project in the IDE. To clear the linker options, click **Reset**.

System stack size (MAUs)

Enter the amount of memory that is available for allocating stack data, measured in minimum addressable units (MAU). Block output buffers are placed on the stack until the stack memory is fully allocated. After that, the output buffers go in global memory. An MAU is typically 1 byte, but its size can vary by target hardware.

This parameter is used in targets to allocate the stack size for the generated application. For example, with embedded processors that are not running an operating system, this parameter determines the total stack space that can be used for the application. For operating systems, this value specifies the stack space allocated per thread.

This parameter also applies to the “Maximum stack size (bytes)” (Simulink) parameter, located in the Optimization > Signals and Parameters pane.

System heap size (MAUs)

Set the default heap size that the target hardware reserves for dynamic memory allocation.

The target hardware uses this heap for functions like printf() and system services code.

The following IDEs use this parameter:

- Analog Devices VisualDSP++
- Wind River Diab/GCC (makefile generation only)

Profile real-time execution

To enable the real-time execution profile capability, select **Profile real-time execution**. With this selected, the build process instruments your code to provide performance profiling at the task level or for atomic subsystems. When you run your code, the executed code reports the profiling information in an HTML report.

Link Automation

When you build a model for a system target file , the code generator automatically creates or uses an existing *IDE link handle object* (named `IDE_Obj`, by default) to connect to your IDE.

Although `IDE_Obj` is a handle for a specific instance of the IDE, it also contains information about the IDE instance to which it refers, such as the target the IDE accesses. In this pane, the **Export IDE link handle to base workspace** option lets you instruct the code generator to export the object to your MATLAB workspace, giving it the name you assign in **IDE link handle name**.

You can also use the IDE link handle object to interact with the IDE using IDE Automation Interface commands.

Maximum time allowed to build project (s)

Specifies how long the software waits for the IDE to build the software.

Maximum time allowed to complete IDE operation (s)

Specifies how long the software waits for IDE functions, such as `read` or `write`, to return completion messages. If you do not specify a timeout, the default value is 10 seconds.

Export IDE link handle to base workspace

Directs the software to export the IDE_Obj object to your MATLAB workspace.

IDE link handle name

Specifies the name of the IDE_Obj object that the build process creates.

Source file replacement

Selects the diagnostic action to take if the software detects conflicts when you replace source code with custom code. The diagnostic message responds to both source file

replacement in the Configuration Parameters under Code Generation > Coder Target parameters and under Code Generation > Custom Code.

The following settings define the messages you see and how the code generation process responds:

- `none` — Does not generate warnings or errors when it finds conflicts.
- `warning` — Displays a warning. `warn` is the default value.
- `error` — Terminates the build process and displays an error message that identifies which file has the problem and suggests how to resolve it.

The build operation continues if you select `warning` and the software detects custom code replacement problems. You see warning messages as the build progresses.

Select `error` the first time you build your project after you specify custom code to use. The error messages can help you diagnose problems with your custom code replacement files. Use `none` when the replacement process works and you do not want to see multiple messages during your build.

Model Reference

The `ert.tlc` system target files provide support for generating code from models that use Model Reference. A referenced model will generate an archive library.

To enable Model Reference builds:

1. Open your referenced model.
2. Select Simulation > Model Configuration Parameters from the model menus.
3. From the list of panes under **Code Generation**, choose **Coder Target**.
4. In the right pane, under Run-Time, select `Archive_library` from the **Build action** list.

If your top-model uses a reference model that does not have the **Build action** set to `Archive_library`, the build process automatically changes the **Build action** to `Archive_library` and issues a warning about the change.

Configuration Parameters in Reference Models

Use the same Coder Target pane settings in Configuration Parameters for the models in the model hierarchy.

XMakefiles for Software Build Tool Chains

In this section...

What is the XMakefile Feature

Overview

You can use makefiles instead of IDE projects during the automated software build process. This approach is described in "Using Makefiles to Generate and Build Software" on page 72-14.

The XMakefile feature lets you choose the *configuration* of a specific software build tool chain to use during the automated build process. The configuration contains paths and settings for your make utility, compiler, linker, archiver, pre-build, post-build, and execute tools.

You can also create a new configuration for a new tool chain, as described in "Creating a New XMakefile Configuration" on page 72-16.

Your requirements for specific features may determine whether you choose makefiles or IDE projects. See "Feature Support" on page 72-13.

Available XMakefile Configurations

The following list describes the configurations in the XMakefile dialog that this product supports:

- `adivdsp_blackfin`: Analog Devices VisualDSP++ & Analog Devices Blackfin®
- `adivdsp_sharc`: Analog Devices VisualDSP++ & Analog Devices SHARC®

- `adivdsp_tigersharc`: Analog Devices VisualDSP++ & Analog Devices TigerSHARC®
- `gcc_target`: GNU Compiler Collection & Host Operating System or Embedded Operating System
- `wrsdiab_arm9_vxworks67_rtp`: Wind River Systems DIAB Compiler & ARM 9 & VxWorks 6.7 & real-time process applications
- `wrsdiab_arm9_vxworks67_rtp_so`: Wind River Systems DIAB Compiler & ARM 9 & VxWorks 6.7 & real-time process applications with shared object
- `wrsdiab_hostsim_vxworks67_rtp`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications
- `wrsdiab_hostsim_vxworks67_rtp_so`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications with shared object
- `wrsdiab_hostsim_vxworks68_rtp`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications
- `wrsdiab_hostsim_vxworks68_rtp_so`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications with shared object
- `wrsgnu_arm9_vxworks67_rtp`: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications
- `wrsgnu_hostsim_vxworks67_rtp`: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications with shared object
- `wrsgnu_hostsim_vxworks68_rtp`: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications with shared object
- `xilinx_ise_14_x`: Xilinx ISE Design Suite & ARM Cortex-A9 running Linux on Xilinx Zynq®-7000 platform

For more information about supported versions of third-party software, see

Feature Support

With makefiles, you cannot use features that rely on direct communications between your MathWorks software and third-party IDEs.

You cannot use the following features with makefiles:

- IDE Project Generation

- IDE Automation Interface
- IDE debugger communications during Processor-in-the-loop (PIL) simulation

Using Makefiles to Generate and Build Software

Configuring Your Model to Use Makefiles

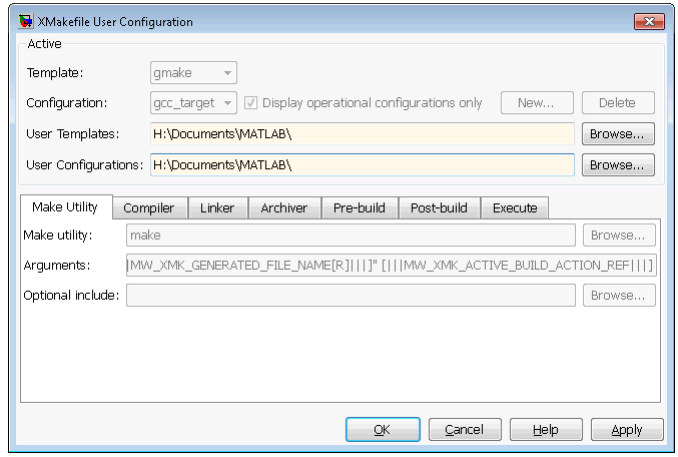
Update your model Configuration Parameters to use a makefile instead of an IDE when you build software from the model:

1. Configure your model for your IDE, tool chain, and target hardware, as described in "Configure Target Hardware Resources" on page 72-3.
2. In the Configuration Parameters dialog, under the **Code Generation** tab, select **Coder Target**.
3. Set **Build format** to `Makefile`. For more information, see "Build format" on page 72-7.
4. Set **Build action** to `Build_and_execute`. For more information, see "Build action" on page 72-7.

Choosing an XMakefile Configuration

Configure how to generate makefiles:

1. Enter `xmakefilesetup` on the MATLAB Command Window. The software opens an XMakefile User Configuration dialog.



2 Set the **Template** parameter to the option that matches the **Configuration** parameter.

> **Note:** In most cases, the only option for **Template** is `gmake`. However, if you have installed a Support Package, **Template** can have multiple options.

3 For **Configuration**, select the option that describes your software build toolchain and target platform. Click **Apply**.

Note: Changing some elements of the XMakefile dialog disables other elements until you apply the changes. Click **Apply** or **OK** after changing:

- **Template**
- **Configurations**
- **User Templates**
- **User Configurations**
- **Tool Directories**

Note: With the XMakefile User Configuration dialog, if you have an Embedded Coder license and do not have a Simulink Coder license, the **Configuration** list includes two unsupported options: `gcc_target` or `msvs_host`. Disregard those two configurations. Choose one of the other configurations.

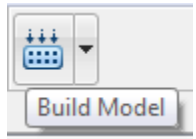
Things to consider while setting **Configuration**:

- Selecting **Display operational configurations only** hides configurations that contain incomplete or invalid information. For a configuration to be operational, the vendor tool chain must be installed, and the configuration must have the valid paths for each component of the vendor tool chain. For more information, see "Making an XMakefile Configuration Operational" on page 72-16.
- To display the configurations, including non-operational configurations, clear **Display operational configurations only**.
- The list of configurations can include non-editable configurations defined in the software and editable configurations defined by you.
- To create a new editable configuration, use the **New** button.

- For more information, see “XMakefile User Configuration dialog” on page 72-22.

Building Your Model

In your model, click **Build Model**.



This action creates a makefile and performs the other actions you specified in **Build action**.

By default, this process outputs files in the `<builddir>/<buildconfiguration>` folder. For example, in `model_name/CustomMW`.

Making an XMakefile Configuration Operational

When the XMakefile utility starts, it checks each configuration file to verify that the specified paths for the vendor tool chain are valid. If the paths are not valid, the configuration is non-operational. Typically, the cause of this problem is a difference between the path in the configuration and the actual path of the vendor toolchain.

To make a configuration operational:

1. Clear **Display operational configurations only** to display non-operational configurations.
2. Select the non-operational configuration from the **Configuration** options.
3. When you click **Apply**, a new dialog prompts you for the folder path of the missing resources the configuration requires.

   Use mapped network drives instead of UNC paths to specify directory locations. Using UNC paths with compilers that do not support them causes build errors.

Creating a New XMakefile Configuration

Overview

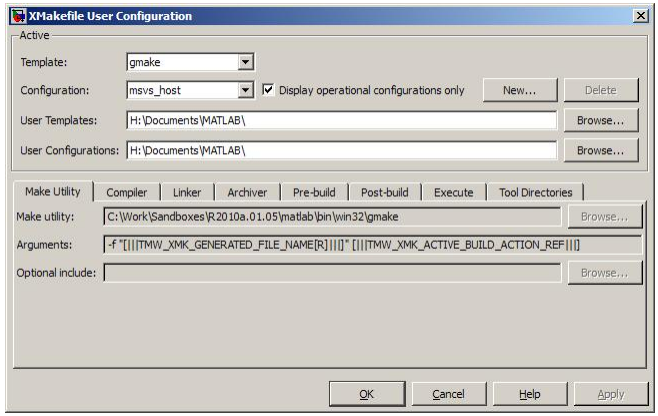
This example shows you how to add support for a software development toolchain to the XMakefile utility. This example uses the Intel Compiler and an IDE.

Note: To specify directory locations, use mapped network drives instead of UNC paths. UNC paths cause build errors with compilers that do not support them.

Create a Configuration

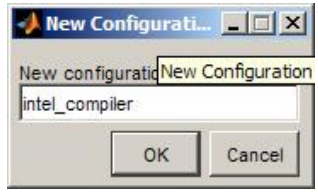
When you click **New**, the new configuration inherits values and behavior from the current configuration. To create a configuration for the Intel Compiler, clone a configuration from one of these configurations: `montavista_arm` and `gcc_target`.

Open the XMakefile User Configuration UI by typing `xmakefilesetup` at the MATLAB prompt. This action displays the following dialog.

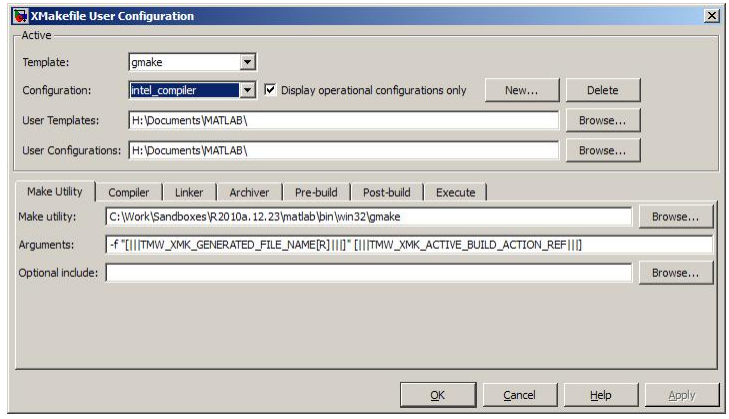


Select an existing configuration, such as `montavista_arm` or `gcc_target`. Click the **New** button.

A pop-up dialog prompts you for the name of the new configuration. Enter `intel_compiler` and click **OK**.



The dialog displays a new configuration called `intel_compiler`, based on the previous configuration.

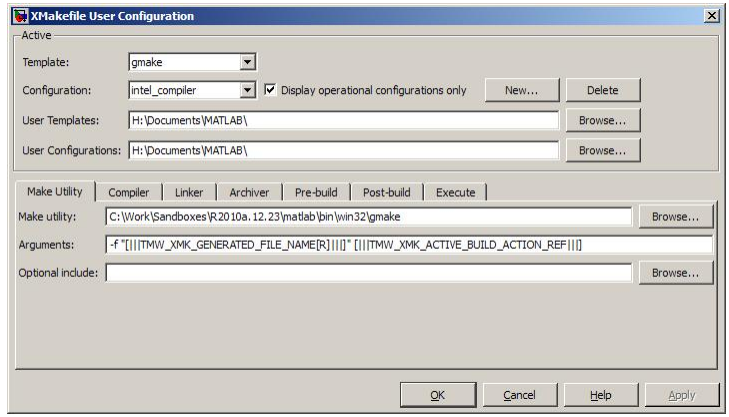


Modify the Configuration

Adjust the compiler, linker, and archiver settings of the newly created configuration. This example assumes the location of the Intel compiler is `C:\Program Files\Intel\Compiler\`.

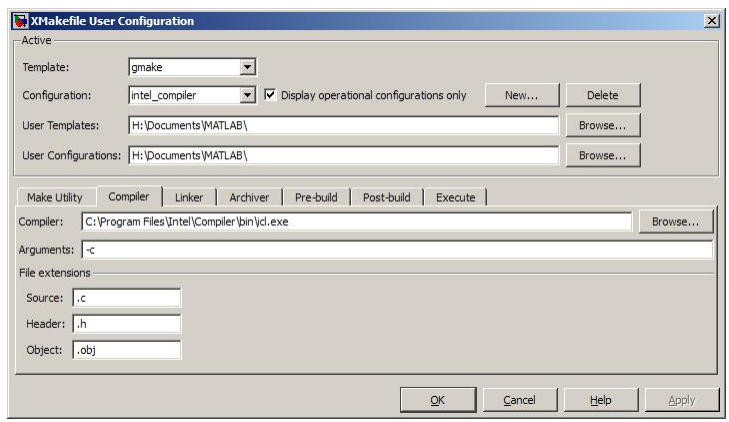
Make Utility

You do not need to make changes. This configuration uses the gmake tool that ships with MATLAB.



Compiler

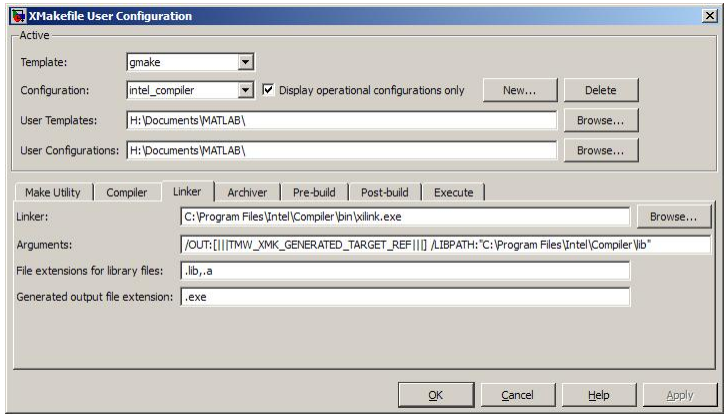
For **Compiler**, enter the location of `icl.exe` in the Intel installation.



Linker

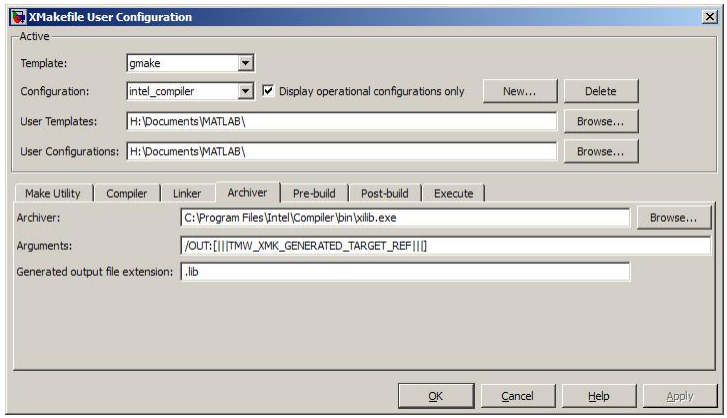
For **Linker**, enter the location of the linker executable, xilink.exe.

For **Arguments**, add the /LIBPATH path to the Intel libraries.



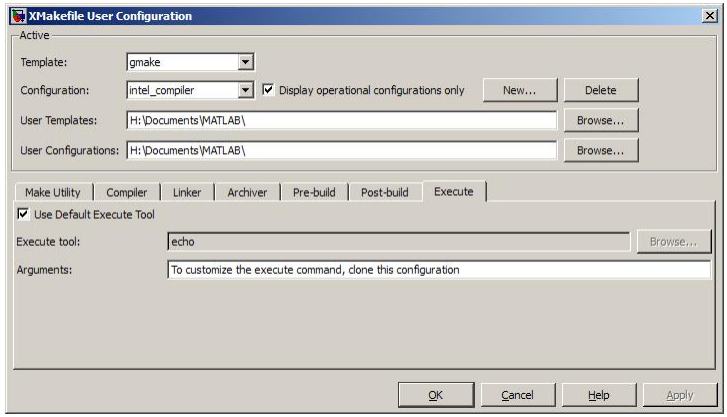
Archiver

For **Archiver**, enter the location of the archiver, `xilib.exe`. Confirm that **File extensions for library files** includes `.lib`.



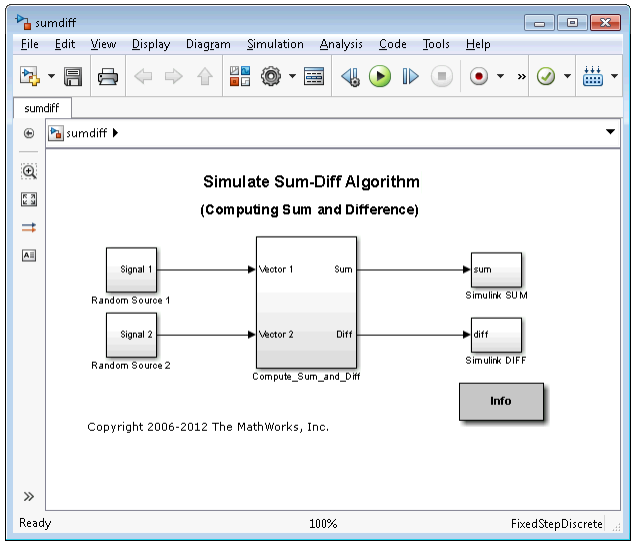
Other tabs

For this example, ignore the remaining tabs. In other circumstances, you can use them to configure additional build actions. In a later step of this example, you will configure the software to automatically build and run the generated code.



Test the Configuration

Open the "sumdiff" model by entering `sumdiff` on the MATLAB prompt.



Configure the `summdiff` model for use with an IDE. Follow the steps in "Configure Target Hardware Resources" on page 72-3, set the **IDE/Tool Chain** parameter, set **Board** to `Custom`, and **Processor** to `Intel x86/Pentium`.

On the Tool Chain Automation page, set **Operating System** to `None` or select `Windows`. Click **OK**.

Open the Configuration Parameters for the sumdiff model by pressing **Ctrl+E**. Set **Build format** to `Makefile` and **Build action** to `Build_and_execute`.

Save the model to a temporary location, such as `C:\Temp\IntelTest\`.

Set that location as a Current Folder by typing cd `C:\temp\IntelTest\` at the MATLAB prompt.

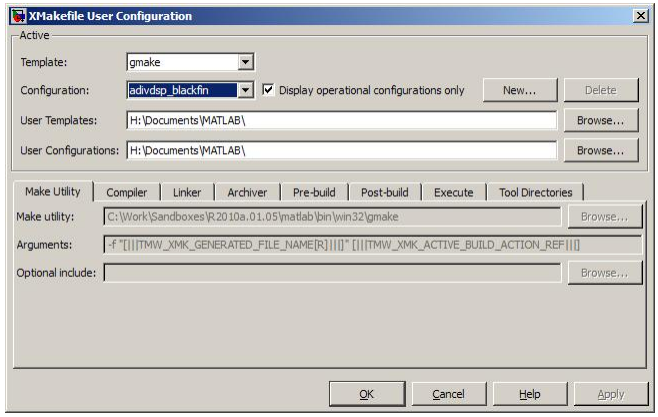
Build the model by pressing **Ctrl+B**. The MATLAB Command Window displays something like:

```
### TLC code generation complete.
### Creating HTML report file sumdiff_codegen_rpt.html
### Creating project: c:\temp\IntelTest\sumdiff_idenameide\sumdiff.mk
### Project creation done.
### Building project...
### Build done.
### Downloading program: c:\temp\IntelTest\sumdiff_idenameide\sumdiff
### Download done.
```

A command window comes up showing the running model. Terminate the generated executable by pressing **Ctrl+C**.

XMakefile User Configuration dialog

Active



Template

Set the **Template** parameter to the option that matches the **Configuration** parameter.

Note: In most cases, the only option for **Template** is `gmake`. However, if you have installed a Support Package, **Template** can have multiple options.

The template defines the syntax rules for writing the contents of the makefile or buildfile. The default template is `gmake`, which works with the GNU make utility.

To add templates to this parameter, save them as .mkt files to the location specified by the **User Templates** parameter. For more information, see “User Templates” on page 72-24.

Configuration

Select the configuration that best describes your toolchain and target hardware.

You cannot edit or delete the configurations provided by MathWorks. You can, however, edit and delete the configurations that you create.

Use the **New** button to create an editable copy of the currently selected configuration.

Use the **Delete** button to delete a configuration you created.

Note: You cannot edit or delete the configurations provided by MathWorks.

Note: Use mapped network drives instead of UNC paths to specify directory locations. Using UNC paths with compilers that do not support them causes build errors.

Display operational configurations only

When you open the XMakefile User Configuration dialog, the software verifies that each configuration provided by MathWorks contains valid paths to the executable files it uses. If the paths are valid, the configuration is operational. If the paths are not valid, the configuration is not operational.

This setting only applies to configurations provided by MathWorks, not configurations you create.

To display valid configurations, select **Display operational configurations only**.

To display the configurations, including non-operational configurations, clear **Display operational configurations only**.

For more information, see "Making an XMakefile Configuration Operational" on page 72-16.

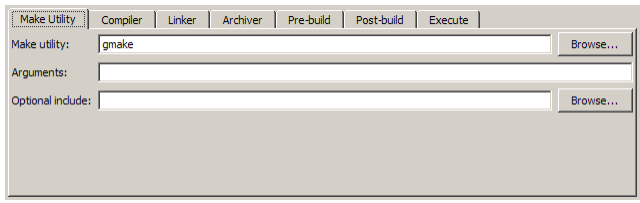
User Templates

Set the path of the folder to which you can add template files. Saving templates files with the .mkt extension to this folder adds them to the **Templates** options.

User Configurations

Set the location of configuration files you create with the **New** button.

Make Utility



Make utility

Set the path and filename of the make utility executable.

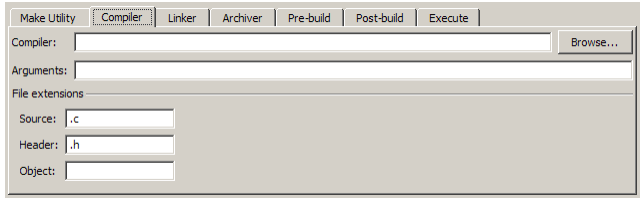
Arguments

Define the command-line arguments to pass to the make utility. For more information, consult the third-party documentation for your make utility.

Optional include

Set the path and file name of an optional makefile to include.

Compiler



Compiler

Set the path and file name of the compiler executable.

Arguments

Define the command-line arguments to pass to the compiler. For more information, consult the third-party documentation for your compiler.

Source

Define the file name extension for the source files. Use commas to separate multiple file extensions.

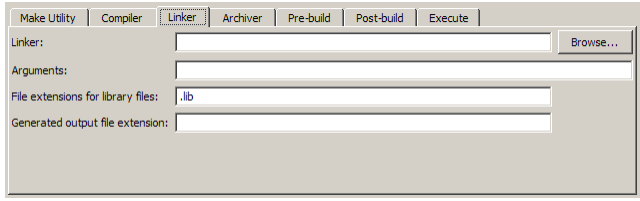
Header

Define the file name extension for the header files. Use commas to separate multiple file extensions.

Object

Define the file name extension for the object files.

Linker



Linker

Set the path and file name of the linker executable.

Arguments

Define the command-line arguments to pass to the linker. For more information, consult the third-party documentation for your linker.

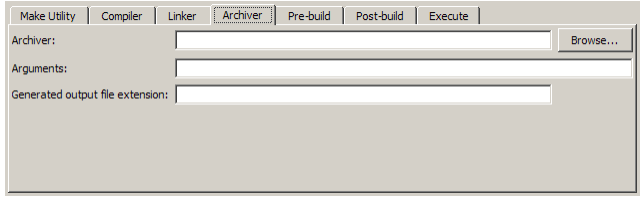
File extensions for library files

Define the file name extension for the file library files. Use commas to separate multiple file extensions.

Generated output file extension

Define the file name extension for the generated libraries or executables.

Archiver



Archiver

Set the path and file name of the archiver executable.

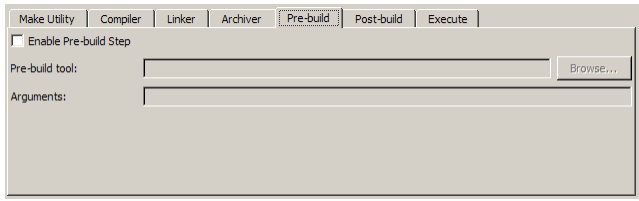
Arguments

Define the command-line arguments to pass to the archiver. For more information, consult the third-party documentation for your archiver.

Generated output file extension

Define the file name extension for the generated libraries.

Pre-build



Enable Prebuild Step

Select this check box to define a prebuild tool that runs before the compiler.

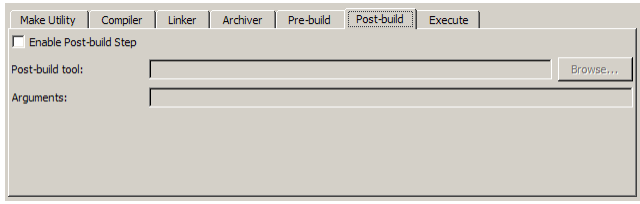
Prebuild tool

Set the path and file name of the prebuild tool executable.

Arguments

Define the command-line arguments to pass to the prebuild tool. For more information, consult the third-party documentation for your prebuild tool.

Post-build



Enable Postbuild Step

Select this check box to define a postbuild tool that runs after the compiler or linker.

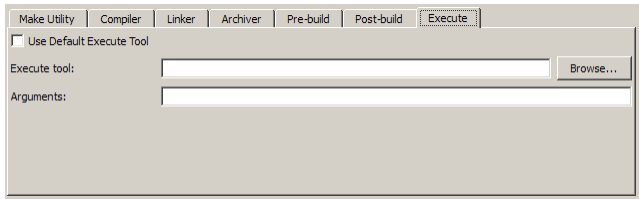
Postbuild tool

Set the path and file name of the postbuild tool executable.

Arguments

Define the command-line arguments to pass to the postbuild tool. For more information, consult the third-party documentation for your postbuild tool.

Execute



Use Default Execute Tool

Select this check box to use the generated derivative as the execute tool when the build process is complete. Uncheck it to specify a different tool. The default value, `echo`, simply displays a message that the build process is complete.

Note: On the Linux operating system, multirate multitasking executables require root privileges to schedule POSIX threads with real-time priority. If you are using makefiles to build multirate multitasking executables on your Linux development system, you cannot use **Execute tool** to run the executable. Instead, use the Linux command, `sudo`, to run the executable.

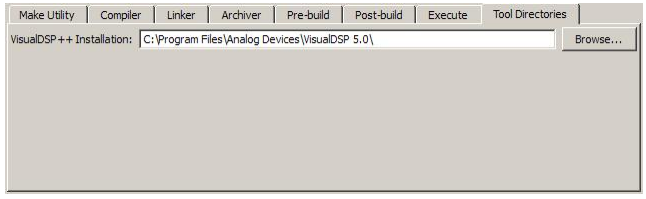
Execute tool

Set the path and file name of the execute tool executable or built-in command.

Arguments

Define the command-line arguments to pass to the execute tool. For more information, consult the third-party documentation for your execute tool.

Tool Directories



Installation

Use the Tool Directories tab to change the toolchain path of an operational configuration.

For example, if you installed two versions of a vendor build tool in separate folders, you can use the **Installation** path to change which one the configuration uses.

Verification and Profiling Generated Code in Embedded Coder

PIL Simulation for IDE and Toolchain Targets

In this section...

Overview

Verification consists broadly of running generated code on a processor and verifying that the code does what you intend. Embedded Coder provides processor-in-the-loop (PIL) simulation to meet this need. PIL compares the numeric output of your model under simulation with the numeric output of your model running as an executable on a target hardware.

With PIL, you run your generated code on a target hardware or instruction set simulator. To verify your generated code, you compare the output of model simulation modes, such as Normal or Accelerator, with the output of the generated code running on the processor. You can switch between simulation and PIL modes. This flexibility allows you to verify the generated code by executing the model as compiled code in the target environment. You can model and test your embedded software component in Simulink and then reuse your regression test suites across simulation and compiled object code. This process avoids the time-consuming process of leaving the Simulink software environment to run tests again on object code compiled for the production hardware.

Embedded Coder supports the following PIL approaches:

- Model block PIL
- Top-model PIL
- PIL block

When you use makefiles with PIL, use the "model block PIL" approach. With makefiles, the other two approaches, "top-model PIL" and "PIL block", and are not supported.

PIL Approaches

Model Block PIL

Use model block PIL to:

- Verify code generated for referenced models (model reference code interface).
- Provide a test harness model (or a system model) to generate test vector or stimulus inputs.
- Switch a model block between normal, SIL, or PIL simulation modes.

To perform a model block PIL simulation, start with a top-model that contains a model block. The top-model serves as a test harness, providing inputs and outputs for the model block. The model block references the model you plan to run on target hardware. During PIL simulation, the referenced model runs on the target hardware.

For more information about using the model block, see Model, Model Variants (Simulink) and "Model Referencing" (Simulink).

By default, your MathWorks software uses the IDE debugger for PIL communications with the target hardware. To achieve faster communications, consider using one of the alternatives presented in "Communications" on page 73-7.

To use model block PIL:

1. Create and share a configuration reference between the top model and the referenced model, as described in "Share a Configuration for Multiple Models" (Simulink).
2. Right-click the Model block, and select **ModelReference Parameters**.
3. When the software displays the **Function Block Parameters: Model** dialog box, set **Simulation mode** to `Processor-in-the-loop (PIL)` and click **OK**.
4. Open the model block.
5. In the referenced model (model block) Configuration Parameters (**Ctrl+E**), under **Code Generation** > **Coder Target**, set **Build action** set to `Archive_library`. This action avoids a warning when you start the simulation.
6. Save the changes to both models.

7 In the top-model menu bar, select **Simulation** > **Run**. This action builds the referenced model in the model block, downloads it to your target hardware, and runs the PIL simulation.

Note: In the top-model Configuration Parameters (**Ctrl+E**), under **Code Generation** > **Coder Target**, leave **Build action** set to `Build_and_execute`. Do not change **Build action** to `Create_Processor_In_the_Loop_Project`.

Top-Model PIL

Use top-model PIL to:

- Verify code generated for a top-model (standalone code interface).
- Load test vectors or stimulus inputs from the MATLAB workspace.
- Switch the entire model between normal and SIL or PIL simulation modes.

Setting Model Configuration Parameters to Generate the PIL Application

Configure your model to generate the PIL executable from your model:

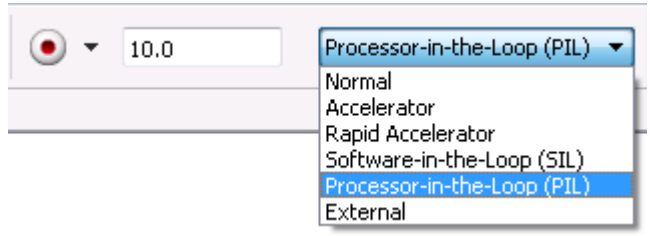
1 Configure your model to run on target hardware, as described in "Configure Target Hardware Resources" on page 72-3.
2 From the model toolstrip, select **Simulation** > **Model Configuration Parameters**.
3 In Configuration Parameters, select **Code Generation**.
4 Set **System Target File** to `idelink_ert.tlc`.
5 From the list of panes under **Code Generation**, choose **Coder Target**.
6 Set **Build format** to `Project`.
7 Set **Build action** to `Create_processor_in_the_loop_project`.
8 Click **OK** to close the Configuration Parameters dialog box.

For more information, see "Code Generation: Coder Target Pane".

Running the Top-Model PIL Application

To create a PIL block, perform the following steps:

1 In the model toolstrip, set the Simulation mode to `Processor-in-the-loop`.



2 In the model toolstrip, click Run.

A new Simulink Editor opens with the new PIL model block in it. The third-party IDE compiles and links the PIL executable file. Follow the progress of the build process in the MATLAB Command Window.

PIL Block

Use the PIL block to:

- Verify code generated for a top-model (standalone code interface) or subsystem (right-click build standalone code interface).
- Represent a component running in SIL or PIL mode. The test harness model or a system model provides test vector or stimulus inputs.

Preparing Your Model to Generate a PIL Block

Start with a model that contains the algorithm blocks you want to verify on the processor as compiled object code. To create a PIL application and PIL block from your algorithm subsystem, follow these steps:

1 Identify the algorithm blocks to cosimulate.

2 Convert those blocks into an unmasked subsystem in your model.

For information about how to convert your process to a subsystem, refer to Creating Subsystems (Simulink) in *Using Simulink* or in the online Help system.

3 Open the newly created subsystem.

4 Configure your subsystem to run on target hardware, as described in “Configure Target Hardware Resources” on page 72-3.

Setting Model Configuration Parameters to Generate the PIL Application

After you create your subsystem, set the Configuration Parameters for your model to enable the model to generate a PIL block.

Configure your model to enable it to generate PIL algorithm code and a PIL block from your subsystem:

1. From the model menu bar, select **Simulation > Model Configuration Parameters**. This action opens the Configuration Parameters dialog box.
2. In the Configuration Parameters dialog box, select **Code Generation**.
3. Set **System Target File** to `idelink_ert.tlc`.
4. From the list of panes under **Code Generation**, choose **Coder Target**.
5. Set **Build format** to `Project`.
6. Set **Build action** to `Create_processor_in_the_loop_project`.
7. Click **OK** to close the Configuration Parameters dialog box.

For more information, see "Code Generation: Coder Target Pane".

Creating the PIL Block from a Subsystem

To create a PIL block, perform the following steps:

1. Right-click the masked subsystem in your model and select **C/C++ Code > Build This Subsystem** from the context menu.

   A new Simulink Editor opens and the new PIL block appears in it. The third-party IDE compiles and links the PIL executable file.

   This step builds the PIL algorithm object code and a PIL block that corresponds to the subsystem, with the same inputs and outputs. Follow the progress of the build process in the MATLAB Command Window.
2. Copy the new PIL block from the new model to your model. To simulate the subsystem processes concurrently, place it parallel to your masked subsystem. Otherwise, replace the subsystem with the PIL block.

   To see a PIL block in a parallel masked subsystem, search the product help for *Getting Started with Application Development* and select the example that matches your IDE.

Note: Models can have multiple PIL blocks for different subsystems. They cannot have more than one PIL block for the same subsystem. Including multiple PIL blocks for the same subsystem causes errors and inaccurate results.

Communications

Choose one of the following communication methods for transferring code and data during PIL simulations:

Method	Speed	Comments
IDE Debugger	Slow	• Supports PIL communications with an executable running an embedded target hardware. • Supports the largest number of targets. • Requires a physical connection between host and target hardware. • Only works with builds from IDE projects. Does not work with builds from makefiles.
TCP/IP	Fast	• Supports PIL communications with an executable running on a Linux or Windows host. • Supports embedded targets running Linux, TI DSP/BIOS, and Wind River VxWorks. • Requires network connection between host and target hardware. • Works with builds from IDE projects and from makefiles.

TCP/IP

You can use TCP/IP for PIL communications with target hardware running:

- Linux

- Wind River VxWorks

Using TCP/IP for PIL communications is typically faster than using a debugger, particularly for large data sets, such as with video and audio applications.

It also works well when you build an application on a remote Linux target using the `remoteBuild` function.

You can use TCP/IP with the following PIL approaches:

- Top-model PIL
- Model block PIL

TCP/IP does not work with the Subsystem PIL approach.

To enable and configure TCP/IP with PIL:

1. Set up a PIL simulation according to the PIL approach you have chosen.
2. In the MATLAB Command Window, use `setpref` to specify the IP address of the PIL server (`servername`).

   If you are running the PIL server on a remote target, specify the IP address of the target hardware. For example:

   ```
   setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','servername','144.212.109.114');
   ```

   If you are running PIL server locally, on your host Windows or Linux system, enter `'localhost'` instead of an IP address:

   ```
   setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','servername','localhost');
   ```
3. Specify the TCP/IP port number to use for PIL data communication. Use one of the free ports in your system. For example:

   ```
   setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','portnum', 17025);
   ```
4. Enable PIL communications over TCP/IP:

   ```
   setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip', true);
   ```

   To disable PIL communications over TCP/IP, change the value to `false`. This action automatically enables PIL communications over an IDE debugger, if an IDE is available.
5. Open the Configuration Parameters in your model. On the Coder Target pane, set the **Operating System** parameter to the operating system your target hardware is running.

Note: You cannot use TCP/IP for PIL when the value of **Operating System** is `None`.

6 Regenerate the code or PIL block.

To disable PIL communications over TCP/IP, enter:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip', false);
```

IDE Debugger

To enable PIL communications over an IDE debugger, disable PIL communications over TCP/IP and SCI by entering the following commands:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip',false);
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enableserial',false);
```

Then regenerate the code or PIL block.

Using IDE debugger for PIL communication only works when you build your code from IDE projects. Using IDE debugger for PIL communication does not work with builds from makefiles.

Configuring Breakpoints

You can use the `setStartApplicationPause` API to set breakpoints in the PIL application on the *first* PIL block simulation. If you do not use the `setStartApplicationPause` API, you can configure breakpoints after the initial run. The breakpoints remain active for subsequent runs.

You can enter the following static API method to pause after loading the application and manually configure breakpoints:

```
rtw.connectivity.Launcher.setStartApplicationPause(pauseAmount)
```

About this method:

- This method tells the MATLAB session to pause immediately after the PIL launcher starts the PIL application.
- `pauseAmount` is a pause time in seconds. To disable the pause, enter 0.

When you do not specify a pause, the software displays the following message:

```
### To pause during PIL application start, run: >> rtw.connectivity.Launcher.
setStartApplicationPause(120)
```

The default pause is 120 sec. You can change this value.

When you specify a pause, a Start PIL Application Pause message box appears and displays following message:

```
Pausing during PIL application start for 120s (click OK to continue).
To disable this pause, see the hyperlink in the MATLAB command window.
```

- The MATLAB Command Window shows the following text:

  ```
  ### To remove the pause during PIL application start,
  run: >> rtw.connectivity.Launcher. setStartApplicationPause(0)
  ```
  where `rtw.connectivity.Launcher. setStartApplicationPause(0)` is a hyperlink.
- The pause times out, or you can clear it early by closing the message box.
- During the pause, you cannot access MATLAB and thus cannot configure breakpoints programmatically via the IDE Automation Interface API.
- For the PIL block, the debugger stays open between simulation runs. When you perform an initial simulation run, you can automatically configure breakpoints via the IDE Automation Interface API before starting the second simulation.

Running Your PIL Application to Perform Simulation and Verification

After you add PIL block to your model, add the required pause in seconds, using the following command in the MATLAB command prompt:

```
rtw.connectivity.Launcher.setStartApplicationPause(120)
```
Then click **Simulation** > **Run** or press **Ctrl+T** to run the PIL simulation and view the results.

Note The pause command is to make sure that the automatic download of PIL completes, before the model starts executing.

Definitions

PIL Algorithm

The algorithmic code, which corresponds to a subsystem or portion of a model, to test during the PIL simulation. The PIL algorithm is in compiled object form to enable verification at the object level.

PIL Application

The executable application that runs on the processor platform. The code generator produces code for a PIL application by augmenting your algorithmic code with the PIL execution framework. The PIL execution framework code compiles as part of your embedded application.

The PIL execution framework code includes the `string.h` header file so that the PIL application can use the `memcpy` function. The PIL application uses `memcpy` to exchange data between the Simulink model and the simulation processor.

PIL Block

When you build a subsystem from a model for PIL, the process creates a PIL block optimized for PIL simulation. When you run the simulation, the PIL block acts as the interface between the model and the PIL application running on the processor. The PIL block inherits the signal names and shape from the source subsystem in your model. Inheritance is convenient for copying the PIL block into the model to replace the original subsystem for simulation.

PIL Issues and Limitations

Consider the following issues when you work with PIL blocks.

Constraints

When using PIL in your models, keep in mind the following constraints:

- Models can have multiple PIL blocks for different subsystems. They cannot have more than one PIL block for the same subsystem. Including multiple PIL blocks for the same subsystem causes errors and inaccurate results.
- A model can contain a single model block running PIL mode.
- A model can contain a subsystem PIL block or a model block in PIL mode, but not both.

Generic PIL Issues

Refer to PIL Feature Support and Limitations on page 64-61 for general information about using the PIL block with embedded link products.

Simulink Coder grt.tlc-Based Targets Not Supported

PIL does not support `grt.tlc` system target files.

To use PIL, set **System target file** in the Configuration Parameters > Code Generation pane to `idelink_ert.tlc`.

Code Execution Profiling for IDE and Toolchain Targets

In this section...

Execution-Time Profiling

You can measure the execution times during a standalone execution or processor-in-the-loop (PIL) simulation. You can generate execution time profiles for synchronous tasks, asynchronous tasks, and atomic subsystems. Use this feature to check whether your code runs in real time on your target hardware. For details, see "Perform Execution-Time Profiling for IDE and Toolchain Targets" on page 73-16.

You can use this profiling for generated code in the following cases:

- **Code Generation** > **System target file** is `ert.tlc` and **Code Generation** > **Target hardware** is not `None`, for example, `ARM Cortex-A9 (QEMU)` or `ARM Cortex-M3 (QEMU)`.
- **Code Generation** > **System target file** is `idelink_ert.tlc`

The following table provides execution time profiling support information.

Mode	Coder Target > Tool Chain Automation > Build format parameter value
Standalone execution or PIL simulation	`Project`
PIL simulation	`Makefile`

Stack Profiling

With stack profiling, you can determine how generated code uses the processor system stack. Using the `profile` method, you can initialize and test the size and usage of the stack. See "Perform Stack Profiling with IDE and Toolchain Targets" on page 73-22. This information can help you optimize both the size of the stack and how your code uses the stack.

You can use this profiling for generated code in the following cases:

- **Code Generation** > **System target file** is `ert.tlc` and **Code Generation** > **Target hardware** is not `None`, for example, `ARM Cortex–A9 (QEMU)` or `ARM Cortex–M3 (QEMU)`.
- **Code Generation** > **System target file** is `idelink_ert.tlc`

Note: Stack profiling is not supported on embedded targets that run an operating system or RTOS.

To provide stack profiling, `profile` writes a known pattern to the addresses in the stack. After you run your application for a while, and then stop your application, `profile` examines the contents of the stack addresses. `profile` counts each address that does not contain the known pattern. The total number of addresses that have been used, compared to the total number of addresses that you allocated, becomes the stack usage profile. This profile process does not determine how often your application changes an address.

You can profile the stack with the manually written code in a project and the code that you generate from a model.

When you use `profile` to initialize and test the stack operation, the software returns a report that contains information about stack size, usage, addresses, and direction. With this information, you can modify your code to use the stack efficiently. The following program listing shows the stack usage results from running an application on a simulator.

```
profile(IDE_Obj,'stack','report')

Maximum stack usage:

System Stack: 532/1024 (51.95%) MAUs used.

           name: System Stack
   startAddress: [512    0]
     endAddress: [1535     0]
      stackSize: 1024 MAUs
growthDirection: ascending
```

The following table describes the entries in the report.

Report Entry	Units	Description
`System Stack`	Minimum Addressable Unit (MAU)	Maximum number of MAUs used and the total MAUs allocated for the stack.
`name`	Character vector for the stack name	Lists the name assigned to the stack.
`startAddress`	Decimal address and page	Lists the address of the stack start and the memory page.
`endAddress`	Decimal address and page	Lists the address of the end of the stack and the memory page.
`stackSize`	Addresses	Reports number of address locations, in MAUs, allocated for the stack.
`growthDirection`	Not applicable	Reports whether the stack grows from the lower address to the higher address (`ascending`) or from higher to lower (`descending`).

Perform Execution-Time Profiling for IDE and Toolchain Targets

In this section...

Execution-Time Profiling During Standalone Execution

During standalone execution, instrumentation in the generated code collects execution-time samples, which are stored in target hardware memory. After halting target hardware execution, you can use the `profile` function to transfer the execution data from target hardware memory to the MATLAB workspace for viewing and analysis.

You can perform profiling by task or subsystem. A profiling sample represents a task or subsystem execution instance. Each sample requires two memory locations, one for the start time and one for the end time. Therefore, you must specify a buffer size that is twice the number of required profiling samples. Sample collection begins with the start of code execution and ends when the buffer is full.

Task Profiling

To configure a model for task execution profiling:

1. In your model, select **Simulation** > **Model Configuration Parameters**.
2. Select the **Code Generation** > **Coder Target** pane.
3. Set **Build format** to `Project` and set **Build action** to `Build_and_execute`.
4. Select **Profile real-time execution**.
5. In the **Profile by** list, select **Tasks**.
6. Specify **Number of profiling samples to collect**, the size of the buffer that stores execution data. Enter a value that is twice the number of profiling samples you require.
7. Click **OK**.

To view the execution profile for your model:

1 Click **Build Model** 
on the model toolstrip. This action builds, loads, and runs your code on the processor.

2 To stop the running program, select **Debug** > **Halt** in the IDE or use `IDE_obj.halt` from the MATLAB command line. Gathering profiling data from a running program can yield inaccurate results.

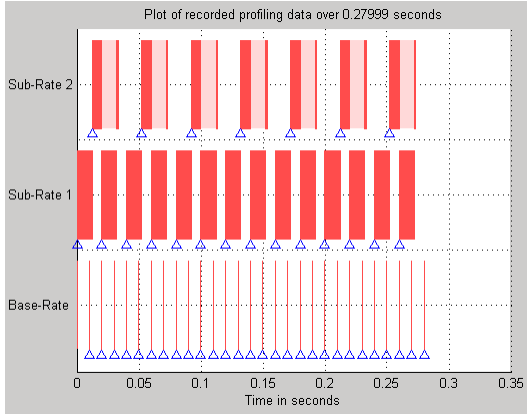
3 At the MATLAB command prompt, enter

```
profile(IDE_Obj,'execution','report')
```

to view the MATLAB software graphic of the execution report and the HTML execution report.

For more information about other reporting options, see the product help for the `profile` function.

The following profiling plot is from an application that runs with three rates — the base rate and two slower rates. Gaps in the `Sub-Rate 2` task bars indicate preempted operations.



Subsystem Profiling

To configure a model for subsystem execution profiling:

1 Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 72-3.

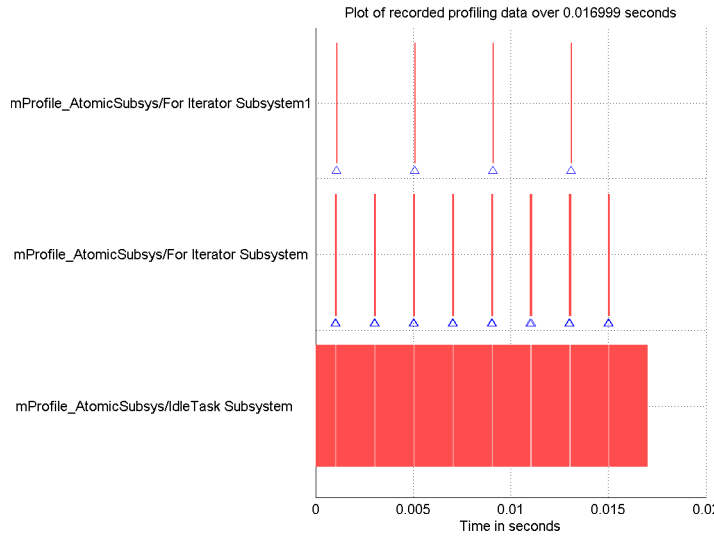
2. On the **Coder Target** pane, set **Build format** to `Project` and set **Build action** to `Build_and_execute`.
3. Select **Profile real-time execution**.
4. In the **Profile by** list, select `Atomic subsystems`.
5. Specify **Number of profiling samples to collect**, the size of the buffer that stores execution data. Enter a value that is twice the number of profiling samples you require.
6. Click **OK**.

To view the execution profile for your model:

1. Click **Build Model** 
on the model toolstrip. This action builds, loads, and runs your code on the processor.
2. To stop the running program, select **Debug** > **Halt** in the IDE or use `IDE_obj.halt` from the MATLAB command line. Gathering profiling data from a running program can yield inaccurate results.
3. At the MATLAB command prompt, enter:

   ```
   profile(IDE_Obj, 'execution','report')
   ```
   to view the MATLAB software graphic of the execution report and the HTML execution report.

The following profiling plot is from an application with three subsystems — `For Iterator Subsystem`, `For Iterator Subsystem1`, and `Idle Task Subsystem`.



Execution-Time Profiling During PIL Simulation

During a processor-in-the-loop (PIL) simulation, you can profile execution times of synchronous tasks. The software stores the profile data in a `coder.profile.ExecutionTime` object, located in the MATLAB workspace. After halting the PIL simulation, you can view and analyze the data.

Gathering Execution Profile Data

1. Configure a model for PIL simulation, as described in "PIL Simulation for IDE and Toolchain Targets" on page 73-2.
2. In your model, select **Simulation** > **Model Configuration Parameters**.
3. In the Configuration Parameters dialog box, select **Code Generation**, and then **Verification**.
4. Select the **Measure task execution time** check box.
5. Provide a valid MATLAB variable name in the **Workspace** edit box. The software uses this name when it creates the `coder.profile.ExecutionTime` object.
6. Click **OK** to close the Configuration Parameters dialog box.

7 Run the PIL simulation, as described in "PIL Simulation for IDE and Toolchain Targets" on page 73-2.

   The software creates the `coder.profile.ExecutionTime` object and stores the execution profile data in it.

8 Halt the PIL simulation.

Analyzing the Execution Profile Data

After halting the PIL simulation, you can view or analyze the data in the `coder.profile.ExecutionTime` object. For more information, see:

- "View and Compare Code Execution Times" on page 58-7
- "Analyze Code Execution Data" on page 58-18

Depending on the target, the execution profile data is measured in seconds or timer ticks.

Targets	Units
Analog Devices Blackfin, SHARC, and TigerSHARC processors with VisualDSP++ IDE	Timer Ticks
ARM processors running Wind River VxWorks	Timer Ticks

The `coder.profile.ExecutionTime` class has property `TimerTicksPerSecond` for getting and setting the data units. You can use this property on the execution profile data object after halting the PIL simulation. When the data unit is timer ticks, using the `TimerTicksPerSecond` property converts the data units to seconds.

See Also

`profile` | `TimerTicksPerSecond`

Related Examples

- "Configure Target Hardware Resources" on page 72-3
- "PIL Simulation for IDE and Toolchain Targets" on page 73-2
- "View and Compare Code Execution Times" on page 58-7

- “Analyze Code Execution Data” on page 58-18

Perform Stack Profiling with IDE and Toolchain Targets

To profile the system stack operation:

1. Load an application.
2. Set up the stack to enable profiling.
3. Run your application.
4. Request the stack profile information.

Follow these steps to profile the stack as your application interacts with it. This particular example uses Texas Instruments Code Composer Studio 3.3. However, you can generalize from this example to another supported IDE.

1. Load the application to profile.
2. Use the `profile` method with the **`setup`** input keyword to initialize the stack to a known state.

   ```
   profile(IDE_Obj,'stack','setup')
   ```

   With the **`setup`** input argument, `profile` writes a known pattern into the addresses that compose the stack.
3. Run your application.
4. Stop your running application. Stack use results gathered from an application that is running may be inaccurate.
5. Use the `profile` method to capture and view the results of profiling the stack.

   ```
   profile(IDE_Obj,'stack','report')
   ```

The following example shows how to set up and profile the stack. The IDE link handle object, `IDE_Obj`, must exist in your MATLAB workspace and your application must be loaded on your processor. This example comes from a TI C6713 simulator.

```
profile(IDE_Obj,'stack','setup')  % Set up processor stack
%by write A5 to the stack addresses.

Maximum stack usage:

System Stack: 0/1024 (0%) MAUs used.

           name: System Stack
   startAddress: [512    0]
     endAddress: [1535     0]
      stackSize: 1024 MAUs
```

```
growthDirection: ascending

run(IDE_Obj)
halt(IDE_Obj)
profile(IDE_Obj,'stack','report') % Request stack use report.

Maximum stack usage:

System Stack: 356/1024 (34.77%) MAUs used.

          name: System Stack
   startAddress: [512    0]
     endAddress: [1535     0]
      stackSize: 1024 MAUs
growthDirection: ascending
```

Processor-Specific Optimizations for Embedded Targets in Embedded Coder

Replace Code for Embedded Targets

In this section...

Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see "What Is Code Replacement?" on page 38-2 and "Replace Code Generated from Simulink Models" on page 38-11. For information about developing code replacement libraries, see "What Is Code Replacement Customization?" on page 51-3 and "Develop a Code Replacement Library" on page 51-27.

Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

1. Enable real-time profiling in your model. Refer to "Code Execution Profiling".
2. Generate code for your project without specifying a code replacement library (the default **Code replacement library** setting is `None`).
3. Profile the code, and save the report.
4. Rebuild your project using a processor-specific code replacement library.

5 Profile the code, and save the second report.

6 Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for "Optimizing Embedded Code via Code Replacement Library" and select the example that matches your IDE.

Code Generation from MATLAB Code

Build Configuration for Code Generation from MATLAB Code

Specify Comment Style for C/C++ Code

In this section...

If you have an Embedded Coder , you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by `//`. Specify multiline style to generate single-line or multiline comments delimited by `/*` and `*/`. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

Specify Comment Style Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **Code Appearance** tab, select the **Include comments** check box if it is not already selected. By default, the **Include comments** check box is selected.
5. Set **Comment Style** to one of the following options.

Value	Description
`Auto(Use standard comment style of the target language)`	For C, generate multiline comments. For C++, generate single-line comments. (default)
`Single-line (Use C++-style comments)`	Generate single-line comments preceded by `//`.
`Multi-line (Use C-style comments)`	Generate single-line or multiline comments delimited by `/*` and `*/`.

Specify Comment Style Using the Command-Line Interface

1. Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

   ```
   cfg = coder.config('lib','ecoder',true);
   ```

2. Set the `CommentStyle` property to one of the following values:

Value	Description
`'Auto'`	For C, generate multiline comments. For C++, generate single-line comments. (default)
`'Single-line'`	Generate single-line comments preceded by `//`.
`'Multi-line'`	Generate single-line or multiline comments delimited by `/*` and `*/`.

   For example, this code sets the comment style to single-line style:

   ```
   cfg.CommentStyle='Single-line';
   ```

More About

- “Configure Build Settings” (MATLAB Coder)

Specify Indent Style for C/C++ Code

In this section...

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```
void addone(const double x[6], double z[6])
{
  int i0;
  for (i0 = 0; i0 < 6; i0++) {
    z[i0] = x[i0] + 1.0;
  }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```
void addone(const double x[6], double z[6])
{
  int i0;
  for (i0 = 0; i0 < 6; i0++)
  {
    z[i0] = x[i0] + 1.0;
```

```
  }
}
```

Specify Indent Style Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **All Settings** tab, under **Advanced**, set **Indent style** to `K&R` or `Allman`.
5. On the **All Settings** tab, under **Advanced**, set **Indent size** to an integer from 2 to 8.

Specify Indent Style Using the Command-Line Interface

1. Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`. For example:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the `IndentStyle` property to `'K&R'` or `'Allman'`. For example:

   ```
   cfg.IndentStyle = 'Allman';
   ```
3. Set the `IndentSize` property to an integer from 2 to 8. For example:

   ```
   cfg.IndentSize = 4;
   ```

More About

- “Configure Build Settings” (MATLAB Coder)

Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

1. Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is matlabcoder_default_template.cgt in the *`matlabroot`*`/toolbox/coder/matlabcoder/templates/` folder.
2. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.
3. View the default template and generated output. For example, here is the default File Banner section:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

When you generate code using this default, the file banner looks similar to this file banner:

```
/*
 * File: coderand.c
```

```
 *
 * MATLAB Coder version            : 2.7
 * C/C++ source code generated on  : 06-Apr-2014 14:34:15
 */
```

4 Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to `box` and a custom token `myCustomToken`:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="box">
File: %<FileName>

My custom token                : %<myCustomToken>

MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

For more information, see “Code Generation Template Files for MATLAB Code” on page 75-9.

5 Create a configuration object for generation of a C static library for an embedded target.

```
% Create configuration object for an embedded target
cfgObj = coder.config('lib','ecoder',true);
```

6 Create a `MATLABCodeTemplate` object from your CGT file and add it to the configuration object.

```
% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

7 Assign values for custom tokens that you added to the template. For example, assign the value `'myValue'` to the `myCustomToken` token that you added in a previous step.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

8 Generate code using the configuration object that you created.

```
codegen -config cfgObj coderand
```

9 View the changes to the generated file banner. For example, here is the file banner for `coderand.c` using the customized CGT file:

```
/*************************************************************************/
/* File: coderand.c                                                      */
/*                                                                       */
/* My custom token               : myValue                               */
/*                                                                       */
/* MATLAB Coder version          : 2.7                                   */
/* C/C++ source code generated on : 06-Apr-2014 14:42:55                 */
/*************************************************************************/
```

Changes to a CGT file do not affect the generated code unless you create a `MATLABCodeTemplate` object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, `myCGTFile.cgt`, used in the previous example, you must repeat these steps:

1 Create a `MATLABCodeTemplate` object from `myCGTFile.cgt` and add it to the configuration object.

```
CGTFile = 'myCGTFile.cgt';
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

2 Assign the value `'myValue'` to the `myCustomToken` token.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

3 Generate code.

```
codegen -config cfgObj coderand
```

- “Code Generation Template Files for MATLAB Code” on page 75-9

Code Generation Template Files for MATLAB Code

In this section...

A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove time stamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see "Generate Custom File and Function Banners for C/C++ Code" on page 75-6.

Default CGT File

You can base your custom template on the default CGT file, matlabcoder_default_template.cgt, in the *`matlabroot`*`/toolbox/coder/matlabcoder/templates/` folder.

Note: If you choose not to customize banners for your generated code, the default template is used for code generation.

CGT File Structure

A CGT file consists of 13 optional sections.

File Banner Section

Contains comments and tokens for use in generating a custom file banner.

Function Banner Section

Contains comments and tokens for use in generating a custom function banner.

Shared Utility Function Banner

Contains comments and tokens for use in generating custom banners for shared utility functions.

File Trailer Section

Contains comments for use in generating a custom trailer banner.

Include Files Banner

Contains comments for use in generating a custom banner for the include files section.

Type Definitions

Contains comments for use in generating a custom banner for the type definitions section.

Named Constants

Contains comments for use in generating a custom banner for the named constants section.

Variable Declarations

Contains comments for use in generating a custom banner for the variable declarations section.

Variable Definitions

Contains comments for use in generating a custom banner for the variable definitions section.

Function Declarations

Contains comments for use in generating a custom banner for the function declarations section.

Function Definitions

Contains comments for use in generating a custom banner for the function definitions section.

Custom Source Code

Contains comments for use in generating a custom banner for the custom source code section.

Custom Header Code

Contains comments for use in generating a custom banner for the custom header code section.

Components of the CGT File Sections

Each CGT file section is defined by open and close tags.

CGT File Section	Open Tag	Close Tag
"File Banner" on page 75-14	`<FileBanner>`	`</FileBanner>`
"Function Banner Section" on page 75-10	`<FunctionBanner>`	`</FunctionBanner>`
"Shared Utility Function Banner" on page 75-10	`<SharedUtilityBanner>`	`</SharedUtilityBanner>`
"File Trailer Section" on page 75-10	`<FileTrailer>`	`</FileTrailer>`
"Include Files Banner" on page 75-10	`<IncludeFilesBanner>`	`</IncludeFilesBanner>`
"Type Definitions" on page 75-10	`<TypeDefinitionsBanner>`	`</TypeDefinitionsBanner>`
"Named Constants" on page 75-10	`<NamedConstantsBanner>`	`</NamedConstantsBanner>`
"Variable Declarations" on page 75-10	`<VariableDeclarationsBanner>`	`</VariableDeclarationsBanner>`

CGT File Section	Open Tag	Close Tag
"Variable Definitions" on page 75-10	`<VariableDefinitionsBanner>`	`</VariableDefinitionsBanner>`
"Function Declarations" on page 75-10	`<FunctionDeclarationsBanner>`	`</FunctionDeclarationsBanner>`
"Function Definitions" on page 75-11	`<FunctionDefinitionsBanner>`	`</FunctionDefinitionsBanner>`
"Custom Source Code" on page 75-11	`<CustomSourceCodeBanner>`	`</CustomSourceCodeBanner>`
"Custom Header Code" on page 75-11	`<CustomHeaderCodeBanner>`	`</CustomHeaderCodeBanner>`

You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a '\t' for formatting.

Note: In the contents of your banner, C comment indicators, '/*' or '*/', can introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

```
<OpenTag style = "style_value" width = "num_width">
```

There are five options for the banner style. The `CommentStyle` and `TargetLang` configuration object properties determine the use of C or C++ comment style. The built-in style options for the `style` attribute are:

- `classic`

  Using C style comments

```
/* single line comments */

/*
 * multiple line comments
 * second line
 */
```

  Using C++ style comments

```
// single line comments

//
// multiple line comments
// second line
//
```

- `box`

  Using C style comments

```
/*********************************************************/
/* banner contents                                       */
/*********************************************************/
```

  Using C++ style comments

```
///////////////////////////////////////////////////////////
// banner contents                                       //
///////////////////////////////////////////////////////////
```

- `open_box`

  Using C style comments

```
/*********************************************************
 * banner contents
 *********************************************************/
```

  Using C++ style comments

```
///////////////////////////////////////////////////////////
// banner contents
```

```
////////////////////////////////////////////////////////////
```

- `doxygen`

  Using C style comments

  ```
  /** single line comments */

  /**
   * multiple line comments
   * second line
   */
  ```

  Using C++ style comments

  ```
  ///single line comments

  ///
  /// multiple line comments
  ///second line
  ///
  ```

- `doxygen_qt`

  Using C style comments

  ```
  /*! single line comments */

  /*!
   * multiple line comments
   * second line
   */
  ```

  Using C++ style comments

  ```
  //!single line comments

  //!
  //! multiple line comments
  //!second line
  //!
  ```

File Banner

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the

CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

Summary of Tokens for File Banner Generation

`FileName`	Name of the generated file (for example, `"kalman.c"`)
`SourceGeneratedOn`	Time stamp of generated file
`MATLABCoderVersion`	Version of MATLAB Coder
`EmbeddedCoderVersion`	Version of Embedded Coder
`HardwareSelection`	Selected target
`OutputType`	Type of output (for example, lib, exe, or dll)

Function Banner

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom function banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<FunctionBanner style="classic">
%<FunctionDescription>
Arguments    : %<Arguments>
Return Type  : %<ReturnType>
%</FunctionBanner>
```

Summary of Tokens for Function Banner Generation

`FunctionName`	Name of function
`FunctionDescription`	Short abstract about the function
`Arguments`	List of function arguments
`ReturnType`	Return type of function

Shared Utility Banner

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<SharedUtilityBanner style="classic">
Arguments    : %<Arguments>
Return Type  : %<ReturnType>
</SharedUtilityBanner>
```

Summary of Tokens for Shared Utility Function Banner Generation

`FunctionName`	Name of function
`FunctionDescription`	Short abstract about the function
`Arguments`	List of function arguments
`ReturnType`	Return type of function

File Trailer

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
```

```
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic">
File trailer for %<FileName>

[EOF]
</FileTrailer>
```

Tokens for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

Include Files Banner

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```
<IncludeFilesBanner  style="classic">
Include Files
</IncludeFilesBanner>
```

Type Definitions Banner

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a banner for this section. The type definitions banner section provided in the default CGT file is:

```
<TypeDefinitionsBanner  style="classic">
Type Definitions
</TypeDefinitionsBanner>
```

Named Constants Banner

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

```
<NamedConstantsBanner  style="classic">
Named Constants
</NamedConstantsBanner>
```

Variable Declarations

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

```
<VariableDeclarationsBanner  style="classic">
Variable Declarations
</VariableDeclarationsBanner>
```

Variable Definitions

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

```
<VariableDefinitionsBanner  style="classic">
Variable Definitions
</VariableDefinitionsBanner>
```

Function Declarations

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```
<functionDeclarationsBanner  style="classic">
Function Declarations
</FunctionDeclarationsBanner>
```

Function Definitions

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```
<FunctionDefinitionsBanner  style="classic">
Function Definitions
</FunctionDefinitionsBanner>
```

Custom Source Code

The custom source code banner section contains comments for generating a custom banner that precedes the custom source code section in the generated code. If you omit the custom source code banner section from the CGT file, the code generator does not generate a banner for this section. The custom source code banner section provided in the default CGT file is:

```
<CustomSourceCodeBanner  style="classic">
Custom Source Code
</CustomSourceCodeBanner>
```

Custom Header Code

The custom header code banner section contains comments for generating a custom banner that precedes the custom header code section in the generated code. If you omit the custom header code banner section from the CGT file, the code generator does not generate a banner for this section. The custom header code banner section provided in the default CGT file is:

```
<CustomHeaderCodeBanner  style="classic">
Custom Header Code
</CustomHeaderCodeBanner>
```

More About

- “Generate Custom File and Function Banners for C/C++ Code” on page 75-6

Customize Generated Identifiers

In this section...

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, _, 0–9).
- The tokens listed in the following table. `$M` is required.

Token	Description
`$M`	Code generator inserts name mangling text to avoid naming collisions. Required.
`$N`	Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated. Improves readability of generated code.
`$R`	Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore (_) character.

Customize Identifiers by Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library`

- `Dynamic Library`
- `Executable`

3 Click **More Settings**.

4 On the **Code Appearance** tab, under **Identifier Format**, for each kind of identifier that you want to customize, enter the macro.

Parameter	Default Macro
Global variables	`$M$N`
Global types	`$M$N`
Field name of global types	`$M$N`
Local functions	`$M$N`
Local temporary variables	`$M$N`
Constant macros	`$M$N`
EMX Array Types	`emxArray_$M$N`
EMX Array Utility Functions	`emx$M$N`

For example, suppose that **Global variables** has the value `glob_$M$N`. For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

Customize Generated Identifiers by Using the Command-Line Interface

1 Create a code configuration object for a library or executable program. For example:

```
cfg = coder.config('lib','ecoder',true);
```

2 For each kind of identifier that you want to customize, specify the macro as a character vector.

Parameter	Description	Default Macro
`CustomSymbolStrGlobalVar`	Global variables	`'$M$N'`
`CustomSymbolStrType`	Global types	`'$M$N'`
`CustomSymbolStrField`	Field name of global types	`'$M$N'`
`CustomSymbolStrFcn`	Local functions	`'$M$N'`

Parameter	Description	Default Macro
`CustomSymbolStrTmpVar`	Local temporary variables	`'$M$N'`
`CustomSymbolStrMacro`	Constant macros	`'$M$N'`
`CustomSymbolStrEMXArray`	EMX Array Types	`'emxArray_$M$N'`
`CustomSymbolStrEMXArrayFcn`	EMX Array Utility Functions	`'emx$M$N'`

For example:

```
cfg.CustomSymbolStrGlobalVar = 'glob_$M$N';
```

For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

Control Signed Left Shifts in Generated Code

In this section...

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight.

```
i <<= 3;
```

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

```
i = i * 8;
```

Control Signed Left Shifts Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **Code Appearance** tab, select or clear the **Use signed shift left for fixed-point operations and multiplication by powers of 2** check box.

Control Signed Left Shifts Using the Command-Line Interface

1. Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

2 Set the `EnableSignedLeftShifts` property to `true` or `false`. For example:

```
cfg.EnableSignedLeftShifts = false;
```

- "Configure Build Settings" (MATLAB Coder)

Control Data Type Casts in Generated Code

In this section...

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

Casting Mode	Description

Nominal	Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:
	`short addone(short x)`
	`{`
	`  int i0;`
	`  i0 = x + 1;`
	`  if (i0 > 32767) {`
	`  i0 = 32767;`
	`  }`
	`  return (short)i0;`
	`}`

Standards Compliant	Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode: `short addone(short x)`

Casting Mode	Description

	{
	  int i0;
	  i0 = (int)x + (int)1;
	  if (i0 > (int)32767) {
	  i0 = (int)32767;
	  }
	
	  return (short)i0;
	}

Explicit	Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:
	
	short addone(short x)
	{
	  int i0;
	  i0 = (int)x + 1;
	  if (i0 > 32767) {
	  i0 = 32767;
	  }
	
	  return (short)i0;
	}

Specify Casting Mode Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.

4 On the **All Settings** tab, under **Advanced**, set **Casting mode** to one of the following values:

- `Nominal`
- `Standards Compliant`
- `Explicit`

Specify Casting Mode Using the Command-Line Interface

1 Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

2 Set the `CastingMode` property to one of the following values:

- `'Nominal'`
- `'Standards'`
- `'Explicit'`

For example:

```
cfg.IndentStyle = 'Standards';
```

Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```
for (i = 0; i < 10; i++) {
    z[5 * (1 + i) - 1] = x[5 * (1 + i)];
  }
```

Here is code generated with the optimization:

```
for (b_i = 0; b_i < 10; b_i++) {
    z[i + 4] = x[i + 5];
    i += 5;
  }
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter `EnableStrengthReduction` to `true`.
- In the MATLAB Coder app, project build settings, on the **All Settings** tab, set **Simplify array indexing** to `Yes`.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

- "Optimization Strategies" (MATLAB Coder)
- "Configure Build Settings" (MATLAB Coder)

Code Replacement for MATLAB Code

What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from the following libraries that MathWorks provides:

- GNU C99 extensions—GNU[16] gcc math library, which provides C99 extensions as defined by compiler option `-std=gnu99`.
- AUTOSAR 4.0—Produces code that more closely aligns with the AUTOSAR standard. Requires an Embedded Coder license.
- Intel IPP for x86-64 (Windows)—Generates calls to the Intel Performance Primitives (IPP) library for the x86-64 Windows platform.
- Intel IPP/SSE for x86-64 (Windows)—Generates calls to the IPP and Streaming SIMD Extensions (SSE) libraries for the x86-64 Windows platform.
- Intel IPP for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP library for the x86-64 Windows platform and MinGW compiler.

16. GNU is a registered trademark of the Free Software Foundation.

- Intel IPP/SSE for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP and SSE libraries for the x86-64 Windows platform and MinGW compiler.
- Intel IPP for x86/Pentium (Windows)—Generates calls to the IPP library for the x86/Pentium Windows platform.
- Intel IPP/SSE for x86/Pentium (Windows)—Generates calls to the Intel Performance IPP and SSE libraries for the x86/Pentium Windows platform.
- Intel IPP for x86-64 (Linux)—Generates calls to the IPP library for the x86-64 Linux platform.
- Intel IPP/SSE with GNU99 extensions for x86-64 (Linux)—Generates calls to the GNU libraries for IPP and SSE, with GNU C99 extensions, for the x86-64 Linux platform.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available . If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

Code Replacement Libraries

A *code replacement library* consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A *code replacement table* contains one or more *code replacement entries*, with each entry representing a potential replacement for a function or operator. Each entry maps a *conceptual representation* of a function or operator to an *implementation representation* and priority.

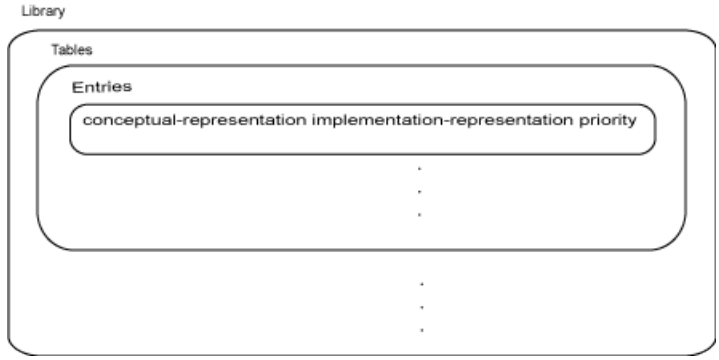

Table Entry Component	Description
Conceptual representation	Identifies the table entry and contains match criteria for the code generator. Consists of: • Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name `'cos'` and operator key `'RTW_OP_ADD'`. • Conceptual arguments that observe code generator naming (`'y1'`, `'u1'`, `'u2'`, ...), with corresponding I/O types (output or input) and data types. • Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.
Implementation representation	Specifies replacement code. Consists of: • Function name. For example, `'cos_dbl'` or `'u8_add_u8_u8'`. • Implementation arguments, with corresponding I/O types (output or input) and data types. • Parameters that provide additional implementation details, such as header and source file names and paths of build resources.

Table Entry Component	Description
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a *call site object* with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions

Term	Definition
	and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: • Function or operator name or key • Conceptual arguments with type, dimension, and complexity specification for inputs and output • Attributes, such as an algorithm and fixed-point saturation and rounding modes
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: • Function name (for example, `'cos_dbl'` or `'u8_add_u8_u8'`) • Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output • Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key `RTW_OP_ADD` identifies the addition operator.
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

Choose a Code Replacement Library

In this section...

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in "What Is Code Replacement?" on page 76-2.
   - See "Explore Available Code Replacement Libraries" on page 76-9.
2. Explore the contents of the library. See "Explore Code Replacement Library Contents" on page 37-9.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

You can select the code replacement library to use for code generation in a project, on the **Custom Code** tab, by setting the **Code replacement library** parameter. Alternatively, in a code configuration object, set the `CodeReplacementLibrary` parameter.

Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2. In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
3. In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
4. In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

   If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

Replace Code Generated from MATLAB Code

This example shows how to replace generated code using a code replacement library. Code replacement is a technique for changing the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that you have installed required software. Required software is:

   - MATLAB
   - MATLAB Coder
   - C compiler

   Some code replacement libraries available in your development environment require Embedded Coder.

   For instructions on installing MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the MATLAB Command Window, enter `ver`.
2. Identify an existing MATLAB function or create a new MATLAB function for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the MATLAB function. Do one of the following:

   - In a project, on the **Custom Code** tab, set the **Code replacement library** parameter.
   - In a code configuration object, set the `CodeReplacementLibrary` parameter.
2. Configure the code generator to produce only code. Before you build an executable, verify your code replacements. Do one of the following:

   - In a project, in the **Generate** dialog box, select the **Generate code only** check box.

- In a code configuration object, set the `GenCodeOnly` parameter.

Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information helps you verify code replacements.

1. Configure the code generator to generate a report.
   - In a project, on the **Debugging** tab, set the **Always create a code generation report** parameter.
   - In a code configuration object, set the `GenerateReport` parameter.
2. Include the code replacement section in the report.
   - In a project, on the **Debugging** tab, select the **Code replacements** check box.
   - In a code configuration object, set the `GenerateCodeReplacementReport` parameter.

Generate Replacement Code

Generate C/C++ code from the MATLAB code. If you configured the code generator to produce a report, generate a code generation report. For example, in the MATLAB Coder app, on the **Generate Code** page, click **Generate**. Or, at the command prompt, enter:

```
codegen -report myFunction -args {5} -config cfg
```

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. Code replacement can sometimes behave differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Storage Classes for Code Generation from MATLAB Code

Storage Classes for Code Generation from MATLAB Code

If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a *storage class* is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term *storage class specifier*.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```
coder.storageClass(global_name, storage_class)
```

`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.

Storage Class	Description
`'ExportedGlobal'`	• Defines the variable in the `Variable Definitions` section of the C file *`entry_point_name`*`.c`. • Declares the variable as an `extern` in the `Variable Declarations` section of the header file *`entry_point_name`*`.h`

Storage Class	Description
	• Initializes the variable in the function *entry_point_name*_initialize.h.
'ExportedDefine'	Declares the variable with a #define directive in the Exported data define section of the header file *entry_point_name*.h.
'ImportedExtern'	Declares the variable as an extern in the Variable Declarations section of the header file *entry_point_name*_data.h. The external code must supply the variable definition.
'ImportedExternPointer'	Declares the variable as an extern pointer in the Variable Declarations section of the header file *entry_point_name*_data.h. The external code must define a valid pointer variable.

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an ExportedDefine storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.

If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an 'ExportedGlobal' storage class. For an 'ExportedGlobal' storage class, the global variable is declared in the file *entry_point_name*.h. When the global variable does not have a storage class, the variable is declared in the file *entry_point_name*_data.h.

Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function `addglobals` that adds four global variables. Declare the global variables in the function.

```
function y = addglobals

% Define the global variables.

global u;
global v;
global x;
global z;

% Assign the storage classes.

coder.storageClass('u','ExportedGlobal');
coder.storageClass('v','ImportedExtern');
coder.storageClass('x','ImportedExternPointer');
coder.storageClass('z','ExportedDefine');
y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```
#include <stdio.h>

/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type `'lib'`, or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.

```
cfg = coder.config('dll','ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';
```

Generate the code. This example uses the `-globals` argument to specify the types and initial values of the global variables `u`, `v`, `x`, and `z`. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables `v` and `x`, the code generator uses the initial values only to determine the type.

```
codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report
```

From the initial values `1`, `2`, `3`, and `4` `codegen` determines that `u`, `v`, `x` and `z` have type `double`. `codegen` defines and declares the exported global variables `u` and `z`. It generates code that initializes `u` to `1.0` and `z` to `4.0`. `codegen` declares the imported global variables `v` and `x`. It does not define these variables or generate code that initializes them. `myfile.c` provides the code that defines and initializes `v` and `x`.

To view the code generated for the global variables, open the report. Click the `View report` link.

View the definition for the exported global `z` in the `Exported data define` section in `addglobals.h`.

```
/* Definition for custom storage class: ExportedDefine */
#define z                              4.0
```

View the definition and declaration for the exported global `u`.

- `u` is defined in the `Variable Definitions` section in `addglobals.c`.

  ```
  /* Variable Definitions */
  /* Definition for custom storage class: ExportedGlobal */
  double u;
  ```

- `u` is declared as `extern` in the `Variable Declarations` section in `addglobals.h`.

  ```
  /* Variable Declarations */
  /* Declaration for custom storage class: ExportedGlobal */
  extern double u;
  ```

- `u` is initialized in `addglobals_initialize.c`.

  ```
  /* Include Files */
  #include "rt_nonfinite.h"
  #include "addglobals.h"
  ```

```
#include "addglobals_initialize.h"

/* Named Constants */
#define b_u                            (1.0)

/* Function Definitions */

/*
 * Arguments    : void
 * Return Type  : void
 */
void addglobals_initialize(void)
{
  rt_InitInfAndNaN(8U);
  u = b_u;
}
```

View the definition and declaration for the imported external global `v` and the imported external global pointer `x`.

`v` and `x` are declared as `extern` in the `Variable Declarations` section in `addglobals_data.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;

/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;
```

Verification of Code Generated from MATLAB Code

Highlight Potential Data Type Issues in a Report

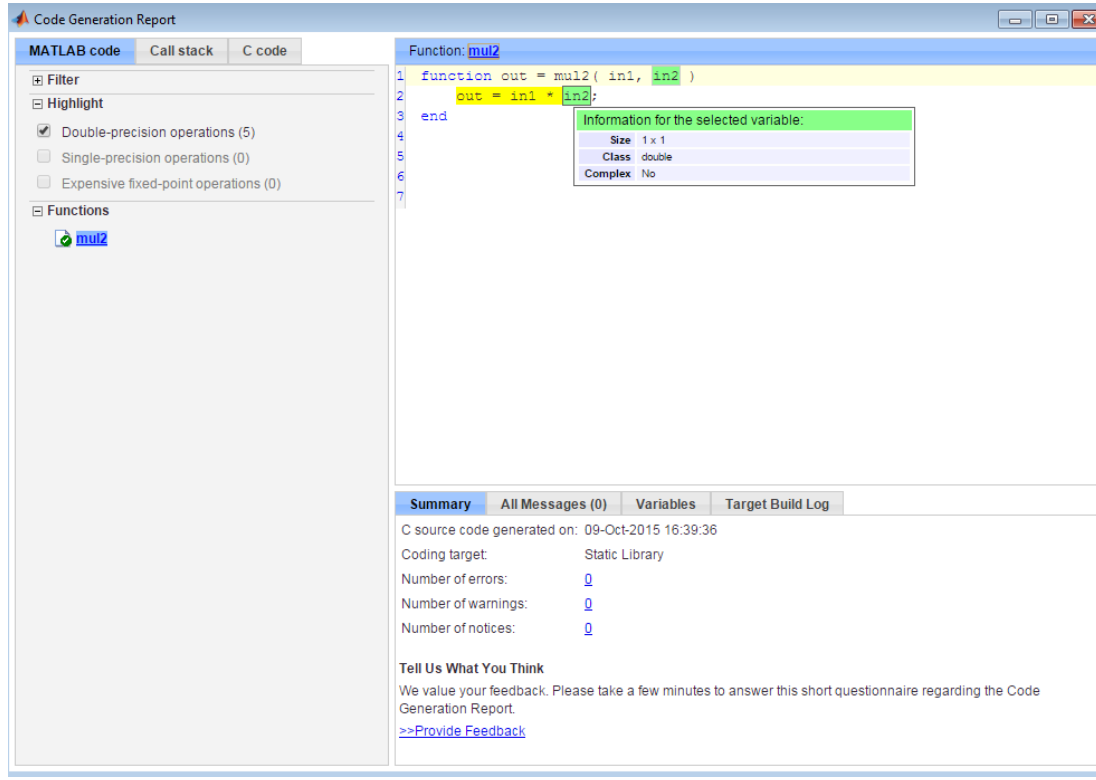
In this section...

If you have an Embedded Coder license, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, the **Highlight** section on the **MATLAB code** tab lists the number of single-precision and double-precision operations in the generated C/C++ code. If you have a Fixed-Point Designer license, it also lists the number of expensive fixed-point operations.

To highlight the MATLAB code that corresponds to the potential data type issues:

1. Select the check box for the type of operation that you want to highlight.
2. Select the function that you want to highlight.

   The report highlights the operations in the selected function. The following example report highlights MATLAB code that results in double-precision operations in the generated code.



The option to highlight potential data type issues is disabled by default.

Enable Highlight Option Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`

3 Click **More Settings**.

4 On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

Enable Highlight Option Using the Command Line Interface

1 Create an embedded code configuration object for `'lib'`, `'dll'`, or `'exe'`:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

2 Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

Find Potential Data Type Issues in Generated Code

In this section...

Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer license.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

  For a strict-single precision design, specify a standard math library that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the **Custom Code** tab, set the **Standard math library** to `C99 (ISO)`.
- The single-precision check highlights expressions that result in a single operation.
- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see "Tips for Making Generated Code More Efficient" (Fixed-Point Designer).

Enable Highlighting of Potential Data Type Issues

Procedure 78.1. Enable the highlight option using the MATLAB Coder app

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

Procedure 78.2. Enable the highlight option using the command-line interface

1. Create an embedded code configuration object for `'lib'`, `'dll'`, or `'exe'`:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

   ```
   cfg.GenerateReport = true;
   cfg.HighlightPotentialDataTypeIssues = true;
   ```

Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer licenses to run. The target word length for the processor in this example is 64.

1. Create the function `myMul`.

   ```
   function out = myMul(in1, in2)
       out = fi(in1*in2, 1, 64, 0);
   end
   ```
2. Generate code for `myMul`.

   ```
   cfg = coder.config('lib');
   ```

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}
```

3. Click **View report**.
4. In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
5. Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.

To resolve this issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length of 64.

Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the `floor` rounding method.

This example requires Embedded Coder and Fixed-Point Designer licenses to run.

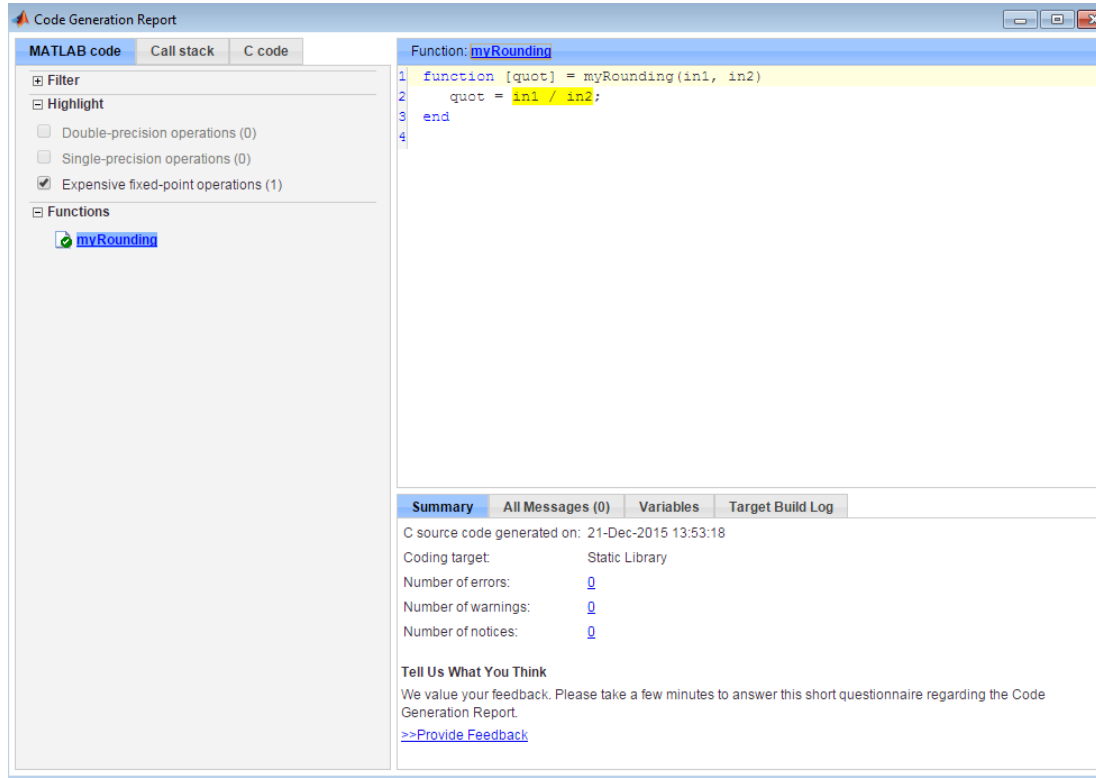
1. Create the function `myRounding`.

```
function [quot] = myRounding(in1, in2)
   quot = in1 / in2;
end
```

2. Generate code for `myRounding`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}
```

3. Click **View report**.
4. In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
5. Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.



This division operation uses the default rounding method, `nearest`. Changing the rounding method to `Floor` provides a more efficient implementation.

Find and Address Expensive Comparison Operations

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer licenses to run.

1 Create the function `myRelop`.

```
function out = myRelop(in1, in2)
    out = in1 > in2;
end
```

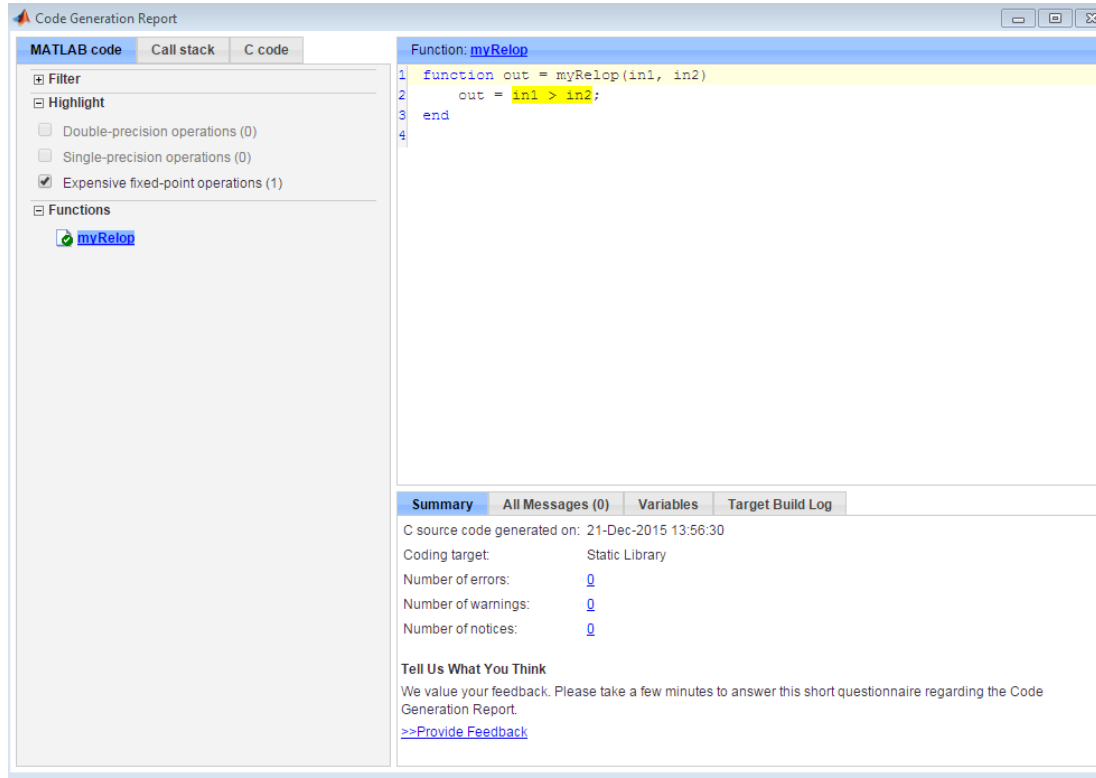
2 Generate code for `myRelop`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
```

3 Click **View report**.

4 In the Code Generation Report, on the left pane, click the **MATLAB code** tab.

5 Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.



The first input argument, `in1`, is signed, while `in2` is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

Find and Address Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local `fimath` properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer licenses to run. The target word length is 64 in this example.

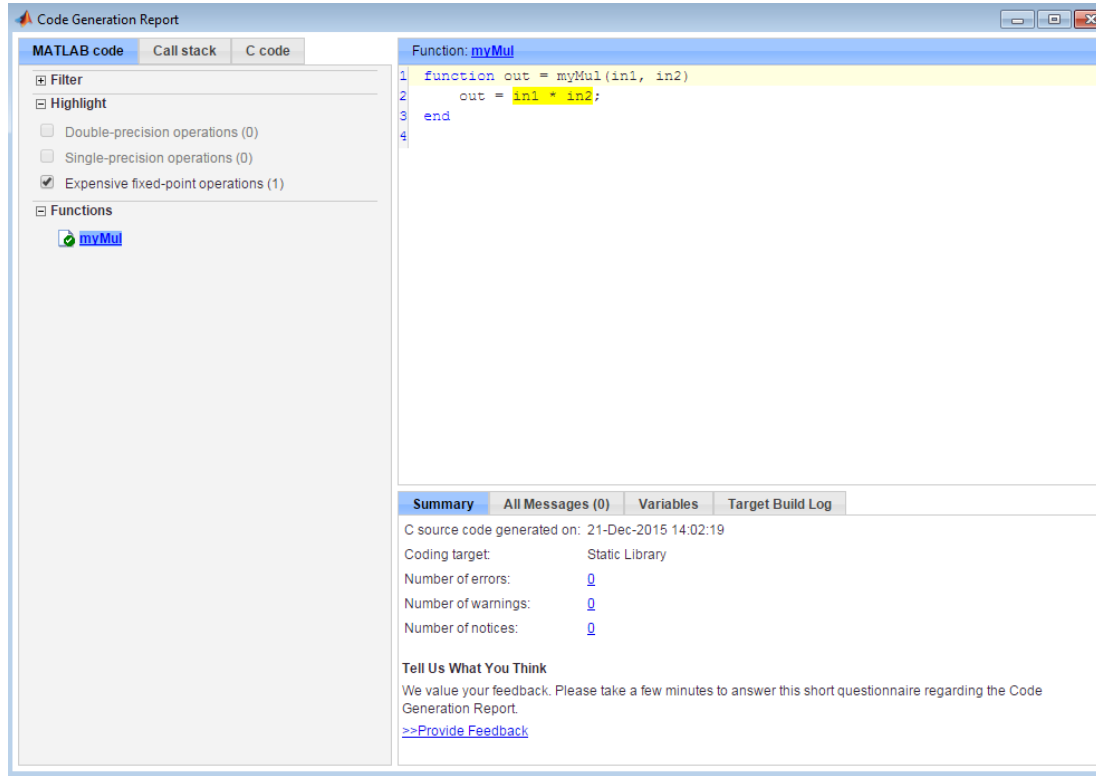
1. Create the function `myMul`.

```
function out = myMul(in1, in2)
    out = in1 * in2;
end
```

2. Generate code for `myMul`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myMul -args {fi(1, 1, 33, 4), fi(1, 1, 32, 4)}
```

3. Click **View report**.
4. In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
5. Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.



The `in1 * in2` operation is highlighted in the HTML report. On the bottom pane, click the **Variables** tab. The word length of `in1` is 33 bits, and the word length of `in2` is 32 bits. Hovering over the highlighted expression reveals that the product has a word length of 65, which is larger than the target word length of 64. Therefore, the software detects a multiword operation.

To resolve this issue, modify the data types of `in1` and `in2` so the word length of the product does not exceed the target word length, or specify the `ProductMode` property of the local `fimath` object.

PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

In the Command Window, select the hardware for PIL execution.

```
hw = coder.hardware('ARM Cortex-A9 (QEMU)')
```

```
hw =

  Hardware with properties:

            Name: 'ARM Cortex-A9 (QEMU)'
    CPUClockRate: 1000
```

When using the BeagleBone hardware, more hardware properties are supported (`Username`, `Password`, and `DeviceAddress`). Set these properties based on your specific hardware or application.

```
hw = coder.hardware('BeagleBone Black')
```

```
hw =

  Hardware with properties:

              Name: 'BeagleBone Black'
     CPUClockRate: 1000
         Password: 'root'
         Username: 'admin'
    DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;
```

Generate PIL code for a function, `averaging_filter`.

```
codegen -config cfg averaging_filter -args {zeros(1,16)}
```

For more information on the `averaging_filter` function, see the “Averaging Filter” example in “MATLAB Coder Examples” (MATLAB Coder).

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. To install the Embedded Coder Support Package for ARM Cortex-A Processors, see “Supported Hardware”.

PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

1. On the **Generate Code** page, in the **Generate** dialog box:
   - Set the **Build type** to `Static Library`.
   - Clear the **Generate code only** check box.
   - Set the **Hardware Board** to `BeagleBone Black` or `ARM Cortex-A9 (QEMU)`.
2. If necessary, modify the settings for your board. To modify the settings, click **More Settings**, and then click **Hardware**.
3. To generate the library, click **Generate**.
4. Set up your PIL execution. Click **Verify Code** to open the **Verify Code** dialog box.

   Because the hardware board is not `MATLAB Host Computer`, the **Verify Code** dialog box is configured for PIL execution.

   In the **Verify Code** dialog box:
   - Enter the name of the test file to use for PIL execution.
   - Select **Generated code**.
5. To start the PIL execution, click **Run Generated Code**.
6. To stop the PIL execution, click **Stop**.

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.
